DFSMSHsm functions are affected as follows in a protect-all environment:

- Recall or deletion of migrated data sets
 - Automatic: DFSMSHsm performs authority checking to ensure that the user initiating automatic recall is at least authorized to use the data set.
 - Command: Security checking is performed when the request originates with a non-DFSMSHsm-authorized user. The request is failed if no profile covers the data set to be recalled or deleted. A generic profile can be created before requesting recall or deletion, or the ADDSD command can be used to simultaneously initiate an implicit recall and create a discrete profile.
- HALTERDS command: If the data set does not yet exist, a generic profile must be created, or the command fails when originated by a non-DFSMSHsm-authorized user.
- HRECOVER command: If a backup profile exists, DFSMSHsm creates a discrete profile. If no backup profile exists, create a discrete or generic profile before issuing the command, or the request fails.
- Remaining DFSMSHsm commands (HBDELETE, HBACKDS, HMIGRATE): Create a discrete or generic profile before issuing the command, or the request fails.

RACF environment for DFSMSHsm

This discussion assumes the following environment:

- All data sets are cataloged in catalogs
- RACF security is based on protection with generic profiles
- RACF always-call support has been established

DFSMSHsm and RACF concepts

Migrated data sets and backup versions are stored in a DFSMSHsm internal format. Data set names for migrated data sets and backup versions are different from the names of the corresponding data sets on the level 0 volume; thus the original RACF protection may not apply.

When DFSMSHsm migrates a cataloged DASD data set, it scratches the data set on the level 0 volume. However, it does not delete the catalog entry; Instead DFSMSHsm changes the original volume serial number to a dummy volume serial number named MIGRAT.

TSO users can explicitly recall (only with DFSMSHsm) their data sets to a level 0 volume if they are authorized by RACF.

In addition to automatic DFSMSHsm functions, TSO commands are available for users to selectively control DFSMSHsm space and availability management activities for their data sets. These TSO commands can also be issued by batch jobs using the terminal monitor program (TMP). Your installation may require users to identify themselves to RACF with the USER and PASSWORD parameters on the JOB card.

When executing a DFSMSHsm function started by a TSO command, DFSMSHsm asks RACF for authorization for the user, specifying the original data set name on the level 0 volume. Thus, when DFSMSHsm and TSO are used, backup and migration operations use the RACF-protection rules of their related data set on the level 0 volume. This occurs regardless of whether the migration or backup support is DASD or tape.

No access authorizations to the migrated or backed up data sets themselves are needed for users issuing DFSMSHsm commands.

Migrated or backed up data sets should not be accessed as normal MVS data sets. RACF generic profiles should be set up to protect these data sets by their real names on DASD, and RACF tape protection must protect the corresponding tape volumes.

Only DFSMSHsm should be authorized to use migrated and backed up data sets as MVS data sets. The RACF generic profiles for these data sets should contain an empty access list, and the default universal access authority (UACC) should be NONE. The DFSMSHsm started task does not need to be on the access lists, because DFSMSHsm sets itself up as a privileged user to RACF. It may be desirable to allow a few storage administrators on these access lists, to repair DASD or tape volumes. The authorization is automatically granted if these users have the RACF OPERATIONS attribute.

Failure to protect migrated and backed up data sets with generic profiles creates integrity exposures such as DFSMSHsm having a record of a backup version or migration copy of a data set when the version or copy has been deleted.

RACF authority needed to perform DFSMSHsm functions

DFSMSHsm bypasses any security checking during automatic volume space management, automatic secondary space management, and availability management.

Undirected automatic recall is caused by reference from JCL, or under TSO, to a cataloged data set that is, in fact, migrated. In such a reference, the target volume is not specified. Once recall has occurred, standard RACF protection applies through OPEN. [Table 53 on page 620](#) shows the authority needed by TSO users to issue DFSMSHsm commands.

Table 53. RACF Authorization Required for DFSMSHsm Functions

DFSMSHsm Function	RACF Resource Access Authority Required
Migrate a data set	UPDATE
Recall a data set	EXECUTE
Delete a migrated data set	ALTER
Back up a data set	UPDATE

Table 53. RACF Authorization Required for DFSMSHsm Functions (continued)

DFSMSHsm Function	RACF Resource Access Authority Required
Recover a backup version without specifying NEWNAME	ALTER
Recover a backup version and specify NEWNAME	READ to original data set; ALTER on the NEWNAME
Delete a backup version	ALTER
Change backup characteristics	ALTER
Aggregate backup	READ

Special considerations apply to the TSO user commands HBDELETE (to delete backup versions) and HALTERDS (to modify backup characteristics):

- **HBDELETE:** If the backed up data set does not exist and the data set was protected by a discrete profile, DFSMSDfp asked RACF to delete the profile when the data set was deleted. DFSMSHsm knows that the backed up data set was RACF-indicated. DFSMSHsm fails the request on this command if there is no backup profile or generic profile honoring access to the data set name, or if the requester does not have ALTER authority on either the generic profile or the backup profile.

If the backed up data set does not exist and if the data set was not RACF-indicated but was protected by a generic profile, DFSMSHsm fails the request only if a generic profile that matches the original data set name does exist and the user does not have ALTER authority on that profile.

- **HALTERDS:** A user might set up backup characteristics for a data set that does not exist yet. As in the preceding item, DFSMSHsm fails the request only if a generic profile that matches the original data set name exists and the requester does not have ALTER authority on that profile. If the data set exists, DFSMSHsm fails the request if no generic profile, discrete profile, or backup profile exists honoring access to the data set name or if the requester does not have ALTER authority on the generic, the discrete, or the backup profile.

RACF security bypassing for DFSMSHsm commands

The previously discussed TSO commands can also be issued by using the operator console. DFSMSHsm operator commands can be entered from the operator console or by a DFSMSHsm-authorized user (a user who has received the DFSMSHsm DATABASEAUTHORITY attribute) under TSO by using the HSEND CMD command. The command keywords of these DFSMSHsm commands are identical to the corresponding TSO commands, except that the leading H of these commands is omitted. For example, for the TSO HDELETE command, the operator enters the DELETE command or the authorized TSO user enters the HSEND CMD DELETE command.

In general there is no RACF checking for DFSMSHsm commands using the operator console. Therefore, the number of DFSMSHsm-authorized users should be limited. An installation can use the ISPF-supplied SVC to run authorized, thus providing a way to issue requests to DFSMSHsm. If DFSMSHsm TSO commands are issued by a user who runs MVS-authorized, no RACF checking is done. If RACF FACILITY class is being used to protect aggregates, a user ID representing the console user must be defined and authorized to the aggregate group profiles before issuing the ABACKUP or ARECOVER commands from a console, or processing fails.

Viewing DFSMSHsm Facility Class Access by using the Security Configuration Assistant (SCA) for z/OS Management Facility (z/OSMF)

z/OS Management Facility (z/OSMF) utility, Security Configuration Assistant (SCA), provides a visual framework for examining the different elements of DFSMSHsm security. The Security Configuration Assistant layout consists of tabbed sections and tabular reports that are expanded or compressed, as needed. This framework provides a comprehensive perspective on your DFSMSHsm security.

DFSMSHsm provides the necessary files that are needed by the Security Configuration Assistant. The necessary files are located in the following directory:

```
/usr/lpp/dfsms/hsm/samples/DFSMSHsm_Admin.json  
/usr/lpp/dfsms/hsm/samples/DFSMSHsm_User.json
```

The files must be copied to the configuration directory for z/OSMF Security Configuration Assistant and is at:

```
USER_DIR/configuration/security/ (defaults to  
/global/zosmf/configuration/security)
```

For information about enabling and using the Security Configuration Assistant, see:

- [Configure the Security Configuration Assistant service](#) in *IBM z/OS Management Facility Configuration Guide*.
- For information about how to use the Security Configuration Assistant, see the z/OSMF online help.

The RACF user ID for DFSMSHsm

DFSMSHsm must be able to bypass RACF during migration and backup of user data sets. You must, therefore, define DFSMSHsm to RACF and give it the necessary level of authority. You do this by defining an entry in the RACF started-procedures module ICHRIN03, which contains the DFSMSHsm startup procedure name and a user ID that you define to RACF by an ADDUSER command. Do not define this user ID with the automatic data set protection (ADSP) attribute.

The following is an example of the RACF command you can use to define DFSMSHsm to RACF.

```
ADDUSER (hsmid) DFLTGRP (grpname)
```

In this example, *hsmid* is the user ID specified in the RACF started-procedure module ICHRIN03, or the RACF user ID associated with the DFSMSHsm STARTED class profile. The default group name is not important, but if it is not specified, RACF sets it to the current connect group of the user issuing the command.

Notes:

1. The user who issues the ADDUSER command must have the RACF SPECIAL attribute.
2. The UID parameter in the DFSMSHsm startup procedure is not related to the RACF user ID.
3. If you are using remote sharing functions (RRSF) to propagate RACF commands to remote hosts, it is suggested that the RACF user ID for DFSMSHsm be defined with the SPECIAL and OPERATIONS attributes on all recipient systems.
4. It is recommended that you define the RACF user ID for DFSMSHsm with the OPERATIONS and SPECIAL attributes to ensure that HSM has the proper settings and its functions do not modify the ACEE.

RACF started task table

Because a started task has a system-generated JOB card and cannot, therefore, supply USER, GROUP, and PASSWORD information, it must be identified to RACF by a different mechanism. SYS1.LPALIB contains a module, ICHRIN03, that contains the information that RACF requires for started tasks, and you must add the name of the DFSMSHsm procedure (or procedures if there are more than one) to this module. You also need to add the name of the ABARS procedure and any DFSMSdss ASID started by DFSMSHsm to this module. In fact, this must be done for any started task that accesses DFSMSHsm data sets (for example, a customized external writer to save the DFSMSHsm log). The module is a nonexecutable table containing 32 bytes of character information for each entry. Each entry contains four 8-byte fields.

<i>procname</i>	<i>user ID</i>	<i>grpname</i>	Flag
-----------------	----------------	----------------	------

The first three fields must be left-justified and padded with blanks. The *gname* field can be left blank; RACF then uses the default specified on the ADDUSER command. The eight flag bytes are set to hexadecimal zeros. For example, if the DFSMSHsm startup procedure is called DFHSM and you want to define a user ID of HSMUSR for DFHSM, the format of the entry you must create is:

DFHSM	HSMUSR		8 x X'00'
-------	--------	--	-----------

See your security administrator to have the correct entries made in ICHRIN03.

Note: If you are using remote sharing functions (RRSF) to propagate RACF commands to remote hosts, see the notes under [“The RACF user ID for DFSMSHsm” on page 622](#).

An alternative method of using the RACF started task table to associate a RACF user ID with a started task is to use the RACF STARTED class method. The RACF STARTED class is a RACF general resource class.

To associate the HSMUSR user ID to the DFHSM procedure in the previous example, the following commands can be used to define a STARTED class profile:

1. **SETR GENERIC(STARTED)**
2. **RDEFINE STARTED DFHSM.* STDATA(USER(HSMUSR) PRIVILEGED(YES))**
3. **SETOPTS RACLIST(STARTED) REFRESH**

If security policies do not allow a customer to run HSM as privileged, the RACF STARTED class for the user identified with the DFHSM started procedure can be set to TRUSTED(YES).

```
RDEFINE STARTED DFHSM.* STDATA(USER(HSMUSR) TRUSTED(YES))
SETOPTS RACLIST(STARTED) REFRESH
```

Use of the TRUSTED attribute makes authorization requests for the started task subject to auditing. This is based on the audit options specified in SETOPTS LOGOPTIONS and the UAUDIT setting in the user ID profile for the HSM started task.

Defining the STARTED class profile with PRIVILEGED or TRUSTED ensures that HSM has the proper settings to perform functions without modifying the ACEE.

When the STARTED class profile is defined for the DFHSM or DFHSMABR procedures, the RACF user ID associated with it should be defined with the OPERATIONS and SPECIAL attributes to prevent the ACEE from being modified.

Always-call support for migrated data sets and backup copies

The DFSMSHsm option NORACFIND in the SETSYS command requires that you protect DASD migration copies and backups with generic profiles in an always-call environment. DFSMSHsm does not set the RACF indicator on for these data sets.

The SETSYS command has MIGRATEPREFIX and BACKUPPREFIX parameters that allow all migration data sets and backup data sets to have a high-level qualifier selected by the installation.

When the SETSYS MIGRATEPREFIX and BACKUPPREFIX parameters are used, you can define one or two generic profiles to protect all the migrated and backed up data sets. These profiles should have an empty (or nearly empty) access list and a UACC value of NONE. The following example shows how RACF definitions can be set up to protect the migrated and backed up data sets.

```
SETOPTS GENERIC (*)
ADDGROUP (prefix)
ADDGROUP (bprefix)
ADDSD 'prefix.*' UACC(NONE)
ADDSD 'bprefix.*' UACC(NONE)
```

For an explanation of *prefix* and *bprefix*, see [“Specifying the first qualifier for names of migrated data sets” on page 53](#) and [“Specifying the first qualifier for names of backup versions” on page 189](#).

- Set the system-wide RACF options to include generic profiles.

- If you choose MIGPREF as the migration prefix and BAKPREF as the backup prefix, generic profiles MIGPREF.* and BAKPREF.* protect all the DFSMSHsm migrated and backed up data sets.
- The ADDSD command builds a generic profile for MIGPREF and another for BAKPREF.

Migration and recall from DASD

When performing DFSMSHsm TSO commands for a user, DFSMSHsm never uses the real migrated data set name to ask RACF for authorization. It always asks for authorization on the original data set name on the original volume.

If the original data set was protected by a generic profile, DFSMSHsm asks for authorization with the RACFIND=NO option, causing RACF to check for generic profile protection. The same protection that was in effect for the original data set applies, regardless of whether a discrete or generic profile was in effect.

The same protection also continues to apply when a data set is moved to an ML2 volume.

Backup and recovery from DASD

As with migration, DFSMSHsm refers to the RACF profile of the active data set for all TSO user interactions with their backups.

To recover a RACF-indicated data set, the corresponding profile must exist. This can be a problem with discrete profiles because deleting the data set also deletes the discrete profile. When the discrete profile has been deleted, a new one must be rebuilt by an appropriately authorized person before the data set can be recovered by a non-DFSMSHsm-authorized user.

DFSMSHsm provides the capability to back up RACF discrete profiles when a RACF-indicated data set is backed up. If you specify the SETSYS PROFILEBACKUP command, the discrete profiles are backed up. Non-DFSMSHsm-authorized users can then recover deleted data sets that had discrete profiles, because DFSMSHsm recovers the backup profile if no discrete profile exists for a RACF-indicated data set.

When a cataloged non-VSAM data set is being recovered to another volume, DFSMSHsm RECOVER gives some assistance by updating the volume serial information of the original RACF discrete profile, if it still exists, or of the recovered backup profile.

When you specify the NEWNAME and REPLACE parameters to recover a VSAM data set, DFSMSHsm deletes any information about newly named data sets from the catalog before it recovers the data set. The newly named data set gets the catalog information that the original data set had, including password and RACF-indication. You must provide the proper RACF protection for the newly named data set.

With generic profiles, most of these considerations do not apply, and no extensive security administration is required. If a generic profile exists that covers data sets that were backed up with discrete profiles, the data sets can be recovered by non-DFSMSHsm-authorized users whether the discrete or backup profiles exist, provided the user is authorized access to the data sets.

Aggregate backup and recovery data set security

When an ABACKUP or ARECOVER command is issued, DFSMSHsm passes the RACF FACILITY class profile name for the command, along with the user's or console operator's user ID, to RACF for authorization checking. If authorization is denied by RACF, DFSMSHsm rejects the request to issue the command. If RACF responds that no profile is defined for the command, DFSMSHsm processes the request only if the user is a DFSMSHsm-authorized user or a console operator. If the user is not a DFSMSHsm-authorized user, DFSMSHsm fails the request to issue the command. See [“Checking authorization during aggregate backup” on page 340](#) for a discussion of comprehensive and restricted ABACKUP and ARECOVER commands.

Backing up RACF-indicated data sets

When an existing data set with a RACF discrete profile is backed up to DASD and the NORACFIND parameter of the SETSYS command has been specified, DFSMSHsm does not set the RACF indicator on in the VTOC entry of the backup version.

Authorizing the use of concurrent copy for data set backup commands

DFSMSHsm uses the STGADMIN.ADR.DUMP.CNCURRNT FACILITY class resource to limit concurrent copy use to those users who are authorized to use the CC option.

By default, all users can use the CC option. However, if RACF indicates a lack of authority, DFSMSHsm fails the data set backup request if the concurrent copy request is specified as REQUIRED, VIRTUALREQUIRED or CACHEREQUIRED. If the concurrent copy request is not specified as REQUIRED, VIRTUALREQUIRED or CACHEREQUIRED and RACF indicates a lack of authority, DFSMSHsm continues to back up the data set as if the concurrent copy keyword were not specified on the backup command.

Small data set packing data set security

Because data sets that migrate to small data set packing (SDSP) data sets are treated as records in the SDSP data set, they must be protected by applying security to the SDSP data set. The security applied to the SDSP data set prevents non-DFSMSHsm access to the data in the data sets treated as records.

To maintain data set security on your system's small data set packing data sets, RACF-protect them with a discrete or generic profile. Erase-on-scratch should be specified in the discrete or generic profile if erase-on-scratch is specified for DFSMSHsm data sets not in SDSP data sets.

If data sets on volumes managed by DFSMSHsm are protected by a password and you specified SETSYS SMALLDATASETPACKING, protect the SDSP data sets on ML1 volumes with a discrete or generic profile to extend the protection of the data sets contained in the SDSP data sets. DFSMSHsm can still access the data sets in a protected SDSP data set without being given access authority to the SDSP data set.

Uncataloging migrated data sets

The DELETE *data set name* NOSCRATCH command can be used to uncatalog migrated data sets. For this command to be used when RACF protection is used for DFSMSHsm-owned data sets, two conditions must exist:

- A RACF group of ARCCATGP must exist.
- The user who issues the DELETE NOSCRATCH command must be authorized to group ARCCATGP.

Controlling command access with RACF FACILITY class

RACF FACILITY class profiles, both generic and discrete, can be used to allow access to all DFSMSHsm commands. If the RACF FACILITY class is active, DFSMSHsm always uses it to protect all DFSMSHsm commands. If the RACF FACILITY class is not active, DFSMSHsm uses the AUTH command to protect all DFSMSHsm commands. The storage administrator must work with the security administrator to give authorization to user and storage administrator commands.

Related reading

For more information about using the RACF FACILITY class environment and the AUTH command environment, see [z/OS DFSMSHsm Implementation and Customization Guide](#).

Chapter 19. Health Checker for DFSMSHsm

The IBM Health Checker for z/OS includes checks for DFSMSHsm. These checks are designed to help you determine if DFSMSHsm is correctly configured and is consistent with IBM's recommendations.

[IBM Health Checker for z/OS User's Guide](#) explains each check provided by IBM.

Check registration

The first MAIN host to initialize on the z/OS image will register all DFSMSHsm Health Checks to Health Checker. Checks will run immediately after this registration is complete. Checks will run subsequently based on intervals and triggering events specific to each check.

In the event the MAIN DFSMSHsm host is not active when a check runs, the check will become disabled. The check is re-enabled when the MAIN DFSMSHsm host initializes.

Chapter 20. Data recovery scenarios

In the data loss and recovery scenarios that follow, a description of a problem is presented, followed by the corrective measures that you can use for that problem. When you have a data-loss situation, you can quickly scan our examples to see if one of the examples matches your problem. If so, you may be on your way to a speedy recovery.

Note: Many data loss situations can be avoided by performing administrative steps before DFSMSHsm implementation.

Case 1: Damaged CDS, full journal

It's a cold Monday morning when Rick, a storage administrator, arrives at work to find the following note on his desk:

Figure 89. Handwritten note from Steve to Rick

What does Rick do after he regains consciousness?

The first thing Rick does is review the DFSMSHsm command activity log to see what caused the ARC0026E journaling error. He sees that the ARC0026E error specifies an EOVS problem; the journal has been completely filled up. Rick then examines the backup activity log to find out what caused the journal to completely fill up. He sees that control data set (CDS) backups fail each time the BACKVOL CDS command is issued. Since the BACKVOL CDS command is failing, the journal is not getting backed up.

Rick also sees that IDCAMS has issued error messages indicating out-of-sequence records in the backup control data set (BCDS). The failures recorded in the backup activity log indicate a “broken” BCDS.

To review the backup activity log, Rick used the DFSMSHsm RELEASE HARDCOPY command. HARDCOPY is an optional parameter of the RELEASE command that is used to specify that DFSMSHsm close any of the four activity logs if they contain data, and either print the logs or send them to DASD. The DFSMSHsm SETSYS ACTLOGTYPE command determines whether the logs are printed or sent to DASD.

When the activity logs are closed, new copies of the logs are allocated for use.

Once Steve had reset the journal, DFSMSHsm was able to operate because DFSMSHsm addresses the virtual storage access method (VSAM) control intervals directly by key. Backup of the CDS failed because a valid VSAM sequence set is required to read CDSs in key sequence.

What happened to the BCDS? Two MVS images, both having DFSMSHsm installed, updated the shared BCDS concurrently. When this happened, duplicate records were created in the BCDS, and the index structure of the BCDS was damaged.

After Rick figures out what happened and what damage was done, he plans his salvage operation. Although the journal records were lost when Steve deleted and reallocated the journal, the same information still exists in the BCDS. The BCDS, however, has duplicate records. So the first thing Rick must do is to delete the duplicate records in the BCDS and back up the CDSs. To delete the duplicate records in the BCDS and back up the CDSs, Rick performs the following tasks:

1. Stops DFSMSHsm on all images.
2. Uses the IDCAMS REPRO command to copy the data component of the BCDS to a sequential file. This can be performed by one of the following methods:
 - a. Direct the IDCAMS REPRO command to make a copy of the data component of the BCDS, as in the following example:

```
REPRO IDS(HSM.BCDS.DATA) ODS(RICK.BCDS.DATA)
```

- b. Direct the IDCAMS REPRO command to make a copy of the BCDS by relative byte address, as in the following example:

```
REPRO IDS(HSM.BCDS) ODS(RICK.BCDS.DATA) FADDR(0)
```

- -
 3. Uses DFSORT to perform the following:
 - a. Sort the sequential file by key, eliminating records with duplicate keys. The record that was most recently updated, where there are duplicates, is the one that is retained.
 - b. Reload the BCDS. The damaged BCDS must be deleted and a new BCDS defined.
 4. Starts DFSMSHsm, and issues the DFSMSHsm BACKVOL CDS command to create a good copy of the BCDS and nullify the journal. The LRECL and RECORDSIZE used in the DEFINE will depend on how your BCDS was defined. Issue LISTCAT ENT('yourbcds') ALL to determine maximum record size. LISTCAT will show you AVGLRECL and MAXLRECL which could be the following:

Maximum record size:

- 6544 bytes, if you need 100 or less active backup versions of any data set, if you use dump class stacking values greater than 99, or if you use fast replication.
- 2093 bytes, if you need 29 or less active backup versions of any data set, or if you use dump class stacking values of 99 or less.
- 2040 bytes, if you need 29 or less active backup versions of any data set, or if you use dump class stacking values of 97 or less.

Average record size:

- When Maximum record size is 6544, RECORDSIZE(334 6544)
- When Maximum record size is 2093, RECORDSIZE(334 2093)
- When Maximum record size is 2040, RECORDSIZE(200 2040)

Rick used the following JCL to accomplish the preceding steps:

The example below uses 2040 as maximum record size. For sequential files created in STEP1 and STEP2, LRECL used will be maximum record size + 4 for record descriptor word(RDW). RDW is a 4 byte field describing the record. In this example, using 2040 as maximum record size, you would use 2044 for sequential files created in these two steps.

```

/*
```

Note: The same procedure can be used for the MCDS and OCDS as well. Be sure to update the example JCL appropriately for the CDS being recovered. For example, the DEFINE CLUSTER definition to use will

depend on the CDS being recovered. For MCDS, BCDS and OCDS example definitions see [Starter set example](#) in *z/OS DFSMSHsm Implementation and Customization Guide*.

Case 2: Damaged journal, undamaged CDS

A damaged journal is often the result of a hardware-caused error on the journal volume. DFSMSHsm issues error message ARC0026E when it encounters an input/output (I/O) error in the journal data set. Message ARC0026E states “JOURNALING DISABLED DUE TO I/O ERROR. MIGRATION, BACKUP, DUMP, TAPECOPY, TAPEREP, RECYCLE, ARECOVER, AUDIT, AND EXPIREBV HELD.”

Once the problem occurs, follow this procedure:

1. Verify the DFSMSHsm CDSs are structurally sound.

Using IDCAMS, run EXAMINE against each of the CDSs. The procedure runs very quickly, and does not require that you bring DFSMSHsm down. The sample JCL to perform this procedure (which follows) comes from [z/OS DFSMS Access Method Services Commands](#).

```
//EXAMCDS JOB
//STEP1 EXEC PGM=IDCAMS
//SYSPRINT DD SYSOUT=A
//SYSIN DD *
EXAMINE -

  ERRORLIMIT(0)
//STEP3 EXEC PGM=IDCAMS
//SYSPRINT DD SYSOUT=A
//SYSIN DD *
EXAMINE -
  NAME(?hlqual.OCDS) -
  ERRORLIMIT(0)
```

If there are no errors reported by EXAMINE, continue to the next step.

If errors **are** reported by EXAMINE, do not proceed to the next step. Go to [“Case 1: Damaged CDS, full journal”](#) on page 629.

2. Stop DFSMSHsm on all images.
3. Do **not** copy the journal.
4. Rename the current journal.
5. Allocate a new journal with the old name. The following JCL allocates a new journal with the old name.

```
//JRNLDEF JOB
//STEP1 EXEC PGM=IEFBR14
//JRNLDD DD DISP=(,CATLG),UNIT=?3390,VOL=SER=?JNLVOL,
// SPACE=(CYL,(100),,CONTIG),DSN=?hlqual.JRNL
```

6. Start DFSMSHsm in EMERG=YES mode, a proclib option.
7. Issue the DFSMSHsm BACKVOL CDS command to keep your CDSs in synchronization with the new journal.
8. Delete the old journal.
9. Issue the DFSMSHsm SETSYS NOEMERGENCY command and then the DFSMSHsm RELEASE command to resume normal processing.

Case 3: Full journal, undamaged CDS

The problem of a full journal with an undamaged CDS occurs because the journal is not large enough or the CDSs are not being backed up often enough. DFSMSHsm issues error message ARC0909E when the

DFSMSHsm journal threshold is met, and continues to issue the error message each time an additional one percent (or more) of the journal is filled. When the journal is full, ARC0909E states: “JOURNAL DATA SET IS ABOUT 100% FULL.” When the journal is 100% full, message ARC0026E is also issued, which states: “JOURNALING DISABLED DUE TO EOV ERROR ON JOURNAL. MIGRATION, BACKUP, DUMP, TAPECOPY, TAPEREP, RECYCLE, ARECOVER, AUDIT, AND EXPIREBV HELD.”

Once the problem has occurred, take this step:

- Issue the BACKVOL CDS command. The BACKVOL CDS command will back up the journal and the control data sets, and null the journal.

Consider using a large format data set for the DFSMSHsm journal if your installation is not already doing so. A large format data set is a physical sequential data set with the ability to grow beyond 65,535 tracks per volume. Using a larger journal data set can allow more DFSMSHsm activity to take place between journal backups and helps to minimize occurrences of journal full conditions.

For information about large format data sets, see *z/OS DFSMS Using Data Sets*.

Case 4: Structurally damaged CDS, missing journal records

A structurally damaged CDS is typically caused by multiple updates occurring at the same instant in time within the same CDS. Simultaneous updates to the same CDS can occur in a multiple-MVS-image environment, if a job running on one image reorganizes the CDS while DFSMSHsm is still running on another image. Without proper share options and serialization methods, the problem of a structurally damaged CDS along with missing journal records can easily happen.

Problems arise when there are no CDS and journal backup versions before the damage. This commonly occurs when damage to a CDS is not immediately detected. As new CDS and journal backups are being created, the older versions are being deleted. By the time the damaged CDS is detected, the backup versions that were created before the error have been deleted.

When you have a structurally damaged CDS and missing journal records, you must work with the records currently in your damaged CDS. To repair your damaged CDS, follow the same steps that Rick followed in “Case 1: Damaged CDS, full journal” on page 629, substituting your damaged CDS for Rick's backup control data set.

Case 5: Time sequence gaps in CDS records, journal records also missing

During a reorganization, user error may cause time sequence gaps in the CDS records, along with missing journal records.

Take the case where an installation uses generation data sets (GDSs) when reorganizing the CDSs. The user attempts to use IDCAMS REPRO to create an output data set for a migration control data set (MCDS). The MCDS is not successfully copied to the output data set, but the user does not notice. Then the user employs IDCAMS REPRO to create a new, reorganized MCDS, not knowing that the input data set is actually the last version of the MCDS successfully copied and is not the current MCDS at all.

After the reorganization completes, the administrator thinks that everything went as planned, and continues with everyday processing.

DFSMSHsm may run with an old copy of the MCDS for a week before a high number of data set recall failures signal that there is a problem. The old MCDS that is being used, of course, does not contain the more recently migrated data sets.

When the storage administrator finally discovers what has happened, he looks to see if he can recover from a backup version. He backs up once a day, and keeps three backup versions. The reorganization, however, was performed seven days ago. That means he doesn't have any backups before when the reorganization occurred, for either the journal or the MCDS.

Recovery in this instance is very complicated. The best course of action is to call your IBM Area Storage Specialist for recovery assistance.

Case 6: Overwritten migration tape

Important: This recovery scenario applies only to an overwritten header label. If the damage to the tape is more extensive than an overwritten label, the following recovery procedure will not work. Also, if the tape has been encrypted, there is similarly no way to recover it. If the tape cannot be recovered due to hardware problems related to the drive itself, consider sending it to your tape drive manufacturer for recovery. This scenario applies only to native tape; it will not work for the recovery of data from virtual tape.

If you have a duplex or a tape copy, perform a tape replace. This procedure is described in [Chapter 69, “TAPEREREPL command: Replacing cartridge-type tape volumes with their alternate volumes,”](#) on page 1235.

In either case, you should route the recovery assistance through IBM. You may open a software problem report to diagnose the root cause of the damage, if it is not known.

Ensure that you have a backup copy of any data set that is going to tape (migration level 2). If a backup copy is available, you can recover from a backup version without having to recover from the damaged tape.

The following information is relevant to know or have available when you open a problem record:

1. Specific failure indications—full message text of any related message that was issued
2. Type of drives that you are using
3. Microcode levels for the drive and controller
4. Reasonably available history for the tape
5. Pervasiveness of the problem
6. Attempted recovery actions taken—RECALL, RECYCLE, DELVOL, and so forth.
7. Customers should gather the following information when the problem arises:
 - List TTOC of the affected volume
 - Library Manager Log for an ATL
 - CTRACE (if you are already writing to an external writer)
 - SYSLOG
 - DFSMSHsm PDA trace
 - A dump on the failure, if it can be trapped using a slip (ABEND637, for example).

In some cases, you cannot recover some or any of the data (depending on the extent of the damage). A backup of the tape ensures that this is not a concern. Back up the data, if the data matters, before going to migration level 2 (ML2).

The main reason for this type of damage is that the wrong tape volume is mounted to satisfy a mount request for a scratch tape. The problem typically remains undiscovered unless you need the overwritten tape volume to recall a data set.

Use the following recovery procedure to restore access to DFSMSHsm data on tape cartridges. This procedure will not work for reel-type tape because of a difference in file format.

1. Copy the damaged tape volume.

(This step is optional.) If the user data that was written over the DFSMSHsm data is wanted, you will need to create a copy of that data. The damaged tape volume will be returned to scratch or to DFSMSHsm for its later use, and the user data that was written on this volume will be lost at the end of this procedure.
2. Reinitialize the damaged tape volume.

Reinitialize the tape volume with the data set name that is used by DFSMSHsm for all of its tape volumes. Write a dummy data set with the first file on the volume named as below:

prefix.**HMIGTAPE.DATASET**

The *prefix* can be any valid qualifier. For example, you can use the migration prefix as specified on the SETSYS MIGRATEPREFIX command, or the UID. This step will create a good tape label on the damaged tape. Once the tape label is valid, the volume can be processed by RECYCLE in step “4” on page 636 of this procedure.

IEBGENER can be used to perform the reinitialization task.

The sample JCL that follows can be used to reinitialize a damaged migration volume. Modify the JCL to fit your needs by doing the following tasks:

- Change the UNIT parameter on the SYSUT2 DD statement, if necessary.
- Change *prefix* to the appropriate prefix.
- Change *ml2volser* to your volume serial number.

Included in the example that follows are the various messages that are generated from this job and the appropriate replies.

Attention: Do not perform the AUDIT MEDIACONTROLS function. AUDIT MEDIACONTROLS will remove all of your data.

```
//GENR      JOB
//STEP1     EXEC PGM=IEBGENER
//SYSUT1    DD DUMMY,LRECL=16384,BLKSIZE=16384,RECFM=F
//SYSUT2    DD DISP=(NEW,KEEP),DCB=*.SYSUT1,UNIT=?3480,
//          DSN=prefix.HMIGTAPE.DATASET,VOL=SER=?ml2volser
//SYSPRINT  DD SYSOUT=*
//SYSIN     DD DUMMY
/*
```

3. Determine if the first data set on the damaged tape volume spanned from another volume.

- Issue the LIST TTOC(*volser*) ODS(*dsname*) command to determine if your damaged tape volume is associated with a previous tape volume. If your damaged tape is associated with a previous tape, it will be listed under the heading “PREV VOL.” When there is a previous tape, it means that the first data set on your damaged tape began on the previous tape.

To verify whether your damaged tape is associated with a previous tape, enter the LIST TTOC(*prev_volser*) command and check to see that the last data set name on the previous tape is the same as the first data set name on your damaged tape. Note that if your installation is using extended tape table of contents, the LIST TTOC command might require an extended period of time to process each tape volume.

- Delete the first data set on your damaged tape volume if it spanned from a previous tape volume. To delete the first data set on a damaged migration tape, issue the following command:

```
DELETE dsn
```

- Issue the following command to recover the first data set that spanned to the previous volume:

```
RECOVER dsn
```

- Depending on the type of error that you are recovering from, it may be necessary to run RECYCLE several times. The following patch command causes DFSMSHsm to re-drive the POINT MACRO up to ten times when an I/O error is encountered during recycle, in order to recover data from a tape that has been overwritten and contains valid DFSMSHsm data beyond the tape marks created by the overwrite. The following patch value (X'0A') is appropriate for IBM 3590-technology tapes. Contact your tape-drive vendor for other tape technologies to determine the correct number of re-points.

```
HSEND PATCH .MCVT.+267 X'0A' VERIFY(.MCVT.+267 X'00')
```

At the end of the recovery procedures, issue the following patch command to prevent the re-drive of the POINT macro.

```
HSEND PATCH .MCVT.+267 X'00' VERIFY(.MCVT.+267 X'0A')
```

Issue the following command:

```
RECYCLE VOLUME(volser) EXECUTE
```

This step should be repeated to ensure that all available data sets are moved without the use of the FORCE parameter of the RECYCLE command.

Note: Readable, complete, and valid data sets are subsequently recycled to a new volume.

- Identify data sets that have been overwritten and build appropriate recovery commands.

Create a list showing which migrated data sets you need to recover (because the RECYCLE command was not able to remove them from the volume), by issuing the following command:

```
LIST TTOC(volser) ODS(dsn)
```

Build RECOVER commands for each data set on the list, but do not process the commands until step “7” on page 637.

An alternate to using the LIST TTOC command is to use DFSORT. The following is an example of a DFSORT job that identifies and builds RECOVER commands for each migrated data set that was overwritten. This job only builds the RECOVER commands; it does not process them.

```
//RCVCMDS JOB
//*****
/* Please change all the following to the appropriate values:
/* ?USERID - to your user id
/* ?DFSMSHsm - to the DFSMSHsm prefix for your MCDS
/* ?VLSER - to the volser of your damaged tape volume
//*****
/* This step uses SORT utility to build RECOVER
/* commands.
//*****
//STEP1 EXEC PGM=SORT,REGION=4096K
//*****
/* The INCLUDE statement selects MCD records (X'00'
/* at offset 51), that have the volser of your damaged tape and
/* have the MCDFASN bit on.
/* The OUTREC statement builds a RECOVER command for each
/* migrated data set found.
//*****
//SYSOUT DD SYSOUT=*
//MCDS DD DSN=?DFSMSHSM.MCDS,DISP=SHR
//CMDS DD DSN=?USERID.TEST.SORTMCD,DISP=(NEW,CATLG),
// DCB=(LRECL=255,BLKSIZE=0,RECFM=VB),
// SPACE=(CYL,(5,1),RLSE),UNIT=SYSDA
//SYSIN DD *
SORT FIELDS=(COPY)
INCLUDE COND=((51,1,BI,EQ,X'00'),AND,
              (69,6,CH,EQ,C'?VLSER'),AND,
              (75,1,BI,EQ,B'1.....'))
OUTREC FIELDS=(1,4,C' HSEND RECOVER ',5,44)
/*
```

- Issue the RECYCLE VOLUME(*volser*) FORCE EXECUTE command for the damaged volume.

The FORCE parameter of the RECYCLE command causes all data sets with errors to be deleted from the control data sets and the catalog. The deletion makes the tape empty, and the tape is removed from DFSMSHsm's inventory of tapes that contain data.

If the RECYCLE command fails with return code 16, you must issue a second RECYCLE VOLUME command to recycle the valid data sets while processing in single buffer mode. For an explanation of return code 16, refer to *z/OS MVS System Messages, Vol 2 (ARC-ASA)* and the table in the appendix titled "Reason Codes for Message ARC0734I when the Action is RECYCLE and Return Code is 16."

7. Issue the RECOVER commands for the migrated data sets that were lost. The RECOVER commands were generated in step "5" on page 636.

Case 7: Overwritten backup tape

This recovery scenario applies only to an overwritten header label. If the damage to the tape is more extensive than an overwritten label, the following recovery procedure will not work. Also, if the tape has been encrypted, there is similarly no way to recover it. If the tape cannot be recovered due to hardware problems related to the drive itself, consider sending it to your tape drive manufacturer for recovery. This scenario applies only to native tape; it will not work for the recovery of data from virtual tape.

If you have a duplex or a tape copy, perform a tape replace. You can reference this procedure in the Chapter 69, "TAPERPL command: Replacing cartridge-type tape volumes with their alternate volumes," on page 1235.

In either case, route the recovery assistance through IBM Support Center. Open a software problem report to diagnose the root cause of the damage, if it is not known.

When you open a problem record, you should be aware of the following information:

1. Specific failure indications—full message text of any related message issued
2. Type of drives
3. Microcode levels for the drive and controller
4. Reasonably available history for the tape
5. Pervasiveness of the problem
6. Attempted recovery actions taken—RECALL, RECYCLE, DELVOL, and so forth.
7. Customers should gather the following information when the problem arises:
 - List TTOC of the affected volume
 - Library Manager Log for an ATL
 - CTRACE (if already writing to an external writer)
 - SYSLOG
 - DFSMSHsm PDA trace
 - A dump on the failure if it can be trapped using a slip (for example, ABEND637).

The main reason for this type of damage is that the wrong tape volume gets mounted to satisfy a mount request for a scratch tape. The problem typically remains undiscovered unless you need the overwritten tape volume to recover a data set.

Use the following recovery procedure to restore access to DFSMSHsm data on single-file-format backup tapes that were partially overwritten by user data.

1. Copy the user data to a safe place.

(This step is optional.) If the user data that was written over the DFSMSHsm data is wanted, you will need to create a copy of that data. The damaged tape volume will be returned to scratch or to DFSMSHsm for its later use, and the user data that was written on this volume will be lost at the end of this procedure.
2. Reinitialize the damaged tape volume.

Reinitialize the tape volume with the data set name that is used by DFSMSHsm for all of its tape volumes. Write a dummy data set with the first file on the volume named as below:

prefix.**BACKTAPE.DATASET**

The *prefix* is one of the following:

- The backup prefix as specified on the SETSYS BACKUPPREFIX command
- The UID if prefixes are not specified with the SETSYS commands

This step will create a good tape label on the damaged tape. Once the tape label is valid, the volume can be processed by RECYCLE in step “5” on page 639 of this procedure.

IEBGENER can be used to perform the reinitialization task.

The sample JCL that follows can be used for a damaged backup volume. Modify the JCL to fit your needs by doing the following tasks:

- Change the VOL=SER parameter, as needed.
- Change the *prefix*, as needed.

Included in the example that follows are the various messages that are generated from this job and the appropriate replies.

```
//GENR      JOB
//STEP1     EXEC PGM=IEBGENER
//SYSUT1    DD DUMMY,LRECL=16384,BLKSIZE=16384,RECFM=F
//SYSUT2    DD DISP=(NEW,KEEP),DCB=*.SYSUT1,UNIT=?3480,
//          DSN=prefix.BACKTAPE.DATASET,VOL=SER=?m12volser
//SYSPRINT  DD SYSOUT=*
//SYSIN     DD DUMMY
/*
                J E S 2   J O B   L O G

```

3. Determine if the first data set on the damaged tape volume spanned from another volume.

Issue the LIST TTOC(*volser*) ODS(*dsname*) command to determine if your damaged tape volume is associated with a previous tape volume. If your damaged tape is associated with a previous tape, it will be listed under the heading “PREV VOL.” When there is a previous tape, it means that the first data set on your damaged tape began on the previous tape.

To verify whether your damaged tape is associated with a previous tape, issue the LIST TTOC(*prev_volser*) command and check to see that the last data set name on the previous tape is the same as the first data set name on your damaged tape.

4. Delete the first data set on your damaged tape volume if it spanned from a previous volume.

Issue the following command:

```
BDELETE dsn VERSIONS(n)
```

The original data set name and the backup generation number will be required. To get this information, issue the FIXCDS command to display the MCC record for the backup version. The backup version

generation number is a 2-byte field contained in the MCCGEN field at offset X'46' in the FIXCDS display output. For example, issuing the following command:

```
HSEND FIXCDS C DFHSM.BACK.T500718.TONY3.AHRENS.I3006
```

gives you the following results:

```
MCH= 01602400 A6F7B92B F4BBC221 A6DAB593 9C8BBA03
*      7 4 B      *
+000 E3D6D5E8 F34BC1C8 D9C5D5E2 4BC2C3C4 E2404040 40404040 40404040 40404040
*TONY3.AHRENS.DATA      *
+020 40404040 40404040 40404040 E7E8E9F9 F0F50003 78048081 18075106 0093006F
*      XYZ905      *
+040 00081000 0000001C 000004DD 0121C0E2 0000243C 00003060 0000E3D6
D5E8F0F5
      .
      .
```

The following patch command causes DFSMSHsm to re-drive the POINT MACRO up to ten times when an I/O error is encountered during recycle in order to recover data from a tape that has been overwritten and contains valid DFSMSHsm data beyond the tape marks created by the overwrite.

```
HSEND PATCH .MCVT.+267 X'0A' VERIFY(.MCVT.+267 X'00')
```

At the end of the recovery procedures, issue the following patch command to prevent the re-drive of the POINT Macro.

```
HSEND PATCH .MCVT.+267 X'00' VERIFY(.MCVT.+267 X'0A')
```

Issue the following command to show all versions of the data set if the tape spanned before BDELETE:

```
LIST dsn
```

The output gives you the original data set name: TONY3.AHRENS.BCDS and the version number: +040 00081000 000000 **1C** 000004DD

The deletion would incorporate the information as follows:

```
BDELETE DSN(TONY3.AHRENS.DATA) VERSION(28)
```

The version number gets converted from 1C to decimal (28).

- Depending on the type of error that you are recovering from, it may be necessary to run RECYCLE several times. Issue the following command:

```
RECYCLE VOLUME(volser) EXECUTE
```

Note: Readable, complete, and valid data sets are recycled to a new volume.

Repeat this step to ensure that all available data sets are moved without the use of the FORCE parameter of the RECYCLE command.

- Identify data sets that were overwritten.

Build BACKDS commands for all the backup data sets that were overwritten and that are the most recent backup version. The following DFSORT job can identify and build the BACKDS commands for these data sets. This job only builds the BACKDS commands; it does not process them.

Note: The LRECL on how your BCDS was defined. Issue LISTCAT ENT('yourbcds') ALL to determine maximum record size. LISTCAT will show you MAXLRECL which could be the following:

Maximum record size:

- 6544 bytes, if you need 100 or less active backup versions of any data set, if you use dump class stacking values greater than 99, or if you use fast replication.
- 2093 bytes, if you need 29 or less active backup versions of any data set, or if you use dump class stacking values of 99 or less.

- 2040 bytes, if you need 29 or less active backup versions of any data set, or if you use dump class stacking values of 97 or less.

The following example uses 2040 as maximum record size. For sequential files created in STEP1, STEP2 and STEP3, LRECL used will be maximum record size + 4 for record descriptor word(RDW). RDW is a 4 byte field describing the record. In this example, using 2040 as maximum record size, you would use 2044 for sequential files created in these two steps.

```
//BDSCMDS JOB
//*****
//*?USERID -TO YOUR USER ID

/*
```

7. Issue the DELVOL *volser* BACKUP(PURGE) command. The DELVOL ... (PURGE) command will perform the same functions as a RECYCLE ... FORCE command against the volume without causing a tape mount. The damaged backup tape volume will be deleted from DFSMSHsm inventory and any other control records describing the contents of the volume. DFSMSHsm deletes any association with a day in the backup cycle or with a set of spill backup volumes.
8. Issue the BACKDS commands that were generated in step “6” on page 639.

Note: If you are backing up a data set (with the BACKDS command) that resides on an ML2 tape volume, you need to use the RECALL command to recall the data set before issuing the BACKDS command.

Case 8: Damaged ML1 volumes

To handle a damaged Migration Level 1 (ML1) volume, perform the following steps:

1. Delete the ML1 volume entry of the damaged volume with the following command:

```
DELVOL volser MIGRATION(PURGE)
```

2. Initialize another DASD volume of the same device type as the damaged volume, using the volume serial number of the damaged volume.
3. Restore the damaged ML1 volume from a dump copy. If DFSMSHsm was used to create the dump copy, you can use the following command to restore the ML1 volume:

```
RECOVER * TOVOLUME(volser) UNIT(unittype) FROMDUMP
```

4. If there was a small data set packing (SDSP) data set on the damaged ML1 volume, check to see if there is a backup copy of the SDSP data set that is more recent than the dump copy that is used to restore the volume. If so, recover the backup copy of the SDSP. If an IDCAMS EXPORT command was used to create the backup copy, use the IDCAMS IMPORT command to recover the data set.
5. Add the restored ML1 volume to the list of volumes that DFSMSHsm owns. Use the ADDVOL command, specifying the DRAIN parameter. The DRAIN parameter prevents the volume from being selected for migration output. For example, issue the following command:

```
ADDVOL volser UNIT(unittype) MIGRATION(ML1 DRAIN)
```

If there was an SDSP data set on your ML1 volume, be sure to specify the SDSP parameter on your ADDVOL command. For example, issue the following command:

```
ADDVOL volser UNIT(unittype) MIGRATION(ML1 DRAIN SDSP)
```

6. Move all valid migration data sets and VTOC copy data sets off the ML1 volume with the following FREEVOL command:

```
FREEVOL MIGRATIONVOLUME(volser) AGE(0) TARGETLEVEL(ML1)
```

It is possible to generate tape mounts for ML2 tape volumes if there are valid, migrated, SMS-managed data sets that have reached the criteria for migrating to ML2.

7. Move all valid backup versions to backup volumes with the following command:

```
FREEVOL ML1BACKUPVERSIONS
```

The FREEVOL command causes all valid backup versions from all ML1 volumes to be moved to backup volumes.

8. Identify all lost migrated data sets.

The following is an example of a DFSORT job that identifies migrated data sets that are lost, and builds HDELETE and HRECOVER commands for each data set. This job only builds the HDELETE and HRECOVER commands; it does not process them.

```
//SMCD JOB
//*****
/* PLEASE CHANGE ALL THE FOLLOWING TO THE APPROPRIATE VALUES:

10. Identify which of the lost backup-version data sets were the most recent backup versions of the original data sets.

The following is an example of a DFSORT job that identifies these data sets, and also builds HSEND BACKDS commands for each of the identified data sets. This job only builds the HSEND BACKDS commands; it does not process them.

You will have to assess whether to create new backup versions at this time. You may also want to inform the owners of the data sets that the most recent backup versions of their data sets were lost.

```
//SMCB JOB
//*****
//*PLEASE CHANGE ALL THE FOLLOWING TO THE APPROPRIATE VALUES:
//* ?USERID - TO YOUR USER ID
//* ?DFSMSHSM - TO THE DFSMSHSM PREFIX FOR YOUR BCDS
//* ?VLSER - TO THE VLSER OF YOUR DAMAGED ML1 VOLUME
//*****
//* THIS STEP USES SORT UTILITY TO LOCATE THE MOST
//* RECENT OF ANY BACKUP VERSIONS THAT WERE LOST FROM THE
//* DAMAGED ML1 VOLUME.
//* IT BUILDS HSEND BACKDS COMMANDS FOR EACH BACKUP VERSION.
//* THE HSEND BACKDS COMMANDS ARE PLACED IN THE DATA SET
//* ?USERID.BACKDS.CMDS.
//*****
//STEP1 EXEC PGM=SORT,REGION=4096K
//SYSOUT DD SYSOUT=*
//SORTIN DD DSN=?DFSMSHSM.BCDS,DISP=SHR
//CMDS DD DSN=?USERID.BACKDS.CMDS,
// DISP=(NEW,CATLG), UNIT=SYSDA,

//* FOR EACH DATA SET FOUND.
//*****
//SYSIN DD *
SORT FIELDS=(COPY)
OUTFIL FNAMES=CMDS,
INCLUDE=((51,1,BI,EQ,X'20'),AND,
(69,6,CH,EQ,C'?VLSER')),
CONVERT,OUTREC=(C' HSEND BACKDS ',5,44,255:X)
/*
```

11. Delete all lost migrated data sets by issuing the HDELETE commands that were generated in step “8” on page 642. This step corrects the MCDS so it no longer lists the lost migration data sets as residing on the ML1 volume, and deletes the catalog entries for the data sets.
12. Recover all lost migrated data sets by issuing the HRECOVER commands that were generated in step “8” on page 642. This step recovers the migrated data sets that were lost on the damaged ML1 from backup copies. The data sets are recovered to a level-0 volume.
13. Delete all backup versions that were lost by issuing the HSEND BDELETE commands that were generated in step “9” on page 643. This step corrects the BCDS so it no longer lists the lost backup version data sets as residing on the ML1 volume.
14. Identify all lost VTOC-copy data sets.

ISMF can be used to easily identify which VTOC-copy data sets are lost. The data sets with the following message are no longer on the ML1 volume:

```
DATA SET NOT FOUND ON VOLUME: volser
```

The backup VTOC-copy data set is named as below:

bprefix.VTOC.Tssmmhh.Vvolser.Dyyddd

The dump VTOC-copy data set is named as below:

bprefix.DUMPVTOC.Tssmmhh.Vvolser.Dyyddd

15. Delete the catalog entries for those VTOC-copy data sets that no longer exist on the ML1 volume.
16. Reinitialize the ML1 volume. This will delete all residual data.
17. Define an SDSP data set, if you want one on the ML1 volume.
 - a. If you had an SDSP data set on the damaged volume, you need to delete the catalog entry for that data set by issuing a DELETE NOSCRATCH command.
 - b. Issue the IDCAMS DEFINE command to define a new SDSP data set for the ML1 volume.
18. Change the ML1 volume so it can be selected for migration output by issuing the ADDVOL command with the NODRAIN parameter. For example, issue this command:

```
ADDVOL volser UNIT(unittype) MIGRATION(ML1 NODRAIN)
```

Be sure to specify other parameters as needed, such as SDSP and AUTODUMP.

Case 9: Reestablish access to previously deleted migrated data sets (no backup exists, ML2 only)

To reestablish access to previously deleted migrated data sets, perform the following steps:

1. Create a catalog entry for the data set. Use the IDCAMS DEFINE NONVSAM command with the VOLSER(MIGRAT) and UNIT(*tapeunit*) parameters.
 - a. If the data set is NON-VSAM, run IDCAMS DEFINE data set to VOLSER of MIGRAT to create the catalog entry.

Example JCL:

```
//IDCAMS JOB ,CLASS=A,MSGCLASS=H
//STEP EXEC PGM=IDCAMS
//SYSPRINT DD SYSOUT=*
//SYSIN DD *
  DEFINE NONVSAM -
    (NAME(dsname) -
    DEVT(device type) -
    VOL(MIGRAT))
/*
```

- b. If the data set is VSAM, use IDCAMS DEFINE base and data component to VOLSER of MIGRAT to create the catalog entry.

Example JCL:

```
//IDCAMS JOB ,CLASS=A,MSGCLASS=H
//STEP EXEC PGM=IDCAMS
//SYSPRINT DD SYSOUT=*
//SYSIN DD *
  DEFINE NONVSAM -
    (NAME(xxxxx.ksds) -
    DEVT(device type) -
    VOL(MIGRAT))
  DEFINE NONVSAM -
    (NAME(xxxxx.ksds.data) -
    DEVT(device type) -
    VOL(MIGRAT))
/*
```

Note: For a VSAM data set, define the NONVSAM entry for the base and data component.

2. The MCD record must be altered, if it exists, or created, if it does not exist.
 - a. Use the following command to display the MCD record, if it exists:

```
FIXCDS D data.set.name DISPLAY
```

Then issue the ASSIGNEDBIT command to turn on the bit, which indicates that the data set has migrated:

```
FIXCDS D data.set.name ASSIGNEDBIT(ON)
```

- b. If the MCD record does not exist (the FIXCDS DISPLAY command failed), the following AUDIT command will create it. The ML2 volser is needed for the audit command. If you do not know the volser, check in one of your journal backup versions to locate the journal entry of the MCD record for the migrated data set. Note the migration volume serial number, which is found at offset X'40' in the MCD record. Run the following command with the volser parameter of the ML2 volume:

```
AUDIT MEDCTL VOLUMES(ML2volser) FIX SERIALIZATION(DYNAMIC)
```

- c. For VSAM data sets, if AUDIT issues ERR169 with the data component name, then the MCD was created with the data component name instead of the base cluster name. As explained in the ERR169 message, change this name to the base cluster name before you perform a recall. Issue the following command to change it:

```
FIXCDS D data.component.name NEWKEY(base.name)
```

3. If the data set spans across tape volumes, you must repeat the AUDIT MEDCTL command for each ML2 volser and issue the following FIXCDS commands for the MCD record:

- a. Expand the MCD record:

```
FIXCDS D data.set.name EXPAND(z)
```

where z = number of volumes to which the data set spans $\times 6$

Example: Data set starts on volume **A** and spans to **B** and **C**; $z = 2 \times 6 = 12$. (2 = additional volumes, 6 = 6 characters for each *volser*)

- b. Add additional volsers to the MCDAVSNO array at offset X'194'

```
FIXCDS D data.set.name PATCH(X'194' volserxvolser)
```

where *volserx* = the first additional volume and *volser* equals the second additional volume.

- c. Alter MCDNVSN with the number of additional tape volumes and MCDNVSN0 with the offset of the list of volsers:

```
FIXCDS D data.set.name PATCH(X'D4' X'zzzz0194')
```

where *zzzz* = the number of *volsers* and 0194 equals the offset to the list of volsers as determined in the note below the following example.

Example: An example command altering the MCDNVSN

```
FIXCDS D data.set.name PATCH(X'D4'X'00020194')
```

Note: To determine if a data set has spanned to additional volumes, inspect the MCD record found in the journal backup. The number of "spanned to" volumes is found in a two-byte field starting at offset X'D4'. The location of the list of "spanned to" volumes is found at offset X'D6'. Offsets are given from the beginning of the MCD record. The MCD record found in the backup copy of the journal is appended at the beginning by a 10 byte MLOG, a 44 byte MCK, and a 20 byte MCH header record.

4. Recall the data set.
5. If you follow all steps correctly and you are still unable to recall the data set, contact IBM Support.

Case 10: Correcting errors within the common recall queue

The following indicate the corruption of the common recall queue (CRQ):

- DFSMSHsm issues message ARC1506E.
- DFSMSHsm issues message ARC1187E.
- DFSMSHsm does not select recall requests for processing.

For this last circumstance, issue the QUERY ACTIVE command and examine message ARC1541I. This message displays the factors that affect the selection of requests from the CRQ. A status of anything other than CONNECTED or a hold level of anything other than NONE is a probable reason why certain recall requests are not selected.

Note: An unexpected loss in connectivity to the CRQ may also introduce errors, but in most cases DFSMSHsm will be able to automatically correct those errors. When this occurs, you may see the multiple issuance of message ARC1102I. DFSMSHsm issues message ARC1102I when it attempts to recall a data

set that was previously recalled. Occurrences of this message at the time of a loss in connectivity is normal and not a problem with the CRQ list structure.

If you believe that the CRQ has become corrupted, issue the AUDIT COMMONQUEUE(RECALL) FIX command. When DFSMSHsm issues this command, it scans the entries in the CRQ and attempts to correct logical inconsistencies within the structure. Note that the audit function cannot correct all types of errors and may report zero errors, even though there are errors in the structure.

If messages ARC1506E and ARC1187E recur, or if certain data sets are not selected for recall processing after running the audit function, then perform the following procedure:

1. Capture a dump of the CRQ structure.

- a. As a general rule for dumps, include COUPLE and XESDATA information in SDUMPs.

To display the current options, issue the following command:

```
D D,0
```

If DFSMSHsm does not list COUPLE or XESDATA as options for SDUMP, then issue the following command:

```
CD SET,SDUMP=(COUPLE,XESDATA)
```

- b. Issue this dump command:

```
DUMP COMM=(CRQ LIST STRUCTURE)
```

See: * *id* IEE094D SPECIFY OPERAND(S) FOR DUMP COMMAND

- c. Issue the following command:

```
R id,STRLIST=(STRNAME=SYSARC_basename_RCL,  
(LNUM=ALL,ADJ=CAP,EDATA=UNSER),CONT
```

where *basename* is the base name of the CRQ structure that the following command specified:

```
SETSYS COMMONQUEUE(RECALL(CONNECT(basename)))
```

See: * *id2* IEE094D SPECIFY OPERAND(S) FOR DUMP COMMAND

- d. Issue the following command:

```
R id2,LOCKE,(EMC=ALL),ACC=NOLIM),END
```

2. Reallocate the structure to remove the errors.

- a. Issue the SETSYS COMMONQUEUE(RECALL(DISC)) command on all DFSMSHsm hosts that are connected to the CRQ structure. This will move all recall requests from the CRQ back to the local DFSMSHsm hosts for processing. Each host will issue message ARC1502I after it disconnects from the structure.

The errors within the CRQ may prevent a particular DFSMSHsm host from disconnecting. If this is the case, DFSMSHsm cannot perform the remainder of the steps until that DFSMSHsm host shuts down.

Recommendation: Discontinue using the CRQ until the DFSMSHsm host can be shut down with minimal impact on other DFSMSHsm functions. At this point, no further action is required to prevent DFSMSHsm from attempting to place new requests onto the CRQ.

- b. Once all DFSMSHsm hosts disconnect from the common recall structure, delete the structure.

To determine if all DFSMSHsm hosts have disconnected, issue the following command:

```
D XCF,STR,STRNAME=SYSARC_basename_RCL
```

The number of connections reported should be zero.

To delete the structure, issue the following command:

```
SETXCF FORCE,STR,STRNAME=SYSARC_<basename>_RCL
```

- c. Issue the following command on each DFSMSHsm host that was previously connected:

```
SETSYS COMMONQUEUE(RECALL(CONNECT(<basename>)))
```

This command will cause each host to automatically move all of its local recall requests back onto the CRQ and to reallocate the structure.

3. Capture the Problem Determination Aid (PDA) data.

See [z/OS DFSMSHsm Diagnosis](#) for information on how to perform this action. The collected PDA includes the data from the time that a problem first occurred, through the time that the audit was performed.

4. Contact IBM Support to report the problem.

Case 11: Recovering a deleted ML1 data set without a backup

This procedure assumes that you have a DUMP of the ML1 volume and that you know when the ML1 data set was deleted. You must determine the ML1 volume and the HSM-generated name from either the journal or activity log. This scenario does not account for data sets in an SDSP on a ML1 volume.

To reestablish access to previously deleted migrated data sets, perform the following steps:

1. Determine the ML1 volume and HSM-generated name from the journal. Use the following jobs to obtain this information:
 - a. Copy the journal using IEBGENER before you use SORT.

```
//COPY JOB ,
//
//STEP1 EXEC PGM=IEBGENER
//SYSPRINT DD SYSOUT=*
//SYSIN DD DUMMY
//SYSUT1 DD DISP=SHR,
//          DSN=journal name (the journal data set where the information
//                           about the deleted migrated data set resides)
//SYSUT2 DD DISP=(NEW,CATLG),UNIT=SYSDA,
//          DCB=(LRECL=6556,BLKSIZE=13112,RECFM=VB),
//          SPACE=(CYL,(10,5),RLSE),
//          DSN= copied journal name
/*
```

- b. Process the SORT job.

```
//SORTANY JOB ,
//
//SORT1 EXEC PGM=SORT
//SYSPRINT DD SYSOUT=*
//SORKWK01 DD UNIT=SYSDA,SPACE=(CYL,(10,10))
//SORKWK02 DD UNIT=SYSDA,SPACE=(CYL,(10,10))
//SORTIN DD DISP=SHR,
//          DSN=copied journal name
//SORTOUT DD DISP=(NEW,CATLG),UNIT=SYSDA,
//          DCB=(LRECL=121,BLKSIZE=27951,RECFM=FB),
//          DCB=(LRECL=32756,BLKSIZE=32760,RECFM=VB),
//          SPACE=(CYL,(500,5),RLSE),
//          DSN=output name
//MSGOUT1 DD SYSOUT=*
//SYSOUT DD SYSOUT=*
//SYSIN DD *
//          OPTION VLSHRT
//          MERGE FIELDS=COPY
//          RECORD TYPE=V
//          INCLUDE COND=((63,1,BI,EQ,X'00'),and,(17,1en,CH,EQ,C'dsn'))
//          END
/*
```

Substitute the length of the user data set name for *len* and the data set name for *dsn*. This job will retrieve the MCD records for the data set that was erroneously deleted.

You will have the journal records for the deleted data set in the sorted output data set. The ML1 volume can be determined by going to +76 into the journal record. The HSM-generated name will be at +232. Record the volser of the ML1 volume and the HSM-generated name.

2. Create a NON-VSAM catalog entry that specifies a DEVT(*device type*) and VOL(MIGRAT) where device type is the device type of the ML1 volume.

```
//IDCAMS JOB ,CLASS=A,MSGCLASS=H
//STEP EXEC PGM=IDCAMS
//SYSPRINT DD SYSOUT=*
//SYSIN DD *
        DEFINE NONVSAM -
                (NAME(dsname) -
                DEVT(device type) -
                VOL(MIGRAT))
/*
```

Note: For VSAM data sets, you must create a NON-VSAM entry for both the base and data components.

3. Run the following command to determine which dump volumes you should use:

```
LIST VOLUME(ml1volser) BCDS ALLDUMPS
```

This will list all of the tape volumes that this ML1 volume was dumped to, and when.

4. Restore the data set. Use the list of volumes created by Step 3 as the source volumes to a DFSMSdss RESTORE job specifying the DFSMSHsm-generated name in DATASET(INCL(dsn)).
5. Run the following command to rebuild the MCD and MCA records for the volume:

```
AUDIT MEDIACONTROLS VOLUMES(ml1volser) FIX
```

6. RECALL the data set.

Case 12: Recovering from a large-scale cyber event

Recovering from a large-scale cyber event may require all of an enterprise's disk storage to be recovered to a point-in-time prior to the cyber event. This recovery may result in the various storage media types (disk, tape, cloud object) representing data at disparate points in time. To prepare your DFSMSHsm environment for this type of scenario:

- **Tape:** Utilize the TS7700 capabilities for Expire Hold and logical WORM. (Or, similar capabilities in non-IBM tape products). These functions ensure that tape data that expired after the recovery point is still available when recovering back to the recovery point.
- **Cloud Object Storage:** Enable DFSMSHsm to maintain migration copies in cloud object storage for a specific number of days beyond the day migration copies would normally be deleted. Refer to the *clouddays* parameter of the SETSYS MIGRATIONCLEANUPDAYS command.

Steps to take to resynchronize DFSMSHsm after a recovering disk environment to a prior point-in-time:

- The disk storing of the DFSMSHsm control data sets, all DFSMSHsm owned disk volumes (ML1, ML2 disk, Backup) and all disk containing DFSMSHsm control data set backup copies must be recovered to the same point-in-time.
- Each DFSMSHsm should be placed in Emergency mode. This will quiesce DFSMSHsm data set processing during the recovery process. Refer to [DFSMSHsm libraries and procedures in z/OS DFSMSHsm Implementation and Customization Guide](#) for instructions on starting DFSMSHsm in emergency mode.
- When utilizing tape, on each DFSMSHsm host, issue the DFSMSHsm **SETSYS PARTIALTAPE (MARKFULL)** command. This ensures that DFSMSHsm will not select any tapes for

append activity from the point to which the DFSMSHsm control data sets were recovered, which will potentially vary from the state of the virtual tapes.

- If the DFSMSHsm control data sets are backed up to disk:
 - Issue the **QUERY CDSVERSIONBACKUP** command.

```
ARC0375I
CDSVERSIONBACKUP, MCDSBACKUPDSN=uid.MCDS.BACKUP, BCDSBACKUPDSN=uid.BCDS.BACKUP,
OCDSBACKUPDSN=uid.OCDS.BACKUP, JRNLBACKUPDSN=uid.JRNL.BACKUP
ARC0376I
BACKUPCOPIES=n, BACKUPDEVICECATEGORY=type, LATESTFINALQUALIFIER=Xnnnnnnn, DATAMOVER=type
```

- Issue catalog command **LISTCAT LEVEL(uid)**, using the *uid* displayed in message ARC0375I.
- If the highest final qualifier from the backup data sets provided by LISTCAT is higher than the value displayed by LATESTFINALQUALIFIER in message ARC0376I, then patch the DFSMSHsm control data set with the highest final qualifier as shown from the data sets listed in the catalog:
 - **FIXCDS S MHCR PATCH(X'B1' nnnnnnn)**
- On the Primary host, issue **BACKVOL CDS** to create a current backup of the control data sets.
- On each host, issue the DFSMSHsm **SETSYS NOEMERGENCY** command.
- For each of the DFSMSHsm control data sets:
 - Perform the EXAMINE function. Refer to [z/OS DFSMS Using Data Sets](#).
 - Perform the DIAGNOSE function. Refer to [z/OS DFSMS Access Method Services Commands](#).
- Run the DFSMSHsm AUDIT commands from a single host. These will take a long time to run. It is recommended that the DFSMSHsm control data sets be accessed using VSAM RLS, which can significantly reduce the elapsed time of these commands. For each command, specify NOFIX and an output data set. From the output of each command, take the appropriate action to correct any reported errors.
 - **AUDIT DATASETCONTROLS(MIGRATION)**
 - Based on functional usage:
 - **AUDIT DATASETCONTROLS(BACKUP)**
 - **AUDIT ABARSCONTROLS**
 - **AUDIT COPYPOOL**
 - **AUDIT FILECONTROLS**
 - If errors are encountered on specific tapes, issue **AUDIT MEDIACONTROLS** for those specific volumes.

Chapter 21. Consolidated commands, storage group definitions, and management classes for the example system

This topic presents the consolidation of all of the DFSMSHsm commands, storage group attributes, and management class attributes that were used to show the automatic storage management of the example system. The examples are separated by the kind of command (ADDVOL, DEFINE, SETSYS, and so forth) and by storage group attributes and management class attributes.

ADDVOL command

The ADDVOL command is used to define DFSMSHsm-owned volumes and non-SMS-managed volumes to DFSMSHsm. It is not used for SMS-managed volumes.

Note: A maximum of eight processing units can ADDVOL a primary or migration volume at the same time.

The consolidated ADDVOL command for the example system is:

```
/* DEFINING ML1 VOLUMES TO DFSMSHsm IN ALL PROCESSING UNITS */
ADDVOL ML1001 UNIT(3390) -
  MIGRATION(MIGRATIONLEVEL1 -
    SMALLDATASETPACKING) THRESHOLD(85)

ADDVOL ML1002 UNIT(3390) -
  MIGRATION(MIGRATIONLEVEL1 -
    SMALLDATASETPACKING) THRESHOLD(90)

ADDVOL ML1003 UNIT(3390) -
  MIGRATION(MIGRATIONLEVEL1 -
    NOSMALLDATASETPACKING) THRESHOLD(90)

/* DEFINING AUTOMATIC DUMP OF ML1 VOLUMES IN PROCESSING */
/* UNIT 2 */
ADDVOL ML1001 UNIT(3390) MIGRATION(AUTODUMP -
  (ONEWEEK,TWOWEEK))

ADDVOL ML1002 UNIT(3390) MIGRATION(AUTODUMP -
  (ONEWEEK,TWOWEEK))

Chapter 22. Preventive methods for avoiding data loss

This topic presents methods for avoiding data loss.

Steps for preventing a full journal (damaged CDS)

To prevent a full journal, perform the following steps:

1. Ensure that no reorganization occurs if DFSMSHsm is running on any image in the complex. You must do two things to accomplish this.
 - Make sure that SYSDSN enqueues are in the system's inclusion list for global resource serialization (GRS). This allows the SYSDSN enqueues to be passed to all images in the complex that share the CDSs.
 - Modify the JCL used for reorganization of the CDSs by using a disposition of OLD whenever a DD statement refers to a CDS.
2. Define the DFSMSHsm CDSs with VSAM SHAREOPTIONS(2 3). You can find information about defining VSAM SHAREOPTIONS for DFSMSHsm in the topic about VSAM SHAREOPTIONS for control data sets and associated CDS considerations in [z/OS DFSMSHsm Implementation and Customization Guide](#).
3. Implement a procedure where the backup of the CDSs is closely monitored.

One method of monitoring the backups of the CDSs is to review the CDS backup and export messages in the DFSMSHsm backup activity log. Specifically, review the number of records processed by the export function in message IDC0005I, for each CDS. Compare the record count of the current CDS backup with the record count from the preceding days. The record count may not be the same, but it should be close.

Normal update and deletion activity causes some fluctuation in the number of records in the CDSs. However, when a large decrease in records is detected, you should be able to account for the large difference.

Some large fluctuations in the number of CDS records are normal, and result from processes that reduce the number of records in a CDS. For example, running the EXPIREBV command deletes records in the BCDS. DFSMSHsm secondary space management deletes records in the MCDS. However, some large fluctuations in the number of records in a CDS can indicate that the CDS has been damaged. For example, in a multiple-MVS-image environment, the reorganization of a CDS occurring on one image while DFSMSHsm is running on another image can damage the structure of the CDS, and cause a large fluctuation in CDS records.

To eliminate any doubt about the soundness of the CDS structure, run the IDCAMS EXAMINE command against the CDS in question. Running the EXAMINE command against your CDSs every day minimizes the chance of CDS damage going undetected.

Preventing a full journal (undamaged CDS)

To help prevent the problem of a full journal, ensure that your journal is of adequate size to record all the activity between backups of the CDSs. In conjunction with that, schedule CDS backups frequently enough so that the journal can handle the activity. Most installations run automatic backup once a day, seven days a week; the journal data set therefore needs to be large enough to contain data for a 24-hour time period.

Consider using a large format data set for the DFSMSHsm journal. A large format data set is a physical sequential data set with the ability to grow beyond 65,535 tracks per volume. Using a larger journal data set can allow more DFSMSHsm activity to take place between journal backups and helps to avoid journal full conditions.

Also, use the SETSYS MONITOR (JOURNAL) command to send your warnings when the journal data set is getting full. When the journal data set is filled to the specified threshold, which you can set to any percentage from 0 to 100 or leave at the DFSMSHsm default value of 80%, a warning message is issued to the system operator. Messages continue to be issued until the journal data set is 100% full. Set your threshold at a value that gives you adequate time to back up your CDSs and journal and to allocate a new journal.

Customers that have NetView or another automation product can monitor the ARC0909E and ARC0026E messages, keying in on the 100% and EOVS message variables. When 100% and EOVS are issued, NetView can automatically issue the BACKVOL CDS command.

Preventing structural damage to CDS and missing journal records

Perform the following steps to prevent structural damage to CDS and missing journal records:

1. Schedule reorganizations of CDSs to occur only when necessary. If the CDS is of adequate size, you should not have to reorganize often.
2. Use the proper procedures to reorganize your CDSs.
3. Ensure that no reorganization can occur when DFSMSHsm is running on any MVS image in the complex. To do this:
 - Make sure that SYSDSN enqueues are in the system's inclusion list for global resource serialization (GRS); this allows the SYSDSN enqueues to be passed to all images in the complex that share the CDSs.
 - Modify the JCL used for reorganization of the CDSs by using a disposition of OLD whenever a DD statement refers to a CDS.
4. Define the DFSMSHsm CDSs with VSAM SHAREOPTIONS(2 3).
5. Use the IDCAMS EXAMINE command to do preventive examines.
6. Reassess the number of backup versions you keep for the CDSs and journal. The more backup versions you have, the greater your chances are of having a good CDS and journal backup version to use should the need arise.

Related reading

- For more information about the procedures used to reorganize your control data sets, see the topic about reorganizing the control data sets in [z/OS DFSMSHsm Implementation and Customization Guide](#).
- For more information about defining VSAM SHAREOPTIONS for DFSMSHsm, see the topic about VSAM SHAREOPTIONS for control data sets and the topic about control data set considerations in [z/OS DFSMSHsm Implementation and Customization Guide](#).

Preventing time sequence gaps in CDS records (journal records also missing)

To prevent time sequence gaps in CDS records, perform the following steps:

1. Call on IDCAMS REPRO to create an output data set, check for a successful completion code on the creation of the output data set, and create an input data set.

If a successful completion code is not received for the creation of the output data set, the job ends, and the input data set is not created.
2. Make CDS data sets large enough that the need for a reorganization is infrequent.

If your CDS is currently too small and you want to change that, the next time you reorganize the data set, add 10 cylinders. If the data set is still too small, the next time you reorganize add another 10 cylinders. Do this until the data set is large enough that the need for reorganizations is infrequent.
3. Do a backup of the CDS before every reorganization, and keep those backup tapes until it is time for the next reorganization.

4. Reorganize your CDSs by utilizing the proper procedures.
5. Protect DFSMSHsm's resources with RACF or a comparable product.

Related reading

For more information about reorganizing your control data sets, see the topic about reorganizing the control data sets in [*z/OS DFSMSHsm Implementation and Customization Guide*](#).

Preventing overwritten migration tape or overwritten backup tape

Perform the following steps to avoid overwriting migration tape or backup tape:

1. Protect DFSMSHsm's resources with RACF or a comparable product.
2. Protect your alternate volumes if your tape management system does not do it for you. DFSMSrmm protects your alternate tape volumes. Some products, however, do not.

Prepare for recovery of a head crash on an ML1 volume

To prepare for recovery of a head crash on an ML1 volume, perform the following steps:

1. Use the IDCAMS EXPORT TEMPORARY command to regularly export SDSPs with high activity.

Note: Be sure to use the TEMPORARY parameter with the EXPORT command so the export function does not delete your original data set.

2. Dump ML1 volumes regularly.

Reestablishing access to previously deleted, migrated data sets (no backup exists, ML2 only)

Perform the following steps to reestablish access to previously deleted, migrated data sets:

1. Keep multiple CDS backup versions so you can recover from situations such as this.
2. Create backup copies of data sets that are important. Without a backup copy, the migration copy of a data set is the only copy you have.
3. Use the DCOLLECT function to track what data exists in active, migrated, or backed up format at the time the DCOLLECT function is run. If you run DCOLLECT daily or a couple of times a week, with output going to a generation data group (GDG), the DCOLLECT information could be a valuable asset in data recovery.

Chapter 23. Linux-z/OS DFSMSHsm dump or restore how-to

This topic describes how to back up your Linux partitions and volumes. z/OS is the IBM operating system. You can include your Linux volumes in an existing z/OS backup solution that uses DFSMSHsm. This backup solution works in two environments: (1) a z/OS focused environment with z/OS running on several LPARs and a few dozen Linux servers running under z/VM® in an LPAR; (2) a Linux-focused environment with z/VM running in BASIC mode, with hundreds to thousands of Linux guests, and one or more z/OS guests that will perform the DFSMSHsm processing.

LINUX is a registered trademark of Linus Torvalds.

To get the latest version of this HOW TO and related utilities, check with your Linux provider.

How DFSMSHsm supports linux

This topic provides a discussion of only the supported DFSMSHsm functions for Linux volumes.

For Linux volumes, DFSMSHsm supports only the dump and recover functions. DFSMSHsm dump is a physical copy of DASD tracks to tape. An automatic dump process initiates dump processing on a repeating schedule. After reading this HOW TO, you will know what to do to have your Linux volumes dumped by DFSMSHsm.

Note: Linux volumes should not be managed by SMS.

Using DFSMSHsm with Linux requirements

This topic presents a discussion of several requirements related to using Linux.

Hardware environment

Linux can run on a mainframe under the following three modes:

BASIC

A single operating system that owns the entire mainframe.

LPAR

A mainframe divided into logical partitions, with each partition running its own operating system image. There can be up to 15 LPARs.

VIRTUAL

z/VM supports hundreds to thousands of guests. Each guest runs its own operating system—for example, one guest using Linux and another using z/OS, all on the same hardware.

DASD background

The mainframe environment can store data on Direct Access Storage Device (DASD) by utilizing an extended count-key-data (ECKD) protocol. DASD is divided into logical units known as volumes. Volumes divide into fixed-size tracks, and the track's geometry determines its size. Linux supports both the 3380 and 3390 track geometries. You can reference a volume by using either a 16-bit device number or a six-character volume serial number (referred to as the *volser*). More than one operating system can access a volume at the same time. A volume can have a different device number for each operating system that has access to it, but only one *volser*. Linux allows multiple volumes to have the same volume serial number, while z/OS allows only one volume per instance of z/OS to have the same volume serial number.

Linux requirements

In order for z/OS to process the Linux volumes, they must be formatted in the compatible disk layout (CDL) using **dasdfmt** version 1.0 or later and partitioned using **fdasd** version 1.0 or later.

Linux disk utilities

dasdfmt

The default disk layout for **dasdfmt** is CDL. Volumes in the original format, Linux disk layout (LDL), are not compatible with the z/OS system and cannot be accessed and backed up by z/OS. Below is an example of how to format a disk with **dasdfmt** at address 0198, having a byte block size of 4096, and a *volser* of LNX200:

```
dasdfmt -n 198 -b 4096 -l lnx200
```

A screen appears like the one below:

```
Drive Geometry: 3339 Cylinders * 15 Heads = 50085 Tracks
I am going to format the device 198 in the following way:
  Device number of device : 0x198
  Major number of device  : 94
  Minor number of device   : 8
  Labelling device         : yes
  Disk label               : VOL1
  Disk identifier          : LNX200
  Extent start (trk no)    : 0
  Extent end (trk no)      : 50084
  Compatible Disk Layout   : yes
  Blocksize               : 4096

----> ATTENTION! <---- All data in the specified range of that device
will be lost. Type "yes" to continue, no will leave the disk untouched:
```

You can see a 3339 cylinder volume that is attached to Linux at address 198 in the screen capture above. The volume serial number (*volser*) is LNX200, and its block size is 4096 bytes—the optimal and recommended block size. The *volser* must be six characters in length. If the output reads: Disk label: VOL1, then a z/OS system can process this volume.

If the output reads: Disk label: LNX1, then it is an LDL volume, and z/OS cannot process volumes that do not have VOL1.

fdasd

After you have formatted a volume with **dasdfmt**, you must partition it before Linux can use it. Use the **fdasd** program to partition the volume. This program is similar to the **fdisk** program that comes with the Linux version that runs on personal computers. One difference is that it creates partitions on ECKD DASD instead of hard drives. With **fdasd**, you can create up to three partitions on a volume. Each partition appears to z/OS as a data set. **fdasd** asks you to choose the beginning track and ending track or size of the partition. The naming conventions for the data sets and partitions are listed in [“Data set and partition naming conventions”](#) on page 675.

Follow these rules when you create partitions with **fdasd** that you want to back up with z/OS tools.

- Create partitions by starting from the lowest possible track.
- Do not leave gaps between partitions.
- If you want to restore a partition, **do not** delete it with **fdasd** first. When you delete the partition with **fdasd**, the naming convention between the partition names and data set names is no longer valid. If you then recover a partition on that volume, you could recover over the wrong partition, losing data. When you restore the partition, you replace the existing partition.
- If you follow the previous rules of thumb above, then you can add partitions to a volume at any time up to a maximum of three partitions or until the entire volume is used. If you need to reorganize the

partitions, you should back up the data on the partitions and then delete all partitions and create new ones in the desired configuration.

z/OS requirements

The tools that IBM supports for backing up Linux volumes are DFSMSdss (Data Facilities Storage Management Subsystem data set services) and DFSMSHsm. DFSMSdss and DFSMSHsm are elements of z/OS for backing up data and managing disk space. The z/OS image must also be able to attach and vary online the volumes that Linux is using that you want backed up.

Authorization requirements

You need to have root authority for Linux in order to mount and unmount the partitions, as well as to format and partition the volumes using **dasdfmt** and **fdasd**. For z/OS, you need authority to submit DFSMSHsm commands and, optionally, to run ADRDSSU, which is the program that is invoked when using DFSMSdss. z/OS sees the Linux partitions as data sets. You can prevent unauthorized access of the Linux partitions by z/OS applications and users by using the IBM RACF, a component of the Security Server for z/OS.

Setting up your dump environment for Linux volumes

A Linux volume is formatted with **dasdfmt** in the CDL format and partitions put on it with **fdasd**. It has a valid VTOC on it and a data set for each Linux partition. A Linux volume holds only Linux partitions. No MVS or VM data sets or any non-Linux data should be allowed on a Linux volume. A Linux volume can hold one to three partitions and can be a 3380 or 3390.

The data sets created by **fdasd** are not added to or removed from the catalog by **fdasd** as they are allocated and deleted. If you manually catalog the data sets, you must uncatalog them if you delete them with **fdasd**. It is recommended that you leave the data sets uncataloged. The partition and data set naming conventions are listed in [“Data set and partition naming conventions”](#) on page 675.

Performing only dumps

DFSMSHsm can only dump and recover from dump those Linux volumes that are formatted with **dasdfmt** and partitioned with **fdasd**. All other DFSMSHsm functions are unsupported for Linux volumes. No data sets should be migrated off or recalled to Linux volumes. Backup is not supported for Linux volumes or partitions. Use Linux volumes only as PRIMARY volumes and use them with the NOAUTOBACKUP, NOAUTOMIGRATION, and NOAUTORECALL options. For the dump class that you use with Linux, use the option VTOCCOPIES(0). VTOCCOPIES is not supported for Linux volumes.

When do you want your dumps performed?

If you already use automatic dump, then a time of day and dump cycle is already in place. If not, then typically the time and day of the week is when the system is not very busy. The daily dump cycle consists of a repeating pattern of up to 31 days where dumps are made or not made. Most DFSMSHsm administrators use a weekly or daily dump cycle. You can choose any days where dumps are made to have your volumes dumped; however, some dump days might be busier than others, limiting tape hardware availability on those days. You can also specify how frequently you perform dumps by the minimum number of days that must pass from one dump to the next. If you do not already have automatic dump set up, then tape hardware availability and DASD write activity are the only factors limiting when you can dump your Linux volumes. You can also perform a manual dump of your volumes for special situations.

When scheduling your dumps, you must ensure that no writes to the volumes that you are dumping occur while the dumps are being made. The best way to ensure the data integrity of your partitions and their dumps is to unmount them or to have them mounted as read-only. By unmounting a partition, you flush all buffered data that has not yet been written to the partition.

How long do you want to keep your dumps?

You can specify how many days you want to retain your dumps. You may want to specify how many days you retain your dumps in multiples of how frequently in days that you dump. Then you will always have the same number of dump generations at your disposal.

How many dumps are stacked on each dump tape?

The capacity of current tape technology allows several DASD volumes to be dumped to one dump tape. Only one dump of a specific volume can exist on a dump tape. Once a dump tape has dumps on it, no new dumps can be added to it on any subsequent dump day. Also, a dump tape holds only dumps from one dump class.

Consideration: If you have data that belongs to customers, you may not want to have data from more than one customer on the same tape. If your customer has a right to request all copies of data, and if the data co-exists on a dump tape with another customer's data, you will have to copy the data to another tape. Assigning different dump classes to different customers ensures that their data is on separate tapes.

How many tape drives do you have?

Your mainframe environment probably has many tape drives, but you probably will not be able to use all of them. To limit the number of tape drives that DFSMSHsm uses for dump, use the SETSYS command with the MAXDUMPTASKS option. Once you set the maximum number of dump tasks, you prevent DFSMSHsm from taking up too many tape drives and delaying other functions that also require tape drives.

Recovering your data

When recovering data, unmount any partitions that are being recovered during the recovery process to ensure data integrity. There are several ways you can recover your data from a DFSMSHsm dump. You can recover an entire volume with DFSMSHsm or DFSMSdss. You can also recover a partition from a dump with DFSMSHsm or DFSMSdss. To use DFSMSdss to process Linux volumes, see [z/OS DFSMSdss Storage Administration](#). When a volume or partition is recovered, the dump overwrites it; the partition or volume then returns to the state at which the dump was made. All changes since the dump was made are lost. See [“Data set and partition naming conventions” on page 675](#) on the data set and partition naming conventions to make sure that the right partition is recovered.

There are some limitations in how you can recover to a Linux volume. For a volume of more than 65536 tracks, you can recover only the full volume from a dump; no individual data sets can be recovered to it with DFSMSHsm. However, you can recover a data set to a volume over 65536 tracks from a DFSMSHsm dump with DFSMSdss. To use DFSMSdss on Linux volumes and partitions, see [z/OS DFSMSdss Storage Administration](#). Either a full volume or an individual data set can be recovered to a volume of less than 65536 tracks by DFSMSHsm. When you recover a data set or volume with DFSMSHsm, you must specify the FROMDUMP(DUMPVOLUME(volser)) option. You can list the dump volumes with the LIST DUMPVOLUME command.

Recovering a volume with DFSMSHsm

To recover a volume with DFSMSHsm, you need to know only the volser of the volume you want recovered and from how far back you want your volume recovered. Remember, you can go only as far back as the number of days you have been keeping your dumps. You can go back by date or by the generation of dump where generation 0 is the most recent dump, generation 1 is the second most recent dump, and so on.

The following command recovers volume LNX400 from the third most recent dump.

```
RECOVER * TOVOLUME(LNX400) UNIT(3390) - FROMDUMP(DUMPGENERATION(2))
```

You can also recover a dump to a volume other than the one that was used to make the dump with DFSMSHsm. For instance, you can dump volume LNX400 and recover the dump to volume SPARE5; but in

the process, volume SPARE5 is renamed with volume LNX400's volser, which is not a problem for Linux as it is for z/OS. The z/OS operating system cannot have two or more volumes with the same volser online at the same time. The original volume must be varied offline before the recovery is started. You need to know the volsers of both the volume you want recovered and the volume you want the dump recovered to.

The following command recovers the most recent dump of volume LNX400 to volume SPARE5 and changes the volser of volume SPARE5 to LNX400. Volume LNX400 must be varied offline in MVS before this recovery command is issued.

```
RECOVER * TOVOLUME(LNX400) UNIT(3390) TARGETVOLUME(SPARE5) - FROMDUMP
```

If you do not have an extra volume attached to your Linux environment, you need to shut it down and reconfigure your environment with the extra volume and reboot your Linux environment. You do not have to do this in MVS.

Recovering a volume with DFSMSdss

To recover a volume from a DFSMShsm dump with DFSMSdss, use the LIST command to find the volser of the dump tape volume that contains the dump you want to recover. See [“The DFSMShsm LIST command” on page 675](#) on how to use the LIST command. You can search the output data set for the volser of the volume you want to recover. Once you find the dump that you want to recover in the output data set, you will find the volser of the dump volume and the data set name of your dump. If you recover the dump to an alternate volume, DFSMSdss does not change the volser to that of the volume that the dump was created from. You need to submit JCL to use DFSMSdss. Once you have the information that you need from the output data set, you can submit a job like the following to recover your volume.

The following JCL recovers the dump data set DFHSM.DMP.DAILY.VLNX300.D01244.T072510 to volume LNX300 from dump tape A02001.

```
//LNXJOB JOB , 'IBMUSER',MSGLEVEL=(1,1),TIME=(5,0),REGION=4096K,
//      MSGCLASS=A,CLASS=A
//STEPDSS EXEC PGM=ADRDSSU
//SYSPRINT DD SYSOUT=*
//SOURCE   DD UNIT=3480,VOL=SER=A02001,DISP=OLD,
//          DSN=DFHSM.DMP.DAILY.VLNX300.D01244.T072510
//TARGET   DD UNIT=3390,VOL=SER=LNX300,DISP=OLD
//SYSIN    DD *
//          RESTORE FULL INDDNAME(SOURCE) OUTDDNAME(TARGET) PURGE
//          /*
```

Recovering a partition with DFSMShsm

When you recover a partition, leave the original damaged partition in place. If you do not still have the original partition or you want to recover the partition to another volume, then you first must preallocate a partition of the exact same number of tracks with **fdasd**. You must know the volser of the volume that contains the partition you want to recover, which partition to recover, and how far back you want to recover from. If you had to preallocate a partition, then you also need to know the volser of the preallocated partition and which partition you preallocated. The preallocated partition does not need a file system.

If a Linux user does not follow the rules of thumb in [“fdasd” on page 666](#), then the data set name of one or more of the partitions could be changed. The **fdasd** utility initially creates the data sets in order where PART0001 is always the data set that has the lowest starting track, PART0002 has the next lowest starting track, and PART0003 has the highest starting track. Once a partition is removed with **fdasd**, any other changes made after the first removal may cause the order and naming not to be valid. See the naming conventions in [“Naming conventions” on page 675](#).

You also need to know the volser of the dump tape that contains the dump from which you want to recover. To find the volser of the dump tape, use the LIST command. See [“The DFSMShsm LIST command” on page 675](#) on how to use the LIST command.

The following command recovers data set LINUX.VLNX300.PART0001.NATIVE on volume LNX300 from the dump of LNX300 on dump tape LX0001. If the dump of volume LNX300 was the only dump on the

dump tape, omit the SOURCEVOLUME parameter, but if dumps from two or more volumes are stacked on the dump tape, then you must specify SOURCEVOLUME.

```
RECOVER LINUX.VLN300.PART0001.NATIVE TOVOLUME(LNX300) - UNIT(3390)
FROMDUMP(DUMPVOLUME(LX0001) SOURCEVOLUME(LNX300)) - REPLACE
```

To recover a data set to an alternate location, use the RENAME and TOVOLUME options to rename the data set (using the naming convention listed in [“Data set and partition naming conventions”](#) on page 675) and to specify the volume that you want the data set recovered to.

The following command recovers data set LINUX.VLN300.PART0002.NATIVE from the dump on dump tape LX0002 to volume LNX100 and renames it LINUX.VLN100.PART0001.NATIVE, replacing the preallocated data set on LNX100.

```
RECOVER LINUX.VLN300.PART0002.NATIVE - FROMDUMP(DUMPVOLUME(LX0002)) -
NEWNAME(LINUX.VLN100.PART0001.NATIVE) REPLACE - TOVOLUME(LNX100) UNIT(3390)
```

Recovering a partition with DFSMSdss

To recover a partition from a DFSMSshm dump with DFSMSdss, use the LIST command to get the same information needed to recover a volume with DFSMSdss. See [“The DFSMSshm LIST command”](#) on page 675 on how to use the LIST command. You also need the data set name for the data set that holds the partition you want recovered and the data set name for the partition that you want the dump recovered to.

The following JCL recovers LINUX.VLN300.PART0001.NATIVE from dump DFHSM.DMP.DAILY.VLN300.D01244.T072510 on dump tape A02001 to volume LNX200 and renames it LINUX.VLN200.PART0001.NATIVE, replacing the data set of the same name on LNX200. If you are restoring the data set to its original volume, then you can omit the RENAME portion.

```
//LNXJOB JOB , 'IBMUSER',MSGLEVEL=(1,1),TIME=(5,0),REGION=0M,
//      MSGCLASS=A,CLASS=A
//STEPDSS EXEC PGM=ADDRSSU
//SYSPRINT DD SYSOUT=*
//SOURCE DD UNIT=3480,VOL=SER=A02001,DISP=OLD,
//        DSN=DFHSM.DMP.DAILY.VLN300.D01244.T072510
//TARGET DD UNIT=3390,VOL=SER=LNX200,DISP=OLD
//SYSIN DD *
//      RESTORE INDDNAME(SOURCE) OUTDDNAME(TARGET) -
//              DATASET(INCLUDE(LINUX.VLN300.PART0001.NATIVE)) -
//              RENAME(LINUX.VLN200.PART0001.NATIVE) REPLACE
//*
```

Example dump environment

This example consists of one 3390-3 volume of about 2.9 gigabytes and one 3390-9 volume of about 8.7 gigabytes and a 65 cylinder 3390 of about 45 megabytes. The volumes will be dumped at 10:00 am to 3480 tapes on two 3480 tape drives. The 3390-3 and 3390-9 will be dumped daily and the 65 cylinder will be dumped weekly. The dump cycle will be a seven day, weekly cycle. The **fdasd** utility will be used to partition each volume as follows.

```

Disk /dev/dasd/0199/disc:
    65 cylinders,
    15 tracks per cylinder,
    12 blocks per track
    4096 bytes per block
volume label: VOL1, volume identifier: LNX100
maximum partition number: 3

-----tracks-----
Device      start    end    length  Id  System
/dev/dasd/0199/part1      2     974     973   1  Linux native

Disk /dev/dasd/0198/disc:
    3339 cylinders,
    15 tracks per cylinder,
    12 blocks per track
    4096 bytes per block
volume label: VOL1, volume identifier: LNX200
maximum partition number: 3

-----tracks-----
Device      start    end    length  Id  System
/dev/dasd/0198/part1      2    3201    3200   1  Linux native
/dev/dasd/0198/part2   3202   50084   46883   2  Linux native

Disk /dev/dasd/019a/disc:
    10017 cylinders,
    15 tracks per cylinder,
    12 blocks per track
    4096 bytes per block
volume label: VOL1, volume identifier: LNX300
maximum partition number: 3

-----tracks-----
Device      start    end    length  Id  System
/dev/dasd/019a/part1      2    3201    3200   1  Linux native
/dev/dasd/019a/part2   3202    4267    1066   2  Linux native
/dev/dasd/019a/part3   4268   150254  145987   3  Linux native

```

The partitions will be mounted as follows.

```

/dev/dasd/0198/part1 on /example type ext2 (rw)
/dev/dasd/0199/part1 on /example/boot type ext2 (rw)
/dev/dasd/0198/part2 on /example/usr type ext2 (rw)
/dev/dasd/019a/part1 on /example/var type ext2 (rw)
/dev/dasd/019a/part2 on /example/tmp type ext2 (rw)
/dev/dasd/019a/part3 on /example/home type ext2 (rw)

```

This example is designed to demonstrate how one might implement a simple DFSMSHsm dump environment for a Linux guest on z/VM. It is not intended to demonstrate how to best partition volumes for Linux.

How to define your dump cycle

Before you start automatic dump, you must define a dump cycle. This environment uses a daily dump cycle. The start date must be today's date or a date that has already passed. You need to use a past date if you are using a dump cycle of more than one day and today is not the first day in the dump cycle.

The command below has the first Y day coincide with the day of 2001/08/26, which is a Sunday. Of the dump classes listed in the next topic, the WEEKLY dump class has a DAY value of 7, so it is dumped on Saturdays. The MONTHLY dump class has a DAY value of 1, so it is dumped on Sundays. Because the DAILY dump class has no DAY value specified, it dumps on all Y days. If an N were in the dump cycle, automatic dump would not dump any volumes on that day.

```
DEFINE DUMPCYCLE(YYYYYYY CYCLESTARTDATE 2001/08/26)
```

How to define your dump classes

LNX100 must be backed up only once a week because it will not change very often. LNX200 and LNX300 change more often and must be backed up daily. Because this environment uses a weekly dump cycle, the

DAY and FREQUENCY options determine which days each dump class is dumped. The daily and weekly dumps are short-term dumps that are not kept for long. Another dump class creates dumps monthly and keeps the dumps for three months. All of the dump classes have a STACK value of three to allow dumps from up to three volumes to be put on one dump tape. One is the default STACK value, meaning that no stacking will occur. The following commands define the dump classes.

```
DEFINE DUMPCLASS(DAILY AUTOREUSE FREQUENCY(0) -  
    RETENTIONPERIOD(3) STACK(3) UNIT(3480) VTCCOPIES(0))  
  
DEFINE DUMPCLASS(WEEKLY AUTOREUSE FREQUENCY(0) DAY(7) -  
    RETENTIONPERIOD(28) STACK(3) UNIT(3480) VTCCOPIES(0))  
  
DEFINE DUMPCLASS(MONTHLY AUTOREUSE FREQUENCY(28) DAY(1) -  
    RETENTIONPERIOD(90) STACK(3) UNIT(3480) VTCCOPIES(0))
```

If, for example, you have only two tape drives at your disposal, use the SETSYS command to set the maximum number of dumps that may be taken at any one time.

```
SETSYS MAXDUMPTASKS(2)
```

How to ADDVOL your volumes

Because the volumes will only be dumped, automatic migration and backup features are not allowed. When the dumps expire, the dump tapes are automatically reused for later dumps.

```
ADDVOL LNX100 UNIT(3390) PRIMARY(AUTODUMP(WEEKLY,MONTHLY) -  
    NOAUTOBACKUP NOAUTOMIGRATION NOAUTORECALL)  
  
ADDVOL LNX200 UNIT(3390) PRIMARY(AUTODUMP(DAILY,MONTHLY) -  
    NOAUTOBACKUP NOAUTOMIGRATION NOAUTORECALL)  
  
ADDVOL LNX300 UNIT(3390) PRIMARY(AUTODUMP(DAILY,MONTHLY) -  
    NOAUTOBACKUP NOAUTOMIGRATION NOAUTORECALL)
```

How to start automatic dumping

To automatically dump the volumes, issue the SETSYS AUTODUMPSTART command with the start and finish times.

```
SETSYS AUTODUMPSTART(1100 1200 0000)
```

The times are in a 24-hour format. The first time is when automatic can start, the second time is the latest that an automatic dump can start, and the third time is the latest that a dump of a volume can start. Because the third time is 0000, all volumes are dumped if automatic dump starts. To turn off automatic dump, resubmit the command with all three times equal to 0000.

To manually dump the volumes, issue the BACKVOL command.

```
BACKVOL VOLUMES(LNX100,LNX300,LNX400) -  
    DUMP(DUMPCLASS(WEEKLY,MONTHLY))
```

If you omit DUMPCLASS(WEEKLY,MONTHLY), the volumes are dumped to the dump classes listed for each volume with the AUTODUMP option when it was added with ADDVOL, but no stacking occurs. You can list up to five dump classes. Dumps made manually are taken into account when recovering from a dump by generation or date. If you are only going to be dumping manually, you can omit the AUTODUMP option when you ADDVOL your volumes. You can use any valid dump class, regardless of the AUTODUMP option.

If you decide to create your dumps manually, you still need to run automatic dump to have old dumps expire. To have automatic dump run without actually taking dumps, you can define a dump cycle of one N day.

Recovering from a dump

Before recovering any data, you must leave any partitions that you want to recover in place or reallocate them with **fdasd**; otherwise, Linux cannot see the partitions that have been recovered. Listed here are only a few basic examples of recovering data. For a full description on how to recover data, see [Chapter 60, “RECOVER command: Recovering a backup version or dump copy of a data set, or UNIX file, or a volume,”](#) on page 997.

Recovering with DFSMSHsm

To recover a volume with DFSMSHsm, issue the RECOVER command.

The following RECOVER command recovers LNX200 from the most recent dump.

```
RECOVER * TOVOLUME(LNX200) UNIT(3390) FROMDUMP
```

The following RECOVER command recovers LNX200 from the most recent dump of the MONTHLY dump class.

```
RECOVER * TOVOLUME(LNX200) UNIT(3390) -  
FROMDUMP(DUMPCLASS(MONTHLY))
```

The following RECOVER command recovers LNX200 from the third most recent dump. Generation 0 is the most recent dump, 1 is the second most recent, and so on.

```
RECOVER * TOVOLUME(LNX200) UNIT(3390) -  
FROMDUMP(DUMPGENERATION(2))
```

To recover a partition from a DFSMSHsm dump with DFSMSHsm, you again use the RECOVER command and the LIST command. See [“The DFSMSHsm LIST command”](#) on page 675 on how to use the LIST command. You must use the LIST command to find the dump tape that has the dump from which you want to recover your partition. You also need to know the data set and partition naming conventions so that you recover the correct data set for your partition. The naming conventions are listed in [“Naming conventions”](#) on page 675.

The following RECOVER command recovers data set LINUX.VLNX200.PART0002.NATIVE that holds partition part2 on LNX200. You must specify the SOURCEVOLUME parameter if the dump class has a STACK value greater than one because the dump tape may hold more than one dump data set.

```
RECOVER LINUX.VLNX200.PART0002.NATIVE -  
FROMDUMP(DUMPVOLUME(LX0001) SOURCEVOLUME(LNX200)) REPLACE
```

Recovering data from DFSMSHsm dump with DFSMSdss

Before you recover a volume from a DFSMSHsm dump with DFSMSdss, you must use the LIST command to see what dumps you have. See [“The DFSMSHsm LIST command”](#) on page 675 on how to use the LIST command. Once you find the dump you want to use, you can write and submit JCL to have DFSMSdss recover the volume.

The following JCL recovers dump data set DFHSM.DMP.MONTHLY.VLNX300.D01245.T234610 to volume LNX300. If there is more than one dump stacked on the tape, you must specify the file sequence number of the label keyword. You can get the file sequence number from the information provided by the LIST command in the next topic.

```
//LNXJOB JOB ,USER=IBMUSER,PASSWORD=IBM,MSGLEVEL=(1,1),TIME=(5,0),REGION=4096K,
//      MSGCLASS=A,CLASS=A
//STEPDSS EXEC PGM=ADRDSSU
//SYSPRINT DD SYSOUT=*
//SOURCE   DD UNIT=3480,VOL=SER=(A02005,A02008,A02010),DISP=OLD,
//          LABEL=(2),DSN=DFHSM,DMP.MONTHLY.VLNX300.D01245.T234610
//TARGET   DD UNIT=3390,VOL=SER=LN300,DISP=OLD
//SYSIN    DD *
RESTORE INDDNAME(SOURCE) OUTDDNAME(TARGET) PURGE
/*
```

To recover a partition from a DFSMSHsm dump with DFSMSdss, use the LIST command like before to find the dump tape and dump data set from which you want to recover your partition. You also need the data set name of your partition. See [“Data set and partition naming conventions” on page 675](#) for the partition and data set naming conventions.

The following JCL recovers data set LINUX.VLNX300.PART0001.NATIVE from dump data set DFHSM.DMP.MONTHLY.VLNX300.D01245.T234610 to volume LN300.

```
//LNXJOB JOB ,USER=IBMUSER,PASSWORD=IBM,MSGLEVEL=(1,1),TIME=(5,0),REGION=4096K,
//      MSGCLASS=A,CLASS=A
//STEPDSS EXEC PGM=ADRDSSU
//SYSPRINT DD SYSOUT=*
//SOURCE   DD UNIT=3480,VOL=SER=(A02005,A02008,A02010),DISP=OLD,
//          LABEL=(2),DSN=DFHSM,DMP.MONTHLY.VLNX300.D01245.T234610
//TARGET   DD UNIT=3390,VOL=SER=LN300,DISP=OLD
//SYSIN    DD *
RESTORE INDDNAME(SOURCE) OUTDDNAME(TARGET) -
        DATASET(INCLUDE(LINUX.VLNX300.PART0001.NATIVE)) REPLACE
/*
```

Submitting DFSMSHsm commands using JCL and FTP

You can submit DFSMSHsm commands by sending JCL files through ftp to z/OS and have output data sets sent back to your Linux system. You must have TCP/IP and ftp running and a userid and password authorized to use ftp. Once you log into the z/OS ftp server you must enter the following command.

```
site filetype=jes
```

```
//LNXDUMP JOB ,CLASS=A,USER=IBMUSER,PASSWORD=IBM,
//      MSGCLASS=H,REGION=4096K,MSGLEVEL=(1,1)
//LISTDUMP EXEC PGM=IKJEFT01
//SYSTSPRT DD SYSOUT=A
//SYSTSIN  DD *
HSEND LIST DUMPVOLUME ODS(LIST.DUMP.VOLUMES)
//FTPDUMP EXEC PGM=FTP,COND=(0,NE,LISTDUMP),
//          PARM='1.2.3.4'
//SYSPRINT DD SYSOUT=*
//OUTPUT  DD SYSOUT=*
//SAVE    DD *
/*
//INPUT    DD *
userid
password
ascii
put 'LIST.DUMP.VOLUMES' dump.list
quit
/*
```

The IKJEFT01 program in the above JCL allows you to submit TSO line commands. The HSEND command allows DFSMSHsm commands to be submitted from TSO. After HSEND you can use any DFSMSHsm command. In the second step, the data set LIST.DUMP.VOLUMES is sent through ftp to IP address 1.2.3.4 and given a file name of dump.list.

Dataset Names	Partition Names
LINUX.Vvolser.PART0001.type	/dev/dasd/yyyy/part1
LINUX.Vvolser.PART0002.type	/dev/dasd/yyyy/part2
LINUX.Vvolser.PART0003.type	/dev/dasd/yyyy/part3

Where *volser* is the volume serial number of the volume that the data set is on. *yyyy* is the device number of the volume in the Linux environment. Type can be NATIVE or SWAP. Only NATIVE partitions need to be backed up. SWAP partitions are the Linux equivalent to page packs.

Volume serial number naming conventions

The volume serial number of a volume must be 6 characters of upper case letters or numbers. The volser can also have @ , # , and \$.

Valid Volsers

LINUXA	LNK100	\$BILLS	VOL#11
123456	A@FB2#	\$@#32A	5#2\$XA

Part 2. DFSMSHsm Storage Administration Reference

This topic contains detailed explanations of the operator, storage administrator, and system programmer commands, which are listed in alphabetical order.

Purposes of DFSMSHsm commands

- Define DFSMSHsm values and volumes,
- Determine status,
- Maintain and recover the control data sets and the DFSMSHsm address space,
- Maintain data sets and volumes,
- Operate DFSMSHsm.

Use the following commands to define the values and volumes for DFSMSHsm:

Command	Purpose
ADDVOL	Adds a new volume to the set of volumes owned or managed by DFSMSHsm and changes existing volume information defined with earlier ADDVOL commands.
AUTH	If the RACF FACILITY class is not active, DFSMSHsm uses the AUTH command to protect storage administrator DFSMSHsm commands.
DEFINE	Defines the structure of DASD level 2 volumes for DFSMSHsm and defines a data set or volume pool related to non-SMS recalls. It also defines the automatic backup cycle, the secondary space management cycle, the dump cycle, dump classes, the volumes for aggregate recovery, and times for automatically demounting tapes currently in use by data set backup.
DELVOL	Removes a volume from the list of volumes managed by DFSMSHsm and changes existing volume information.
SETSYS	Changes the values of various DFSMSHsm parameters from their current values or defaults.

Use the following commands and parameters to determine status:

Command	Purpose
AUDIT	Detects and reports discrepancies about data set information in the computing system catalog, the aggregate backup and recovery ABR record, the DFSMSHsm control data set records, and the VTOC of the DASD storage volume on which the data set resides. Note: This command also corrects discrepancies in the common recall queue.
LIST	Lists data set, user, volume, TTOC, and control data set record-serialization records from the DFSMSHsm control data sets.
QUERY	Lists values of parameters specified with DFSMSHsm commands, lists DFSMSHsm statistics, or lists the status of pending requests.
REPORT	Generates reports based on the DFSMSHsm statistics recorded in the MCDS.

Use the following commands to maintain and recover the control data sets and the DFSMSHsm address space. Note, that the first four commands are only for diagnosis and repair.

Command	Purpose
DISPLAY	Displays the contents of locations within the DFSMSHsm address space identified by an absolute address, a relative address, or a qualified address.
FIXCDS	Displays, modifies, and adds and deletes records in the MCDS, BCDS, and OCDS.
PATCH	Modifies storage within the DFSMSHsm address space.
TRAP	Specifies whether DFSMSHsm should write a log entry or cause a dump to be taken when the error specified with the TRAP command occurs.

Command	Purpose
UPDATEC	Combines the entries in the journal data set with a restored backup copy of one or all of the control data sets. See “Recovering control data sets using the enhanced CDS recovery function” on page 508 for the recommended way to recover control data sets that run outside the DFSMSHsm address space.
UPDTCDS	Update specific fields within the control data sets: the expiration date of copy pool dump copies.

Use the following commands to directly manage data sets or volumes (as opposed to the automatic management functions of DFSMSHsm):

Command	Purpose
ALTERDS	Changes the number of backup versions maintained and the frequency of creating backup versions for a non-SMS-managed data set.
ABACKUP	Backs up aggregate groups of user-defined data sets for recovery at another location.
ARECOVER	Recovers the data sets that were backed up by the ABACKUP command.
BACKDS	Creates a backup version of a specific data set.
BACKVOL	Requests that DFSMSHsm back up eligible data sets on one or more volumes, in one or more storage groups, or on all primary volumes; or that it back up the control data sets. This command can also request that DFSMSHsm invoke DFSMSdss to dump one or more volumes, or one or more storage groups.
BDELETE	Deletes all the backup versions or specific backup versions of a specific data set.
DELETE	Deletes a migrated data set without recalling the data set.
EXPIREBV	Deletes all eligible expired backup versions from all backup volumes.
FRBACKUP	Creates a fast replication backup version for each volume in a specified copy pool.
FRDELETE	Deletes one or more unneeded fast replication backup versions.
FREEVOL	Moves all migration copies meeting a specified age criteria between DFSMSHsm migration or backup volumes.
FRRECOV	Uses fast replication to recover a single volume or a pool of volumes from the managed backup versions.
MIGRATE	Moves eligible data sets from DFSMSHsm-managed volumes to migration volumes or from migration volumes to other migration volumes. It can also delete non-SMS-managed data sets from either DFSMSHsm-managed volumes or migration volumes.
RECALL	Returns migrated data sets to DFSMSHsm-managed volumes.
RECOVER	Obtains backed-up or dumped data sets and copies them to DFSMSHsm-managed volumes.
RECYCLE	Consolidates onto fewer DFSMSHsm-owned tapes valid data that is interspersed with invalid data on many DFSMSHsm-owned tapes.
SETMIG	Changes the space management status of a specific data set or group of data sets on DFSMSHsm-managed, non-SMS-managed volumes.
TAPECOPY	Makes copies of classes of DFSMSHsm-owned tapes or of individual DFSMSHsm-owned tapes and identifies the copies as alternate tapes to the original tapes.
TAPEREPL	Replaces references to original tapes with references to alternate tapes.

Use the following commands to operate DFSMSHsm:

Command	Purpose
CANCEL	Cancels existing queued DFSMSHsm requests for: <ul style="list-style-type: none"> • A specific request number • All requests for a particular user • All requests for a particular data set
HOLD	Prevents all or part of DFSMSHsm’s functions from running. Also causes the data set backup switchtapes action to occur immediately.
HSEND CMD	Issues DFSMSHsm-authorized-user commands from a TSO terminal.

Command	Purpose
LOG	Enters information into the DFSMSHsm log.
RELEASE	Releases for processing all or part of the DFSMSHsm functions that have been held.
STOP	Causes an orderly shutdown of DFSMSHsm.
SWAPLOG	Causes DFSMSHsm to exchange its LOGX data set for its LOGY data set or exchange its PDOX data set for its PDOY data set.

Command function changes for SMS

In a non-SMS environment, DFSMSHsm is controlled by commands and several parameters that describe the configuration and determine how and when DFSMSHsm functions are performed. In an SMS environment, the storage management functions defined in the management class and the storage group control the SMS-managed data sets in place of the parameter or command definitions within DFSMSHsm. The parameters formerly used on the SETSYS command and shown in [Table 54 on page 679](#) do not apply to SMS-managed data sets.

Table 54. SETSYS Parameters Not Applicable to SMS-Managed Data Sets

DFSMSHsm Parameter, Non-SMS	SMS Equivalent
DAYS	PRIMARY DAYS NON-USAGE
MIGRATIONLEVEL1DAYS	LEVEL 1 DAYS NON-USAGE
None	PARTIAL RELEASE
SETMIG (command)	COMMAND OR AUTO MIGRATE
None	ADMIN OR USER COMMAND BACKUP
None	# GDG ELEMENTS ON PRIMARY
None	ROLLED-OFF GDS ACTION
FREQUENCY	BACKUP FREQUENCY
None	GUARANTEED BACKUP FREQUENCY
VERSIONS	NUMBER OF BACKUP VERSIONS (DATA SET EXISTS)
None	NUMBER OF BACKUP VERSIONS (DATA SET DELETED)
None	RETAIN DAYS ONLY BACKUP VERSION (DATA SET DELETED)
None	RETAIN DAYS EXTRA BACKUP VERSIONS
None	EXPIRE AFTER DAYS NON-USAGE
None	EXPIRE AFTER DATE/DAYS

The functions of certain DFSMSHsm commands are assumed by management class and storage group attributes for SMS-managed data sets and volumes. [Table 55 on page 679](#) shows these commands and the SMS construct that assumes their functions.

Table 55. DFSMSHsm Commands Not Used for SMS Storage Management

DFSMSHsm Command, Non-SMS	SMS Class
DEFINE POOL	Storage group
DEFINE VOLUMEPOOL	Storage group

Table 55. DFSMSHsm Commands Not Used for SMS Storage Management (continued)

DFSMSHsm Command, Non-SMS	SMS Class
ADDVOL	Storage group
ALTERDS	Management class
SETMIG	Management class
SETMIG VOLUME	Storage group

Long-running commands

The AUDIT, EXPIREBV, LIST, RECYCLE, REPORT, and TAPECOPY commands are known as long-running commands. Long-running commands are limited to having only one of each such command being performed by DFSMSHsm at any time.

Other commands can also run for a long time. If a command is running for a long time and is returning data to your terminal, you can be prevented from performing other operations at your terminal. An example might be a LIST or AUDIT command that is returning large amounts of data. To stop such a command from interfering with your use of your terminal, have the computer system operator issue a HOLD command for the function that is causing the interference. The operator can then issue a RELEASE command for the function, but the command that was being performed does not restart. For example, if a LIST command returns data to your terminal and prevents you from using it, have the operator issue a HOLD LIST and RELEASE LIST command sequence. The list command that is causing you trouble does not restart.

Chapter 24. DFSMSHsm commands

There are four groups of DFSMSHsm commands:

- User
- Operator
- Storage administrator
- System programmer

The user commands are listed here for your information, but *z/OS DFSMSHsm Managing Your Own Data* describes them in detail. This book contains detailed explanations of the operator, storage administrator, and system programmer commands, which are listed in alphabetical order.

Several commands listed below can be specified in the ARCCMDxx PARMLIB member at startup time. The descriptions for the appropriate commands are found in "DFSMSHsm Libraries and Procedures" in the *z/OS DFSMSHsm Implementation and Customization Guide*.

User commands

The following user commands are used by application programmers, TSO terminal users, and other data processing personnel involved in storage administration:

HALTERDS

Changes the data set parameters that affect backup

HBACKDS

Backs up a specific data set

HBDELETE

Deletes a backup version of a data set

HCANCEL

Cancels an existing queued request

HDELETE

Deletes a migrated data set on a level 1 or level 2 volume

HLIST

Lists information from the migration and backup control data sets

HMIGRATE

Migrates a specific data set

HQUERY

Lists DFSMSHsm requests

HRECALL

Recalls a specific data set

HRECOVER

Recovers a backup version of a data set

Operator commands

The following operator commands are submitted primarily by a system operator from the system console. They can also be submitted by an authorized user from a TSO terminal.

CANCEL

Cancels an existing request

HOLD

Suspends all or part of DFSMSHsm functions

LOG

Enters data into the DFSMSHsm log

QUERY

Lists the status of DFSMSHsm parameters and pending requests

RELEASE

Releases for processing all or part of the DFSMSHsm functions

STOP

Shuts down DFSMSHsm

SWAPLOG

Switches between the DFSMSHsm log data sets

Storage administrator commands

The following storage administrator commands are submitted primarily by an authorized storage administrator who uses the HSEND CMD command to issue these commands from a TSO terminal. All storage administrator commands, except the HSEND CMD and the ONLYIF commands, and BEGIN and END operators, can also be submitted by a system operator from the system console.

ABACKUP

Backs up a specified aggregate group

ADDVOL

Adds or changes the volumes DFSMSHsm manages or owns

ALTERDS

Changes the data set parameters that affect back up

ALTERPRI

Alters the priority of queued DFSMSHsm requests

ARECOVER

Recovers a specified aggregate group

AUDIT

Audits DFSMSHsm

AUTH

Identifies authorized DFSMSHsm users

BACKDS

Backs up a specific data set

BACKVOL

Backs up or dumps data sets from a volume

BDELETE

Deletes backup versions of a data set

DEFINE

Defines control structures for use by DFSMSHsm

DELETE

Deletes a migrated data set from a migration volume

DELVOL

Removes a volume from the list of volumes DFSMSHsm manages or owns

EXPIREBV

Deletes unwanted backup versions from DFSMSHsm-owned storage

FRBACKUP

Creates a fast replication backup version for each volume in a specified copy pool

FRDELETE

Deletes one or more fast replication backup versions in a specified copy pool

FREEVOL

Moves migration or backup copies

FRRECOV

Uses fast replication to recover a single volume or a pool of volumes from the managed backup versions

HSEND CMD

Issues authorized user commands from a TSO terminal

LIST

Lists information from the MCDS, BCDS, and OCDS

MIGRATE

Requests a space management function

ONLYIF

Allows conditional execution of the single command, or group of commands contained within a BEGIN...END block, immediately following the ONLYIF command in ARCCMDxx.

RECALL

Recalls a specific data set

RECOVER

Recovers a backup version or dump copy of a data set or volume

RECYCLE

Consolidates valid data on one tape from other tapes

REPORT

Requests reports based on daily or volume statistics records

SETMIG

Changes the space management status of data sets or volumes

SETSYS

Establishes or changes the values of various DFSMSHsm control parameters

TAPECOPY

Copies cartridge-type single-file tape volumes

TAPEREPL

Replaces cartridge-type single-file tape volumes

UPDTCDS

Updates the control data sets

System programmer commands

The following system programmer commands are submitted primarily by an authorized system programmer who uses the HSEND CMD command to issue these commands from a TSO terminal. They can also be submitted by an authorized user from a TSO terminal or by a system operator from the system console.

DISPLAY

Displays DFSMSHsm storage locations

FIXCDS

Displays or modifies MCDS, BCDS, and OCDS records

PATCH

Modifies storage within DFSMSHsm

TRAP

Requests a dump when a specified error occurs

UPDATEC

Recovers the control data sets

Note: DISPLAY, FIXCDS, PATCH, and TRAP are commands used only for maintenance and are explained in the *z/OS DFSMSHsm Diagnosis*.

Using RACF FACILITY class to control authorization of commands

The use of the RACF FACILITY class allows security administrators to control who can issue DFSMSHsm commands. Security administrators can define RACF profiles that DFSMSHsm honors.

In order to use RACF FACILITY class checking, the RACF FACILITY class must be active when DFSMSHsm is started. If the RACF FACILITY class is active, DFSMSHsm uses RACF FACILITY class checking for all authorized and user commands. Adding or modifying the RACF FACILITY class resources does not require a restart of DFSMSHsm. If the RACF FACILITY class is used to control access to DFSMSHsm commands, the resources defined at the time a command is processed will be used to determine authorization for that command.

If the RACF FACILITY class is not active when DFSMSHsm starts, DFSMSHsm uses the AUTH command to process all storage administrator commands.

Related reading

For a full list of RACF FACILITY class resource names, see the topic about authorizing and protecting DFSMSHsm resources in *z/OS DFSMSHsm Implementation and Customization Guide*.

Using DFSMSHsm commands

Before using the DFSMSHsm commands and their parameters, you should read and understand the following use and notational conventions for DFSMSHsm commands.

A command consists of a command name usually followed by one or more operands. The maximum size of a DFSMSHsm command and its operands is 1024 bytes. All operands described in this book are called parameters, which qualify certain commands to perform the requested functions.

Example: The parameters associated with the BACKDS command specify the name of the data set that you want DFSMSHsm to back up and, optionally, the volume and unit that contains the data set to be backed up. An example of the BACKDS command is:

```
BACKDS TEST.CASES VOLUME(VOL123) UNIT(3390) /*comment*/
```

where:

BACKDS

is the command name.

TEST.CASES

is the name of the data set you want to back up.

VOLUME(VOL123)

is the parameter, specifying the volume that contains the uncataloged data set to be backed up.

UNIT(3390)

is the parameter, specifying the unit where the volume can be allocated.

/*comment*/

is a comment about the command, the parameter, or both.

All TSO conventions apply to the syntax of DFSMSHsm commands. DFSMSHsm commands use positional and keyword parameters.

Positional parameters

Positional parameters follow the command name in a prescribed sequence. There are two types of positional parameters: required and optional. You must specify required positional parameters immediately after the command name. If you use optional positional parameters, you must specify

them immediately after any required positional parameters. If the command does not have any required positional parameters, you must specify any optional positional parameters immediately after the command name. If you specify a list of items to replace a positional parameter, you must put parentheses around the list; otherwise, you do not have to use the parentheses. For example, you can specify a list of data set names with the ALTERDS command by putting parentheses around the list of data set names. If you specify only one data set name, you do not have to use parentheses.

Keyword parameters

Keyword parameters are specific words or symbols that have a meaning to DFSMSHsm. They follow positional parameters and can occur in any order.

Italic type specifies values or variables that you supply to DFSMSHsm. You can specify values or variables with some keyword parameters by putting them in parentheses after the keyword parameter. An example of a keyword with a value follows:

```
VOLUME(volser)
```

Some keyword parameters are separated by a vertical bar, for example, `TERMINAL | SYSOUT | OUTDATASET`. This bar shows keywords that conflict with one another. You can consider the bar to be a logic **OR**. The above statement would read, `TERMINAL OR SYSOUT OR OUTDATASET`. Do not use the vertical bar when you submit the command.

Note:

1. If you enter conflicting parameters in a single command, the last parameter entered in the command overrides all previously entered conflicting parameters and is the only parameter of those in conflict that is processed. All the previous conflicting parameters within the command are ignored.
2. If you enter the same parameter more than once in a single command, only the last of the repeated parameters entered in the command is processed.
3. As long as valid parameters are specified on a command, extraneous parameters are ignored.
4. Unless you are specifically restricted in a parameter explanation, you can code numeric parameters in three different ways:
 - Decimal (EBCDIC)
 - Hexadecimal (X'n')
 - Binary (B'n')

If you issue commands from the system console, you must enter the DFSMSHsm commands in the following manner:

```
F DFSMSHSM,command
```

You should replace the **DFSMSHSM** abbreviation with the procedure name in the startup procedure in SYS1.PROCLIB.

Abbreviating commands and parameters

The TSO abbreviation convention applies for all DFSMSHsm storage administrator, system programmer, and operator command names and parameters. The TSO abbreviation convention requires you to specify as much of the command name or parameter as is necessary to distinguish it from the other command names or parameters. For example, the VERSIONS parameter of the ALTERDS command can be abbreviated as V (also VE, VER, VERS, VERSI, VERSIO, and VERSION).

Some DFSMSHsm keyword parameters allow unique abbreviations. All unique abbreviations are shown in the command syntax diagrams.

Delimiters

When issuing a DFSMSHsm command, use one or more blanks to separate the command name from the first parameter. To separate succeeding parameters use one or more blanks or a comma. Do not use a semicolon as a delimiter because any characters that follow a semicolon are ignored.

Line continuations

When you continue a command to the next line during batch processing (for instance from the batch reader or a PARMLIB member), insert a plus or minus sign as the last character of each line except the last line of the command. If a comment is included on the same line, the plus or minus sign follows the comment. Refer to [“Comments” on page 686](#) for information about comments. When you use a plus sign, leading delimiters are removed from the continued line.

For commands entered from a TSO terminal, do not use a line-continuation character. All command examples in this book are commands entered for batch processing.

Example: The following is an example of a line continuation with a comment and a line continuation that does not have a comment.

```
SETSYS AUTOBACKUPSTART(1800 2100 2300) /* set start times */ +
AUTOMIGRATIONSTART(2300 0600 0800) +
BACKUP BACKUPPREFIX(HSM)
```

Data set naming conventions

When you specify a data set name with a DFSMSHsm command, the data set name must conform to TSO data set naming conventions. With DFSMSHsm, you can use the characters \$, @, and # as the first character in the data set name. A hyphen (-) can be used as a character in a data set name; however, when a hyphen is used as the last character in a data set name, it may be mistaken for a continuation symbol.

You cannot specify an alias data set name for authorized commands. See [“Storage administrator commands” on page 682](#) for a list of authorized commands.

Comments

You can add comments to DFSMSHsm commands anywhere that a blank might appear. To set off your comments, enter them between the symbols /* and */. You can continue a comment to the next line by using a line continuation character (+ or -) at the end of the line following the */ of the comment.

Example: The following is an example of using comments:

```
COMMAND1 PARAMETER1 /* comment */ +
PARAMETER2 /* comment */ +
/* more comments */ +
PARAMETER3 /* comment */
COMMAND2 PARAMETER1 +
PARAMETER2 /* comment */
```

TSO attention key

If your terminal is locked because DFSMSHsm is executing a command with the WAIT parameter specified, message ARC1020I explains that you can cancel the wait state by pressing the attention key. If you press the attention key, you will receive the following message:

```
ARC1023A CONVERTING TO A NON-WAIT WILL FAIL THE USER REQUEST,
BUT WILL ALLOW THE {RECALL | RECOVER | MIGRATE | BACKUP |
DELETE | HSEND CMD} TO COMPLETE IN THE BACKGROUND.
CONVERT Y OR N?
```

If you respond Y, you are released from the wait state while the command completes processing. If you respond N, the wait state continues until the command has completed processing.

If your terminal is locked because DFSMSHsm is executing an HLIST command with the WAIT parameter specified and if you press the attention key, you will receive the following message:

```
ARC1025A DO YOU WISH TO CANCEL DFSMSHsm LIST REQUEST? ENTER Y OR N
```

If you respond Y, DFSMSHsm terminates processing of the HLIST command. If you respond N, DFSMSHsm completes processing of the HLIST command.

Note: If you are in full screen mode when the TSO attention key is pressed (for example, ISPF browse), the screen that is displayed after the attention interrupt does not show correct information. Press the refresh key, which is usually the PA2 key, to display the correct information on your screen.

How to read syntax diagrams

See [“How to read syntax diagrams”](#) on page liv.

Considering the command sequence

In the DFSMSHsm environment, certain commands must follow a particular sequence to ensure that the command does not malfunction or fail. The following table lists these sequences:

Table 56. Command sequence	
Issue This Command	Before This Command
ADDVOL	DEFINE POOL or DEFINE VOLUMEPOOL
DEFINE DUMPCLASS	ADDVOL with either AUTODUMP or DUMPCLASS parameters
SETSYS JES2 or JES3	ADDVOL commands
SETSYS SMALLDATASET PACKING	ADDVOL with SDSP
SETSYS SYSOUT	SETSYS ACTLOGTYPE
SETSYS UNITNAME	SETSYS CDSVERSIONBACKUP
SETSYS USERUNITTABLE	ADDVOL
	ARECOVERUNITNAME(unittype)
	DEFINE with a DUMPCLASS(unittype)
	ABACKUP
	ARECOVER
	SETSYS BACKUP(tape)
	SETSYS CDSVERSIONBACKUP
	SETSYS MIGUNITNAME
	SETSYS RECYCLEOUTPUT
	SETSYS SPILL
	SETSYS TAPEMIGRATION
	SETSYS UNITNAME

Submitting DFSMSHsm commands

A DFSMSHsm user with access to the system can submit the operator, storage administrator, and system programmer commands from the system console. If you want to submit these same commands from

a TSO terminal, you must be an authorized user. To issue these commands from a TSO terminal, the authorized user must preface each command with the HSEND CMD command. For example, if you want to submit the HOLD MIGRATION command from a TSO terminal, you specify the following:

```
HSEND CMD HOLD MIGRATION
```

If you are authorized by the database authority control attribute, you can use the AUTH command to add another user to the list of users with DFSMSHsm authorization. If you are an authorized user, you can submit the AUTH command from a TSO terminal. If you submit a command from a TSO terminal, DFSMSHsm checks your TSO identification for DFSMSHsm authorization.

In systems with RACF, a component of the Security Server for z/OS, you can submit the operator, storage administrator, and system programmer commands for processing in batch mode if you are an authorized user. To do this, your TSO identification must be specified on the JOB statement of the MVS JCL (`USER=userid`). RACF scans the *userid* field and builds the control blocks DFSMSHsm uses to confirm the authorization of the person who submitted the command.

If the batch submittal fails because the user ID is missing or invalid, DFSMSHsm cannot issue a message to your terminal but notes the exception in the DFSMSHsm log. The following example shows the MVS JCL for submitting the system programmer REPORT command to request DFSMSHsm daily and volume statistics reports:

```
//REPTJOB JOB ...,USER=userid,...
//STEP1 EXEC PGM=IKJEFT01,REGION=512K
//SYSPRINT DD SYSOUT=A
//SYSTSPRT DD SYSOUT=A
//SYSTSIN DD *
        HSEND CMD REPORT DAILY FUNCTION
        HSEND CMD REPORT VOLUME FUNCTION
/*
```

Commands in a system without RACF: Method 1

In a system without RACF, you can submit operator, storage administrator, and system programmer commands for batch processing by defining the HSEND CMD command to the terminal monitor program (TMP) as an authorized command and by providing a STEPLIB or JOBLIB card to an authorized program facility (APF) authorized version of module ARCMCMD.

To use method 1, do the following:

- Instead of specifying `USER=userid` on the JOB card, add the HSEND CMD command to the authorized commands table in TMP so that this command can be invoked and submitted to DFSMSHsm as an acceptable, authorized command.
- Modify the CSECT IKJEFT2 within the IKJEFT02 load module to indicate that HSEND CMD is an authorized command and should be attached with APF authorization.
 - Make this modification to the first entry in IKJEFT2 that contains eight blanks, and ensure that one blank entry remains in the authorized command table to indicate the end of the table.
 - In the *z/OS TSO/E Customization*, the authorized command table has been moved to a CSECT in a separate load module named IKJTABLS. The IKJTABLS load module is located in the SYS1.LPALIB.
- Link-edit the DFSMSHsm module ARCMCMD (the HSEND CMD command processor) into an APF-authorized library as an authorized program.
- Ensure that the job submitting the HSEND CMD command uses a STEPLIB or JOBLIB card to this library.
- Restrict access to this APF library to prevent unauthorized use of the HSEND CMD command.

The system programmer is responsible for ensuring that any DFSMSHsm maintenance to module ARCMCMD is also applied to the authorized copy of ARCMCMD. All concatenated STEPLIBs must be authorized. The APF library name must appear either in the system LINKLIST or in the appropriate IEAAPFxx of the SYS1.PARMLIB. (The IEAAPFxx member is used to identify program libraries that

require APF authorization). See [z/OS MVS Initialization and Tuning Guide](#) for more information about the IEAAPFxx member.

The following job step link-edits the ARCMCMD module to create an authorized copy of ARCMCMD:

```
//LINKED EXEC PGM=IEWL,PARM='LIST,LET,NCAL,XREF,RENT,REUS'
//SYSPRINT DD SYSOUT=A
//SYSUT1 DD UNIT=SYSDA,SPACE=(CYL,(1,1))
//SYSLMOD DD DISP=SHR,DSN=DFHSM.AUTHLIB
//IN DD DISP=SHR,DSN=SYS1.CMDLIB
//SYSLIN DD *
INCLUDE IN HSENDCCMD
SETCODE AC(1)
ENTRY ARCMCMD
NAME HSENDCCMD(R)
/*
```

The successful execution of this link-edit results in message IEW0461 for ARCWTU2 and ARCCVT.

Commands in a system without RACF: Method 2

You can use another method to process authorized commands from a batch TMP on a system without RACF installed. To use this option, you must ensure that the TSO user ID is stored in the protected step control block (PSCB).

First, define the user ID as an authorized user by entering the following command:

```
AUTH userid DATABASEAUTHORITY(USER)
```

The AUTH command is submitted as part of the PARMLIB member being processed during DFSMSHsm startup.

Then enter the following command:

```
SETSYS ACCEPTPSCBUSERID
```

DFSMSHsm retrieves the user ID for the TSO batch requests from the PSCB and associates it with the previously defined user ID.

For more information about adding authorized commands to the TSO/E environment, see [z/OS TSO/E Customization](#).

Chapter 25. ABACKUP command: Backing up aggregated data sets

The DFSMSHsm ABACKUP command creates a copy of a specified, user-defined aggregate group of data sets. Aggregated data sets can be any combination of data sets treated as an entity, for example, an application. The aggregated data sets must be cataloged. A BCDS must be defined at the backup site prior to issuing an ABACKUP command; otherwise, the command fails.

Note: In some topics, you will find the term *Application Backup and Recovery* used rather than *Aggregate Backup and Recovery*. The two terms are interchangeable.

To create a copy of aggregate data sets with the ABACKUP command, you must:

- Specify the name of the predefined aggregate group that identifies the user-defined aggregated data sets.
- Specify the EXECUTE parameter of the ABACKUP command.

Note: To determine if any changes are required to either the existing SMS constructs or SMS environment prior to actual data movement, run the ABACKUP command with the VERIFY parameter prior to running the ABACKUP command with the EXECUTE parameter. The VERIFY parameter detects whether any errors exist in the aggregate backup configuration and lists all input tape volumes that are required at the aggregate backup site when a subsequent EXECUTE is submitted.

The ABARS backup error installation exit (ARCBEEEXT) allows you to skip a data set when DFSMSdss errors occur while DFSMSdss is dumping level 0 DASD data sets in the INCLUDE list. Specifying the SETSYS EXITON(BE) command is only required if you wish to skip data sets in error and it must be specified prior to issuing the ABACKUP command.

If you have volumes protected by peer-to-peer remote copy (PPRC) or extended remote copy (XRC), you can direct ABACKUP processing to skip backing up data sets from those volumes.

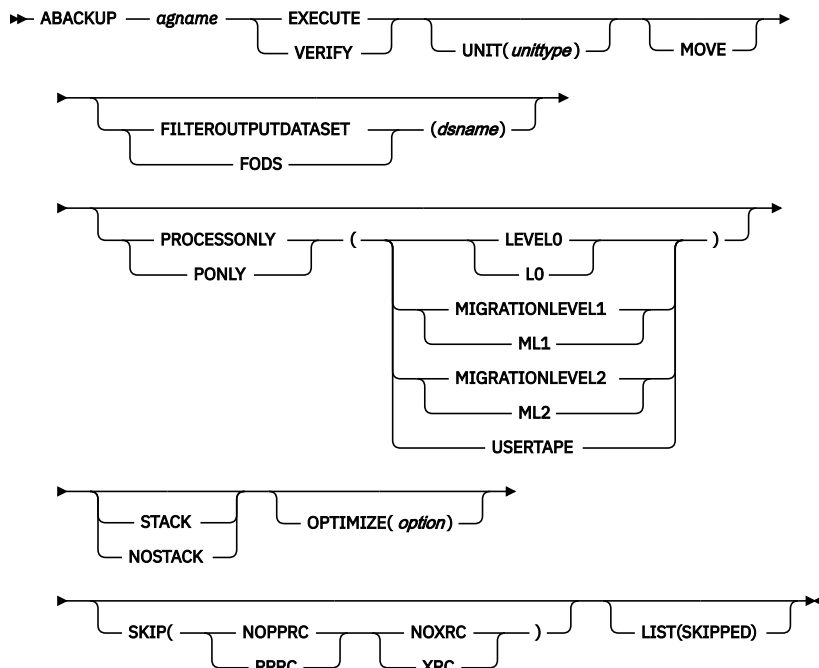

Upon successful completion of ABACKUP processing, an aggregate backup and recovery support (ABARS) activity record (ABR record) is created and written to the DFSMSHsm backup control data set (BCDS) at the backup site. When multiple ABACKUP copies are created, there is one ABR record created for each copy of the output files. See Chapter 8, “Aggregate backup and recovery support (ABARS),” on page 319 for a description of the information contained in the ABR record.

You can use the ARECOVER command to recover the data sets previously backed up with the ABACKUP command.

Note: Issuing the ABACKUP and ARECOVER commands while SETSYS DEBUG is in effect causes the commands to be processed as if the VERIFY parameter were in effect. For additional information on SETSYS DEBUG, see “Using DEBUG to determine the results of DFSMSHsm processing without moving data sets” on page 587.

For information on defining aggregate groups using ISMF panels, see [z/OS DFSMSdfp Storage Administration](#).

Syntax of the ABACKUP command

Note:

1. SMS must be active on your system before you can issue the ABACKUP command.
2. The SETSYS MAXABARSADDRESSSPACE command determines the number of ABACKUP commands that can run at one time. The maximum number is 64.
3. Only one ABACKUP command for each aggregate group name can process at one time.
4. In a multiple address space for DFSMSHsm environment, ABARS commands, like ABACKUP, can only be issued by the host identified as the main host. DFSMSHsm ignores the ABARS commands if directed to a host identified as HOSTMODE=AUX.

Required parameters of the ABACKUP command

This topic describes the required parameters of the ABACKUP command.

agname: Specifying the aggregate group name

Explanation: *agname* is a required parameter specifying the SMS aggregate group name that defines the data sets you want backed up. It contains the necessary control information to perform the aggregate backup. For *agname*, substitute the name of the SMS aggregate group.

Defaults: None.

Note: You must define the aggregate group before issuing the ABACKUP command. If you have specified a management class name in the aggregate group definition, make sure that you also define or update that management class prior to issuing the ABACKUP command. Refer to [z/OS DFSMSdfp Storage Administration](#) for information on how to define the aggregate group using ISMF panels.

EXECUTE and VERIFY: Specifying whether data movement processing or data verification occurs

Explanation: **EXECUTE** | **VERIFY** are mutually exclusive required parameters specifying whether actual data movement should occur or whether a validation of the aggregate data sets should be performed.

EXECUTE specifies that DFSMSHsm is to create the backup copies of the aggregate data sets.

VERIFY determines if errors exist that would prevent ABACKUP from completing successfully. If no errors have occurred during verification processing, VERIFY specifies that DFSMSHsm issue message ARC6166I to the aggregate backup and recovery activity log and list all data sets (migrated and nonmigrated) backed up as a result of inclusion in the INCLUDE/EXCLUDE, ACCOMPANY/ACCOMPANYEXCLUDE, ALLOCATE/ALLOCATEEXCLUDE lists of a selection data set. The data sets are not actually backed up.

Note: Either the EXECUTE or the VERIFY parameter must be used. If not, the ABACKUP command will fail.

Defaults: None.

Optional parameters of the ABACKUP command

This topic describes the optional parameters of the ABACKUP command.

FILTEROUTPUTDATASET: Specifying the output data set

Explanation: **FILTEROUTPUTDATASET(dsname)** is an optional parameter specifying the name of a data set to which the lists of data sets selected from INCLUDE/EXCLUDE, ALLOCATE/ALLOCATEEXCLUDE, ACCOMPANY/ACCOMPANYEXCLUDE filtering are written.

dsname specifies the name of the output data set. The data set name may be 1 to 44 characters in length. If the data set already exists on DASD and has the correct data set attributes, then the existing data set is used. If the data set does not exist, then a new data set is created.

Note: If the user has restricted ABACKUP command authority, then that user must have a minimum of update authority in order to append to the existing RACF protected filter output data set or allocation authority in order to create the new filter output data set.

When the FILTEROUTPUTDATASET parameter is specified along with the PROCESSIONLY parameter, then the filter output data set contains those data sets that passed the filtering criteria and also match the category designated in the PROCESSIONLY parameter.

Defaults: None.

LIST: Listing data sets not backed up due to the SKIP parameter

Explanation: LIST (SKIPPED) is an optional parameter that specifies whether DFSMSHsm should list, in the ABARS activity log, those data sets not backed up because the SKIP(PPRC) or SKIP(XRC) parameter is also specified.

The LIST parameter has no effect if you specify VERIFY.

Defaults: None.

MOVE: Removing the data sets

Explanation: MOVE is an optional parameter that specifies whether to delete, uncatalog, or both delete and uncatalog all selected data sets after a successful aggregate backup.

After a successful backup of an application, the MOVE option causes ABACKUP to delete all of the data sets in the application. The data set types in the application are affected in the following manner:

- DASD data sets are deleted
- TAPE data sets are uncataloged
- ACCOMPANY data sets are uncataloged
- ALLOCATE data sets are deleted from DASD (except ICF user catalogs in the ALLOCATE list)
- MIGRATED data sets are deleted

Defaults: None.

OPTIMIZE: Overriding the SETSYS ABARSOPTIMIZE command

Explanation: **OPTIMIZE(option)** is used to override the usage of the SETSYS ABARSOPTIMIZE command. The OPTIMIZE parameter is passed to and used by DFSMSdss when backing up level 0 DASD data sets.

The valid specifications for the *option* value are:

- If value is 1, then DFSMSdss reads one track at a time
- If value is 2, then DFSMSdss reads two tracks at a time
- If value is 3, then DFSMSdss reads five tracks at a time
- If value is 4, then DFSMSdss reads one cylinder at a time

Defaults: The default value for *option* is the value specified on the SETSYS ABARSOPTIMIZE command. If SETSYS ABARSOPTIMIZE was not specified, then this parameter defaults to 3.

PROCESSONLY: Designating the categories to process

Explanation: **PROCESSONLY** is an optional parameter that directs DFSMSHsm to process only the specified subcategories. The subcategories can be specified in any order. Specification of all four subcategories is accepted but is equivalent to not specifying the PROCESSONLY parameter.

Note: Migration copies of data sets that reside in the cloud are not supported. If you select any migration copies, the ABACKUP command fails.

The subparameters in the following table are mutually exclusive required choices.

Subparameter	Explanation
LEVEL0	PROCESSONLY(LEVEL0) specifies that only data sets residing on user DASD are processed.
MIGRATIONLEVEL1	PROCESSONLY(MIGRATIONLEVEL1) specifies that only data sets residing on DFSMSHsm migration level 1 DASD are processed.
MIGRATIONLEVEL2	PROCESSONLY(MIGRATIONLEVEL2) specifies that only data sets residing on DFSMSHsm migration level 2 tape or DASD are processed.
USERTAPE	PROCESSONLY(USERTAPE) specifies that only data sets residing on user tape are processed.

Defaults: None.

SKIP: Skipping data sets on volumes protected by PPRC or XRC

Explanation: SKIP is an optional parameter that specifies whether DFSMSHsm should skip data sets on volumes protected by PPRC or XRC.

Subparameter	Explanation
The following subparameters are mutually exclusive required choices.	
PPRC	SKIP(PPRC) If a data set in the aggregate group is on a volume or volumes protected by peer-to-peer remote copy, specifying SKIP(PPRC) causes ABACKUP to not back up the data set.
NOPPRC	SKIP(NOPPRC) If you specify SKIP(NOPPRC), this causes ABACKUP to back up the corresponding data set.
The following subparameters are mutually exclusive required choices.	
XRC	SKIP(XRC) If a data set is on a volume or volumes that are protected by extended remote copy, specifying SKIP(XRC) causes ABACKUP to not back up the data set.

Subparameter	Explanation
NOXRC	SKIP(NOXRC) If you specify SKIP(NOXRC), this causes ABACKUP to back up the corresponding data set.

Defaults: Each option for this parameter defaults to the corresponding setting of the SETSYS ABARSKIP parameter.

STACK and NOSTACK: Overriding the SETSYS ABARSTAPES setting

Explanation: **STACK** | **NOSTACK** is an optional parameter used to override the SETSYS ABARSTAPES setting.

STACK specifies that DFSMSHsm will stack the ABACKUP output files onto a minimum number of tape volumes during ABACKUP processing.

NOSTACK specifies that DFSMSHsm will not stack the ABACKUP output files during ABACKUP processing.

Defaults: This parameter defaults to the setting specified on the SETSYS ABARSTAPES command. If SETSYS ABARSTAPES was not specified, then this parameter defaults to STACK.

UNIT: Designating the output device

Explanation: **UNIT(unittype)** is an optional parameter specifying the type of tape unit where aggregate backup output files can be allocated. For *unittype*, substitute the type of tape unit. If this parameter is not specified on the ABACKUP command, the UNIT defaults to the UNIT specified in the ABARSUNITNAME parameter of the SETSYS command.

The following are valid types of tape units:

- 3480
- 3480X
- 3490
- 3590-1

You can substitute an esoteric tape unit defined with the SETSYS USERUNITTABLE command. If you specify an esoteric tape unit name that does not exist in the user unit table, the command fails. If you specify:

- 3480 or 3480X, you use all the functions of the 3480 Magnetic Tape Subsystem.
- 3490, you use all the functions of the 3490 Magnetic Tape Subsystem.
- 3590-1, you use all the functions of the 3590 Magnetic Tape Subsystem.

If you define both 3592-E05 and 3592-J1A to the same esoteric group, the E05 must use the EFMT1 recording format.

You can define a 3592-E05 or 3592-J1A to the 3590-1 generic group. If so, you must ensure drive compatibility or segmentation when using the 3590-1 in a non-SMS environment.

When you are specifying esoteric names and dealing with units that can use the 3480X or 3490 Improved Data Recording Capability (IDRC), all devices (or none of them) associated with an esoteric name are required to have the 3480X or 3490 IDRC.

Note: In a tape library environment, SMS ACS routines override this parameter at allocation time.

Defaults: None.

Examples of how to code the ABACKUP command

The following examples present different ways to code the ABACKUP command.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Displaying the application data sets to be backed up and verifying application backup

In this example, the data sets to be backed up, as indicated in the aggregate group PAY1, are displayed. The ABACKUP command is verified to ensure that it can complete successfully with no errors. No data sets are backed up.

```
ABACKUP PAY1 VERIFY
```

Backing up the application data sets

In this example, the data sets to be backed up, as indicated in the aggregate group PAY1, are backed up. A 3590-1 is specified as the tape unit type for the control and data files.

```
ABACKUP PAY1 EXECUTE UNIT(3590-1)
```

Backing up the application data sets to a minimum number of tapes

In this example, the data sets to be backed up, as indicated in the aggregate group PAY1, are backed up and the output files are stacked onto a minimum number of tape volumes.

```
ABACKUP PAY1 EXECUTE STACK
```

Sample activity log created when you specify ABACKUP with the VERIFY parameter

Figure 91 on page 696 is a sample activity log created when you specify ABACKUP with the VERIFY parameter. The processing has been successful. The data sets listed in the sample activity log would actually be backed up if you issued the ABACKUP command with the EXECUTE parameter.

```

Figure 91. Sample Activity Log Created When You Specify ABACKUP with the VERIFY Parameter

Chapter 26. ADDVOL command: Adding or changing DFSMSHsm volumes

The DFSMSHsm ADDVOL command adds new non-SMS-managed volumes to the list of volumes that DFSMSHsm manages or owns and defines the attributes of those volumes. You must issue the ADDVOL command for each non-SMS-managed volume that you want DFSMSHsm to manage or own, including those volumes defined for aggregate recovery with the DEFINE ARPOOL command. In addition, the initialization procedure for DFSMSHsm must issue an ADDVOL command for each primary and migration level 1 volume each time you start DFSMSHsm.

Attention: Do not issue simultaneous ADDVOL commands for backup volumes from multiple systems because this may, in rare cases, create duplicate BVR entries in DFSMSHsm control data sets records.

Use the ADDVOL command for the following purposes:

- Add to DFSMSHsm control a non-SMS-managed volume that has never been added before.
- Add to DFSMSHsm control a primary or migration level 1 volume that has been added previously, but not since the current DFSMSHsm startup.

Note: You do not need to specify migration level 2, backup, or dump volumes each time you start DFSMSHsm.

- Change the attributes specified for a volume previously added.
- Prevent a volume from being selected for migration output.
- Add all aggregate recovery volumes to DFSMSHsm as soon as possible after an ARECOVER command has successfully completed processing if the volumes had not been previously added.

Note:

1. In a JES3 environment, you cannot add a primary volume to DFSMSHsm after initialization.
2. If you try to issue an ADDVOL command for an SMS-managed volume, a volume whose management cannot be determined, or for a volume that is not online, the ADDVOL command is rejected.
3. The ADDVOL command must be issued on each system in the DFSMSHsm plex where this volume is to be used.

You can change attributes within each volume category, but you cannot change the volume category. Volume categories are:

- PRIMARY
- BACKUP(DAILY)
- BACKUP(SPILL)
- MIGRATIONLEVEL1
- MIGRATIONLEVEL2
- DUMP

For example, if a volume has been added to DFSMSHsm as a primary volume, you cannot use the ADDVOL command to change it to a migration or backup volume.

You can change any of the following space management techniques to be used for a primary volume:

- Migrate
- Delete-by-age
- Delete-if-backed-up

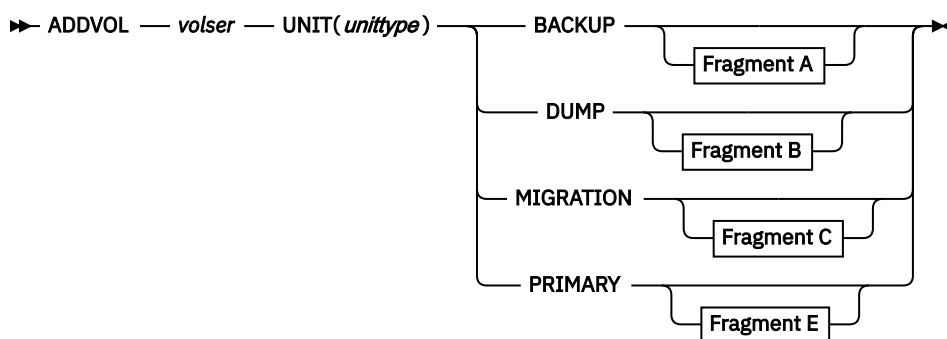

Use caution when you change the attributes of a primary volume if the volume is using migration as the space management technique. If you change the primary volume attributes so that no volume has the same attributes that existed when DFSMSHsm first migrated the data set from the primary volume, an undirected recall may fail. The undirected recall *will* fail if *all* of the following are true:

- You are using the LIKE subparameter of the SETSYS RECALL PRIVATEVOLUME or ANYSTORAGEVOLUME command.
- No available volume has a space management technique of MIGRATE and a recall technique of AUTORECALL.
- Pools are not defined.

To avoid the problem, you can specify the following UNLIKE subparameters of the SETSYS RECALL command to allow the recall to occur when the attributes do not match:

- AUTOMIGRATION
- AUTOBACKUP
- NOAUTOMIGRATION
- NOAUTOBACKUP
- BACKUPDEVICECATEGORY

Syntax of the ADDVOL command

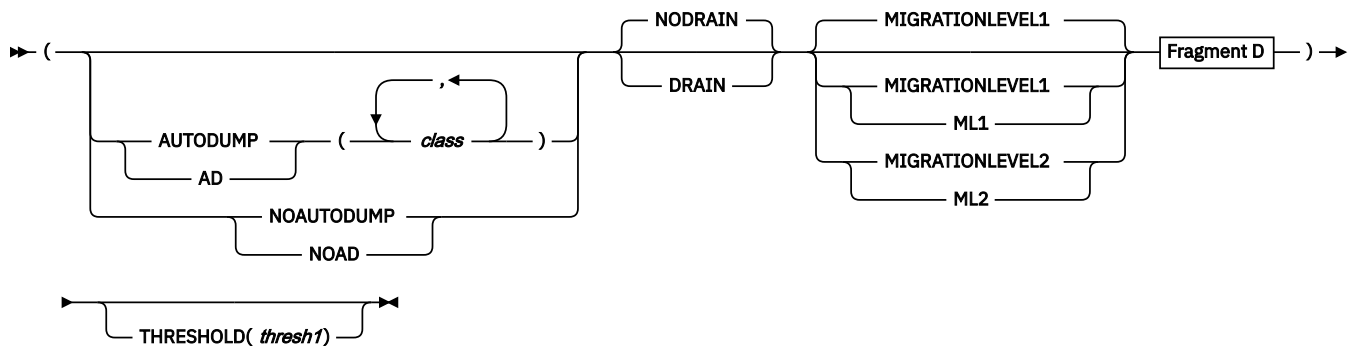

A: BACKUP optional parameters

B: DUMP optional parameters

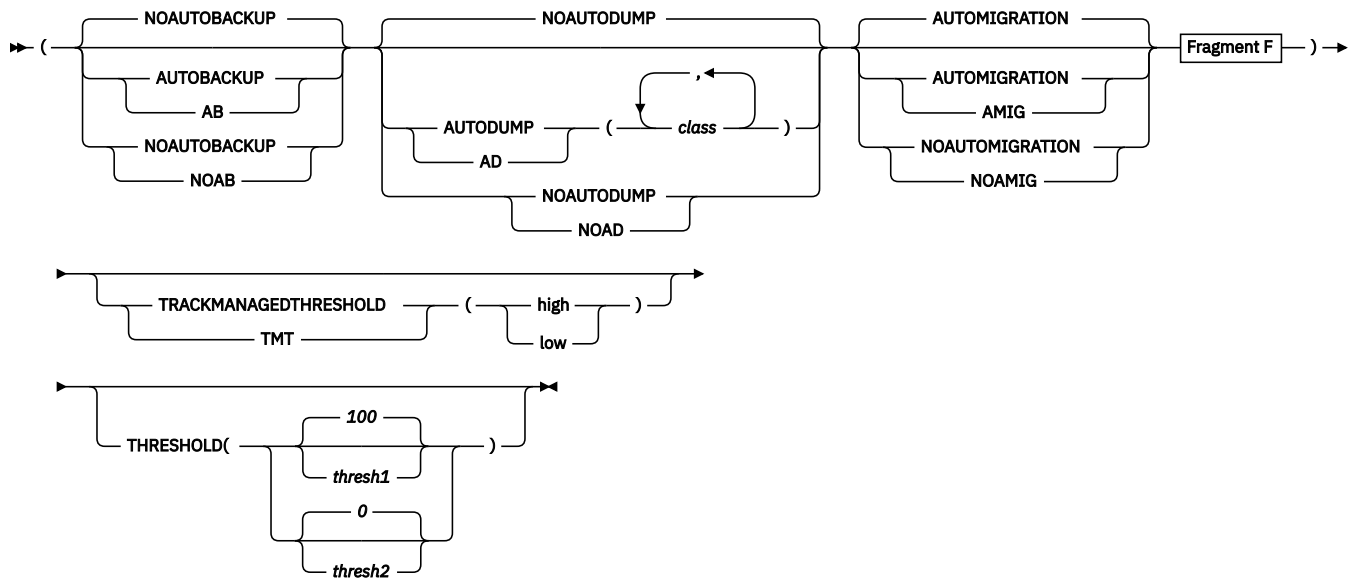

C: MIGRATION optional parameters

D: MIGRATION optional parameters

E: PRIMARY optional parameters

F: PRIMARY optional parameters

Note:

1. The required parameters BACKUP, DUMP, MIGRATION, and PRIMARY are volume-type parameters; that is, they specify the type of volume to be managed by DFSMSHsm.
2. The ADDVOL command cannot be used with SMS-managed volumes.

3. If multiple optional subparameters are used in one ADDVOL command, they are placed within one set of parentheses with a space between each subparameter, as shown below:

```
ADDVOL PRIM01 UNIT(3390) +
PRIMARY(AUTOBACKUP MIGRATE(8) AUTORECALL) THRESHOLD(90 70)
```

Required parameters of the ADDVOL command

This topic describes the required parameters of the ADDVOL command.

volser: Specifying the volume to be added or changed

Explanation: *volser* is a required positional parameter specifying the serial number of (1) a non-SMS-managed volume to be added to DFSMSHsm control, (2) a volume currently managed or owned by DFSMSHsm, and (3) a volume previously defined for aggregate recovery.

For *volser*, substitute the serial number of the volume being added or changed.

Defaults: None.

Note:

1. Because *volser* is a required positional parameter, you must specify it immediately after the command name.
2. When an attempt is made to add an SMS-managed volume using the ADDVOL command, the command is rejected and a message is issued.
3. A volume previously defined to aggregate recovery with the LOVOLS parameter of the DEFINE ARPOOL command can be subsequently added to DFSMSHsm only as a PRIMARY volume.
4. A volume previously defined to aggregate recovery with the ML1VOLS parameter of the DEFINE ARPOOL command can be subsequently added to DFSMSHsm only as an ML1 volume.
5. If a specific scratch volume managed by RMM is added to DFSMSHsm, RMM rejects it with message EDG4036I when DFSMSHsm attempts to use it.

BACKUP, DUMP, MIGRATION, and PRIMARY: Identifying the type of volume

Explanation: BACKUP, DUMP, MIGRATION, and PRIMARY are mutually exclusive, required parameters that identify for DFSMSHsm the type of volume you are adding or changing.

BACKUP

identifies a volume to be used as a backup volume.

DUMP

identifies a volume to be used as the output of a full-volume dump. DFSMSHsm supports only tape units for the DUMP function. The *unittype* must be a valid tape unit or the ADDVOL command will fail.

MIGRATION

identifies a volume to be used as a migration volume. Migration level 1 volumes must be DASD. Migration level 2 volumes can be either DASD or tape.

PRIMARY

identifies a volume to be used as a primary volume. Primary volumes must be DASD.

Defaults: None.

Note: If a volume record already exists for the specified *volser*, you cannot change the type of volume.

UNIT: Specifying the type of device

Explanation: UNIT(*unittype*) is a required parameter specifying the type of unit where the volume can be allocated.

For *unittype*, substitute the type of DASD or tape unit on which the volume can be allocated.

The following are valid types of DASD units:

- 3380
- 3390
- 9345

The BACKUP, DUMP, and MIGRATE functions use the same types of tape units.

The following are valid types of tape units:

- 3480
- 3480X
- 3490
- 3590-1

You can substitute an esoteric tape unit defined with the SETSYS USERUNITTABLE command. If you specify an esoteric tape unit name that does not exist in the user unit table, the command fails. If you specify:

- 3480 or 3480X, you use all the functions of the 3480 Magnetic Tape Subsystem.
- 3490, you use all the functions of the 3490 Magnetic Tape Subsystem.
- 3590-1, you use all the functions of the 3590 Magnetic Tape Subsystem.

When you want to add a tape volume to DFSMSHsm's control while using the Improved Data Recording Capability (IDRC) of the 3480X, specify 3480X. If output is restricted to 3480X, this may change the unit name. It will not allow an incompatible change, such as an attempt to change a tape volume from 3480X to 3480, when that tape volume already contains compacted data. See the SETSYS TAPEHARDWARECOMPACT parameter for more information.

When you specify esoteric unit names and when you deal with units that can use the 3480X IDRC, all devices associated with an esoteric name must have the IDRC or none of them can.

Defaults: None.

Note:

1. If you specify a tape unit for a primary or migration level 1 volume, the ADDVOL command fails.
2. If you specify a DASD unit for a dump volume, the ADDVOL command fails.
3. If a DASD volume record already exists for the specified *volser*, you cannot change the *unittype*.

You can re-ADDVOL a tape with a different unit type as long as the new one is compatible with the existing device type and the unit type (such as an esoteric) is defined to MVS and known to DFSMSHsm. To make the unit type known to DFSMSHsm, use the SETSYS USERUNITTABLE command.

Optional parameters of the ADDVOL command

This topic describes the optional parameters of the ADDVOL command.

AUTOBACKUP and NOAUTOBACKUP: Specifying whether the primary volume is eligible for automatic backup

Explanation: AUTOBACKUP and NOAUTOBACKUP are mutually exclusive , optional subparameters of the PRIMARY parameter specifying whether the data sets on the primary volume are eligible for automatic backup.

AUTOBACKUP

specifies that the data sets on the primary volume are eligible for automatic backup.

NOAUTOBACKUP

specifies that the data sets on the primary volume are not eligible for automatic backup.

Defaults: If you are adding a primary volume to DFSMSHsm, the default is NOAUTOBACKUP. If you are changing the attributes of a primary volume and do not specify either subparameter, the backup status is not changed.

Note: In a multiple-DFSMSHsm-host environment, you can add the same volume to different DFSMSHsm hosts. When you do, you can also assign to that volume a different automatic backup attribute in each DFSMSHsm host.

AUTODUMP and NOAUTODUMP: Specifying whether a volume is eligible for automatic dumping to tape or cloud

Explanation: AUTODUMP(*class*) and NOAUTODUMP are mutually exclusive, optional subparameters of the PRIMARY and MIGRATION parameters specifying whether the volume is eligible for a full-volume automatic dump.

AUTODUMP

Specifies that the primary or migration volume is eligible for a full-volume automatic dump and selects the dump classes that contain the dump copies. For *class*, substitute one previously defined dump class for each of the output copies wanted for the dump. You must have a minimum of one class that is selected, but you can select a maximum of five classes. Each dump class, *class*, must be predefined using the DUMPCLASS parameter of the DEFINE command before you attempt to use the AUTODUMP parameter of the ADDVOL command.

The FREQUENCY and DAY subparameters of the DUMPCLASS parameter of the DEFINE command determine how often a primary volume is dumped to a given dump class.

NOAUTODUMP

Specifies that the primary or migration volume is not eligible for a full-volume automatic dump.

Defaults: If you are adding a primary or migration level 1 volume to DFSMSHsm, the default is NOAUTODUMP.

Note:

1. In a multiple-DFSMSHsm-host environment, the AUTODUMP parameter can be different in the different DFSMSHsm hosts. If you add a volume to more than one DFSMSHsm host with different dump class values, the dump classes are that of the last ADDVOL command processed.
2. The migration volume eligibility is applicable only to migration level 1 volumes and is ignored for migration level 2 volumes.
3. Autodump processing creates up to five dump copies (classes) if none of them designates cloud object storage.
4. You can select a maximum of five dump classes for AUTODUMP specification, including a mixture of TAPE and CLOUD classes with wanted FREQUENCY and DAY values to determine how often a primary volume is dumped to a given dump class. Your AUTODUMP and DUMPCLASS specifications should avoid having multiple CLOUD or mixed TAPE/CLOUD dump classes be eligible to dump on the same day in the autodump cycle because during an automatic dump session, if an eligible dump class designates cloud object storage, it is restricted to dumping to a single class.
5. Do not select a dump class with CLOUD attribute for migration volumes. Dumping migration volumes to cloud object store is not supported.

AUTOMIGRATION and NOAUTOMIGRATION: Specifying whether the primary volume is eligible for automatic volume space management

Explanation: AUTOMIGRATION and NOAUTOMIGRATION are mutually exclusive, optional subparameters of the PRIMARY parameter specifying whether the data sets on the primary volume are eligible for automatic volume space management.

AUTOMIGRATION

specifies that the data sets on the primary volume are eligible for automatic volume space management.

NOAUTOMIGRATION

specifies that the data sets on the primary volume are not eligible for automatic volume space management.

Defaults: If you are adding a volume to DFSMSHsm, the default is AUTOMIGRATION. If you are changing the attributes of a volume and do not specify either subparameter, the volume space management status is not changed.

Note: In a multiple-DFSMSHsm-host environment, you can add the same volume to different DFSMSHsm hosts. When you do that, you can also assign to that volume a different automatic space management attribute in each DFSMSHsm host.

AUTORECALL and NOAUTORECALL: Specifying whether the primary volume is eligible for automatic recall

Explanation: AUTORECALL and NOAUTORECALL are mutually exclusive, optional subparameters of the PRIMARY parameter specifying whether the primary volume is eligible to receive data sets that are automatically recalled.

AUTORECALL

specifies that the primary volume is eligible to receive automatically recalled data sets.

NOAUTORECALL

specifies that the primary volume is not eligible to receive automatically recalled data sets.

Defaults: If you are adding a primary volume to DFSMSHsm, the default is AUTORECALL. If you are changing the attributes of a volume and do not specify either subparameter, the recall status is not changed.

Note:

1. DFSMSHsm can override the AUTORECALL and NOAUTORECALL subparameter in certain circumstances. If you use the DEFINE command to associate the same volume to a special recall pool, the volume is always eligible to receive automatically recalled data sets.
2. If you also specify the DELETEBYAGE or DELETEIFBACKEDUP subparameter, DFSMSHsm ignores the AUTORECALL or NOAUTORECALL subparameter.

BACKUPDEVICECATEGORY: Specifying where backup versions reside

Explanation: BACKUPDEVICECATEGORY is an optional subparameter of the PRIMARY parameter specifying the type of device that receives the backup versions of the data sets when DFSMSHsm backs up the primary volume. The parameters of the BACKUPDEVICECATEGORY parameter are explained:

TAPE

specifies that the backup version of a data set on the primary volume resides on a tape daily backup volume.

DASD

specifies that the backup version of a data set on the primary volume resides on a DASD daily backup volume.

NONE

specifies that DFSMSHsm selects the first available, nonfull tape or DASD daily backup volume where the backup version of a data set resides.

Defaults: If you are adding a primary volume to DFSMSHsm and do not specify BACKUPDEVICECATEGORY, the default is NONE. If you are changing the attributes of a volume and do not specify BACKUPDEVICECATEGORY, the previous backup device category remains in effect.

Note:

1. If you change the backup device category for a volume with a subsequent ADDVOL command, DFSMSHsm could fail an undirected recall of a migrated data set when the LIKE subparameter of the SETSYS RECALL command is in effect. With the LIKE subparameter specified on the SETSYS

RECALL command, DFSMSHsm automatically recalls a data set to a volume only if that volume has the same backup device category as the primary volume that the data set used to be on. Therefore, if DFSMSHsm cannot find a primary volume with the same backup device category as the original primary volume, DFSMSHsm cannot automatically recall the migrated data set. To avoid this problem, you can specify the UNLIKE subparameter with the SETSYS RECALL command.

2. In a multiple-DFSMSHsm-host environment, you can add the same volume to different DFSMSHsm hosts. When you do that, the backup device category for that volume should be the same in all DFSMSHsm hosts or the last one specified with the ADDVOL command is the one in effect.

DAILY and SPILL: Identifying the type of backup volume

Explanation: DAILY(*day*) and SPILL are mutually exclusive, optional subparameters of the BACKUP parameter to specify the use of the backup volume.

DAILY

specifies that the volume receive backup versions of data sets from primary volumes or migration volumes. For *day*, substitute a decimal number from 1 to 31 to represent the day in the backup cycle that you want this volume assigned to. You define the backup cycle with the DEFINE command.

SPILL

specifies that the volume receive valid backup versions from DASD daily backup volumes. A tape spill backup volume can also receive all valid backup versions of data sets from a recycled tape backup volume.

Defaults: If you are adding a backup volume to DFSMSHsm and do not specify DAILY or SPILL, DFSMSHsm considers the volume to be either a daily or a spill backup volume. DFSMSHsm then determines which type of backup volume it needs when it selects a backup volume. If you are changing the attributes of a volume and do not specify either subparameter, the type of backup volume remains in effect.

If you do not specify a day with the DAILY parameter and DFSMSHsm needs another daily backup volume, DFSMSHsm assigns the volume to a day in the backup cycle.

Note: When you specify BACKUP, you can specify DAILY or SPILL, but not both. If you want to use tape for backup for a given day, you must assign at least one tape to that day in the backup cycle or on that day you must back up a volume whose backup device category is tape. Otherwise, you cannot use tape for that day in the backup cycle.

DELETEBYAGE, DELETEIFBACKEDUP, and MIGRATE: Specifying the type of space management on a primary volume

Explanation: DELETEBYAGE, DELETEIFBACKEDUP, and MIGRATE are mutually exclusive, optional subparameters of the PRIMARY parameter specifying the space management type on the primary volume.

DELETEBYAGE (*days*)

specifies that cataloged and uncataloged data sets that reside on a primary volume are scratched if they have been inactive for a specified number of days and the current expiration date has been reached. If you specify this subparameter, a current backup version of the data sets on the primary volume is not required. For *days*, if you are in a single-DFSMSHsm-host environment, substitute a number from 1 to 999. In a multiple-DFSMSHsm-host environment, you can specify a number from 2 to 999. For example, if you specify *days* as 20, DFSMSHsm scratches those data sets on a primary volume that have been inactive for at least 20 days.

DELETEIFBACKEDUP(*days*)

specifies that the data sets on a primary volume can be scratched if they have been inactive for a specified number of days and if the data sets on the primary volume have current backup versions. For *days*, in a single-DFSMSHsm-host environment, substitute a decimal number from 1 to 999. In a multiple-DFSMSHsm-host environment, you can specify a decimal number from 2 to 999. For example, if you specify *days* as 30, DFSMSHsm scratches those data sets that have been inactive for 30 days and that have a current backup version.

MIGRATE

specifies that the data sets that reside on a primary volume are migrated according to the number of days they have been inactive.

MIGRATE(days)

depends on whether you have defined valid thresholds of occupancy. If you do not define thresholds of occupancy, migration causes all data sets not accessed in the last *days* days to migrate. If you define thresholds of occupancy, DFSMSHsm migrates data sets until the low threshold of occupancy is met or until all the data sets inactive for the number of *days* specified have migrated. For *days*, you can specify a decimal number from 0 to 999. For example, if *days* is specified as 25, DFSMSHsm migrates those data sets on the primary volume that have been inactive for at least 25 days until the low threshold of occupancy is met (if you have defined thresholds of occupancy) or until all data sets inactive for 25 days or longer have been migrated.

Defaults: If you are adding a primary volume to DFSMSHsm, the default is MIGRATE. If you are changing the attributes of a volume and do not respecify a subparameter, the space management technique does not change.

Note:

1. If you do not specify *days* with the MIGRATE subparameter, or you specify 0, or you specify 1 in a multiple-DFSMSHsm-host environment when USERDATASETSERIALIZATION is not specified, the number of days the data set can remain inactive before it is allowed to migrate is the value specified with the DAYS parameter of the SETSYS command.
2. In a multiple-DFSMSHsm-host environment, you can add the same volume to different DFSMSHsm hosts. When you do that, the space management technique for that volume must be the same in all DFSMSHsm hosts, or the last one specified with the ADDVOL command is the one that is in effect.
3. DFSMSHsm automatically recalls a data set to a primary volume whose space management technique is MIGRATE even if the data set migrated from a volume whose type of space management is DELETEBYAGE or DELETEIFBACKEDUP. This is true even if you specified SETSYS RECALL(LIKE).

DENSITY: Specifying the tape density

Explanation: DENSITY is an optional parameter specifying the density of the tape dump volume. The values of the DENSITY parameter are explained:

2

specifies a tape density of 32 bytes per millimeter (800 bytes per inch).

3

specifies a tape density of 63 bytes per millimeter (1600 bytes per inch).

4

specifies a tape density of 246 bytes per millimeter (6250 bytes per inch)

Defaults: If you are adding a tape dump volume to DFSMSHsm, the default is the highest density the device can support. If you are changing the attributes of a tape dump volume and do not specify a subparameter, the density does not change.

Note:

1. The use of the DENSITY parameter is no longer supported for tape backup or ML2 volumes. The DENSITY parameter is still supported for dump volumes and for existing volumes already defined to DFSMSHsm.
2. If you specify DENSITY and UNIT, the density must match the density capability of that type of unit or the command fails. If you specify a density of 2, 3, or 4 for the 3480 Magnetic Tape Subsystem, DFSMSHsm ignores it.

DRAIN and NODRAIN: Specifying whether a volume should be selected for migration output

Explanation: DRAIN and NODRAIN are mutually exclusive, optional subparameters of the MIGRATION parameter that specify whether a volume can be selected for migration output.

DRAIN

specifies that the DASD volume be emptied. The DRAIN attribute prevents a migration level 1 volume from being selected for migration output. It prevents a migration level 2 volume from being associated with a keyrange.

NODRAIN

specifies that a migration level 1 volume can be selected for migration output or that a migration level 2 volume can be associated with a keyrange.

Defaults: When adding a DASD migration volume to DFSMSHsm, the default is NODRAIN.

If you are changing the attributes of a migration volume and do not specify either subparameter, the previous drain status is not changed.

Note:

1. DRAIN and NODRAIN pertain only to DASD volumes. The ADDVOL command fails if either parameter is specified for tape volumes.
2. The selection of a migration level 1 volume is performed as each data set is being migrated. If a migration level 1 volume has the DRAIN attribute, it will not be selected for migration output.
3. The selection of a DASD migration level 2 volume differs greatly from that of a migration level 1 volume. Migration level 2 selection is the process of associating the volume with a given keyrange of user data sets. The association of a migration level 2 volume with a particular keyrange is recorded in the migration level 2 control record (L2CR). This association takes place during:
 - Processing of the DEFINE MIGRATIONLEVEL2 command.
 - Migration of a data set whose keyrange is not associated with any volume in the L2CR.
 - Migration of a data set when an out-of-space condition occurs on the volume associated with the keyrange for that data set. In this case, another migration level 2 volume is associated with the appropriate keyrange.

The DRAIN attribute does not allow any association of a migration level 2 volume with a keyrange, and thus makes the volume not eligible for migration output. If, however, you use the ADDVOL command with the DRAIN attribute to add a migration level 2 volume that is already recorded in the L2CR, that volume remains eligible for migration output. If you want to prevent migration output eligibility for such a volume, you must (1) issue the DELVOL command with the UNASSIGN subparameter for that volume before (2) adding that volume with the ADDVOL command and the DRAIN attribute. To determine which DASD migration level 2 volumes are associated with a keyrange, use the QUERY MIGRATIONLEVEL2 command.

4. A volume can be reassigned or removed at any time and added again with the same or a different DRAIN attribute.
5. When changing the DRAIN | NODRAIN option for an ML1 volume in a multiple-DFSMSHsm-host environment, the target volume selection is affected immediately on only that host where the ADDVOL is entered. Therefore, you need to enter the ML1 DRAIN | NODRAIN option on each system that performs migration to that ML1 volume before that system performs any automatic space management.

DUMPCCLASS: Restricting the specified volume to use a specific dump class

Explanation: DUMPCCLASS(*class*) is the subparameter of the DUMP parameter restricting the specified volume to use a specific dump class. For *class*, substitute the name of a previously defined dump class for the output copy wanted for the dump.

If *class* is not specified, the dump volume can be used by any dump class. The FREQUENCY and DAY subparameters of the DUMPCLASS parameter of the DEFINE command determine how often a primary volume is dumped to a given dump class.

Defaults: None.

Note:

1. When you assign a dump volume to a specific dump class, the unit that is specified by the UNIT parameter of the ADDVOL command is not checked for compatibility with the unit that is currently defined for the dump class. This allows volumes of multiple unit types to be assigned to the same dump class at the same time. You can switch between using different unit types for the same dump class by redefining the unit for the dump class.
2. You cannot assign a dump volume to a dump class with a CLOUD attribute. The ADDVOL command fails if the specified dump class currently has a CLOUD(cloud_network_connection_name) attribute defined.

MIGRATIONLEVEL1 and MIGRATIONLEVEL2: Specifying the migration level

Explanation: MIGRATIONLEVEL1 and MIGRATIONLEVEL2 are mutually exclusive, optional subparameters of the MIGRATION parameter that you use to specify the level of the migration volumes.

MIGRATIONLEVEL1

specifies that the migration volume receives migrated data sets from primary volumes. A migration volume specified with this subparameter is called a migration level 1 volume. If the migration level 1 volume you are adding or changing is not mounted when you issue the ADDVOL command, DFSMSHsm allocates the volume, which sends a mount request to the operator.

MIGRATIONLEVEL2

specifies that the migration volume receives data sets migrating automatically from migration level 1 volumes and by command from primary volumes or migration level 1 volumes. A migration volume specified with this subparameter is called a migration level 2 volume.

Defaults: If you are adding a migration volume to DFSMSHsm, the default is MIGRATIONLEVEL1. If you are changing the attributes of a migration volume, it remains at the same level as it was when it was added to the list of volumes owned or managed by DFSMSHsm. If you are changing the attributes of a migration volume and you specify the incorrect level, the ADDVOL command fails.

Note: If DFSMSHsm migrates data sets from primary volumes directly to a tape migration level 2 volume, you can decide not to add additional migration level 1 volumes to this DFSMSHsm host. However, you must have at least one migration level 1 volume added to this DFSMSHsm host if:

- SMS data sets require migration level 1 volumes as specified by their management class attributes
- You allow backup versions generated using the BACKDS or HBACKDS commands to be written to migration level 1 volumes.
- You want DFSMSHsm to do extent reduction
- You want DFSMSHsm to do any type of volume backup and volume dump when you are keeping dump VTOC copy data sets

OVERFLOW and NOOVERFLOW: Specifying the usage of a level 1 volume for data set migration and backup versions

Explanation: OVERFLOW and NOOVERFLOW are mutually exclusive optional subparameters of the MIGRATION parameter that you use to specify how a level 1 volume is considered during selection for placement of a data set migration or backup version.

OVERFLOW

specifies that the volume is considered if either of the following are true:

1. The data you are migrating or backing up is larger than a given size, as specified on the SETSYS ML1OVERFLOW(DATASETSIZE(dssize)) command.

2. DFSMSHsm cannot allocate enough space on a NOOVERFLOW volume.

NOOVERFLOW

specifies that the volume is considered with other level 1 volumes for migration data and backup versions of any size.

Defaults: If you are adding a migration volume to DFSMSHsm, the default is NOOVERFLOW. If you are changing the attributes of a volume and do not specify either subparameter, the overflow attribute is not changed.

Note: The OVERFLOW and NOOVERFLOW subparameters do not apply to the MIGRATIONLEVEL2 parameter. If you specify the OVERFLOW or NOOVERFLOW subparameter when it does not apply, DFSMSHsm ignores it.

SMALLDATASETPACKING and NOSMALLDATASETPACKING: Specifying small data set packing on the level 1 volume

Explanation: SMALLDATASETPACKING and NOSMALLDATASETPACKING are mutually exclusive, optional subparameters of the MIGRATION parameter specifying whether small data set packing can be done on the migration level 1 volume.

SMALLDATASETPACKING

specifies that small data set packing can be done on the migration level 1 volume.

NOSMALLDATASETPACKING

specifies that small data set packing cannot be done on the migration level 1 volume.

Defaults: If you are adding a migration level 1 volume to DFSMSHsm, the default is NOSMALLDATASETPACKING. If you are changing the attributes of a volume and do not specify either subparameter, the small data set packing status does not change.

Note:

1. The SMALLDATASETPACKING and NOSMALLDATASETPACKING subparameters do not apply to the MIGRATIONLEVEL2 subparameter. If you specify the SMALLDATASETPACKING or NOSMALLDATASETPACKING parameter when it does not apply, DFSMSHsm ignores it.
2. Before small data set packing can be done on a migration level 1 volume, you must define a VSAM key-sequenced data set as the small-data-set-packing data set on the migration level 1 volume. Refer to the [z/OS DFSMSHsm Implementation and Customization Guide](#) for details about how to allocate the small-data-set-packing data set. In addition, the SMALLDATASETPACKING parameter must be specified with the SETSYS command. Small-data-set-packing data sets are not required on all migration level 1 volumes.
3. The number of SDSP data sets defined must be at least equal to the maximum number of concurrent volume migration tasks that could be executing in your complex. Additional SDSPs are recommended for RECALL processing and ABARS processing and if some SDSPs should become full during migration.

THRESHOLD: Specifying thresholds of occupancy

Explanation: THRESHOLD is an optional parameter specifying the limits for the percentages of space used on the volume.

The values you specify with THRESHOLD are used differently for the primary volumes, the migration level 1 volumes, and the DASD backup volumes that you define with ADDVOL. To be valid, threshold values must be specified from 0 to 100. A threshold value of 100, however, is interpreted to mean the volume has no thresholds defined.

THRESHOLD(thresh1)

specifies the limit (high threshold) for the percentage of occupied space you want on a volume. When *thresh1* is reached or exceeded, it causes the volume to be eligible for one of the following to occur:

- Interval migration of data sets from a primary volume
- Migration of data sets from level 1 volumes to level 2 volumes during secondary space management

DFSMSHsm uses spill or cleanup processing to reduce the amount of occupied space on a full DASD daily backup volume. When the spill process completes on a full DASD daily backup volume or the cleanup process completes on a full DASD spill backup volume and the percentage of occupied space is less than or equal to the percentage specified by *thresh1*, DFSMSHsm no longer considers the DASD volume to be full and uses it for further backup or spill processing.

THRESHOLD(*thresh2*)

specifies the limit (low threshold) for the percentage of space you want to remain occupied on a primary volume after interval migration or volume migration of data sets from the volume that has been completed.

The threshold values as they apply to each volume type are explained:

Volume Type	Threshold Values
Primary volumes	Both high and low thresholds apply. If the first limit (high threshold) is specified as 100 or if it is not greater than the second limit (low threshold), or if the low threshold is equal to zero, no thresholds are defined for the volume.
Migration level 1 volumes	Only one threshold applies to NOOVERFLOW volumes (this is the ADDVOL default). If you specify a <i>thresh2</i> values for NOOVERFLOW migration level 1 volumes then DFSMSHsm ignores it. Both thresholds are ignored for OVERFLOW volumes. You can specify THRESHOLD for the OVERFLOW volume pool by using the SETSYS ML1OVERFLOW command. See “ML1OVERFLOW: Manage ML1 OVERFLOW volumes” on page 1160 in Chapter 65, “SETSYS command: Establishing or changing the values of DFSMSHsm control parameters,” on page 1057.
DASD backup volumes	Only one threshold applies. If you specify a <i>thresh2</i> value for DASD backup volumes, DFSMSHsm ignores it.
Migration level 2 volumes	No threshold values applies. If you specify the THRESHOLD parameter for migration level 2 volumes, DFSMSHsm ignores it.
Tape backup volumes	No threshold values applies. If you specify the THRESHOLD parameter for tape backup volumes, DFSMSHsm ignores it.
Dump volumes	No threshold values applies. If you specify the THRESHOLD parameter for dump volumes, DFSMSHsm ignores it.

Defaults: If you are adding a primary volume to DFSMSHsm, the default value for *thresh1* is 100, and the default value for *thresh2* is 0. Therefore, a primary volume has no valid default thresholds. If you are adding a migration level 1 volume to DFSMSHsm, the default value for *thresh1* is 100. Therefore, a migration level 1 volume has no valid default threshold. If you are adding a DASD backup volume to DFSMSHsm, the default value for *thresh1* is 90.

If you are changing the attributes of a volume and do not specify threshold values, the thresholds are not changed. For a primary volume, if you specify only the high threshold, the low threshold is not changed. If, however, the new high threshold is less than or equal to the low threshold or is equal to 100, the volume no longer has valid thresholds.

Note:

1. If you do not define valid thresholds of occupancy for a primary volume, automatic migration occurs only during automatic primary space management (no interval migration occurs) and is based on the minimum migration age.
2. The *thresh1* and *thresh2* values are positional. For a primary volume, you must specify both a high threshold and a low threshold.
3. In specifying the threshold parameter for migration level 1 volumes, you want to maintain equal free space on all of your migration level 1 volumes. If you use different device types for migration level 1 volumes, you must calculate the appropriate percentages that will make the same amount of free space available on each device type. For example, if you have a mixture of 3390 models 1 and 2, you might specify 88% for model 1 (92M) and 94% for model 2 (96M).

TRACKMANAGEDTHRESHOLD: Specifying the high and low threshold for the track-managed space of a non-SMS level 0 extended address volume

Explanation: TRACKMANAGEDTHRESHOLD is an optional parameter, only valid with the PRIMARY keyword, specifying the required high and low threshold for the track-managed space of a non-SMS level-0 extended address volume (EAV).

TRACKMANAGEDTHRESHOLD is used to ensure that enough free space is maintained in the track-managed space of a volume separate from the free space on the entire volume. This is done to ensure that the track-managed space of an EAV has enough free space for data sets to be allocated on it. Even if a volume's low THRESHOLD has been met, space management will continue for data sets that reside in the track-managed space if the low TRACKMANAGEDTHRESHOLD has not been met.

If TRACKMANAGEDTHRESHOLD is not specified, then the corresponding values for THRESHOLD will be used. If no threshold values are specified, then all threshold values will use the default values. If TRACKMANAGEDTHRESHOLD is specified, then both high and low are required subparameters. If only one value is specified for TRACKMANAGEDTHRESHOLD, then the command will fail.

The following table indicates the threshold values as they apply to each volume type:

Primary Volume Type	Threshold Values
EAV volume	Both high and low thresholds apply. If the first limit (high threshold) is specified as 100 or if it is not greater than the second limit (low threshold), or if the low threshold is equal to zero, no thresholds are defined for the volume.
Non-EAV volume	If you specify the TRACKMANAGEDTHRESHOLD parameter for a non-EAV volume, the ADDVOL command will fail.

Selecting thresholds for volumes

When you choose thresholds for your volumes, consider the following:

- Size of data sets
- Rate that users require data space
- Frequency of interval migration

Follow this guideline when you set the thresholds of occupancy: The larger the data set is, the lower the threshold. Set the thresholds so users have space for their data sets but data set thrashing is minimized. *Thrashing* is a condition in which the system can do little useful work because of excessive data movement between primary and migration volumes. Data set thrashing can be caused by any of the following reasons:

- Not enough primary volume space
- The high threshold is set too low, causing DFSMSHsm to migrate data sets more often than is necessary during interval migration.

- The low threshold is set too low, causing DFSMSHsm to migrate too many data sets from primary volumes.
- The minimum migration age is set too low. DFSMSHsm uses the minimum migration age for volume processing as a lower limit to determine which data sets are eligible for migration. If the minimum migration age is too low, automatic primary space management forces the migration of data sets that were recently referred to and are likely to be referred to again soon.

Examples of how to code the ADDVOL command

The following examples present different ways to code the ADDVOL command:

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Adding a primary volume

In this example, a primary non-SMS-managed volume is added to the control of DFSMSHsm. The volume is added with the characteristics of automatic volume space management, automatic backup, and automatic recall; and thresholds of occupancy are specified.

```
ADDVOL VOL004 UNIT(3390) PRIMARY(AUTOMIGRATION +
    AUTOBACKUP AUTORECALL) THRESHOLD(90 65)
```

Adding a primary extended addressable volume

In this example, a primary non-SMS-managed extended address volume is added to the control of DFSMSHsm. The extended address volume will have track-managed occupancy thresholds of 80 and 40 respectively and thresholds of occupancy for the entire volume are 85 and 60 respectively.

```
ADDVOL PRIM01 UNIT(3390) PRIMARY(AB AM) TRACKMANAGEDTHRESHOLD(80 40) THRESHOLD(85 60)
```

Adding a migration level 1 volume

In this example, a migration level 1 volume is added to the control of DFSMSHsm. The volume is added with the characteristics of no small data set packing, and a threshold of occupancy is specified.

```
ADDVOL VOL123 UNIT(3390) MIGRATION(MIGRATIONLEVEL1 +
    NOSMALLDATASETPACKING) THRESHOLD(90)
```

Adding a dump volume

In this example, a dump volume is added to the control of DFSMSHsm. The volume is specified as a dump volume with a dump class of DAILY.

```
ADDVOL DMP001 UNIT(3590-1) DUMP(DUMPCCLASS(DAILY))
```

Adding a tape spill backup volume

In this example, a backup volume is added to the control of DFSMSHsm. The volume is specified as a spill volume, and a threshold of occupancy is specified.

```
ADDVOL BKP002 UNIT(3590-1) BACKUP(SPILL) THRESHOLD(85)
```

Adding a tape daily backup volume

In this example, a tape backup volume is added. The volume is specified as a daily backup volume assigned to day 7 in the backup cycle.

```
ADDVOL BKP006 UNIT(3590-1) BACKUP(DAILY(7))
```

Adding a tape migration level 2 volume

In this example, a tape migration level 2 volume is added.

```
ADDVOL M2TP01 UNIT(3590-1) MIGRATION(MIGRATIONLEVEL2)
```

Changing the characteristics of a primary volume

In this example, the backup characteristics of a primary volume under control of DFSMSHsm are changed from no automatic backup to automatic backup, and from a low threshold of 65% to a low threshold of 75%. Because you are changing the low threshold, you must specify the high threshold again to correctly position the new value for the low threshold. You do not have to specify any parameter again for a characteristic that is not to be changed, but the volume must be specified as being in the same volume category.

```
ADDVOL VOL003 UNIT(3390) PRIMARY(AUTOBACKUP) THRESHOLD(90 75)
```

Assigning the space management attribute to a primary volume

In this example, the delete-if-backed-up space management attribute is assigned to a primary volume. A backup device category of tape is specified.

```
ADDVOL VOL005 UNIT(3390) PRIMARY(DELETEIFBACKEDUP(10) +  
    BACKUPDEVICECATEGORY(TAPE))
```

Preventing a volume from being selected for migration output

In this example, DFSMSHsm stops targeting a migration volume for any further migration or backup activity.

```
ADDVOL MIG113 U(3390) MIGRATION(ML1 DRAIN)
```

Specifying a primary volume to be automatically dumped

In this example, a primary volume is automatically dumped to specified classes (DAILY and WEEKLY) during automatic dump processing.

```
ADDVOL PRIM14 UNIT(3390) PRIMARY(AUTODUMP(DAILY,WEEKLY))
```

Specifying a migration volume to be automatically dumped

In this example, a migration volume is to be automatically dumped to specified classes (WEEKLY and MONTHLY) during automatic dump processing.

```
ADDVOL MIG019 UNIT(3390) MIGRATION(ML1 AUTODUMP(WEEKLY,MONTHLY))
```

Adding a migration volume previously defined for aggregate recovery

In this example, a volume that had previously been defined as a migration level 1 volume for aggregate recovery with the DEFINE ARPOOL command is added to DFSMSHsm.

```
ADDVOL MIG123 UNIT(3390) MIGRATION(ML1)
```

Specifying a migration volume to hold large backup or migration versions

In this example, a ML1 volume becomes an overflow volume, a repository for large data set backup or migration versions. The size of data sets that will backup or migrate to this volume will be determined by the SETSYS ML1OVERFLOW command. See [“ML1OVERFLOW: Manage ML1 OVERFLOW volumes” on page 1160 in Chapter 65, “SETSYS command: Establishing or changing the values of DFSMSHsm control parameters,” on page 1057.](#)

```
ADDVOL MIG201 UNIT(3390) MIGRATION(ML1 OVERFLOW)
```

Chapter 27. ALTERDS command: Changing the backups for a non-SMS-managed data set

The DFSMSHsm ALTERDS command alters the number of backup versions that are maintained for a non-SMS-managed data set or UNIX file and the frequency of creating the backup versions for the data set or UNIX file.

If an ALTERDS command is issued for an SMS-managed data set or UNIX file that is contained in an SMS-managed zFS, the command fails and a message is issued. The number of versions and frequency of backup for an SMS-managed data set is determined from the data set's management class attributes. The number of versions of backup for a UNIX file that is contained in an SMS-managed zFS is determined from the management class of the zFS data set.

You can either specify new values with the VERSIONS and FREQUENCY parameters or revert to the DFSMSHsm default values with the SYSVERSIONS or SYSFREQUENCY parameters.

- When you specify a frequency of backup for your data set, the value overrides any frequency value that you specified with the BACKVOL command or the current DFSMSHsm value for FREQUENCY.
- When you specify a value for the VERSIONS parameter for your data set or UNIX file, the value overrides the current DFSMSHsm value for VERSIONS.
- When you specify SYSVERSIONS or SYSFREQUENCY, DFSMSHsm uses the value that you specified with the VERSIONS parameter or the FREQUENCY parameter of the SETSYS command.

If you did not use the SETSYS command to specify these values, DFSMSHsm uses the current DFSMSHsm default values for the number of backup versions or the frequency of creation of the backup versions.

You do not have to repeat any of these parameters each time you start DFSMSHsm because the values are stored in the BCDS data set record. The record is not deleted even if all of the backup versions for the data set or UNIX file are deleted. To delete this record from the BCDS, along with the record of each backup version, use the ALTERDS command with the SYSVERSIONS and SYSFREQUENCY parameters (reverts to DFSMSHsm default values). Then use the BDELETE command to delete the backup versions.

If you specify the ALTERDS command without any parameters, you receive a message that the command has completed successfully. DFSMSHsm, however, does not change any of the data set or UNIX file parameters that affect backup.

Syntax of the ALTERDS command

Note:

1. You can specify VERSIONS or SYSVERSIONS, FREQUENCY or SYSFREQUENCY, or a combination of these parameters with the ALTERDS command, but you must specify at least one parameter with the ALTERDS command to change the backup parameters.
2. Due to the order of processing to determine eligibility for backup, DFSMSHsm checks certain conditions prior to processing the ALTERDS parameters. For example, DFSMSHsm fails a data set with an unsupported data set organization prior to checking the ALTERDS parameters.

Required parameters of the ALTERDS command

This topic describes the required parameter of the ALTERDS command.

name: Specifying the name of the data set or UNIX file being altered

Explanation: *name* ... is a required positional parameter specifying the fully qualified data set or absolute UNIX path name or list of fully qualified data sets of the non-SMS-managed data sets or UNIX files whose backup attributes are being changed.

Defaults: None.

Note:

1. Because *name* ... is a required positional parameter, you must specify it immediately after the command name.
2. DFSMSHsm does not handle partitioned data set members individually. If you specify a member name of a partitioned data set, DFSMSHsm changes the backup parameters for the entire partitioned data set.
3. The UNIX path name must be enclosed in single quotation marks and be an absolute path that starts from root (/).

Optional parameters of the ALTERDS command

This topic describes the optional parameters of the ALTERDS command.

FREQUENCY and SYSFREQUENCY: Specifying the frequency of backup versions

Explanation: **FREQUENCY** and **SYSFREQUENCY** are mutually exclusive, optional parameters specifying the number of days between backup versions of data sets. If the data set has changed since the last time it was backed up and the specified number of days (frequency) has elapsed since the last backup version was created, a new backup version of the data set is created during incremental volume backup. If, however, the specified number of days has elapsed but the data set was not changed, a new backup version of the data set is not created during volume backup unless you specified the TOTAL parameter of the BACKVOL command.

FREQUENCY(days) is specified to change the number of days between backup versions of the specified data set. For *days*, substitute a decimal number from 0 to 999. For example, if you specify *days* as 5, DFSMSHsm backs up the data set if the data set has changed since the last time DFSMSHsm backed it up and the latest backup version is at least five days old. If you specify 0, DFSMSHsm creates a backup version of a changed data set every day that automatic backup runs.

SYSFREQUENCY is specified to revert to the value you specified with the SETSYS command or to the DFSMSHsm default for the frequency of data set backup.

Defaults: None.

Note: Specify the SYSFREQUENCY parameter only if a previous ALTERDS command has changed the frequency of backup versions for this data set and if you want to return to the frequency specified on the SYSFREQUENCY setting. If you specify the FREQUENCY parameter of the BACKVOL command and also specify the SYSFREQUENCY parameter of the ALTERDS command, DFSMSHsm uses the frequency set in the BACKVOL command. DFSMSHsm determines the frequency of backup in descending order:

- ALTERDS
- BACKVOL
- SETSYS
- DFSMSHsm default

VERSIONS and SYSVERSIONS: Specifying the number of backup versions to maintain

VERSIONS and SYSVERSIONS are mutually exclusive, optional parameters specifying the maximum number of backup versions to be kept when additional versions are made for the data set or UNIX file.

VERSIONS(*limit*) is specified to change the number of backup versions to be kept for the specified data set or UNIX file. The maximum number of backup versions is limited to 29 versions or 100 versions based on the BCDS record length. The following values are the valid maximum allowable number of backup versions for different BCDS record lengths:

- Record length of 2040 to 6543 — 29 versions maximum
- Record length of 6544 or more — 100 versions maximum

For *limit*, substitute a decimal number from 0 to 100. If you specify 0, DFSMSHsm does not back up the data set.

SYSVERSIONS is specified to revert to the value you specified with the SETSYS command or to the DFSMSHsm default for the number of backup versions to be kept for backup data sets.

Defaults: None.

Note:

1. Specify the SYSVERSIONS parameter only if a previous ALTERDS command has changed the number of backup versions for this data set or UNIX file and if you want to return to the number of backup versions specified on the SYSVERSIONS setting. DFSMSHsm determines the number of backup versions in the following order:

- ALTERDS
- SETSYS
- DFSMSHsm default

2. If you reduce the number of backup versions with this command, DFSMSHsm does not delete existing backup versions when the ALTERDS command is processed.

The existing excess backup versions will be deleted to match the specified limit at the time a new backup version is created for the data set or UNIX file. The EXPIREBV command can be used to delete unwanted backup versions of data sets or UNIX files without creating any new backup versions.

3. DFSMSHsm can keep a maximum of 29 versions or 100 versions, depending on the BCDS record length. Some versions may be kept for a cataloged data set with that name, and some versions kept for uncataloged data sets with that name.

The VERSIONS or SYSVERSIONS parameter indicates the number of backup versions kept for (1) the cataloged data set and (2) the uncataloged data sets. UNIX files are always considered to be cataloged. DFSMSHsm gives priority, if necessary, to versions of the cataloged data set. For example, if you specify VERSIONS(15), when the 15th backup version of the cataloged data set is made, no more than 14 versions will be kept for the uncataloged data sets.

4. If the file was backed up by a NEWNAME request, and the directory did not exist at the time of backup, DFSMSHsm was unable to store the name of the containing zFS. Thus DFSMSHsm is unable to use that zFS data set name for SMS-management checking. DFSMSHsm will then check for current existence of the file, and use the current containing zFS data set for the SMS-management check. If the file also does not exist, DFSMSHsm cannot determine whether the file is SMS-managed or not and the ALTERDS will fail.

Examples of how to code the ALTERDS command

The following examples present different ways to code the ALTERDS command.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Changing the number of elapsed days between backup versions

In this example, the number of elapsed days between creation of backup versions of the specified data set is changed to 3.

```
ALTERDS PAC4485.INPUT.LOAD FREQUENCY(3)
```

Changing the maximum number of backup versions that are kept

In this example, the maximum number of backup versions kept for the specified data set is changed to twenty-one.

```
ALTERDS JAB3364.REPORT.TEXT VERSIONS(21)
```

Specifying zero number of backup versions that are kept

In this example, you do not want DFSMSHsm to keep any backup versions of the specified data set.

```
ALTERDS RTJ2219.REPORT.TEXT VERSIONS(0)
```

Chapter 28. ALTERPRI command: Altering the priority of queued requests

The ALTERPRI command allows you to alter the priority of queued requests for some DFSMSHsm functions. You can alter the priority of queued requests by the request number, by the user ID that issued the request, or by the data set, or UNIX file named in the request. You can alter the priority to make the request either the highest or lowest priority in its queue.

You can use the ALTERPRI command to alter the queueing priority for the following types of requests:

- ABACKUP
- ARECOVER
- BACKDS
- BACKVOL
- DELETE
- FRBACKUP
- FREEVOL
- FRRECOV
- MIGRATE
- RECALL
- RECOVER

You cannot alter the queueing priority of BACKVOL CDS commands and requests that have already been selected for processing.

Use the ALTERPRI command on an as-needed basis only. The ALTERPRI command only works for queued requests and will have no effect on any new requests.

Note:

1. To prioritize a request on the Common Recall Queue, enter the ALTERPRI command on the same host that originated the recall request.
2. The BACKVOL STORAGEGROUP, BACKVOL VOLUMES, FRBACKUP DUMP, FRBACKUP DUMPONLY, and FRRECOV DSNAME commands, and requests for single volume recovery from incremental backups, each generate multiple requests (one request per volume), all with the same request number. Therefore, an ALTERPRI REQUEST command entered for one of these requests will alter the priority of all requests that are generated for the command.
3. This command is security that is protected, so a security profile must be defined and users must be given access to it before the ALTERPRI command can be issued. For information about defining FACILITY class profiles, see [z/OS Security Server RACF Security Administrator's Guide](#).
4. Changing the priority of queued requests running in the Common Dump Queue or the Common Recover Queue will be completed for queued requests that originated on the host issuing the ALTERPRI command for a request number or user ID that matches the parameters on the ALTERPRI command. A single ALTERPRI by USERID affects requests in both common queues.

The QUERY COMMONQUEUE(RECOVER) command or the QUERY COMMONQUEUE(DUMP) command can be used to determine the requests running in their respective common queues. This will identify the HOST id of the originating host for the request and can be used to determine the host from which a corresponding ALTERPRI should be issued.

For a host that is connected to a Common Dump or Recover Queue and is not the Master Scheduler, the local queue will be searched and the Master Scheduler member's group queue will be searched. For a host that is the Master Scheduler, only the local queue will be searched.

Syntax of the ALTERPRI command

Required parameters of the ALTERPRI command

This topic describes the required parameter of the ALTERPRI command.

REQUEST, USERID, and DATASETNAME, and FILENAME: Specifying the requests to be reprioritized

Explanation

REQUEST, USERID, DATASETNAME, and FILENAME are mutually exclusive, required parameters that identify the requests to be reprioritized.

REQUEST(*reqnum*)

Requests having the specified request number *reqnum* are to be altered in queuing priority.

USERID(*userid*)

Requests issued by the specified user *userid* are to be altered in queuing priority.

userid is an 8-character TSO/E user ID. To alter the priority for operator-initiated recalls, specify a value of **OPER*.

DATASETNAME(*dsname*)

Requests for the specified data set *dsname* are to be altered in queuing priority.

FILENAME(*fname*)

Requests for the specified UNIX file *fname* are to be altered in queuing priority. The specified UNIX file name must be enclosed in single quotation marks and begin with the forward slash character.

Defaults

None.

Usage notes:

1. You can use the QUERY REQUEST command to determine the request number of a request for which you want to alter the queuing priority.

Optional parameters of the ALTERPRI command

This topic describes the optional parameter of the ALTERPRI command.

HIGH and LOW: Specifying the new priority of a request

Explanation

HIGH and LOW are mutually exclusive, optional parameters that indicate how to alter the priority of the specified requests.

HIGH

The specified request is to be given the highest priority on its respective queue.

LOW

The specified request is to be given the lowest priority on its respective queue.

Defaults

If neither the HIGH or LOW parameter is specified, the default is HIGH.

Examples of how to code the ALTERPRI command

The following examples present different ways to code the ALTERPRI command.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Altering the queuing priority of all requests for a specific data set

To alter the queuing priority of all requests for a particular data set, enter the ALTERPRI command with the DATASETNAME parameter specified. In this example, all requests for data set USERA.DSET01 are updated so that they have the highest priority on their respective queues.

```
ALTERPRI DATASETNAME(USERA.DSET01)
```

Altering the queuing priority of all requests with a specific request number

To alter the queueing priority of all requests with a particular request number, enter the ALTERPRI command with the request number specified. In this example, all requests with request number 1078 are updated so that they have the highest priority on their respective queues.

```
ALTERPRI REQUEST(1078) HIGH
```

Altering the queueing priority of all requests issued by a specific user

To alter the queueing priority of all requests issued by a particular user, enter the ALTERPRI command with the userid specified. In this example, all of the requests issued by user USERA are updated so that they have the lowest priority on their respective queues.

```
ALTERPRI USERID(USERA) LOW
```

Altering the queueing priority of all operator-initiated requests

To alter the queueing priority of all operator-initiated requests, enter the ALTERPRI command with a value of **OPER* for USERID. In this example, all operator-initiated requests are updated so that they have the lowest priority on their respective queues.

```
ALTERPRI USERID(**OPER*) LOW
```

Chapter 29. ARECOVER command: Recovering a specified aggregate group

The ARECOVER command performs a recovery of specified aggregated data sets previously backed up with the ABACKUP command. A BCDS must be defined at the aggregate recovery site prior to issuing an ARECOVER command; otherwise, the command fails.

Note: In some topics, you will find the term *Application Backup and Recovery* used rather than *Aggregate Backup and Recovery*. The two terms are interchangeable.

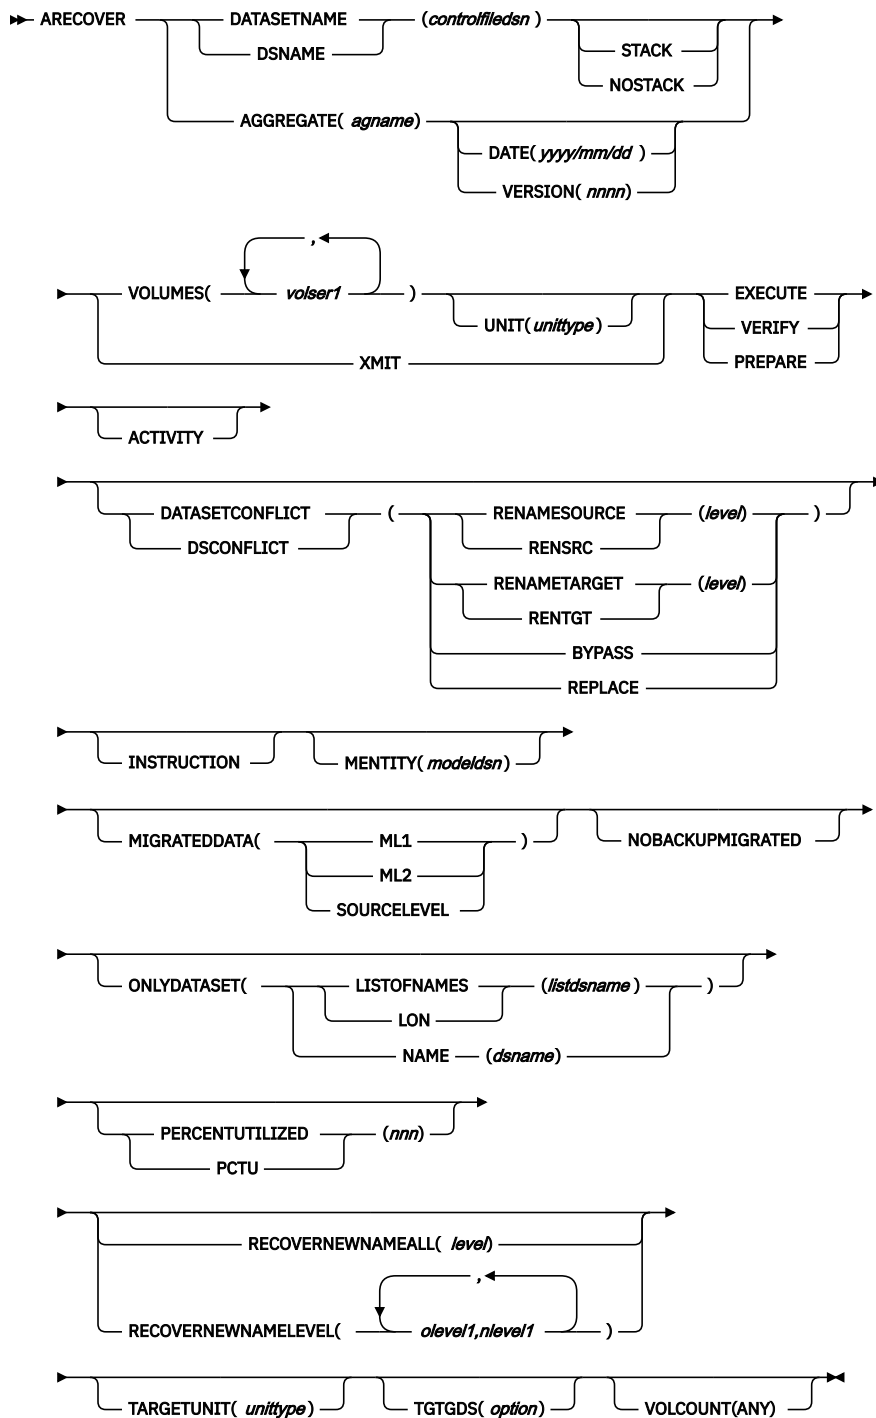

The ABR record contains the information necessary to maintain an inventory of aggregate backup and recovery activities for a particular aggregate group. To create an ABR record, issue the ARECOVER command with the PREPARE option, catalog the aggregate backup files, and add the ABACKUP output volumes to the HSMABR RACF tape volume set if requested. This allows you to issue subsequent ARECOVER commands using the aggregate group name. If the ABR record has not been created prior to issuing the ARECOVER command, the command must include the DATASETNAME and VOLUMES parameters. Once the ARECOVER command is issued and it is determined that an ABR record does not exist, one is automatically created.

If you issue the ARECOVER command with the AGGREGATE parameter, an aggregate backup and recovery support (ABARS) activity record (ABR record for the specific aggregate) must exist in the BCDS at the recovery site in order to perform a successful recovery of the previously backed-up aggregate data sets. To create an ABR record, see [Chapter 8, “Aggregate backup and recovery support \(ABARS\),” on page 319](#) for a description of the information contained in the ABR record.

You can also use the ARECOVER command to recover individual data sets from an aggregate backup version. You can specify a single fully qualified data set name on the ARECOVER command to recover a particular data set. In order to recover multiple data sets, you can supply the name of a data set that contains a list of data set names to be recovered from a specific aggregate backup version.

Note: Issuing the ABACKUP and ARECOVER commands while SETSYS DEBUG is in effect causes the commands to be processed as if the VERIFY parameter were in effect. For additional information on SETSYS DEBUG, see [“Using DEBUG to determine the results of DFSMSHsm processing without moving data sets” on page 587](#).

Syntax of the ARECOVER command

Note:

1. The SETSYS MAXABARSADDRESSSPACE command determines the number of ARECOVER commands that can run at one time. The maximum number is 64.
2. DFSMSHsm can process only one ARECOVER command for each control file data set name or aggregate group at one time.
3. The volumes must be listed in the order that they are to be mounted or the command fails.
4. Issuing ARECOVER with AGGREGATE requires that ARECOVER DATASETNAME be issued previously using the PREPARE parameter.

5. In a multiple address space for DFSMSHsm environment, ABARS commands, like ARECOVER, can only be issued by the host identified as the main host. DFSMSHsm ignores the ABARS commands if directed to a host identified as HOSTMODE=AUX.

Required parameters of the ARECOVER command

This topic describes the required parameters of the ARECOVER command.

AGGREGATE: Specifying the aggregate group to be recovered

Explanation: **AGGREGATE(*agname*)** is a required parameter that identifies the aggregate group to be recovered.

When you specify **AGGREGATE(*agname*)**, the most current version of the backup output is used for recovery unless **DATE** or **VERSION** is specified.

An ABR record must exist at the recovery site to support the **AGGREGATE** parameter. During **AGGREGATE** processing, the ABR record is read for the aggregate group. All files associated with the ABR record must be cataloged. If the files are not cataloged and ABR records exist for multiple copies, the process is repeated until an ABR record is found for one of the copies, with the proper files cataloged. If no ABR record is found with the proper files cataloged, a message is issued and the ARECOVER **AGGREGATE** fails. If this occurs, you must use **ARECOVER DATASETNAME(*controlfiledsn*)** with the **PREPARE** parameter to create the ABR record and catalog the proper files. See [“How to create the ABR record” on page 733](#) to create the ABR record.

Note:

1. Do not specify **AGGREGATE** when **DATASETNAME** is specified.
2. You must specify either **EXECUTE**, **VERIFY**, or **PREPARE** when **AGGREGATE** is specified.
3. If **PREPARE** is specified with the **AGGREGATE** parameter, **INSTRUCTION**, **ACTIVITY**, or both parameters must also be specified.

Defaults: None.

DATASETNAME: Specifying the control file

Explanation: **DATASETNAME(*controlfiledsn*)** is a required parameter used to identify the control file that contains information about the aggregated data sets previously backed up with the **ABACKUP** command.

controlfiledsn specifies the aggregate backup control file to be recovered by aggregate recovery. For *controlfiledsn*, substitute the name of the control file you want recovered. The control file name is stored in the volume header label in the format *outputdatasetprefix.C.CccVnnnn*. This is the *outputdatasetprefix* previously specified in the aggregate group.

If the control file is not catalogued at your recovery site, you can use **ARECOVER DATASETNAME(*controlfiledsn*)** with the **PREPARE** parameter to create the ABR record, which contains the control file names. See [“How to create the ABR record” on page 733](#) to create the ABR record.

Note:

1. You must specify either **VOLUMES(*volser1...*,*volsern*)** or **XMIT** when **DATASETNAME** is specified.
2. You must specify either **EXECUTE**, **VERIFY**, or **PREPARE** when **DATASETNAME** is specified.
3. Do not specify **AGGREGATE** when **DATASETNAME** is specified.

Defaults: None.

VOLUMES and XMIT: Specifying the volume type

Explanation: **VOLUMES(*volser1...*,*volsern*)** | **XMIT** are mutually exclusive, required parameters identifying the volumes associated with aggregate recovery processing.

Note: **VOLUMES** and **XMIT** are valid only when **DATASETNAME** is specified.

VOLUMES(*volser1...volsern*) specifies from 1 to 15 volumes where the control file to be recovered resides. For (*volser1...volsern*), substitute the serial numbers of the volumes where the control file resides. The serial numbers must be specified in the same order as they are listed in message ARC6061I issued at the conclusion of the ABACKUP processing.

XMIT tells DFSMSHsm that the ABACKUP output has been transmitted, and it also tells DFSMSHsm *not* to use the *volser* and *unit* information in the control file to drive the recovery. Instead, ARECOVER searches the catalog for the control and data files and, if found, uses the *unit* and *volser* from the catalog when allocating these data sets. UNIT and VOLUMES are invalid if the XMIT parameter is present, and if they are specified, ARC6002E reports an error.

Defaults: None.

EXECUTE, VERIFY, and PREPARE: Specifying whether data movement or verification should occur or whether an ABR record should be created

Explanation: **EXECUTE** | **VERIFY** | **PREPARE** are mutually exclusive, required parameters specifying whether aggregate recovery or error checking is performed or an ABR record is created.

EXECUTE specifies that DFSMSHsm perform aggregate recovery.

VERIFY specifies that DFSMSHsm should only verify the aggregate recovery configuration. No data sets will be recovered. Verification determines if errors or data set conflicts exist.

PREPARE specifies that an ABR record should be created without further verification processing or data movement if it does not already exist at the recovery site.

When PREPARE is specified, and an ABR record already exists for the specified aggregate group version and all the associated ARECOVER input files are properly cataloged, a message is issued and the PREPARE function ends. If the ABR record already exists but one or more associated files are not cataloged, a message is issued for each file that is not cataloged, the ABR record is deleted (with an accompanying message), and the PREPARE function continues.

During ARECOVER processing, when VERIFY or PREPARE is specified, messages are issued indicating the amount of storage required to perform a successful aggregate recovery. The amounts of L0, ML1, and ML2 storage required are retrieved from the ABR record and displayed separately along with the combined total storage requirement.

Note:

1. Issue the ARECOVER VERIFY command to determine the storage requirements for data movement prior to issuing the ARECOVER EXECUTE command, and ensure that sufficient storage space is available. Refer to the text below for storage requirement information when using the VERIFY parameter.
2. If the ABR record does not exist at the recovery site when EXECUTE or VERIFY is specified on an ARECOVER DATASETNAME(controlfiledsn) command, the ABR record is created at the recovery site and EXECUTE or VERIFY processing continues.
3. You must specify either EXECUTE, VERIFY, or PREPARE when DATASETNAME or AGGREGATE is specified.
4. If PREPARE is specified with the AGGREGATE parameter, INSTRUCTION, ACTIVITY, or both parameters must also be specified.

Defaults: None.

Optional parameters of the ARECOVER command

This topic describes the optional parameters of the ARECOVER command.

ACTIVITY: Recovering the activity log

Explanation: **ACTIVITY** is an optional parameter specifying the recovery of the activity log data set if one exists on the output tape for the specified aggregate group.

Specify the **ACTIVITY** parameter the first time **ARECOVER** is executed. Specifying **ACTIVITY** with the **EXECUTE**, **VERIFY**, or **PREPARE** parameters causes recovery of the activity log, if one exists. If the activity log data set does not exist on the **ABACKUP** output tapes and **ACTIVITY** is specified, an error message is issued and **ARECOVER** processing continues.

Refer to the [“Aggregate recovery output” on page 411](#) for the information contained in the activity log data set.

Defaults: None.

DATASETCONFLICT: Resolving data set naming conflicts

Explanation: **DATASETCONFLICT** is an optional parameter used to resolve any data set naming conflicts.

Note: **DATASETCONFLICT** may be specified in conjunction with the **RECOVERNEWNAMEALL** or **RECOVERNEWNAMELEVEL** parameters.

Subparameter	Explanation
RENAMESOURCE	DATASETCONFLICT(RENAMESOURCE(<i>level</i>)) specifies that data sets from the aggregate backup output files are recovered with the new high-level qualifier specified by the <i>level</i> option.
RENAMETARGET	RENAMETARGET(<i>level</i>) specifies that existing data sets at the recovery site are renamed with the high-level qualifier specified by <i>level</i> , and data sets from the aggregate backup output files are recovered with their original names. An ALTER NEWNAME is performed for the existing data set name. For a detailed explanation of the ALTER NEWNAME function, refer to z/OS DFSMS Access Method Services Commands .
BYPASS	DATASETCONFLICT(BYPASS) specifies that the data sets from the aggregate backup output files are skipped and not recovered.
REPLACE	DATASETCONFLICT(REPLACE) specifies that the existing data set at the recovery site is deleted and replaced with the data set from the aggregate backup output files.

Special care should be taken when changing the high-level qualifier so that the existing data set does not become uncataloged. This may occur when no catalog alias exists for the new high-level qualifier.

Note: When using **REPLACE**, the data set is deleted prior to attempting the recovery of the data set from the aggregate backup output files. If the recovery fails for any reason, the data set remains deleted. Reasons for failure include, among others:

- I/O errors on the input tape
- Failure to allocate the new data set
- Recovering at a site that does not support the type of data set being recovered.

Not all actions performed by **DATASETCONFLICT** subparameters are valid for all data sets. If conflicts still exist, see [“Performing aggregate recovery” on page 391](#) for more information on data set naming resolution.

Defaults: None.

DATE and VERSION: Specifying the specific aggregate group to be recovered

Explanation: **DATE** | **VERSION** are optional parameters you can use to specify the specific aggregate group to recover.

Note: DATE or VERSION are valid only when you specify AGGREGATE(*agname*).

DATE(*yyyy/mm/dd*) indicates the date of the aggregate group version you want recovered.

- *yyyy* is the 4-digit year
- *mm* is the month (01-12)
- *dd* is the day of the month (01-31)

Note: If more than one aggregate version has been created on the date you specify, the most current version on the specified date is selected.

VERSION(*nnnn*) indicates the specific version of the aggregate group to be recovered.

Defaults: If neither DATE nor VERSION is specified, the most current aggregate group version is recovered.

INSTRUCTION: Recovering the instruction data set

Explanation: **INSTRUCTION** is an optional parameter to recover the instruction data set if one exists on the output tape for the specified aggregate group at the backup site.

Specify the INSTRUCTION parameter the first time ARECOVER is executed for a given aggregate group. Specifying INSTRUCTION with the EXECUTE, VERIFY, or PREPARE parameters causes recovery of the instruction data set, if one exists. If the instruction data set does not exist on the ABACKUP output tapes and INSTRUCTION is specified, an error message is issued and ARECOVER processing continues.

Refer to the [Chapter 8, “Aggregate backup and recovery support \(ABARS\),” on page 319](#) for the information contained in the instruction data set.

Defaults: None.

MENTITY: Specifying a model entity

Explanation: **MENTITY**(*modeldsn*) is an optional parameter specifying the predefined model entity. It is used to define discrete profiles to RACF for data sets to be recovered. For *modeldsn*, substitute the data set name of the predefined model entity. Only those data sets previously protected by discrete profiles and defined to RACF before aggregate backup are protected by discrete profiles using the model entity. If the MENTITY parameter is specified in the ARECOVER command but the model entity is not predefined, aggregate recovery fails.

If MENTITY is not specified and a discrete profile is not predefined, the data set is recovered with a default discrete profile. The profile owner is set to the high level qualifier of the data set, and UACC is set to NONE. If a RACF profile has been predefined for the data sets, they are recovered with this predefined profile.

For more information on RACF discrete profiles and model entities, see [z/OS Security Server RACF Security Administrator's Guide](#).

Defaults: None.

MIGRATEDDATA: Specifying the migration level for recovering migrated data sets

Explanation: **MIGRATEDDATA** is an optional parameter specifying the migration level when recovering migrated data sets.

Note: Since ABACKUP of data sets migrated to the cloud is not supported, none will be included in the recovery.

Subparameter	Explanation
ML1	MIGRATEDDATA(ML1) specifies that all migrated data sets are recovered to migration level 1 DASD. This is the default if you do not specify MIGRATEDDATA.
ML2	MIGRATEDDATA(ML2) specifies that all migrated data sets are recovered to nonspecific tape volumes which are then managed by DFSMSHsm as migration level 2 volumes.
SOURCELEVEL	MIGRATEDDATA(SOURCELEVEL) specifies that all ML1 migrated data sets at the ABACKUP site are recovered to migration level 1 DASD; all ML2 DASD or ML2 tape migrated data sets are recovered to nonspecific tape volumes and then ADDVOLed as migration level 2 volumes.

Defaults: None.

Note: You must specify the tape unit name when recovering migrated data sets to nonspecific volumes. Use the SETSYS ARECOVERML2UNIT command to specify the tape unit name in a nonspecific volume request. Valid tape unit names or esoteric unit names specified in the SETSYS USERUNITTABLE command are also accepted. If the unit name is not specified, the default tape unit name is 3590-1. You must specify a machine type specific esoteric name when in a mixed tape machine-type environment.

NOBACKUPMIGRATED: Specifying that automatic backup does not occur for recovered migrated data sets

Explanation: **NOBACKUPMIGRATED** is an optional parameter to specify that recovered migrated data sets are *not* backed up during automatic backup. If you do not specify the parameter, DFSMSHsm backs up recovered migrated data sets residing on ML1 DASD the next time automatic backup occurs.

Defaults: None.

ONLYDATASET: Recover a single data set or a group of data sets from an aggregate group backup

Explanation: **ONLYDATASET** is an optional parameter to specify that a particular data set or a group of data sets are to be recovered from the backup copy of an aggregate group. ONLYDATASET parameter has two subparameters: NAME and LISTOFNAMES. Use NAME if you wish to only restore one fully qualified data set name from aggregate group backup tapes or LISTOFNAMES if you wish to create a file containing a list of multiple fully qualified data set names you wish to restore from the aggregate group backup tapes.

ONLYDATASET can be abbreviated as ONLYDS.

Subparameter	Explanation
NAME	ONLYDATASET(NAME(dsname)) specifies the fully qualified name of the data set to be recovered from the aggregate group backup.
LISTOFNAMES	ONLYDATASET(LISTOFNAMES(listdsname)) specifies that data sets listed in a separate file are to be recovered from the backup copy of an aggregate group. For the list file (<i>listdsname</i>), specify a single fully qualified data set name.

If you specify a data set that is not found in the aggregate group backup, the system issues an error message and the ARECOVER command ends with a non-zero return code.

To recover more than one data set from the aggregate group, use the LISTOFNAMES subparameter.

Defaults: None.

LISTOFNAMES: Recover multiple data sets from an aggregate group backup

Explanation: **LISTOFNAMES**(*listdsname*) is an optional parameter to specify that data sets listed in a separate file are to be recovered from the backup copy of an aggregate group. For the list file (*listdsname*), specify a single fully qualified data set name.

LISTOFNAMES can be abbreviated as LON.

If one or more of the data sets in the list specified on the LISTOFNAMES parameter are not found on the tapes for that aggregate version, ARECOVER will recover the data sets that are found, fail those data sets that are not found, and end with a non-zero return code.

The LISTOFNAMES data set must be a sequential data set, fixed-block, a logical record length (LRECL) of 80 and must also be cataloged. If the LISTOFNAMES data set is not cataloged or properly allocated, ARECOVER processing fails with a non-zero return code.

In the LISTOFNAMES data set, specify only one fully qualified data set name per record. Specifying multiple data set names per record, or using partially qualified data set names will cause ARECOVER processing to fail with a non-zero return code. Each record in the LISTOFNAMES data set should only contain 1 fully qualified data set name per 80 character record. There is no limit to the number of records that could be contained in the file. The LISTOFNAMES parameter should be used when you want to recover more than 1 data set from the aggregate group, but you do not wish to recover all data sets in the aggregate group.

To recover just one data set from the aggregate group, use the NAME subparameter of the ONLYDATASET parameter.

Defaults: None.

PERCENTUTILIZED: Specifying the percentage of DASD space used during ARECOVER of data sets to non-SMS volumes

Explanation: **PERCENTUTILIZED**(*nnn*) is an optional parameter that allows DFSMSdss to fill the L0 volumes in the associated ARPOOL up to 100% (100) for this aggregate.

For *nnn*, substitute an integer between 1 and 100.

Defaults: If you do not specify a PERCENTUTILIZED value, the default value is specified by the SETSYS ARECOVERPERCENTUTILIZED parameter. The SETSYS ARECOVERPERCENTUTILIZED default value is 80% (080).

RECOVERNEWNAMEALL and RECOVERNEWNAMELEVEL: Specifying a high-level qualifier for recovered data sets

Explanation: **RECOVERNEWNAMEALL** is an optional parameters that you use to specify a new high-level qualifier for recovered data sets.

RECOVERNEWNAMEALL(*level*): You use this parameter to rename all data sets that you want to recover with the high-level qualifier *level* option.

RECOVERNEWNAMELEVEL(*olevel1,nlevel1, ...*): You use this parameter to specify that all data sets having a high-level qualifier of *olevelx* are recovered with a new high-level qualifier of *nlevelx*. The maximum number of *olevelx,nlevelx* qualifier pairs is 30.

Note:

1. The RECOVERNEWNAMEALL and RECOVERNEWNAMELEVEL parameters allow data sets to be renamed before verification checks for like-named conflicts. These rename parameters apply to data sets in the INCLUDE and ALLOCATE lists (except for ICF user catalogs in the ALLOCATE list), but do not apply to ACCOMPANY data sets. In addition, migrated source VSAM data sets may not be renamed. If a rename criterion applies to a migrated source VSAM data set, a message is issued and the data set is not renamed.

2. If a rename criterion applies to a nonmigrated source VSAM data set, the new component names are not generated by ARECOVER processing but are generated by DFSMSdss if the data set name is from the INCLUDE list or by SMS VSAM allocation if the data set is from the ALLOCATE list.
3. If RECOVERNEWNAMEALL is specified, a message indicates that all data sets will be renamed with the specified level. If RECOVERNEWNAMELEVEL is specified, a message lists the level pairs specified, indicating that each data set matching the old level will be renamed to the corresponding new level. Each data set meeting a rename criterion is recovered with the new name during data movement. Like-named conflicts created by the new name are evaluated during the conflict resolution process. See [Chapter 8, “Aggregate backup and recovery support \(ABARS\),” on page 319](#) for more information about data set name conflict resolution.

Defaults: None.

STACK and NOSTACK: Specifying whether or not the ABACKUP output is STACKED

Explanation: **STACK** | **NOSTACK** are optional parameters you can use to specify to the ARECOVER DATASETNAME processing whether or not the ABACKUP output was stacked. When the ABACKUP output files are stacked, the ARECOVER processing will allocate file sequence number four.

STACK specifies that DFSMSHsm stacked the ABACKUP output files onto a minimum number of tape volumes during ABACKUP processing.

NOSTACK specifies that DFSMSHsm did not stack the ABACKUP output files during ABACKUP processing. The NOSTACK parameter allows an installation the capability to ARECOVER backups performed on a down-level version of DFSMSHsm.

TARGETUNIT: Specifying unit types to be used for ARECOVER

Explanation: **TARGETUNIT(*unittype*)** is an optional parameter specifying the tape unit type for data sets being recovered to tape devices during an aggregate recovery.

For *unittype*, substitute the type of tape unit.

The following are valid types of tape units:

- 3480
- 3480X
- 3490
- 3590-1

You can substitute an esoteric tape unit defined with the SETSYS USERUNITTABLE command. If you specify an esoteric tape unit name that does not exist in the user unit table, the command fails. If you specify:

- 3480 or 3480X, you use all the functions of the 3480 Magnetic Tape Subsystem.
- 3490, you use all the functions of the 3490 Magnetic Tape Subsystem.
- 3590-1, you use all the functions of the 3590 Magnetic Tape Subsystem.

If you define both 3592-E05 and 3592-J1A to the same esoteric group, the E05 must use the EFMT1 recording format.

You can define a 3592-E05 or 3592-J1A to the 3590-1 generic group. If so, you must ensure drive compatibility or segmentation when using the 3590-1 in a non-SMS environment.

Note: When you perform an ABACKUP function with the 3480X or 3490 IDRC, you must use the same tape unit (3480X or 3490 IDRC) to do a successful RECOVER. Otherwise, the data cannot be read.

Defaults: If you do not specify this parameter, DFSMSHsm uses the unit type specified with the SETSYS ARECOVERUNITNAME parameter.

TGTGDS: Overriding the SETSYS ARECOVERTGTGDS command

Explanation: **TGTGDS(option)** is used to override the specification of the SETSYS ARECOVERTGTGDS command. The TGTGDS parameter is passed to DFSMSDss and provides greater flexibility managing SMS-managed generation data sets that are being restored to level 0 DASD.

The valid values for *option* are as follows:

Option	Explanation
DEFERRED	TGTGDS(DEFERRED) specifies that the target data set is to be assigned the DEFERRED status.
ACTIVE	TGTGDS(ACTIVE) specifies that the target data set is to be assigned the ACTIVE status, for example, rolled into the GDG base.
ROLLEDOFF	TGTGDS(ROLLEDOFF) specifies that the target data set is to be assigned the ROLLEDOFF status.
SOURCE	TGTGDS(SOURCE) specifies that the target data set is to be assigned the same status as that of the source data set.

Defaults: This parameter defaults to the setting specified on the SETSYS ARECOVERTGTGDS command. If SETSYS ARECOVERTGTGDS was not specified, then this parameter defaults to SOURCE.

UNIT: Specifying unit types used for ARECOVER

Explanation: **UNIT(unittype)** is an optional parameter specifying the tape unit type to be allocated for the recovering of data sets. The VOLUMES parameter is required when you use UNIT.

For *unittype*, substitute the type of tape unit.

The following are valid types of tape units:

- 3480
- 3480X
- 3490
- 3590-1

You can substitute an esoteric tape unit defined with the SETSYS USERUNITTABLE command. If you specify an esoteric tape unit name that does not exist in the user unit table, the command fails. If you specify:

- 3480 or 3480X, you use all the functions of the 3480 Magnetic Tape Subsystem.
- 3490, you use all the functions of the 3490 Magnetic Tape Subsystem.
- 3590-1, you use all the functions of the 3590 Magnetic Tape Subsystem.

If you define both 3592-E05 and 3592-J1A to the same esoteric group, the E05 must use the EFMT1 recording format.

You can define a 3592-E05 or 3592-J1A to the 3590-1 generic group. If so, you must ensure drive compatibility or segmentation when using the 3590-1 in a non-SMS environment.

Note: When you perform an ABACKUP with the 3480X or 3490 IDRC, you must use the same tape unit (3480X or 3490 IDRC) to do a successful RECOVER. Otherwise, the data cannot be read.

Defaults: If *unittype* is not specified, the default is the *unittype* specified on the SETSYS ABARSUNITNAME command. If UNIT has not been specified with the ARECOVER command nor the SETSYS ABARSUNITNAME command, the default is 3590-1.

VOLCOUNT: Allowing data sets to expand to multivolume as necessary during ARECOVER

Explanation: **VOLCOUNT(ANY)** is an optional parameter that affects how DFSMSHsm will invoke DFSMSdss during the ARECOVER of data sets that were dumped by DFSMSdss.

ANY specifies for DFSMSHsm to pass the VOLCOUNT(ANY) parameter to DFSMSdss during the ARECOVER of data dumped by DFSMSdss (L0 data sets). This parameter affects the way SMS-managed data set allocations are performed by DFSMSdss for the L0 data sets dumped from primary volumes. Refer to [z/OS DFSMSdss Storage Administration](#) for more specific information about the restrictions and limitations of the DFSMSdss VOLCOUNT parameter. The result is the allocation of the target data sets on as many volumes as required, to a maximum of 59.

The VOLCOUNT parameter is used to override the global SETSYS ABARSVOLCOUNT environment. Your current environment can be determined by issuing the QUERY ABARS command and examining the ARC6036I messages.

Defaults: None.

How to create the ABR record

If the ABR record does not exist for any reason, one must be created. The ARECOVER command syntax to create the ABR record is shown below. Only the relevant command parameters are listed.

► ARECOVER — DATASETNAME — (— *controlfiledsn* —) ►

Note:

1. DATASETNAME is the keyword parameter used to specify the control file data set name.
2. Either VOLUMES or XMIT is required. When VOLUMES is specified (UNIT is optional), the volume list is used to allocate the control file to read it. When XMIT is specified, the required files must already be cataloged, and the system supplies the volume list.
3. PREPARE, VERIFY, and EXECUTE are mutually exclusive. Use the PREPARE parameter with ARECOVER to create the ABR record without the overhead of verification processing or data movement. If you specify VERIFY or EXECUTE, the ABR record is created followed by the VERIFY or EXECUTE processing.

Examples of how to code the ARECOVER command

The following examples reflect the simplified ARECOVER commands, which require the user only to know the name of the aggregate group that has been backed up. You do not need to enter the control file data set name (and VOLUMES/UNIT, if XMIT is not specified) each time an aggregate recovery is performed.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Preparing a new ABR record

In this example, the ARECOVER command for the aggregate group, PAY1.C.C01V0001, is prepared. This preparation eliminates the overhead of verification processing or data movement associated with the VERIFY or EXECUTE parameter. TAPE23 is specified as the volume for the aggregate group, and 3590-1 is specified as the tape unit type to be allocated for the aggregate group. INSTRUCTION recovers the instruction data set and ACTIVITY recovers the activity log data set.

```
ARECOVER DATASETNAME(PAY1.C.C01V0001) VOLUMES(TAPE23) +  
UNIT(3590-1) PREPARE INSTRUCTION ACTIVITY
```

Verifying aggregate recovery

In this example, the ARECOVER command for the aggregate group, PAY1.C.G0001V00, is verified. This verification ensures that the command can complete successfully with no errors. The data sets to be recovered, as indicated by the aggregate group, are checked to ensure that no like-named data set conflicts exist. No data sets are recovered.

```
ARECOVER AGGREGATE(PAY1) VERIFY
```

Recovering the aggregated data sets

In this example, the data sets to be recovered, as indicated by the aggregate group, PAY1.C.G0001V00, are recovered. 3590-1 is specified as the tape unit type for receiving data sets recovered to tape devices.

```
ARECOVER AGGREGATE(PAY1) EXECUTE TARGETUNIT(3590-1)
```

Replacing like-named aggregated data sets during recovery

In this example, the data sets specified by the aggregate group, PAY1.C.G0001V00, are recovered. Any like-named data set that exists at the aggregate recovery site is deleted and is replaced with the corresponding aggregate backup data set. DATASETCONFLICT (REPLACE) is the proper parameter which deletes the existing data set at the ARECOVER site and recovers the ABACKUP data set.

```
ARECOVER AGGREGATE(PAY1) EXECUTE DATASETCONFLICT(REPLACE)
```

Recovering RACF-protected aggregated data sets

In this example, the data sets to be recovered as indicated by the aggregate group, PAY1.C.G0001V00, are recovered. When those data sets previously protected by discrete profiles and defined to RACF before aggregate backup are recovered, they are protected by the predefined model entity, USRT004.MODEL.PROF.

```
ARECOVER AGGREGATE(PAY1) EXECUTE MENTITY(USRT004.MODEL.PROF)
```

Specifying the percentage of DASD space for non-SMS volumes

This example shows how to fill NON-SMS Level 0 volumes to 90% of capacity during ARECOVER processing.

```
ARECOVER AGGREGATE(PAY1) EXECUTE PERCENTUTILIZED(090)
```

Specifying the migration level of recovered migrated data sets

This example shows how to recover all migrated data sets to ML2 tape volumes during ARECOVER processing.

```
ARECOVER AGGREGATE(PAY1) EXECUTE MIGRATEDDATA(ML2)
```

Specifying a high-level qualifier

This example shows how to rename all data sets that are recovered from ABACKUP output files with the high level qualifier of PAY1. The existing high level qualifier will be replaced.

```
ARECOVER AGGREGATE(PAY1) EXECUTE RECOVERNEWNAMELEVEL(PAY1)
```

Recovering an aggregate containing L0 data sets in the include list which failed due to inadequate space

In this example, L0 data sets were not recovered successfully by DFSMSdss because an inadequate space condition occurred. The ARECOVER command can be issued again with the VOLCOUNT parameter, allowing the failing data sets to be recovered to as many volumes as needed (maximum of 59) for successful allocation.

```
ARECOVER DSNAME(PAY1.C.C01V0002) VOLUMES(TAPE24) VOLCOUNT(ANY) EXECUTE
```

Sample activity log output for the ARECOVER command

Figure 92 on page 735 is sample activity log output for the ARECOVER command.

Chapter 30. AUDIT command: Auditing DFSMSHsm

The AUDIT command operates differently depending on whether it is issued for a control data set or for a common queue. The following two topics describe how the AUDIT command works with control data sets and common queues.

Auditing control data sets

The AUDIT command detects, reports, diagnoses, and often provides repairs for discrepancies between control data sets.

The purpose of DFSMSHsm is to manage your inactive data and to make DASD space available where it is needed. It does this by automating tasks and providing interactive tools. Automated tasks help you to move from a *user-managed* to a *system-managed* environment. The most important goal of DFSMSHsm, however, is to provide data integrity.

To ensure that you have data integrity, DFSMSHsm uses numerous data set records to track individual data sets. These records are contained in:

- Master catalog, which is a list of data sets for the entire system
- User catalog, which is a list of data sets accessible from that catalog
- Journal, which keeps a running record of backup and migration transactions
- SDSP data sets contained on migration volumes
- MCDS, which is an inventory of migrated data sets
- BCDS, which is an inventory of backed up data sets, UNIX files and volumes, dumped volumes, and backed up aggregates
- OCDS, which contains a tape table of contents (TTOC) inventory of migration and backup tape volumes

In normal operation, these records stay in synchronization. However, because of data errors, hardware failures, or human errors, it is possible for these records to become unsynchronized. The AUDIT command allows the system to cross-check the various records concerning data sets and DFSMSHsm resources. AUDIT can list errors and propose diagnostic actions or, at your option, complete most repairs itself.

Consider using the AUDIT command for the following reasons:

- After any CDS restore (highly recommended)
- Periodic checks
- After an ARC184I message (error when reading/writing DFSMSHsm CDS records)
- Errors on the RECALL or DELETE of migrated data sets
- Errors on BDELETE or RECOVER of backup data sets and UNIX files
- DFSMSHsm tape-selection problems
- RACF messages (mismatches)
- Power or hardware failure
- Check the consistency of fast replication CDS record relationships

You can use AUDIT to cross-check the following sources of control information:

- MCDS or individual migration data set records
- BCDS or individual backup data set records or UNIX files records or ABARS records or fast replication records
- OCDS or individual DFSMSHsm-owned tapes
- DFSMSHsm-owned DASD volumes

- Migration-volume records
- Backup-volume records
- Recoverable-volume records (from dump or incremental backup)
- Contents of SDSP data sets
- Fast Replication dump, volume pair, version, and volume copy pool association records
- DFSMSHsm-owned cloud containers

Auditing common queues

Common queues have interrelated entries that may become corrupted due to abends and unexpected losses of connectivity. A corrupted common queue may cause certain requests to not be processed. DFSMSHsm automatically corrects some inconsistencies, but for others, it is necessary to issue the AUDIT COMMONQUEUE command. The AUDIT command enables DFSMSHsm to dynamically correct inconsistencies with minimal impact on processing.

Consider using AUDIT COMMONQUEUE in the following situations:

- After receiving an ARC1506E message
- After receiving an ARC1187E message
- When recall requests are unexpectedly not being selected for processing

The structure of the common queues is not externalized. Message ARC1544I is the only output that AUDIT COMMONQUEUE returns. It does not return a specific message for each error because individual error messages are of no value. The OUTDATASET, SYSOUT, and TERMINAL parameters are not used with AUDIT COMMONQUEUE.

Unlike other AUDIT functions, auditing a common queue is not time intensive and may be performed at any time.

Using the AUDIT command

Before using the AUDIT command, read the descriptions of the available options in Chapter 75, “Using the AUDIT command,” on page 1255. Appendix A discusses which conditions are detected by each option.

It is best to use AUDIT at times of low system activity, as some audit processes can run for quite some time. However, the AUDIT process can be used at any time.

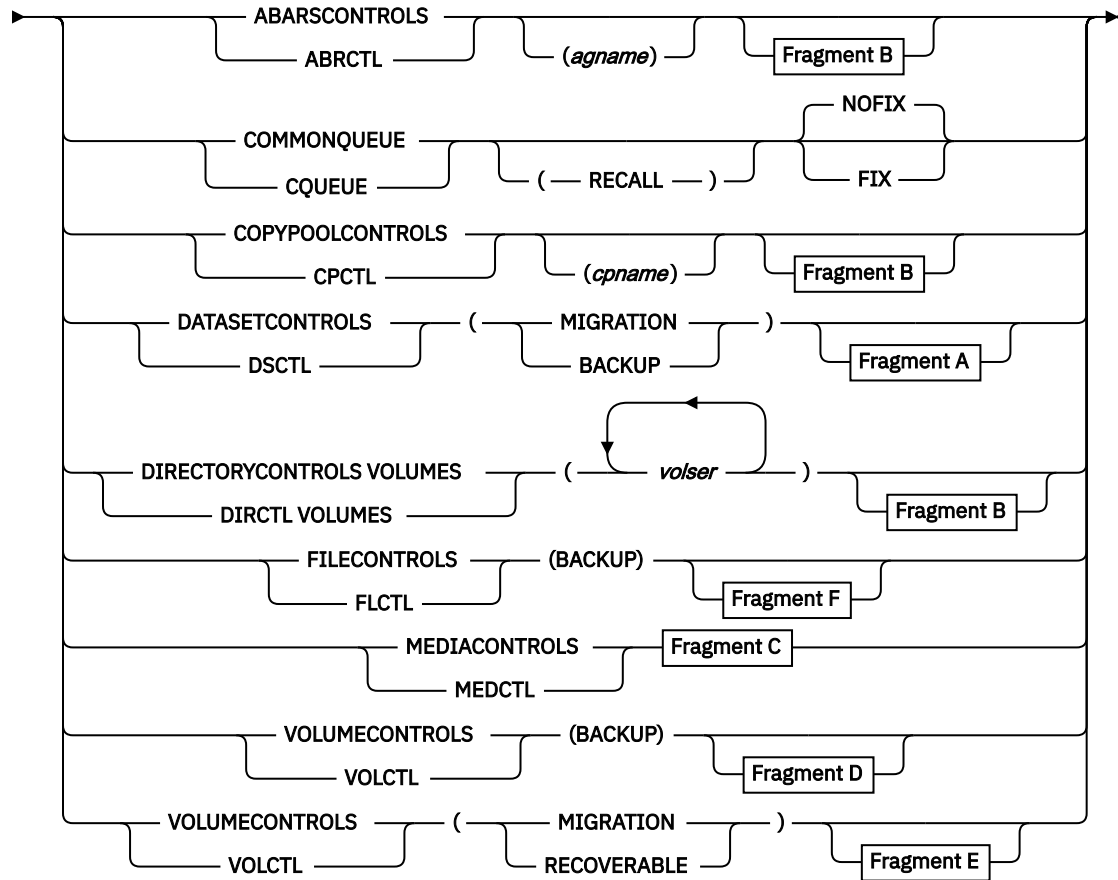

SMS-managed *volumes* cannot be audited with the AUDIT command and the process for auditing SMS-managed *data sets* is similar to that for auditing non-SMS-managed data sets.

Note: If AUDIT is executing and backup of the DFSMSHsm control data sets is started (via BACKVOL CDS command or AUTOBACKUP), all DFSMSHsm functions on the host that started this backup are halted until the AUDIT function and the backup of the DFSMSHsm CDS's have completed.

Syntax of the enhanced AUDIT commands

When you issue the AUDIT command, you must specify one of the required parameters, to indicate a primary category of control information, which will “drive” that invocation of AUDIT. The optional parameters qualify what to audit, the output destination, and other qualifying information.

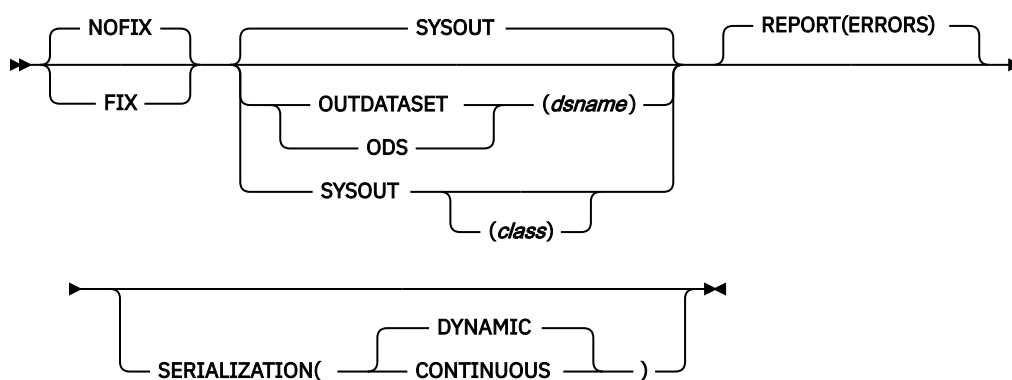

➤ AUDIT ➤

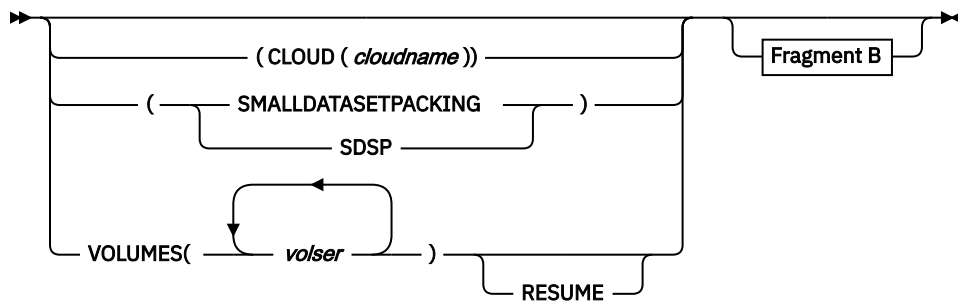

A: DATASETCONTROLS optional parameters

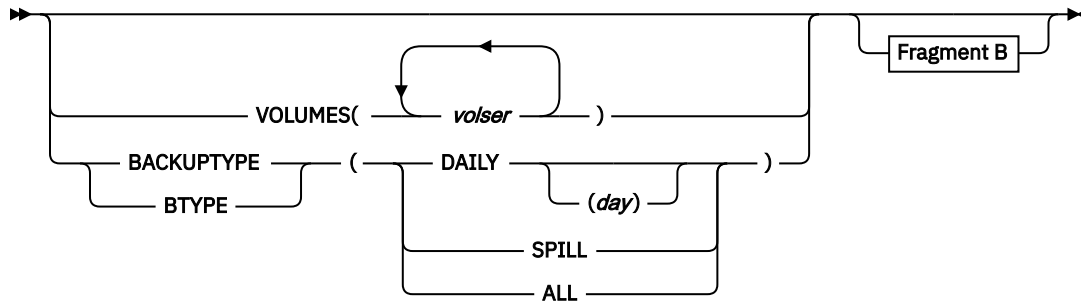

B: Additional optional parameters

C: MEDIACONTROLS parameters

D: VOLUMECONTROLS (BACKUP) optional parameters

E: VOLUMECONTROLS (MIGRATION and RECOVERABLE) optional parameters

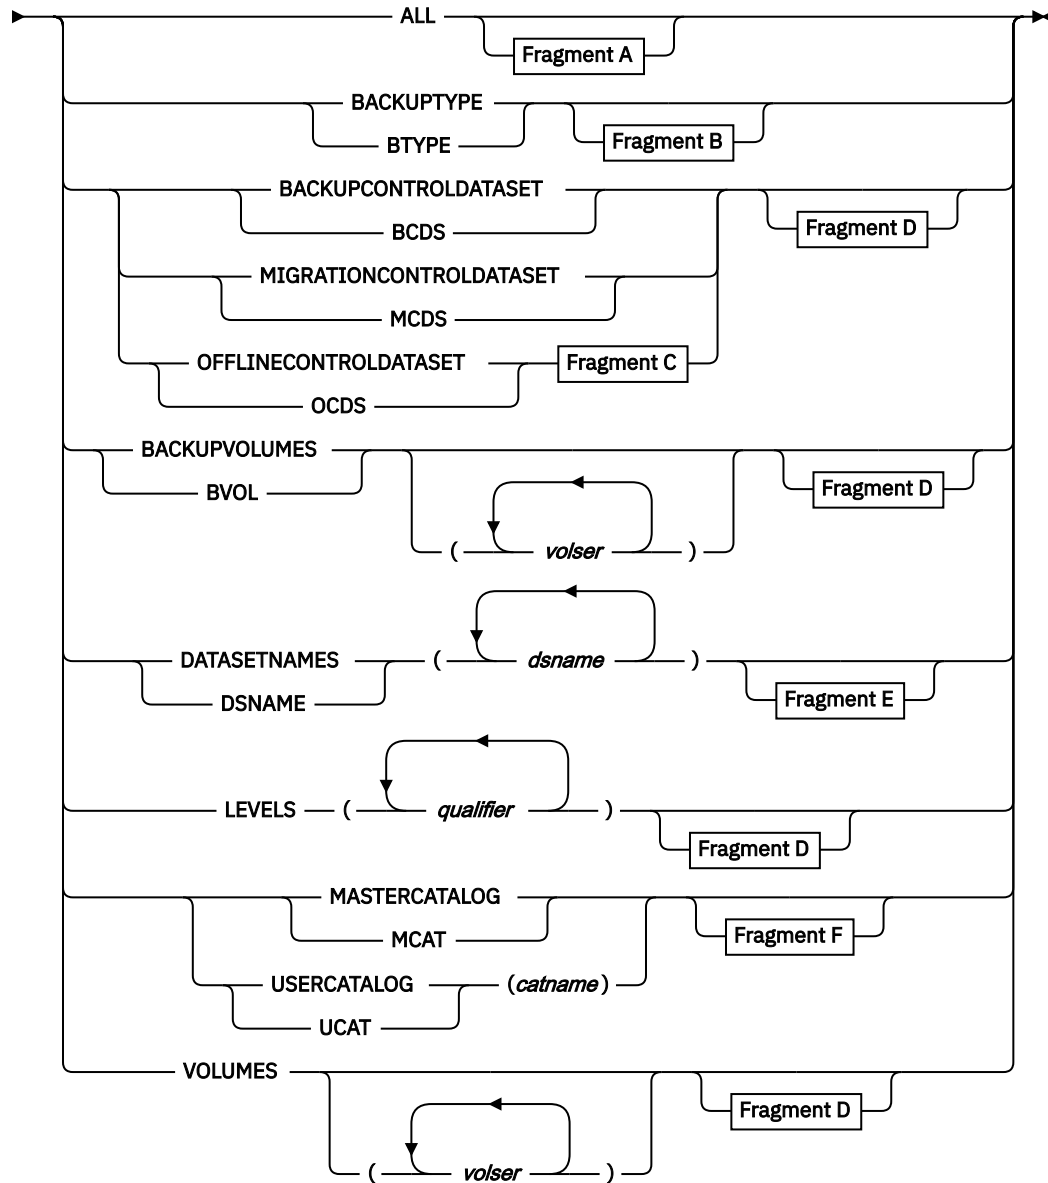

F: FILECONTROLS optional parameters

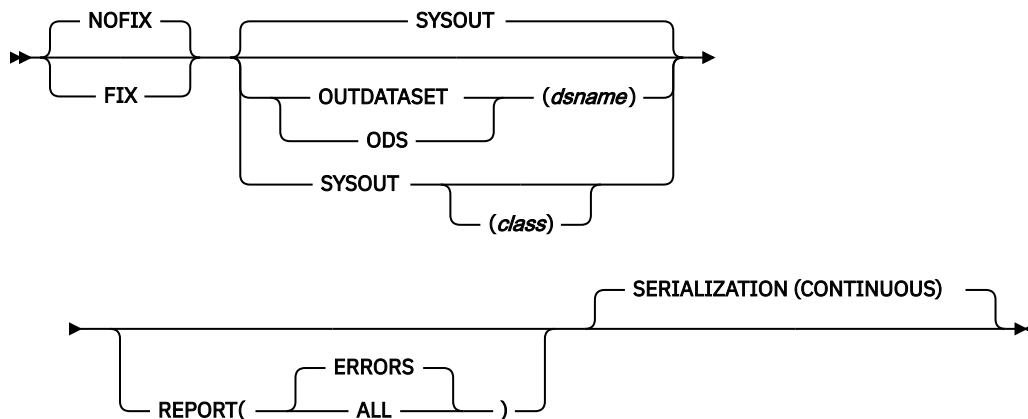

Syntax of the original AUDIT commands

The following options provide less comprehensive auditing, and somewhat less flexible output, than the previous options, but are available for compatibility with CLISTs or job streams developed for use with older versions of DFSMSHsm.

➡ AUDIT ➡

A: ALL optional parameters

B: BACKUPTYPE parameters

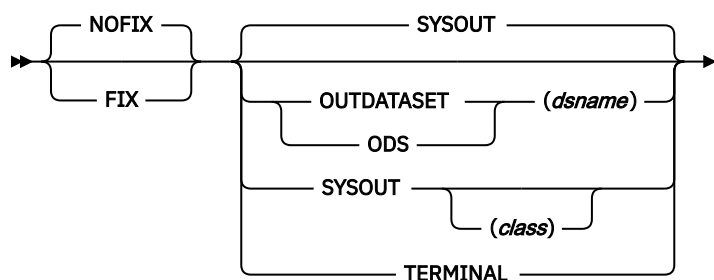

AUDIT command for DFSMSHsm

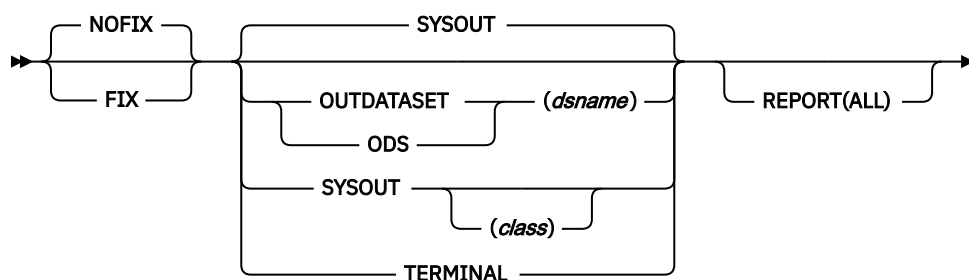

C: OFFLINECONTROLDATASET parameters

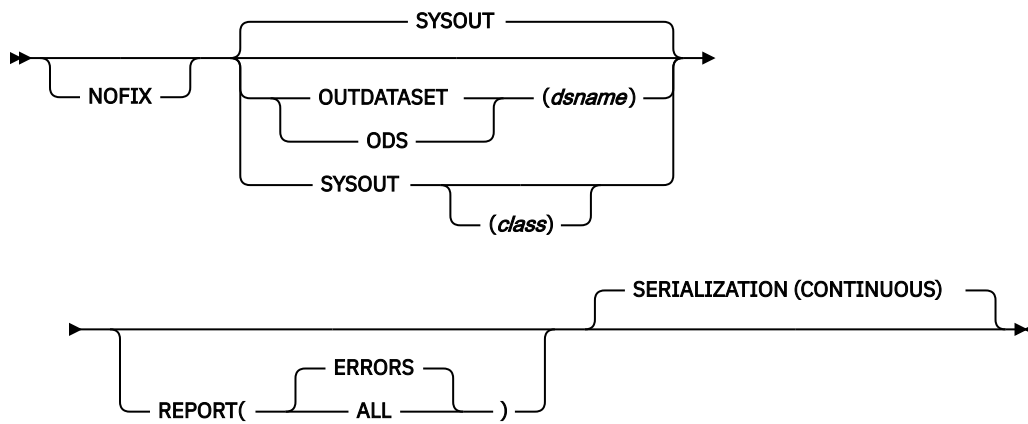

D: Additional optional parameters

E: DATASETNAMES optional parameters

F: MASTERCATALOG and USERCATALOG optional parameters

Required and optional parameters of the AUDIT command

This topic describes the required parameters of the AUDIT command. Some of the parameters listed in this topic are used as both required and optional parameters in the syntax diagrams. They are described in this topic and identified as such.

ABARSCONTROLS: Requesting an audit of ABR records in the BCDS

Explanation: **ABARSCONTROLS** is specified to audit the ABR records in the BCDS.

ABARSCONTROLS(*agname*) is an optional parameter that allows you to perform an audit of all ABR records matching the specified aggregate-group name.

IF AUDIT ABARSCONTROLS is issued and no ABR records are found, or if AUDIT ABARSCONTROLS(*agname*) is issued and no ABR records matching the *agname* specified are found, an error message is issued.

Defaults: None.

ALL, BACKUPCONTROLDATASET, MIGRATIONCONTROLDATASET, and OFFLINECONTROLDATASET: Requesting an audit of data sets

Explanation: **ALL**, **BACKUPCONTROLDATASET**, **MIGRATIONCONTROLDATASET**, and **OFFLINECONTROLDATASET** are mutually exclusive parameters that you use to audit sources of data set names, such as all control data sets or a specific control data set. Each of these represents a source of data set names.

ALL is specified to audit the migration control data set, the backup control data set, and the offline control data set. **ALL** is not used to audit the common queues.

BACKUPCONTROLDATASET is specified to audit the DFSMSHsm backup control data set.

MIGRATIONCONTROLDATASET is specified to audit the DFSMSHsm migration control data set.

OFFLINECONTROLDATASET is specified to audit the DFSMSHsm offline control data set. The TTOC records are the source of information to determine which data sets are audited. **DAILY** | **ML2** | **SPILL** | **ALL** are mutually exclusive, optional subparameters of the **OFFLINECONTROLDATASET** parameter used to specify which tape volumes to audit.

Subparameter	Explanation
DAILY	<p>OFFLINECONTROLDATASET(DAILY) is specified to audit tape daily backup volumes. For DAILY(day), substitute a decimal number from 1 to 31 to represent the day in the backup cycle. If you do not specify a particular day, the audit output occurs in the following order:</p> <ul style="list-style-type: none"> • All volumes assigned to day 1 • All volumes assigned to day 2 • And so forth, until all tape daily backup volumes have been audited <p>For each day, the order of the audit output is in ascending volume serial number sequence.</p>
ML2	<p>OFFLINECONTROLDATASET(ML2) is specified to audit all tape migration level 2 volumes. The order of audit output occurs in ascending volume serial number sequence for migration level 2 volumes.</p>
SPILL	<p>OFFLINECONTROLDATASET(SPILL) is specified to audit all tape spill backup volumes. The order of audit output occurs in ascending volume serial number sequence for spill volumes.</p>
ALL	<p>OFFLINECONTROLDATASET(ALL) is specified to audit all tape volumes. The audit output occurs in the following order:</p> <ul style="list-style-type: none"> • All daily backup volumes. The daily backup volumes are listed for each day, and the volumes assigned to each day are listed in ascending volume serial number sequence. • All spill backup volumes. The spill backup volumes are listed in ascending volume serial number sequence. • All unassigned backup volumes. The unassigned backup volumes are listed in ascending volume serial number sequence. • All migration level 2 volumes. The migration level 2 volumes are listed in ascending volume serial number sequence.

Note:

1. When you request an audit of the MCDS or BCDS, DFSMSHsm uses the VTOC of the primary volumes to ensure that the volume specified in the catalog contains the data set referred to. Therefore, those primary volumes (including those managed by SMS) must be mounted.
2. If you specify the OFFLINECONTROLDATASET parameter without a subparameter, the AUDIT command fails.
3. Dump volumes are not audited.

BACKUPTYPE, BACKUPVOLUMES, and VOLUMES: Requesting an audit of primary, migration, or backup volumes

The VOLUMES parameter can be used either as a primary option or as an optional parameter. Therefore, it is listed both ways in the syntax tables at the beginning of this topic.

Explanation: BACKUPTYPE, BACKUPVOLUMES, and VOLUMES are mutually exclusive parameters that you use to audit data set names; such as, one or more backup volumes, non-SMS-managed primary volumes, or migration volumes. Each of these represents a source of data set names.

BACKUPTYPE is specified to audit a type of backup volume. **DAILY | SPILL | ALL** are mutually exclusive, optional subparameters of the BACKUPTYPE parameter, specifying the type of backup volume DFSMSHsm is to audit.

Subparameter	Explanation
DAILY	<p>BACKUPTYPE(DAILY) is specified to audit daily backup volumes. For DAILY(day), substitute a decimal number from 1 to 31 to represent the day in the backup cycle. If <i>day</i> is specified, DFSMSHsm audits all backup volumes assigned to the specified day in the backup cycle. The order of the audit output is by entries in the daily backup cycle volume record (BVR) for the specified day. If you do not specify a particular day, the audit output occurs in the following order:</p> <ul style="list-style-type: none"> • All volumes assigned to day 1 • All volumes assigned to day 2 • And so forth, until all tape daily backup volumes have been audited <p>For each day, the order of the audit output is by entries in the backup cycle volume record (BVR).</p>
SPILL	<p>BACKUPTYPE(SPILL) is specified to audit all spill backup volumes. The order of the audit output is by entries in the spill backup cycle volume record (BVR).</p>
ALL	<p>BACKUPTYPE(ALL) is specified to audit all daily and spill backup volumes. The order of the audit output is all daily backup volumes and then all spill backup volumes.</p>

BACKUPVOLUMES and **BACKUPVOLUMES(volser...)** is specified to audit specific backup volumes or all backup volumes. For *(volser...)*, substitute the volume serial numbers of the backup volumes you want DFSMSHsm to audit. If you specify particular volumes, the order of the audit output is the same as the order of the volumes you specified. If you do not specify a particular volume, the order of the audit output occurs in ascending volume serial number order.

VOLUMES and **VOLUMES(volser...)** is specified to audit one or more non-SMS-managed volumes. For *(volser...)*, substitute a volume serial number or list of volume serial numbers for volumes that you want in the audit. SMS-managed volumes are not included in the audit. If a volume serial number for an SMS-managed volume is specified, DFSMSHsm does not audit that volume. **VOLUMES(volser...)** can be used with the **VOLUMECONTROLS** primary option and is required with the **DIRECTORYCONTROLS** and **MEDIACONTROLS** primary options.

Defaults: If you specify **VOLUMES** without *(volser...)*, DFSMSHsm audits all non-SMS-managed primary volumes, migration level 1 volumes, and all migration level 2 DASD volumes.

If you specify **BACKUPVOLUMES** without *(volser...)*, DFSMSHsm audits all backup volumes with a volume record in the BCDS.

There is no default for **BACKUPTYPE**. If you do not specify a subparameter with the **BACKUPTYPE** parameter, the **AUDIT** command fails.

Note: If the **VOLUMES** parameter specifies a migration level 1 volume, be aware of the following items:

- The **MEDIACONTROLS (SDSP)** primary option must be used to audit the control information in a small-data-set-packing data set.
- When you use the **BACKDS** command to back up a data set, the backup version temporarily resides on a migration level 1 volume. DFSMSHsm audits these data sets.

COMMONQUEUE: Requesting an audit of common queues

Explanation: **COMMONQUEUE** is a parameter you specify to audit all of the DFSMSHsm common queues. The data in a common queue can be corrupted by abends and unexpected losses of connectivity. A corrupted common queue may cause certain requests to not be processed. Specify **COMMONQUEUE** to enable DFSMSHsm to dynamically correct inconsistencies with minimal impact on processing.

Specify **COMMONQUEUE(RECALL)** to audit just the common recall queue.

If possible, issue AUDIT COMMONQUEUE(RECALL) when all the typical hosts are connected to the common queue.

Defaults: None.

COPYPOOLCONTROLS: Requesting an audit of fast replication CDS record relationships

Explanation: **COPYPOOLCONTROLS** is a parameter you specify to confirm that the fast replication CDS record relationships are correct for the copy pools that are managed by DFSMSHsm. The AUDIT function identifies any discrepancies that are discovered.

COPYPOOLCONTROLS

audits all copy pool records.

COPYPOOLCONTROLS(*cpname*)

audits the copy pool records for a specific copy pool.

Defaults: None.

DATASETCONTROLS: Requesting an audit of data set control records

Explanation: DATASETCONTROLS audits either the records in the MCDS or the records in the BCDS. It checks all (or specified) records for synchronization with other CDS records.

Subparameter	Explanation
MIGRATION	DATASETCONTROLS (MIGRATION) specifies that the data set records in the MCDS are cross-checked and a list of errors is produced.
BACKUP	DATASETCONTROLS (BACKUP) specifies that the data set records in the BCDS are cross-checked and a list of errors is produced.

Along with this parameter, other useful optional parameters are DATASETNAMES(*dsname...*), LEVELS(*qualifier...*), or RESUME.

Defaults

- When using the DATASETCONTROLS command, you must specify either MIGRATION or BACKUP. If you do not specify one or the other, you will get an error message.
- If you specify AUDIT DATASETCONTROLS(MIGRATION) without optional parameters, you will get an audit of all data set records in the MCDS.
- If you specify AUDIT DATASETCONTROLS(BACKUP) without optional parameters, you will get an audit of all data set records in the BCDS.

DATASETNAMES, LEVELS, and RESUME: Requesting an audit of data sets

The DATASETNAMES and LEVELS parameter can be used either as a primary option or as an optional parameter. Therefore, each is listed both ways in the syntax tables at the beginning of this topic.

Explanation: **DATASETNAMES(*dsname...*)** | **LEVELS(*qualifier...*)** | **RESUME** are mutually exclusive parameters to audit a data set, a list of data sets, a data set group, or a list of data set groups.

DATASETNAMES(*dsname...*) is specified to audit a data set or list of data sets. For (*dsname...*) substitute the fully qualified name or a list of fully qualified names for the data sets you want DFSMSHsm to audit. You can specify a data set name of up to 44 characters.

LEVELS(*qualifier...*) is specified to audit a group or list of groups of data sets with the same set of initial characters in the data set name. If you specify this parameter, DFSMSHsm audits all MCDS records for data sets that begin with the supplied qualifiers. If a qualifying data set found in the MCDS also has a BCDS entry, the BCDS entry will also be audited. For (*qualifier...*), substitute the set of initial characters in

the data set name or list of the set of initial characters for the data sets you want DFSMSHsm to audit. You can specify a qualifier of up to 44 characters.

RESUME applies only to the DATASETCONTROLS(MIGRATION) and DATASETCONTROLS(BACKUP) parameters of the AUDIT command. The RESUME function enables you to continue a previous audit of DATASETCONTROLS that for some reason has not been completed.

AUDIT processing does not run to completion when an operator enters a HOLD command. AUDIT processing might not complete if DFSMSHsm ends abnormally. If you entered the original command without the DATASETNAMES or LEVELS parameters, you can re-enter the command, using the RESUME parameter, and the audit will resume.

Note: The HOLD command informs DFSMSHsm to stop the audit as soon as AUDIT finishes processing the current data set. All AUDIT commands that have not been processed remain in the queue. The RELEASE command allows the execution of AUDIT commands that are in the queue, but will not cause an interrupted command to be restarted; thus you must issue another AUDIT command that includes the RESUME parameter.

Defaults: None.

Note:

1. When you specify the DATASETNAMES parameter, DFSMSHsm prints all audit information for each audited data set, whether or not errors are found for that data set.
2. When you specify the LEVELS parameter, DFSMSHsm prints MCDS and BCDS entries for each group.
3. DFSMSHsm does not handle partitioned data set members individually. If you specify a partitioned data set with a member name, DFSMSHsm audits the entire partitioned data set.

DIRECTORYCONTROLS VOLUMES: Comparing a VTOC or a TTOC to CDS records

Explanation: **DIRECTORYCONTROLS VOLUMES(volser...)** is specified to compare information in the DASD VTOC or the TTOC with that of the control records in the MCDS or BCDS.

VOLUMES(volser...) is a required parameter. For (volser...), substitute a volume serial number or a list of volume serial numbers. Each serial number must identify a DFSMSHsm-owned tape backup or migration volume or a DFSMSHsm-owned DASD migration volume.

Defaults: None.

FILECONTROLS: Requesting an audit of UNIX file control records

FILECONTROLS audits the records in the BCDS. It checks all (or specified) records for synchronization with other CDS records.

Subparameter	Explanation
BACKUP	FILECONTROLS (BACKUP) specifies that the UNIX file records in the BCDS are cross-checked and a list of errors is produced.

Along with this parameter, other useful optional parameters are FILE(filepath...), FILELEVELS(partofpath...), or RESUME.

Defaults

- When using the FILECONTROLS command, you must specify BACKUP. If it is not specified, you will get an error message.
- If you specify AUDIT FILECONTROLS(BACKUP) without optional parameters, you will get an audit of all UNIX file records in the BCDS.

FILE, FILELEVEL, and RESUME: Requesting an audit of UNIX files

The FILE and FILELEVEL parameter can be used either as a primary option or as an optional parameter. Therefore, each is listed both ways in the syntax tables at the beginning of this topic

FILE(filepath...) | **FILELEVEL(partofpath...)** | **RESUME** are mutually exclusive parameters to audit a UNIX file.

FILE(filepath...) is specified to audit a UNIX file. For (filepath...) substitute a single absolute UNIX file path name that you want DFSMSHsm to audit. The UNIX file path name must be enclosed in single quotation marks.

FILELEVEL(partofpath...) is specified to audit a group of files that begin with the specified partofpath partial path. Only a single absolute UNIX path to a directory may be specified. partofpath name must be enclosed in single quotation marks.

RESUME applies only to the FILECONTROLS(BACKUP) parameter of the AUDIT command. The RESUME function enables you to continue a previous audit of FILECONTROLS that for some reason has not been completed. AUDIT processing does not run to completion when an operator enters a HOLD command.

AUDIT processing might not complete if DFSMSHsm ends abnormally. If you entered the original command without the FILE or FILELEVEL parameters, you can reenter the command, using the RESUME parameter, and the audit will resume.

Defaults: None.

Note:

1. When you specify the FILE parameter, DFSMSHsm prints all audit information for each UNIX file, regardless if errors are found for that UNIX file.
2. When you specify the FILELEVEL parameter, DFSMSHsm prints BCDS entries for each directory.

MASTERCATALOG and USERCATALOG: Requesting an audit of a catalog

Explanation: **MASTERCATALOG** and **USERCATALOG** are mutually exclusive parameters that you use to audit data set entries in a catalog, which is a source of data set names.

MASTERCATALOG is specified to audit the master catalog.

USERCATALOG(catname) is specified to audit a particular user catalog. For (catname), substitute the name of the user catalog you want DFSMSHsm to audit.

Defaults: None.

Note: You cannot specify the TERMINAL parameter with the MASTERCATALOG or USERCATALOG parameters.

MEDIACONTROLS VOLUMES, MEDIACONTROLS(SDSP) VOLUMES and MEDIACONTROLS(CLOUD): Requesting an audit of control information

Explanation: **MEDIACONTROLS VOLUMES** and **MEDIACONTROLS(SDSP) VOLUMES(volser...)** are mutually exclusive parameters that are specified to audit control records as follows:

MEDIACONTROLS audits control information contained in migration copies and backup versions.

MEDIACONTROLS(SMALLDATASETPACKING) audits only the SDSP (small data set packing) data sets on the specified volumes.

In either case, **VOLUMES(volser...)** is a required parameter. For (volser...) substitute a volume serial number or a list of volume serial numbers. Each serial number must identify a DFSMSHsm-owned, single-file format, tape backup or migration volume or a DASD migration volume.

MEDIACONTROLS(CLOUD(cloud_network_connection_name)) audits control information in migration copies and full volume dump copies in the cloud. The cloud_network_connection_name refers to a defined cloud_network_connection_name. MEDIACONTROLS(CLOUD(cloud_network_connection_name))

examines containers created using the current HSMplex name. The CLOUD parameter is mutually exclusive with the VOLUMES and SMALLDATASETPACKING parameters. The RESUME parameter does not apply.

Defaults: None.

Note:

1. If DFSMSHsm is unable to complete output processing to backup or migration tapes, an incomplete TTOC is created. When an audit is performed against these tapes, the AUDIT function positions to the last data set described by that portion of the TTOC that was written successfully and then proceeds to audit the tape from that point forward.

RESUME can be specified on the AUDIT MEDCTL VOLUMES(tape volser) FIX Command in order to resume a previously interrupted audit in the case where the AUDIT was held, DFSMSHsm was stopped, or SETSYS EMERGENCY was specified.

RESUME is only valid for migration and backup tapes. It is not valid when specified with SDSP or when the volser specified is for a DISK volume.

RESUME is only valid when FIX is also specified. If the initial AUDIT is issued without specifying FIX and the AUDIT is held, and then the generated FIXCDS commands are manually issued, the results of AUDIT MEDCTL with RESUME are unpredictable. Manually entering patches generated by NOFIX is discouraged by IBM.

AUDIT will not be able to RESUME after abends or experiencing an I/O error or a point or note failure. If you CANCEL the AUDIT TASK using the CANCEL TCADDRESS Command, be sure to first HOLD AUDIT in order for RESUME to execute.

If RESUME is validly specified, but the required information and records are not available, AUDIT will start at the beginning of the tape.

If RESUME is specified on the command, message ARC0877I will be issued stating the volser and extension on which AUDIT is starting.

Note: When audit is held or stopped, the function terminates. After audit terminates and before the AUDIT MEDCTL RESUME command is issued, the volume is available for all functions. Following are some situations that will affect the resumed audit:

- If the volume is RECYCLED and then DELVOLED, the TTOC is deleted and the audit cannot be resumed.
- If RECALLS or RECONNECTIONS occur for data sets already audited, the valid block count will not reflect this when the resumed audit completes.
- If additional entries are added to the volume by migration or backup, the audit will resume at the interrupt point and continue on through the new entries as usual.
- However, if the additional entries result in a FAILEDCREATE situation where the TTOC is not consistent with the contents of the tape media and TTCFAIST is ON, the RESUME parameter will be ignored and audit will add the missing TTOC entries. On completion of this audit, the AUDIT MEDCTL RESUME command can be issued again and audit will then resume with the last data set being processed when audit was held.

VOLUMECONTROLS (BACKUP, MIGRATION, and RECOVERABLE): Requesting an audit of control information

Explanation: **VOLUMECONTROLS (BACKUP, MIGRATION, and RECOVERABLE)** are mutually exclusive parameters that are specified to audit control records as follows:

Subparameter	Explanation
BACKUP	BCDS control records for backup volumes are audited.
MIGRATION	MCDS control records for migration volumes are audited.

Subparameter	Explanation
RECOVERABLE	BCDS control records that concern recoverable volumes (volumes which have been backed up, dumped, or both) are audited.

Note: The optional parameter VOLUMES(*volser...*) can be used to specify a volume serial number or a list of volume serial numbers for any of the VOLUMECONTROLS options listed above.

Defaults: None.

Optional parameters of the AUDIT command

This topic describes the optional parameters of the AUDIT command.

FIX and NOFIX: Specifying whether auditing repairs errors

Explanation

FIX and NOFIX are mutually exclusive, optional parameters specifying whether auditing repairs any error it can when an error is found.

FIX

Auditing repairs any error it can.

NOFIX

Auditing reports errors, but does not fix them. For COMMONQUEUE, the number of errors only is reported.

Tip: The output data set contains executable FIXCDS commands to create or correct CDS records, but those CDS changes are only a subset of the corrective actions taken by audit processing. In addition, the CDS records can be read multiple times during the course of an audit. If the NOFIX option is specified, the changes to a record generated on its initial read are not reflected in that record when it is read a subsequent time, this might result in incorrect action being taken. For these reasons, you should not later submit output from an AUDIT NOFIX command as a substitute for an AUDIT FIX command.

Defaults

The default is NOFIX.

Usage notes:

1. The number of errors reported by AUDIT COMMONQUEUE FIX may be lower than the number of errors reported by a previous AUDIT COMMONQUEUE NOFIX. This is acceptable since the errors in the common queues are interrelated. Hence, fixing one error may actually fix several other errors.
2. If you specify the FIX parameter and the parameter applies, DFSMSHsm issues a message indicating whether the fix was successful or unsuccessful.
3. The FIX parameter can degrade performance. When you specify it with the MASTERCATALOG or USERCATALOG parameter, DFSMSHsm does not fix the audited information. If you specified the FIX parameter with the MASTERCATALOG or USERCATALOG parameter, DFSMSHsm allows the operator to cancel an audit by replying N to the following message:

```
ARC0803A  WARNING:  AUDIT OF CATALOG MAY DEGRADE PERFORMANCE,
           REPLY 'Y' TO START AUDIT OR 'N' TO CANCEL
           AUDIT COMMAND
```

4. You must use the FIXCDS command to correct any discrepancies between the catalog and the MCDS.
5. If you specify the FIX parameter when you audit a primary or migration volume, DFSMSHsm scratches and uncatalogs all utility data sets on the volume even if the utility data sets have expiration dates.

6. If you use the CDSR=YES startup parameter, DFSMSHsm issues the RESERVE macro to keep the other z/OS images from accessing the three volumes containing the MCDS, BCDS, and OCDS under the following conditions:
 - You are in a multiple-image environment.
 - You have specified the FIX command.
 - You have specified SERIALIZATION(CONTINUOUS).
 - When the primary audit category is one of the following:
 - ALL | BACKUPCONTROLDATASET | MIGRATIONCONTROLDATASET | OFFLINECONTROLDATASET(DAILY(*day*) | ML2 | SPILL | ALL)
 - MASTERCATALOG | USERCATALOG(*catname*)
 - BACKUPTYPE(DAILY(*day*) | SPILL | ALL) | BACKUPVOLUMES | BACKUPVOLUMES(*volser...*) | VOLUMES | VOLUMES(*volser...*)
 - DATASETNAMES(*dsname...*) | LEVELS(*qualifier...*)
7. The reserve applies to the three volumes that contain the control data sets; therefore, no other data sets on those volumes can be accessed from another z/OS image.
8. If you specify the FIX parameter when you audit a volume, DFSMSHsm catalogs the uncataloged data sets (excluding rolled-off GDG data sets) on the volume. Consequently, AUDIT should not be run concurrently with other jobs that are creating uncataloged data sets.

OUTDATASET, SYSOUT, and TERMINAL: Specifying the output location for the report

Explanation: **OUTDATASET(dsname)**, **SYSOUT**, and **TERMINAL** are mutually exclusive, optional parameters that specify the output location for the report you are requesting.

OUTDATASET(dsname) specifies the name of the data set where DFSMSHsm is to write the output data. For (*dsname*), substitute the fully qualified name of the data set to receive the audit report. These parameters are not applicable with AUDIT COMMONQUEUE.

If the data set does not exist, DFSMSHsm dynamically allocates and catalogs an output data set with the following characteristics:

- Data set name specified (*dsname*)
- Record format of fixed-blocked with ANSI control characters (FBA)
- Logical record length of 121
- Data set is system reblockable
- Primary allocation of 20 tracks (see second note)
- Secondary allocation of 50 tracks (see second note)
- Unit of SYSALLDA (see second note)

If the data set already exists, DFSMSHsm will use the data set. The data set must have the following characteristics:

- The data set must be cataloged and on DASD.
- The data set record format must be FBA, and the logical record length must be 121.
- The data set is system reblockable.
- The user can choose the primary space allocation.
- If the data set does not contain data, DFSMSHsm starts writing output data at the beginning of the data set.
- If the data set contains data, DFSMSHsm writes the output data after the existing data.

SYSOUT(class) specifies that the report is to go to the specified output class. For (*class*), substitute one alphanumeric character for the class you want.

TERMINAL specifies that the report is to be printed at the same terminal where the command was issued, and is to be printed to SYSOUT using only the output class specified with the SYSOUT parameter of the SETSYS command or the DFSMSHsm default for SYSOUT.

Defaults: The default is SYSOUT, and the default for (*class*) is the value specified with the SETSYS command. If you do not use the SYSOUT parameter of the SETSYS command to specify the output location, the default is class A.

Note:

1. DFSMSHsm does not handle partitioned data set members individually. If you specify a partitioned data set with a member name as the output data set, the audit report could be written over existing data.
2. If you select the OUTDATASET option, you can use the PATCH command to change the unit name, primary allocation, and secondary allocation. If you select the SYSOUT option, you can use the PATCH command to change whether, and how, DFSMSHsm limits the lines of SYSOUT output. Refer to the [z/OS DFSMSHsm Implementation and Customization Guide](#) for the PATCH command.

REPORT: Specifying how much audit information to print

Explanation: **REPORT** is an optional parameter specifying how much audit information you want printed. These parameters are not applicable with AUDIT COMMONQUEUE nor AUDIT COPYPOOLCONTROLS.

Subparameter	Explanation
ALL	REPORT(ALL) specifies that all audit information, including the error-condition information for the specified data sets, volumes, levels, catalogs, or control data sets is printed.
ERRORS	REPORT(ERRORS) specifies that only the error-condition information for the specified volumes, catalogs, or control data sets is printed.

Defaults: The default is ERRORS, except when using the DATASETNAMES parameter. For DATASETNAMES, the ALL parameter always applies.

Note: The ERRORS subparameter of REPORT does not apply for DATASETNAMES. If you specify ERRORS when it does not apply, DFSMSHsm ignores it and uses the ALL parameter.

SERIALIZATION: Stabilizing control information

Explanation: **SERIALIZATION** is an optional parameter stabilizing the control information. DFSMSHsm control information changes dynamically as DFSMSHsm operates. For AUDIT to detect an out-of-synchronization condition, diagnose the problem, and apply a repair, AUDIT must stabilize (serialize) access to control data sets and records to maintain a stable environment. These parameters are not applicable with AUDIT COMMONQUEUE.

Subparameter	Explanation
DYNAMIC	SERIALIZATION(DYNAMIC) specifies that an enqueue is placed on the CDSs only when the audit function finds a discrepancy in a record relationship. This enqueue is released periodically to allow other functions access to the CDSs. SERIALIZATION(DYNAMIC) is the option of choice; however, if you need to complete an audit function in the shortest time possible, SERIALIZATION(CONTINUOUS) is the better performer.
CONTINUOUS	SERIALIZATION(CONTINUOUS) specifies that an enqueue is placed on the CDSs for the entire audit. Use SERIALIZATION(CONTINUOUS) when it is important for the DFSMSHsm AUDIT command to complete in the shortest period of time, such as just after a CDS RESTORE. Be careful if you select the SERIALIZATION(CONTINUOUS) option, as no other DFSMSHsm functions can process until the audit function is complete.

Note: Continuous is functional only when DFSMSHsm is processing in a multihost environment and the FIX parameter is specified on the AUDIT command.

Defaults: The default for the Enhanced Audit commands is SERIALIZATION(DYNAMIC) and the default for the Original Audit commands is SERIALIZATION(CONTINUOUS).

Using the AUDIT command

For more discussion of the AUDIT function, see [Chapter 75, “Using the AUDIT command,” on page 1255](#).

Chapter 31. AUTH command: Identifying authorized users

There are two methods used to authorize user commands. DFSMSHsm allows an installation to control the authorization of its commands through the use of either RACF FACILITY class profiles or the AUTH command.

If the RACF FACILITY class is active when DFSMSHsm starts, the following processing occurs:

- DFSMSHsm uses RACF FACILITY class checking for all authorized and user commands
- DFSMSHsm honors profiles in the FACILITY class that are added or modified

See "Authorizing and Protecting DFSMSHsm Commands in a FACILITY Class Environment" in the [z/OS DFSMSHsm Implementation and Customization Guide](#) for information on setting up the RACF environment.

If the RACF FACILITY class is not active when DFSMSHsm starts, DFSMSHsm uses the AUTH command to determine authorized DFSMSHsm users and commands.

The AUTH command identifies both the authorized user who can only issue authorized DFSMSHsm commands and the authorized user who cannot only issue authorized DFSMSHsm commands but can also add, delete, and change the authority of other DFSMSHsm users. When DFSMSHsm is installed, the storage administrator with responsibility for DFSMSHsm should be identified as the authorized user who can affect the authority of other DFSMSHsm users.

The AUTH command can be submitted only by users who are already authorized users having the database authority control attribute, or the command must be part of the PARMLIB member being processed during DFSMSHsm startup.

You need not repeat the AUTH command each time you start DFSMSHsm. If you do not specify any parameters with the AUTH command, DFSMSHsm accepts the command but does not add or remove any names from the list of authorized users.

Note:

1. Use the AUTH command carefully because anyone who is an authorized user can issue DFSMSHsm user commands without having RACF check the security of the command issuer.
2. The AUTH command cannot be issued from the system console.
3. If you issue the AUTH command when the RACF FACILITY class is active, it completes with a return code of four. The authorized user record (MCU) is still created or updated, but access to the DFSMSHsm storage administrator commands is still controlled by the RACF FACILITY class. Maintaining accurate MCU records is helpful when the RACF FACILITY class is not active or when using StorWatch DFSMSHsm Monitor.

Syntax of the AUTH command

Required parameters of the AUTH command

This topic describes the required parameters of the AUTH command.

userid: Specifying the user whose authorization is to be changed

Explanation: *userid* is a required positional parameter that specifies the identification of the user whose authority to issue any authorized command is to be changed. Authorized user commands are the storage administrator, operator, and system programmer commands.

For *userid*, substitute a string of 1-8 alphanumeric characters for the identification of the user whose authorization is to be changed. The first character of the character string must be alphabetic or #, \$, or @, and the remainder of the string can be alphanumeric and #, \$, or @.

Defaults: None.

Note:

1. Because *userid* is a required positional parameter, you must specify it immediately after the command name.
2. The first authorized user, CONTROL, or USER (preferably CONTROL), must be authorized by the PARMLIB member.

DATABASEAUTHORITY and REVOKE: Giving authority to or revoking authority of a user

Explanation: **DATABASEAUTHORITY** and **REVOKE** are mutually exclusive, required parameters giving or revoking DFSMSHsm authorization of the specified user.

DATABASEAUTHORITY specifies the level of authorization of the specified user.

Subparameter	Explanation
USER	DATABASEAUTHORITY(USER) is an optional parameter that gives authorization to the specified user. The user specified with <i>userid</i> is authorized to use any DFSMSHsm command except the AUTH command.
CONTROL	<p>DATABASEAUTHORITY(CONTROL) is an optional parameter that gives a higher-level of authorization to the specified user. The user specified with <i>userid</i> is authorized to use the AUTH command to add, delete, or change the DFSMSHsm authorization of other users.</p> <p>Note: The CONTROL subparameter should be limited to as few user IDs as possible.</p>

REVOKE specifies that the *userid* identified is no longer authorized to issue all DFSMSHsm commands. The user can still issue DFSMSHsm user commands.

See [Figure 93 on page 757](#) for an illustration of DFSMSHsm authorization.

The DFSMSHsm user commands are described in [z/OS DFSMSHsm Managing Your Own Data](#).

Defaults: If the DATABASEAUTHORITY parameter is specified without a subparameter, the default is USER.

Figure 93. Identifying Authorized DFSMSHsm Users

Examples of how to code the AUTH command

The following examples present different ways to code the AUTH command:

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Authorizing a user to issue all DFSMSHsm commands

The following command allows user ID JXX3154 to add, delete, or change the DFSMSHsm authorization of other users.

```
AUTH JXX3154 DATABASEAUTHORITY(CONTROL)
```

Authorizing a user to issue DFSMSHsm commands

The following command allows user ID XXX3151 to issue all authorized user commands except the AUTH command. This command can be issued by user ID JXX3154 or placed in the PARMLIB member.

```
AUTH XXX3151 DATABASEAUTHORITY
```

Revoking authority of a user

The following command cancels the authority to issue authorized DFSMSHsm commands for user ID XXX3152. This command can be issued by JXX3154 or placed in the PARMLIB member.

```
AUTH XXX3152 REVOKE
```

Chapter 32. BACKDS command: Backing up a specific data set

The BACKDS command creates a backup version of a specific data set or UNIX file. When you enter the BACKDS command, DFSMSHsm does not check whether the data set has changed or has met the requirement for frequency of backup. When you enter the BACKDS command for a UNIX file, DFSMSHsm will check whether the file has changed since its last backup. When DFSMSHsm processes a BACKDS command, it stores the backup version on either tape or the ML1 volume with the most available space.

Note: If the size of a data set or UNIX file that is targeted to DASD exceeds the free space on the ML1 volume having the most free space, then the data set backup fails. If there is no overflow ML1 volume available or the data set or UNIX file does not qualify for placement on an overflow ML1 volume, then the data set or UNIX file backup fails.

You can issue a BACKDS command for the following:

- An SMS-managed data set (if allowed by its management class).
- A data set that resides on a level 0 volume.
- A migrated data set currently residing on a migration level 1 volume.
- An uncataloged data set (DFSMSHsm is used as the datamover).
- A user data set that resides on a migration level 1 or a DASD migration level 2 volume. We do not recommend that users directly allocate data sets on migration volumes.
- A UNIX file.
- UNIX files within a directory, or directory sub-tree.

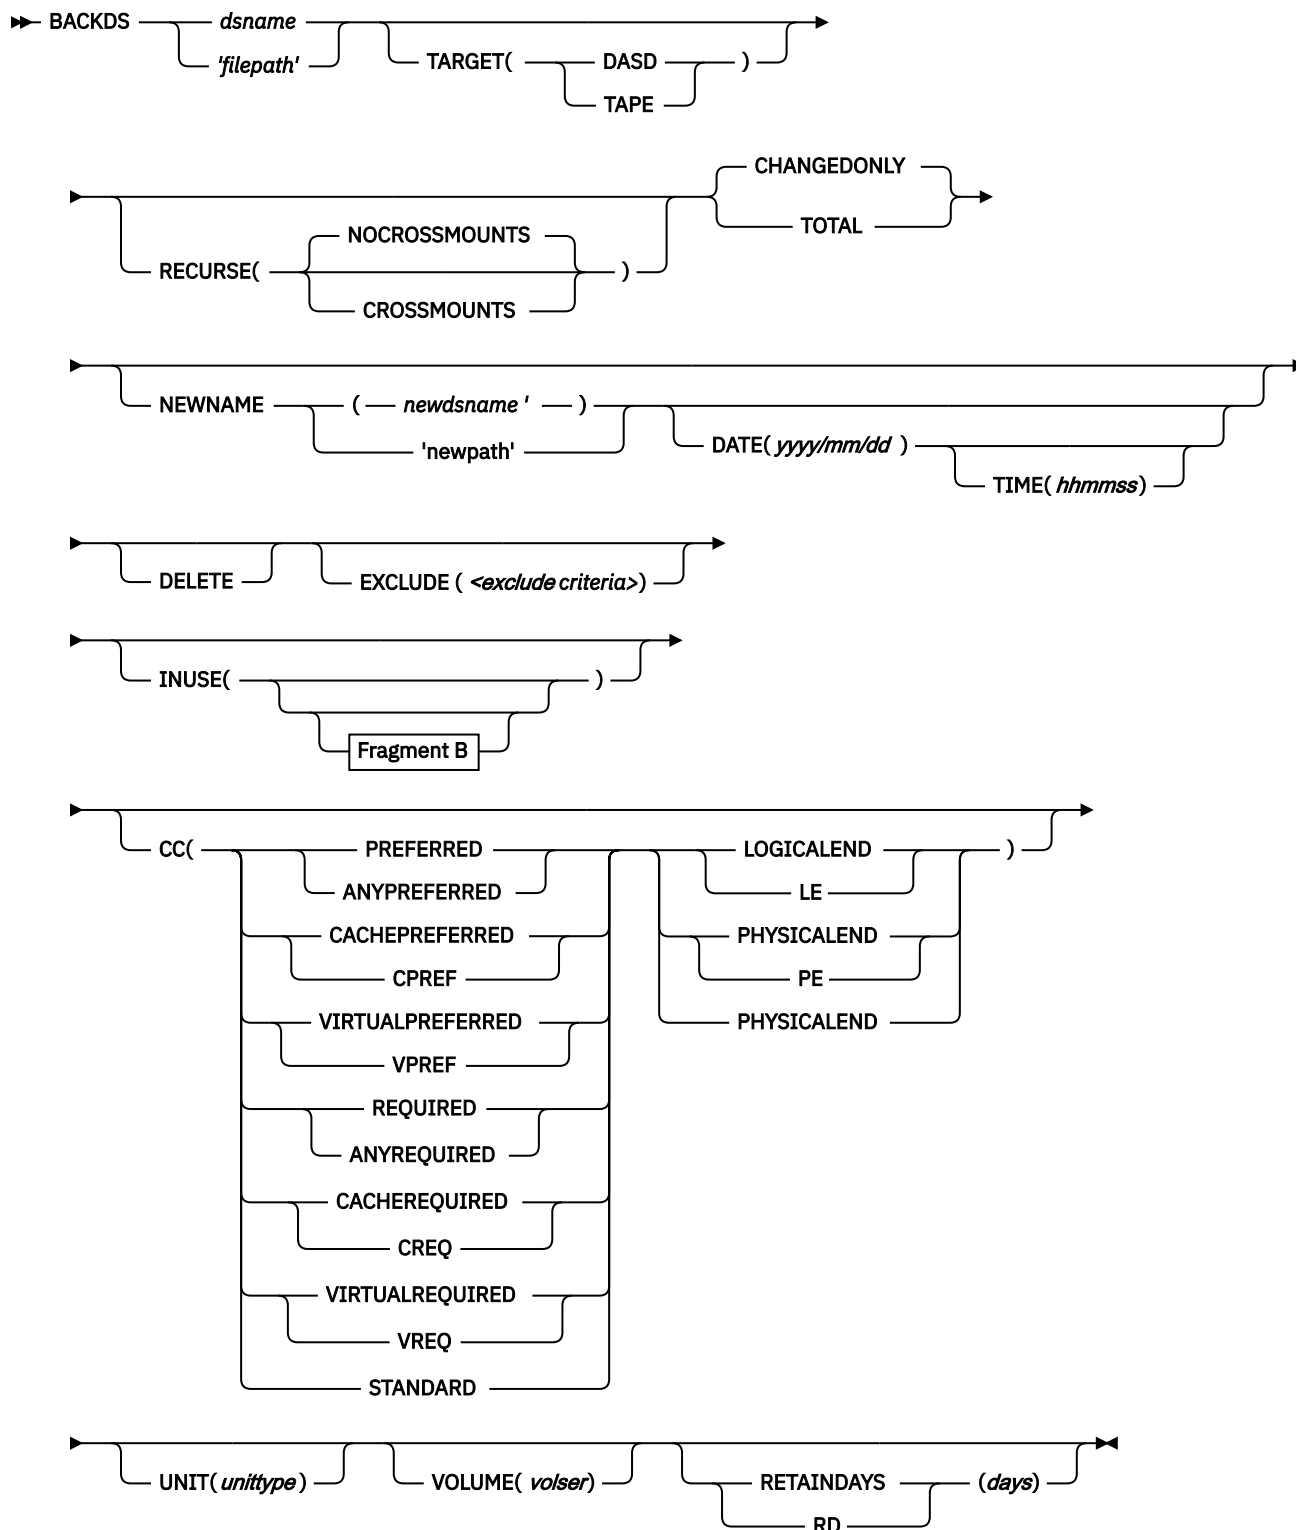

Regardless of the status or location of the data set, the volume containing the data set must be mounted and online, or the command fails.

When you want to back up an uncataloged data set, you must specify the volume serial number of the volume that contains the data set. In addition, you must specify the type of unit of the volume specified.

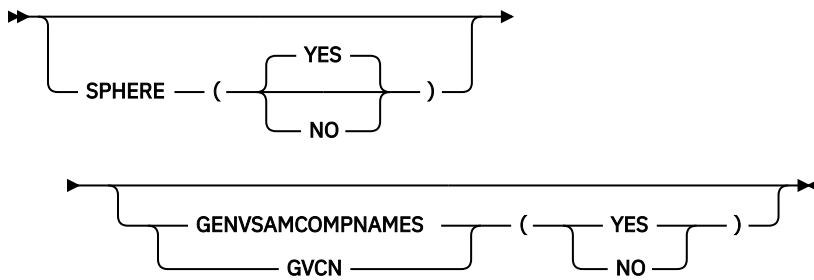

Note: If you specify a data set currently migrated to a migration level 2 volume, DFSMSHsm does not back up the data set.

Note: Any files that reside in an encrypted zFS will be decrypted as they are written to the backup.

Syntax of the BACKDS command for a UNIX file

A: NEWNAME optional parameters

B: INUSE optional parameters

Note: The UNIT and VOLUME parameters do not apply to cataloged data sets.

Required parameters of the BACKDS command

This topic describes the required parameters of the BACKDS command.

The *dsname* and *filepath* parameters are mutually exclusive, required parameters that identify the data set or UNIX file to be backed up.

***dsname*: Specifying the name of the data set to be backed up**

Explanation: *dsname* is a required positional parameter that specifies the fully qualified name of the data set you want DFSMSHsm to back up. For *dsname*, substitute the fully qualified name of the data set.

Defaults: None.

Note:

1. Because *dsname* is a required positional parameter, you must specify it immediately after the command name. You cannot specify an alias for *dsname*. If you do, DFSMSHsm does not back up the data set.
2. The volume where the data set resides must be mounted before you issue the BACKDS command.
3. DFSMSHsm does not handle partitioned data set members individually. A member name of a partitioned data set, DFSMSHsm backs up the entire partitioned data set.

***filepath*: Specifying the name of the UNIX file to be backed up**

Explanation: *filepath* The specified name must be enclosed in single quotation marks and is considered to be made up of two parts: an absolute directory path that ends in a forward slash, followed by a *pattern* (for example, /directory/path/*pattern*):

Defaults: None.

- The directory path must begin with a forward slash and indicates a directory where DFSMSHsm should begin its search for a file or empty directory to back up.
- The pattern can contain any valid file name characters, and may contain wildcard characters question mark (?) and asterisk (*). If the name of the file should contain the specific ?, *, or \ characters, the backslash character (\) must be used to escape that character, indicating it is not a wildcard. (for example, \?, *, or \\)

- If the pattern doesn't contain any wildcard characters, this is treated as an absolute path to a file – (/u/dir1/file1.txt) That single file will be backed up.
- If the pattern doesn't contain any characters at all, or is only a single asterisk, this is treated as an absolute path to a directory - (for example, /u/dir1/ or /u/dir1/*) All files and empty directories found within the directory will be backed up.
- Wildcard in the pattern - An asterisk (*) can be used to match any number of characters within a file name. An asterisk may be used at any position in the pattern. A second asterisk may also be used at the end of the pattern to indicate any number of characters following the pattern is acceptable. A question mark (?) can be used to represent any single character in the file name. Multiple question mark characters are allowed.

Note: Because the filename is a required positional parameter, you must specify it immediately after the command name.

Optional parameters for the BACKDS command

This topic describes the optional parameters for the BACKDS command.

CC: Specifying concurrent copy for data set backup

CC is an optional parameter that specifies concurrent copy during BACKDS processing of data sets, or UNIX File Snapshot during BACKDS processing of UNIX files to provide a point-in-time backup copy. The parameters of the CC parameter are explained:

STANDARD

Specifies that you want to use standard backup methods without using concurrent copy or UNIX File Snapshot .

PREFERRED

ANYPREFERRED

Specifies the data is to be processed with concurrent copy if possible. Virtual concurrent copy is attempted first, if the storage subsystem on which the data resides is capable of virtual concurrent copy and working-space data sets have been defined. Otherwise, cache-based concurrent copy is attempted if the storage subsystem is capable of it. If both types of concurrent copy are not possible or fail, the data is processed by using standard I/O as if CONCURRENT were not specified.

When processing a UNIX file, DFSMSHsm will attempt to create a file snapshot of the file and take the backup from the clone after releasing serialization on the original. If the file snapshot cannot be successfully created, serialization will be obtained on the file and will be processed as if STANDARD was requested.

CACHEPREFERRED

CPREF

Specifies that data is to be processed with cache-based concurrent copy. Otherwise, the data is processed using standard I/O as if CONCURRENT were not specified. Virtual concurrent copy is not attempted.

When processing a UNIX file, DFSMSHsm will attempt to create a file snapshot of the file and take the backup from the clone after releasing serialization on the original. If the file snapshot cannot be successfully created, serialization will be obtained on the file and will be processed as if STANDARD was requested.

VIRTUALPREFERRED

VPREF

Specifies that data is to be processed with virtual concurrent copy if possible. Otherwise, the data is processed using standard I/O as if CONCURRENT were not specified. Cache-based concurrent copy is not attempted.

When processing a UNIX file, DFSMSHsm will attempt to create a file snapshot of the file and take the backup from the file snapshot after releasing serialization on the original. If the file snapshot cannot be successfully created, serialization will be obtained on the file and will be processed as if STANDARD was requested.

REQUIRED**ANYREQUIRED**

Specifies the data is to be processed with concurrent copy if possible. Virtual concurrent copy is attempted first, if the storage subsystem on which the data resides is capable of it and working-space data sets have been defined. Otherwise, cache-based concurrent copy is attempted if the storage subsystem is capable of it. If both types of concurrent copy are not possible or fail, the data will not be processed.

When processing a UNIX file, DFSMSHsm will attempt to create a file snapshot of the file. If the file snapshot cannot be successfully created, the backup will fail.

Note: Some files such as hard links cannot be processed with Clone. If backing up a directory or many files, the overall request will fail if one of these types is encountered and is unable to be processed.

CACHEREQUIRED**CREQ**

Specifies that data is to be processed with cache-based concurrent copy if possible. If a cache-based concurrent copy session cannot be established, the data set will not be backed up. Virtual concurrent copy and standard I/O are not attempted.

DFSMSHsm will attempt to create a file snapshot of the file. If the file snapshot cannot be successfully created, the backup will fail.

Note: Some files such as hard links cannot be processed with Clone. If backing up a directory or many files, the overall request will fail if one of these types is encountered and is unable to be processed.

VIRTUALREQUIRED**VREQ**

Specifies that data is to be processed with virtual concurrent copy if possible. If a virtual concurrent copy session cannot be established, the data set will not be backed up. Cache-based concurrent copy and standard I/O are not attempted.

DFSMSHsm will attempt to create a file snapshot of the file. If the file snapshot cannot be successfully created, the backup will fail.

Note: Some files such as hardlinks cannot be processed with Clone. If backing up a directory or many files, the overall request will fail if one of these types is encountered and is unable to be processed.

PHYSICALEND**PE**

Specifies that control returns to the application or user only after the backup physically completes.

LOGICALEND**LE**

Specifies that control returns to the application or user when concurrent copy or UNIX File Snapshot initialization completes.

Defaults: If you do not specify any subparameters with the CC parameter, the defaults are STANDARD and PHYSICALEND.

If you do not specify CC, then DFSMSHsm does not use concurrent copy for non-SMS data sets. However, for SMS data sets or UNIX files contained in an SMS-managed zFS, DFSMSHsm uses the values from the management class.

Note:

1. If LOGICALEND is used with PREFERRED, VIRTUALPREFERRED, or CACHEPREFERRED, and concurrent copy is unavailable for the data set, the backup continues and DFSMSHsm ignores the CC options.
2. If LOGICALEND is used with STANDARD, the command fails.
3. UNIX File Snapshot can only be initiated from the owning system for files in a zFS that is mounted NORWSHARE. If the zFS is mounted RWSHARE, UNIX file Snapshot can be used from any system in

the sysplex. Use the z/OS UNIX shell command **zfsadm fsinfo** to see details about the attributes of a file system. For example:

```
zfsadm fsinfo -owner file_system_name
```

CHANGEDONLY/TOTAL: Specifying whether to back up UNIX files that have a last backup date in their metadata

CHANGEDONLY/TOTAL

Specifies whether DFSMSHsm backs up only those UNIX files specified (explicitly or by a filter) that have a last backup date in their metadata that is older than the modification or metadata modification date. Additionally, if the change dates in the file metadata are newer than the most recent version in the DFSMSHsm inventory, or DFSMSHsm does not have a backup of the file, DFSMSHsm will create a backup. A change in the metadata modification date, but not the modification date, can be caused by truncation of the file, as well as a change to the number of hard links to the file. CHANGEDONLY is not valid when a data set name is specified. An error message (parsing) will be issued. The CHANGEDONLY keyword is overridden if specified or defaulted when NEWNAME is specified.

Abbreviations: CHGD

Defaults: CHANGEDONLY

TOTAL is an optional parameter that requests DFSMSHsm take a backup of the UNIX file regardless of the last backup date value.

Note:

This parameter does not apply to backup requests for data sets.

For restrictions please refer to topic "Data set backup using NEWNAME" <https://www.ibm.com/docs/en/zos/3.1.0?topic=backup-data-set-using-newname>

DELETE: Specifying whether to delete the UNIX file after a successful backup

DELETE is an optional parameter that specifies whether DFSMSHsm should remove the UNIX file after a successful backup has been performed. Directories are not removed. If the RETAINDAYS keyword is not specified, a default RETAINDAYS value of 365 (patchable **MCVT_ARCHIVE_RD_DEFAULT** field value) is used as the period to retain the backup of this file regardless of other backup versions that are subsequently taken. If the RETAINDAYS keyword is specified, then the specified value is used as the retention period.

Backup versions are not automatically rolled off by DFSMSHsm, even if retention period is passed. To remove backup versions that have passed the RETAINDAYS criteria the EXPIREBV command should be issued, backup versions will be removed then in compliance with the EXPIREBV logic.

Abbreviations: The TSO abbreviation convention applies for DELETE. There are no additional abbreviations

Defaults: DFSMSHsm does not delete a UNIX file after backup processing has been performed.

EXCLUDE and EXCLUDEF: Specifying files or directories to be excluded from processing

EXCLUDE | EXCLUDEF are mutually exclusive, optional parameters that are used to specify files and directories that are to be excluded during Unix File backup processing.

EXCLUDE(<exclude_criteria>) - specifies a comma-separated list of exclude criteria directly on the command. This criteria is to be applied to the UNIX files examined during the UNIX File backup processing.

The exclude criteria list specified on the command with EXCLUDE keyword has the following restrictions and rules unique to the keyword:

- The *exclude_criteria* list must be specified in single quotes
- The *exclude_criteria* list cannot exceed 1023 characters

EXCLUDEF('<filepath>') - specifies the UNIX path to a file that contains the exclude criteria to be applied to the UNIX files examined during the UNIX File backup processing. The file path must be specified in single-quotes and must be an absolute path. Any imbedded single quotes in the filename must be specified with a second single quote, e.g. the filename exclude'criteria.txt would be specified as: 'exclude"criteria.txt'. (optional)

The exclude criteria file specified using the EXCLUDEF keyword has the following restrictions and rules unique to the keyword:

- Line starting with a blank character is a comment.
- Each line can only contain one criterion.
- A single line cannot be longer than 1023 characters.
- Total length of all exclude criteria with added commas to separate them cannot exceed 32767 characters. For 'n' number of criteria, 'n-1' number of COMMA should also be accounted for to calculate the total size.

Exclude criteria, whether specified on the command in a comma separated list using the EXCLUDE keyword or specified within a file using the EXCLUDEF keyword, must conform to the following rules:

- Absolute directory path, beginning and ending with a forward-slash character.
- Partial directory path, ending with a forward-slash character. If the directory name begins with a forward slash character, then it is considered an absolute path. If the directory name does not begin with a forward slash character, it is considered a relative path that begins at the directory requested on the command. A directory name that is a relative path is considered relative to the directory requested on the command only, even when the command requests recursion.
- Filename pattern (does not contain forward slashes). Can contain * or ? wildcard. An asterisk (*) can match with 0 or more characters in a filename. A question mark (?) can match with a single character. Wildcard characters may be escaped with the backslash character if desired.
- A filename pattern can begin with an absolute or relative path, however wildcard characters can only be used in the filename pattern. A directory path containing an asterisk (*) or question mark (?) is considered an invalid pattern.
- If a filename contains special characters that are not to be treated as wildcard or escape characters i.e. an asterisk (*), a question mark (?), or backslash (\), these characters must be escaped using a backslash (\). If these characters are not escaped, they will be treated as wildcard or escape characters.
- A directory wildcard may be specified in the directory portion of a criterion by specifying /.../ (<forward slash><period><period><period><forward slash>). A directory wildcard can match with 0 or more directories.
- If a criterion begins with a directory wildcard (/.../) then it is treated as relative path.
- A comma cannot be used with the exclude criterion.
- A single criterion cannot exceed 1023 characters.
- A single forward slash or a single asterisk are treated as invalid patterns.
- A directory path cannot contain consecutive forward slashes.

The example below shows sample criteria in a file specified by the EXCLUDEF keyword. The same criteria could be specified on the command using the EXCLUDE keyword where each criterion is separated by a comma.

```

Useful comment (maybe with commas) <= blank in 1st position - ignored
/a/b/c/                                     <= empty line - ignored
/a/b/c/x1.txt                             <= absolute directory
/a/.../d/.../g/syslog1.txt                <= absolute directory with filename
/a/.../d/.../g/*log?.txt                  <= absolute directory with wildcards
/a/.../d/.../g/*log?.txt                  <= absolute directory and filename with wildcards
e/f/g                                     <= relative directory
e/f/g/mvs.log                             <= relative directory with filename
d/e/f/g/*log?.txt                         <= relative directory with filename wildcard
d/.../g/sys*. *                           <= relative directory and filename with wildcards
/.../d/.../g/sys*. *                     <= relative difrectory and filename with wildcards
*.log                                     <= filename with wildcards
*.log2                                   <= blank in 1st position makes a comment, ignored
\*abc                                    <= escaping wildcards - files with exact name *abc
\\abc                                   <= escaping wildcards - files with exact name \abc

```

Defaults: No files are excluded from processing.

INUSE: Tailoring backup processing of UNIX files in use at the time of backup

The INUSE keyword is an optional parameter that specifies how UNIX files that are in use at the time of backup should be processed.

When the INUSE keyword is specified, UNIX files that are in use at the time of backup will have their backup retried up to a specified maximum number of times, delaying a specified number of minutes in between each retry. On retry an attempt to obtain exclusive serialization to the UNIX file will be made. If on retry exclusive serialization is obtained then a normal backup of the UNIX file will be made. If exclusive serialization cannot be obtained, then additional retries of the backup will be made until the max number of retries have been made. If after the maximum number of retries exclusive serialization cannot be obtained, the backup request will either fail or a backup of the file will be taken anyway, depending on if the command specified serialization was required or preferred.

The INUSE keyword has subkeywords, RETRY, DELAY, and SERIALIZATION that enable the user to specify the maximum number of retries, the time to delay in between retries, and whether exclusive serialization is required or preferred.

INUSE(RETRY(*nn*),DELAY(*min*),SERIALIZATION(REQUIRED|PREFERRED))

- RETRY(*nn*) - DFSMSHsm will retry a maximum of *nn* times to back up a UNIX file after the first attempt fails because the UNIX file is in use. For *nn*, specify a value 0 to 99. The default value is 0.
- DELAY(*min*) - DFSMSHsm delays for *min* minutes before retrying a backup attempt which failed because the UNIX file in use. DFSMSHsm will delay *min* minutes in between each retry. For *min*, specify a value from 0 to 999. The default value is 15.
- SERIALIZATION(PREFERRED|REQUIRED) - Specifies whether exclusive serialization of the UNIX file is required after the max number of retries of the backup have been made. The default value for SERIALIZATION is REQUIRED.
 - PREFERRED - If the UNIX file is still in use after the max number of retries for the backup have been made, the UNIX file will be backed up anyway. A message indicating a fuzzy backup was made will be issued. If the UNIX file is not in use at that time, a normal backup will be made. If RETRY(0) is in effect and exclusive serialization could not be obtained on the first attempt then a fuzzy backup will be made.
 - REQUIRED - If the UNIX file is still in use after the max number of retries for the backup is made, the backup request will fail.

The subkeywords are optional and any that are omitted will have the default value for that subkeyword used.

All supported UNIX file types can be backed up with the INUSE keyword, however only Regular Files will be checked to be in use. Symbolic links, FIFOs, and directories will not be checked to be in use and will not have their backup retried.

zFS File Snapshot is not supported for in use UNIX files. If SERIALIZATION(PREFERRED) and CC(PREF) or CC(REQ) are specified on the command and the UNIX file is in use at the time of backup, the backup request will still fail.

NEWNAME: Specifying a name to assign to the backup version

NEWNAME is an optional parameter. *dsname* is the name of the data set to back up, and *newdsname* is the data set name to assign to the new backup version that is created by specifying BACKDS. Both *dsname* and *newdsname* must be fully qualified and in the standard data set name format. DATE, TIME, SPHERE, and GENVSAMCOMPNames are optional parameters that are only valid with the NEWNAME parameter.

newpath is a new directory path for the UNIX file backups. When processing a UNIX file, this subparameter requests DFSMSHsm to create a backup of the requested UNIX files as if it had come from the specified directory *newpath*. The specified *newpath* must be a subset of the request directory path, and must start and end with a forward slash. When processing a request with the *newpath* parameter, the *newpath* value is checked against the request directory path starting at the end of the path, moving to the higher directory levels to ensure that the specified *newpath* is a subset matching the requirements above. If an intermediate directory of the request directory path is specified as the *newpath*, the remaining lower directory portions of the request directory path are appended (see example 1.4). The resulting new directory should not be equal to the request directory path (see examples 1.5 - 1.7 below which result in ARC1381I REAS=10). If the *newpath* is not a subset of the request directory, then the ARC1334I BACKUP VERSION NOT CREATED with REAS=23 is issued (see example 1.8).

The NEWNAME keyword is intended to assist migrating backups from a previous product into DFSMSHsm. Backups would be recovered into a temporary directory, and then those files would be backed up by DFSMSHsm, specifying the new root directory of the files using the NEWNAME keyword. DFSMSHsm matches the last directory subset of the request. The CHANGEDONLY keyword is overridden if specified or defaulted when NEWNAME is specified.

Examples:

```
BACKDS '/tmp/2017-07-08/prod/webapp1/*' RECURSE NEWNAME('/prod/webapp1/') DATE(2017/07/08)
```

```
BACKDS '/tmp/2017-07-08/*' RECURSE NEWNAME('/') DATE(2017/07/08)
```

Incorrect:

```
BACKDS '/tmp/2017-07-08/prod/webapp1/*' RECURSE NEWNAME('/user/myapp/')
```

Examples showing the resulting backup when using different paths specified in the NEWNAME keyword.

BACKDS '/x/y/z/file.txt' with various *newpath* values:

1.1. NEWNAME('/') - is backed up as /file.txt.

1.2. NEWNAME('/z/') - is backed up as /z/file.txt.

1.3. NEWNAME('/y/z/') - is backed up as /y/z/file.txt.

1.4. NEWNAME('/y/') - is backed up as /y/z/file.txt, since '/z/' of the source path is appended to '/y/', and 'file.txt' is backed up as if it came from '/y/z/' directory.

1.5. NEWNAME('/x/y/z/') - is an error with ARC1381I REAS=10 issued.

1.6. NEWNAME('/x/') - is an error with ARC1381I REAS=10 issued.

1.7. NEWNAME('/x/y/') - is an error with ARC1381I REAS=10 issued.

1.8. NEWNAME('/not_subset/') - is an error with ARC1334I REAS=23 issued.

Tip: It is best if the NEWNAME directory exists at the time of the backup. DFSMSHsm stores the name of the containing zFS data set in the backup record for future SMS-management checks. (This attribute is used for the number of versions to keep for roll-off processing, ALTERDS checking, and whether the Recover processing should end due to a No-Crossmounts condition on a recursive file request. If

the NEWNAME directory does not exist, DFSMSShsm cannot store the containing zFS name, and some functions, such as ALTERDS might be unable to be performed.

The parameters of the NEWNAME parameter are explained:

DATE

Specifies the date to assign to the backup version. If DATE is specified without the NEWNAME parameter, the BACKDS command fails. If DATE is specified without TIME, the current time is assigned to the backup version. The date format is: *yyyy/mm/dd*; where *yyyy* is the 4-digit year, *mm* is the 2-digit month, and *dd* is the 2-digit day.

TIME

Specifies the time to assign to the new backup version. If TIME is specified without DATE, the BACKDS command fails. If DATE is specified without TIME, the current time is assigned to the backup version. If TIME is not specified, and a backup copy with the date specified on the command and the current time already exists, the command fails. The time format is: *hhmmss*; where *hh* is 2-digit hour, *mm* is the 2-digit minute, and *ss* is the 2-digit second.

SPHERE

Specifies whether AIX and PATH components of a VSAM data set is backed up with the base cluster. SPHERE(YES) indicates that a backup of the entire VSAM sphere is performed. SPHERE(NO) indicates that a backup of the base cluster is performed, and any associated AIXs or PATHs is not backed up. SPHERE(YES) is the default. If SPHERE is specified without NEWNAME, the BACKDS command fails.

GENVSAMCOMPNames**GVCN**

Specifies whether to override the SETSYS DSBACKUP(GENVSAMCOMPNames) value. If GENVSAMCOMPNames(YES) is specified and *dsname* is a VSAM data set and *newdsname* is a migrated or uncataloged data set, the command is processed, and default names are assigned to the data and index components. If GENVSAMCOMPNames(NO) is specified, and *dsname* is a VSAM data set and *newdsname* is a migrated or uncataloged data set, the command fails. If *newdsname* is a cataloged data set and is not migrated, or if *dsname* is a non-VSAM data set, the GENVSAMCOMPNames parameter is ignored.

Defaults: If date and time are not specified, the current date and time are assigned to the backup version.

Note: The following restrictions apply when using the BACKDS NEWNAME command to back up a VSAM data set:

- No more than one PATH can be defined for the data set to be backed up, and no more than one PATH can be defined for the new name data set.
- No more than one AIX can exist for the data set to be backed up, and no more than one AIX can exist for the new name data set.
- The NEWNAME keyword cannot be specified with the UNIT and VOLUME keywords.
- A backup version created with (H)BACKDS NEWNAME DATE always has a VERSION NUMBER = 000.

newpath is a new directory path for the UNIX file backups. When processing a UNIX file, this subparameter requests DFSMSShsm to create a backup of the requested UNIX files as if it had come from the specified directory *newpath*. The specified *newpath* must be a subset of the request directory path, and must start and end with a forward slash. The parameter is the absolute path of the directory name that the files should have after the backup is complete. The backups are made as if they came from root.

The NEWNAME keyword is intended to assist migrating backups from a previous product into DFSMSShsm. Backups would be recovered into a temporary directory, and then those files would be backed up by DFSMSShsm, specifying the new root directory of the files using the NEWNAME keyword. DFSMSShsm matches the last directory subset of the request. The CHANGEDONLY keyword is overridden if specified or defaulted when NEWNAME is specified.

Examples:

```
BACKDS '/tmp/2017-07-08/prod/webapp1/*' RECURSE NEWNAME('/prod/webapp1/') DATE(2017/07/08)
```

```
BACKDS '/tmp/2017-07-08/*' RECURSE NEWNAME('/') DATE(2017/07/08)
```

Incorrect:

```
BACKDS '/tmp/2017-07-08/prod/webapp1/*' RECURSE NEWNAME('/user/myapp/')
```

Examples showing the resulting backup when using different paths specified in the NEWNAME keyword.

- BACKDS '/x/y/z/file.txt' 1.1. NEWNAME('/') is backed up as /file.txt.
- 1.2. NEWNAME('/z/') is backed up as /z/file.txt.
- 1.3. NEWNAME('/y/z/') is backed up as /y/z/file.txt.
- 1.4. NEWNAME('/x/y/z/') is an error.
- 1.5. NEWNAME('/y/') is backed up as /y/z/file.txt.

Note: It is best if the NEWNAME directory exists at the time of the backup. DFSMSHsm stores the name of the containing zFS data set in the backup record for future SMS-management checks. (This attribute is used for the number of versions to keep for roll-off processing, ALTERDS checking, and whether the Recover processing should end due to a No-Crossmounts condition on a recursive file request. If the NEWNAME directory does not exist, DFSMSHsm cannot store the containing zFS name, and some functions, such as ALTERDS might be unable to be performed.

RECURSE: Examine subdirectories of the specified UNIX file path

Explanation: RECURSE is an optional parameter that requests DFSMSHsm go into subdirectories as it looks for files to process. As new directories are examined, the pattern is used to match with file names within that directory.

RECURSE(CROSSMOUNTS|CMT|NOCROSSMOUNTS|NCM)

NOCROSSMOUNTS is the default behavior and means that as DFSMSHsm is traversing the directory sub-tree, it should not cross into a different mounted filesystem while looking for files to process. If a different filesystem is encountered, examination of that sub-tree will stop.

CROSSMOUNTS tells DFSMSHsm that it should cross into different filesystems as it is traversing the file tree while looking for files that match *pattern* to backup.

Defaults: None. Recursion into sub-directories is not done by default. Only the requested directory is examined for files that match *pattern*.

Note: This parameter does not apply to data set backup requests.

RETAIN_DAYS: Specifying the number of days to retain a backup copy

Explanation: RETAIN_DAYS is an optional parameter specifying a number of days to retain a specific backup copy of a data set. If you specify RETAIN_DAYS, number of retain days is a required parameter that specifies a minimum number of days (0–50000) that DFSMSHsm retains the backup copy. If you specify 99999, the data set backup version never expires. Any value greater than 50000 (and other than 99999) causes a failure with an ARC1605I error message. A retain days value of 0 indicates that:

- the backup version might expire within the same day that it was created if EXPIREBV processing takes place or when the next backup version is created,
- the backup version is kept as an active copy before roll-off occurs,
- the backup version is not managed as a retained copy.

Restriction: RETAIN_DAYS applies only to cataloged data sets.

Defaults: None.

Related reading: For more information about the RETAIN_DAYS processing, see [“Specifying the number of days to retain a backup copy of a data set” on page 183](#).

TARGET: Specifying a required target output device

Explanation: TARGET is an optional parameter specifying a required output device type, such as ML1 DASD or backup tape. If you do not specify the TARGET parameter, DFSMSHsm selects the output device.

The parameters of the TARGET parameter are explained:

DASD

specifies that DFSMSHsm backs up the data set to ML1 DASD.

TAPE

specifies that DFSMSHsm backs up the data set to tape.

Defaults: None.

UNIT: Specifying the type of device

Explanation: UNIT is an optional parameter specifying the type of unit where the volume containing the uncataloged data set to be backed up can be allocated.

unittype

is the type of unit.

The following are valid types of DASD units:

- 3380
- 3390
- 9345

Defaults: None.

Note: You must specify the UNIT parameter if you want to back up an uncataloged data set. UNIT, you must also specify the VOLUME parameter. Do not specify this parameter if you want to back up a cataloged data set.

VOLUME: Specifying the volume where the data set resides

Explanation: VOLUME is an optional parameter specifying the volume where the uncataloged data set to be backed up resides.

volser

is the serial number of the volume where the uncataloged data set to be backed up resides.

Defaults: None.

Note: You must specify the VOLUME parameter if you want to back up an uncataloged data set. VOLUME, you must also specify the UNIT parameter. Do not specify this parameter if you want to back up a cataloged data set.

Delete expired backup versions of UNIX files

Retained backup versions that have met their retention period are not automatically deleted. You will have to use the EXPIREBV command to find and delete unneeded backup versions. When the EXPIREBV command is processing a backup of a UNIX file, the management class of the zFS data set containing the UNIX file is used to determine the expiration criteria for the backup.

- If the zFS data set that contained the UNIX file does not exist, the management class that was associated with the file when the last backup version was made is used.
- If the UNIX file is determined to be non-SMS managed, then the DELETEIFBACKEDUP or CATALOGEDDATA subparameters of the NONSMSVERSIONS parameter criteria is used.

Examples of how to code the BACKDS command

The following examples present different ways to code the BACKDS command:

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Backing up an SMS-managed data set

In this example, DFSMSHsm backs up an SMS-managed data set to a target device of tape. DFSMSHsm requires a concurrent copy session, and DFSMSHsm returns control after the session is established and before DFSMSHsm makes the copy.

```
BACKDS P234823.PSFB.H39SC230.DS230 TARGET(TAPE) CC(REQUIRED LE)
```

Backing up a cataloged data set

In this example, DFSMSHsm backs up a cataloged data set.

```
BACKDS JBH6798.PSFB.F40RC001.DSET01
```

Backing up an uncataloged data set

In this example, DFSMSHsm backs up an uncataloged data set. You must specify the VOLUME and UNIT parameters to back up an uncataloged data set.

```
BACKDS FMT1315.PROJ53.REV VOLUME(VOL110) UNIT(3390)
```

Chapter 33. BACKFILE command: Backing up a specific UNIX file

The BACKFILE command is an alias to the BACKDS command. All parameters valid on the BACKDS command are acceptable on the BACKFILE command.

Chapter 34. BACKDS command: Backing up a specific data set

The BACKDS command creates a backup version of a specific data set or UNIX file. When you enter the BACKDS command, DFSMSHsm does not check whether the data set has changed or has met the requirement for frequency of backup. When you enter the BACKDS command for a UNIX file, DFSMSHsm will check whether the file has changed since its last backup. When DFSMSHsm processes a BACKDS command, it stores the backup version on either tape or the ML1 volume with the most available space.

Note: If the size of a data set or UNIX file that is targeted to DASD exceeds the free space on the ML1 volume having the most free space, then the data set backup fails. If there is no overflow ML1 volume available or the data set or UNIX file does not qualify for placement on an overflow ML1 volume, then the data set or UNIX file backup fails.

You can issue a BACKDS command for the following:

- An SMS-managed data set (if allowed by its management class).
- A data set that resides on a level 0 volume.
- A migrated data set currently residing on a migration level 1 volume.
- An uncataloged data set (DFSMSHsm is used as the datamover).
- A user data set that resides on a migration level 1 or a DASD migration level 2 volume. We do not recommend that users directly allocate data sets on migration volumes.
- A UNIX file.
- UNIX files within a directory, or directory sub-tree.

Regardless of the status or location of the data set, the volume containing the data set must be mounted and online, or the command fails.

When you want to back up an uncataloged data set, you must specify the volume serial number of the volume that contains the data set. In addition, you must specify the type of unit of the volume specified.

Note: If you specify a data set currently migrated to a migration level 2 volume, DFSMSHsm does not back up the data set.

Note: Any files that reside in an encrypted zFS will be decrypted as they are written to the backup.

Chapter 35. BACKFILE command: Backing up a specific UNIX file

The BACKFILE command is an alias to the BACKDS command. All parameters valid on the BACKDS command are acceptable on the BACKFILE command.

Chapter 36. BACKVOL command: Backing up data sets from volumes or dumping volumes

You can use the BACKVOL command to request that DFSMSHsm perform any of the following tasks:

- Back up eligible data sets on one or a list of volumes, or dump one or a list of DASD volumes
- Back up eligible data sets from all primary volumes
- Back up control data sets and the journal
- Back up eligible data sets from all volumes in one or more storage groups
- Dump all volumes in one or more storage groups

Use the BACKUPDEVICECATEGORY parameter to specify whether to back up the data sets to tape or to DASD daily backup volumes.

Backup messages are always recorded in the backup activity log.

When you issue the BACKVOL command with the DUMP optional parameter, DFSMSHsm requests that DFSMSdss does a full-volume dump of either (1) each DASD volume specified with the VOLUMES parameter or (2) each eligible DASD volume in each storage group specified with the STORAGEGROUP parameter. In the first case, the full-volume dumps are stacked on dump volumes in those dump classes if:

- Dump classes specified on the command call for stacking, or
- The STACK or MINSTACK subparameter is specified

In the second case, the full-volume dumps are stacked on dump volumes if:

- Dump classes specified on the command call for stacking, or
- The STACK or MINSTACK subparameter is specified, or
- The dump classes associated with a storage group or volume call for stacking

For full-volume dumps, you can decide to print dump messages at the system console (TERMINAL). Dump messages are always recorded in the dump activity log.

You can specify the BACKVOL command with the CONTROLDATASETS parameter to back up the DFSMSHsm control data sets and journal or you can specify CONTROLDATASETS(NULLJOURNALONLY) to null the journal without backing up the control data sets. Backup messages for the control data sets are written to the backup activity log.

Backing up data sets from one or more SMS-managed volumes or dumping SMS-managed volumes

The BACKVOL command requests that DFSMSHsm backs up eligible data sets from specific SMS-managed volumes or from the volumes in one or more storage groups. Only those data sets for which the management class allows command backup are processed. The frequency of backup for an SMS-managed data set is obtained from the data set management class attribute.

When you issue the BACKVOL command for an SMS-managed volume, that volume becomes DFSMSHsm-managed. DFSMSHsm maintains control records for the volume until you issue the DELVOL command against it. When processing a BACKVOL command having the STORAGEGROUP parameter, the management class selection criterion that is used is AUTOBACKUP instead of COMMAND. This means that DFSMSHsm treats a BACKVOL STORAGEGROUP command as if it is autobackup running for the referenced volumes.

You can specify, on the command, the type of backup to be done. You can choose to back up the following:

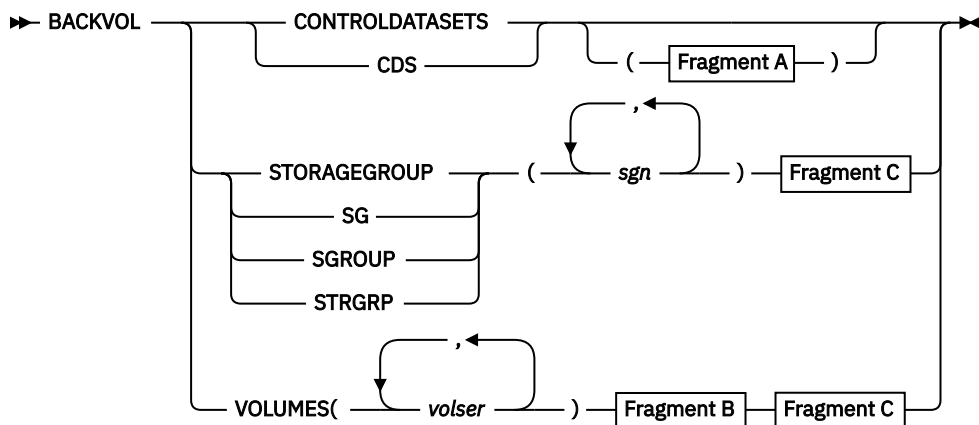

BACKVOL command for DFSMSHsm

- Data sets that have changed since the last backup (INCREMENTAL)
- All data sets on a volume (TOTAL)

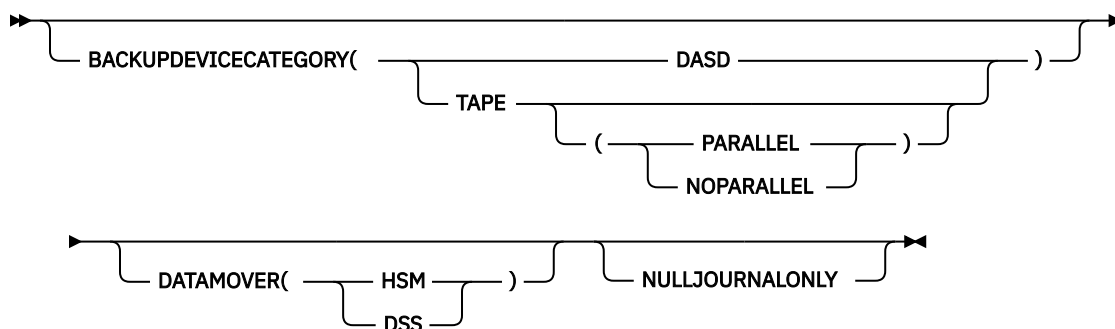

The BACKVOL command requests DFSMSHsm to dump specific SMS-managed volumes or volumes in one or more storage groups. When a BACKVOL command with the DUMP parameter is issued for an SMS-managed volume, the dump functions performed for the volume are the same as those performed for an automatic dump of that volume.

If dump classes are specified on the BACKVOL command, those dump classes are used to perform the dump function, overriding the dump classes defined for the SMS storage group associated with that volume.

Syntax of the BACKVOL command with SMS-managed volumes

A: CONTROLDATASETS optional parameters

B: VOLUMES optional parameters

C: STORAGEGROUP and VOLUMES optional parameters

D: DUMP optional parameters

Required parameters for SMS-managed volumes

This topic describes the required parameters of the BACKVOL command.

CONTROLDATASETS: Specifying the control data sets to be backed up

Explanation: CONTROLDATASETS is a required parameter specifying that DFSMSHsm back up the control data sets and journal.

Defaults: None.

Note:

1. The BACKVOL CONTROLDATASETS command is not affected by running DFSMSHsm in debug mode (using the SETSYS DEBUG command). Control data sets are backed up in both debug and normal (no debug) mode.
2. Do not issue the CONTROLDATASETS parameter of the BACKVOL command during a period of high DFSMSHsm activity, because the control data sets cannot be changed while this function is running. However, this is *not* true if you are using DFSMSdss with the concurrent copy function as the datamover. Most DFSMSHsm functions change the control data sets. The only way to prevent DFSMSHsm from backing up the control data sets after someone issues the BACKVOL command with the CONTROLDATASETS parameter is to stop DFSMSHsm.
3. DFSMSdss must be specified as the datamover for CDS backup when you are using RLS mode. If BACKVOL CDS is issued, and DFSMSdss was not specified as the datamover, or is not the default, or the backup is directed to tape and PARALLEL was not specified or is not the default, then message ARC0792I will be issued, and the command will fail. If CDS backup is invoked automatically, and either DFSMSdss is not specified as the datamover, or the backup is directed to tape and PARALLEL was not specified, then these values will override the existing values and message ARC0793I will be issued.

STORAGEGROUP: Specifying the storage group to back up or dump

Explanation: STORAGEGROUP(*sgn*,...) is a required parameter specifying that DFSMSHsm backs up the eligible data sets on the volumes in one or more storage groups or it dumps the volumes in one or more storage groups. For *sgn*, substitute the names of the storage groups that DFSMSHsm processes. (A storage group name appearing more than once in the list is backed up or dumped only once.)

If you specify DUMP, DFSMSHsm concurrently targets dump copies to one or more dump classes (specified in the command or associated with the storage groups). If stacking is specified (in the command or in the dump class definitions), DFSMSHsm uses its dump stacking process to stack multiple dump copies on dump volumes. Specifying DUMPCLASS means that DFSMSHsm dumps all storage groups specified to the same set of specified dump classes.

Defaults: None.

Note:

1. A message is issued, and the backup or dump is not processed if DFSMSHsm is running in a non-SMS environment.
2. A message is issued and the backup or dump will not be processed for any volumes which are in initial status or can not be determined to be SMS-managed volumes.
3. If you specify STORAGEGROUP without *sgn*, the command fails. If you specify STORAGEGROUP with more than 30 storage groups, only the first 30 are processed.

4. If you specify DUMP with DUMPCLASS, and at least one of the dump classes specified has a stacking value greater than one (specified with the STACK subparameter or within a dump class definition), DFSMSHsm uses its dump stacking process to stack one or more dump copies on each dump volume selected.
5. If you specify DUMP but not DUMPCLASS, and at least one of the dump classes associated with a specified storage group has a stacking value greater than one, DFSMSHsm uses its dump stacking process to stack one or more dump copies of the volumes in that storage group on dump volumes in the associated dump classes.
6. For any dump class with a stacking value of one (specified on the command or within a dump class definition), DFSMSHsm limits that class's dump volumes to one dump copy per volume.
7. If you specify DUMP but not DUMPCLASS, then depending on how storage groups and their associated dump classes are defined, DFSMSHsm may not dump the eligible volumes in the order in which the storage groups are specified. In particular, if the dump classes for a given storage group do not specify stacking, the volumes of that storage group are dumped (one dump copy per dump volume) after the volumes of those storage groups using stacking.
8. Dump copies of volumes in more than one storage group (specified on the same BACKVOL command) can be stacked on a given dump volume.
9. All stacking to a given dump volume is done while that tape is mounted. DFSMSHsm always selects empty dump volumes to mount as targets for DUMP.
10. When you use BACKVOL to dump one or more storage groups, DFSMSHsm treats all volumes being dumped as having affinity to the host issuing the command which means that they are all processed on the single host where the command is submitted.
11. If a batch job issues the WAIT BACKVOL STORAGEGROUP command, DFSMSHsm processes the command, but does not ensure that the action completes before returning control to the caller. As a result, it is possible for the batch job to complete with return code zero before all of the volumes are processed.
12. If you are using the BACKVOL STORAGEGROUP command, data sets that are assigned to a Management Class with AUTO BACKUP=N will not be considered eligible for backup.

VOLUMES: Specifying the volumes to be backed up or dumped

Explanation: VOLUMES(*volser*,...) is a required parameter specifying that DFSMSHsm is to (1) back up the eligible data sets on, or (2) dump, each of the specified volumes. For *volser*, substitute the serial number of the volumes to be backed up or dumped. (A volume serial number appearing more than once in the list is backed up or dumped only once.) A message is issued and the backup or dump of an SMS-managed volume is not processed if:

- DFSMSHsm is running in a non-SMS environment
- The SMS-managed volume is in *initial* status (contains both SMS-and non-SMS-managed data sets while in the process of being converted to an SMS-managed volume).
- DFSMSHsm cannot determine if the specified volume is SMS-managed.

Defaults: None.

Note:

1. A volume list can include both SMS-managed volumes and non-SMS-managed volumes.
2. If you specify the VOLUMES parameter with more than 80 volumes, DFSMSHsm processes only the first 80 volumes.
3. If DUMP is specified with DUMPCLASS, and at least one of the specified dump classes (or the optional STACK subparameter) specifies a stacking value greater than one, DFSMSHsm attempts to stack the dumps of the volumes in the order specified. A volume in use by another DFSMSHsm volume function will be moved to the end of the stack.

Optional parameters for SMS-managed control data sets

This topic describes the optional parameters of the BACKVOL command.

BACKUPDEVICECATEGORY: Specifying the backup device for the control data sets and journal

Explanation: BACKUPDEVICECATEGORY is an optional parameter of CONTROLDATASETS that specifies the type of device that receives the backup copies of the DFSMSHsm control data sets and the journal when DFSMSHsm backs them up.

Subparameter	Explanation
DASD	BACKUPDEVICECATEGORY(DASD) specifies that DASD is the device on which the backup copies will be recorded.
TAPE	<p>BACKUPDEVICECATEGORY(TAPE) specifies that tape is the device on which the backup copies will be recorded.</p> <p>TAPE(PARALLEL) specifies that all control data sets and the journal should be backed up in parallel. By specifying this subparameter, you can cause one tape drive to be allocated for each control data set and the journal.</p> <p>TAPE(NOPARALLEL) specifies that the control data sets and the journal should be backed up serially. When NOPARALLEL is specified, the control data sets are backed up one at a time followed by the backup of the journal. By specifying this parameter, you can cause only one tape drive to be allocated for all the control data set backups. TAPE(NOPARALLEL) may not be specified when DATAMOVER(DSS) is specified.</p>

SETSYS Defaults: None.

DFSMSHsm Defaults: If you do not specify BACKUPDEVICECATEGORY, the backup device used will be determined by the SETSYS CDSVERSIONBACKUP subparameter BACKUPDEVICECATEGORY. If the SETSYS CDSVERSIONBACKUP subparameter BACKUPDEVICECATEGORY has not been previously specified, the DFSMSHsm default is BACKUPDEVICECATEGORY(TAPE(NOPARALLEL)).

Note:

1. If BACKVOL CDS specifies DATAMOVER(DSS), or if BACKVOL CDS does not specify a datamover and the DFSMSHsm CDS Version Backup environment indicates DATAMOVER(DSS), then TAPE(NOPARALLEL) may not be specified.
2. If you are attempting to backup to tape, ensure that you have previously issued the SETSYS CDSVERSIONBACKUP(BACKUPDEVICECATEGORY(TAPE (UNITNAME(*unit*))) command to properly configure the CDSVERSIONBACKUP parameter table.

DATAMOVER: Specifying the type of data movement used when backing up the control data sets

Explanation: DATAMOVER is an optional parameter of CONTROLDATASETS specifying the type of data movement to be used when performing a backup of the DFSMSHsm control data sets. DFSMSdss must be specified as the datamover for CDS backup when you are using RLS mode.

Subparameter	Explanation
HSM	DATAMOVER(HSM) specifies that the DFSMSHsm control data sets are backed up using the AMS EXPORT function. The journal is backed up using sequential I/O.

Subparameter	Explanation
DSS	DATAMOVER(DSS) specifies that the DFSMSHsm control data sets are backed up using a DFSMSdss logical dump. Using DFSMSdss as the datamover allows you to exploit the concurrent copy function. The journal is backed up using sequential I/O. Data sets are backed up in parallel.

When you use DFSMSdss rather than DFSMSHsm as the data mover, concurrent copy can be used and the CDSs will be validated as they are backed up. Concurrent copy allows the CDS backup to complete as soon as the journal has been backed up so that DFSMSHsm can begin processing requests before the CDS backups are completed.

BACKVOL Defaults: None.

DFSMSHsm Defaults: If you do not specify DATAMOVER, the type of data movement used is determined by the SETSYS CDSVERSIONBACKUP command subparameter DATAMOVER. If the SETSYS CDSVERSIONBACKUP command subparameter DATAMOVER has not been previously specified, the DFSMSHsm default is DATAMOVER(HSM).

Note:

1. If DATAMOVER is specified, either HSM or DSS must be specified.
2. If BACKVOL CDS specifies DATAMOVER(DSS) without BACKUPDEVICECATEGORY, and the DFSMSHsm CDS version backup environment indicates TAPE(NOPARALLEL), the BACKVOL CDS command will not be successful, and an error message will be generated.
3. Each control data set and the journal will be backed up to separate data sets whose names are generated using the values specified in the SETSYS CDSVERSIONBACKUP command subparameters of MCDSBACKUPDSN, BCDSBACKUPDSN, OCDSBACKUPDSN, and JRNLBACKUPDSN. These names are appended with a DFSMSHsm-defined final qualifier of 'Vnnnnnnn' if the datamover is DFSMSHsm, or 'Dnnnnnnn' if the datamover is DFSMSdss. If the backup fails, independent of the datamover specified, the data set name field of the failed backup will be given a final qualifier of 'Xnnnnnnn'.

NULLJOURNALONLY: Specifying that DFSMSHsm null the journal

Explanation: NULLJOURNALONLY is an optional parameter of CONTROLDATASETS specifying that DFSMSHsm null the journal without making backup copies of the control data sets.

Defaults: None.

Note:

1. If you specify this parameter, no other parameters for the BACKVOL CDS are allowed.
2. The journal must have been inhibited by a journal processing error before this parameter is specified, otherwise the BACKVOL CDS NULLJOURNALONLY command will fail.

Optional parameters for SMS-managed volumes

This topic describes the optional parameters of the BACKVOL command.

BACKUPDEVICECATEGORY: Specifying where the backup versions are to reside

Explanation: BACKUPDEVICECATEGORY is an optional parameter of VOLUME specifying the type of device, tape or DASD, that receives the backup versions of the data sets when they are backed up.

Subparameter	Explanation
TAPE	BACKUPDEVICECATEGORY(TAPE) specifies that the backup versions of the data sets on the volume reside on a tape daily backup volume when the data sets are backed up.

Subparameter	Explanation
DASD	BACKUPDEVICECATEGORY(DASD) specifies that the backup versions of the data sets on the volume reside on a DASD daily backup volume when the data sets are backed up.

Defaults: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is TAPE.

Note:

1. When you specify BACKUPDEVICECATEGORY, you can specify either TAPE or DASD, but not both.
2. The BACKUPDEVICECATEGORY parameter does not apply when you specify the DUMP parameter.

DUMP, INCREMENTAL, and TOTAL: Specifying which data sets are backed up

Explanation: DUMP, INCREMENTAL, and TOTAL are mutually exclusive, optional parameters of VOLUME specifying which data sets are to be backed up. A message is issued and the backup or dump is not processed if:

- DFSMSHsm is running in a non-SMS environment.
- The SMS-managed volume is in *initial* status (contains both SMS-and non-SMS-managed data sets while in the process of being converted to an SMS-managed volume).
- DFSMSHsm cannot determine if the specified volume is SMS-managed.

DUMP

specifies that a DFSMSdss full-volume dump be performed for a single volume. All specified subparameters process the volume and thereby override the dump classes, defined for the storage group which is associated with the volume.

Note: The DUMP subparameters DUMPClass, RETENTIONPERIOD, and STACK, are described separately.

INCREMENTAL

specifies that only those data sets that have never been backed up or have been changed since their last backup version was created are eligible for backup. If a data set is a changed data set, the frequency requirement as defined in the data set's management class must be met before DFSMSHsm backs up the data set.

TOTAL

specifies that all the data sets on the volume are to be backed up unless the data set is excluded by its management class.

Defaults: The default is INCREMENTAL.

DUMPClass: Specifying that each dump copy be targeted to a particular dump class

Explanation: DUMPClass(*class*) is an optional parameter of DUMP requesting that each dump copy be targeted to a particular dump class. At least one *class* and no more than five *classes* must be specified if DUMPClass is specified. If dump classes are not specified, they are taken from the storage group definition to which the volume belongs. If none exist for the storage group and none are specified on the command, the command fails.

Defaults: If the DUMPClass parameter is not specified, the dump classes from the storage group definition to which the volume belongs are used.

Note:

1. DUMPClass is applicable only when the DUMP parameter is used.
2. Do not specify the same dump class more than once.

- Do not specify more than one dump class if it targets cloud object storage. Creating multiple dump copies concurrently for a storage group or volume during one BACKVOL DUMP command or automatic dump session is not supported if one or more of the dump classes (copies) designate cloud object storage.

RETENTIONPERIOD: Requesting a specific retention period for the dump copy

Explanation: RETENTIONPERIOD is an optional parameter of DUMP, requesting a specific retention period for the dump copy or copies.

The list of retention periods corresponds to the list of dump classes. The dump copy targeted to the first dump class in the list is retained for the number of days specified by the first retention period in the list, and so forth.

Subparameter	Explanation
<i>days</i>	RETENTIONPERIOD(days) specifies a number of days to retain the dump copy. For <i>days</i> , substitute a decimal number from 1 to 9999 or NOLIMIT. If <i>days</i> is specified as 5, DFSMSShsm retains the dump copy for five days before expiring the dump copy.
*	RETENTIONPERIOD(*) is specified as a placeholder to denote that the retention period for the corresponding dump class specified with the DUMPCLASS parameter should be used.
NOLIMIT	RETENTIONPERIOD(NOLIMIT) indicates to DFSMSShsm to not expire the dump copy automatically.

Defaults: If fewer retention periods are listed than dump classes, the retention periods are taken from the corresponding dump class definitions.

Note:

- The BACKVOL command fails if the number of retention periods that are specified for RETENTIONPERIOD is greater than the number of classes specified for DUMPCLASS.
- RETENTIONPERIOD is applicable only if DUMPCLASS is specified.
- If DUMPCLASS is specified without RETENTIONPERIOD, the retention periods are taken from the dump classes specified.
- DFSMSShsm will not automatically delete the last and only copy of a source volume, regardless of the RETENTIONPERIOD set. To delete the dump volumes in this copy, issue the DELVOL command with the LASTCOPY option for one of the dump volumes. All of the volumes in the copy will be deleted.

STACK/MAXSTACK and MINSTACK: Specifying the maximum and minimum number of dump copies to be stacked for the specified dump classes

Explanation: STACK/MAXSTACK and MINSTACK are optional parameters of DUMP, specifying the maximum and minimum number of dump copies to stack on a dump volume in a specified dump class.

The list of stack values corresponds to the list of dump classes. A dump volume in the first specified dump class has no more dump copies than specified in the first stack value, and so on.

Dump volumes from multiple copy pools with the same dump class are stacked on the same tape volume as allowed by the values specified for MAXSTACK and MINSTACK.

Subparameter	Explanation
<i>maxv</i>	<p>STACK(<i>maxv</i>) or MAXSTACK(<i>maxv</i>) specifies the preferred maximum number of dump copies that the system should place on a tape volume for the corresponding dump class. This value overrides the value in the dump class definition. In some cases, the available MAXDUMPTASKS tasks might be under utilized if <i>maxv</i> is too large. This might occur when the number of dump copies are not large enough to fill a tape volume to the maximum number of dump copies defined for every available dump task. For <i>maxv</i>, specify a value from 1 to 255.</p> <p>If the STACK/MAXSTACK value is not specified, the value from the corresponding dump class will be used, which then might also be adjusted to be compatible with the MINSTACK value.</p>
<i>minv</i>	<p>MINSTACK(<i>minv</i>) specifies the preferred minimum number of dump copies that the system should place on a tape volume for each corresponding dump class. This value overrides the value in the dump class definitions. The minimum value is used by the system to determine the number of available MAXDUMPTASKS tasks to utilize for the dump copies. The effect is that the system might utilize more available dump tasks for the dump copies as compared to using <i>maxv</i>, but might also have less dump copies on the tape volume. The <i>minv</i> might also be used with the common queue dump group to maximize the use of available dump tasks in all the group members in the HSMplex. The system places dump copies on a tape volume until the <i>maxv</i> is reached. If a value is specified, it must not be greater than any of the <i>maxv</i> values.</p> <p>If the MINSTACK value is not specified, the value from the corresponding dump class will be used, which then might also be adjusted to be compatible with the MAXSTACK value.</p>
*	<p>STACK(*) or MAXSTACK(*) is specified as a placeholder to denote that the stack value for the corresponding dump class should be taken from that dump class definition.</p>

Defaults: If fewer stack values are listed than dump classes, stack values beyond those specified are taken from the corresponding dump class definitions.

Note:

1. The BACKVOL command fails if the number of stack values that are specified for STACK/MAXSTACK is greater than the number of dump classes that are specified for DUMPCLASS.
2. If you use BACKVOL to dump a single volume, the STACK/MAXSTACK parameter is ignored.
3. STACK/MAXSTACK is applicable only if DUMPCLASS is specified and the STACK/MAXSTACK values apply to the specified dump classes.
4. If DUMPCLASS is specified without STACK/MAXSTACK, the stack values are taken from the dump classes that are specified.
5. If DUMPCLASS or STACK/MAXSTACK are not specified, the stack values for each storage group are taken from the dump classes that are associated with that storage group.
6. For environments where the common dump queue is enabled, system affinity of dump copies and the volser order in the BACKVOL VOLUMES parameter is not applicable.
7. STACK/MAXSTACK and MINSTACK are not applicable if the specified dump class designates CLOUD.

TERMINAL: Requesting that backup or dump messages appear at the terminal

Explanation: TERMINAL is an optional parameter of VOLUME specifying that any data set backup or dump messages be sent to the system console and to either the backup activity log or the dump activity log.

Defaults: If you do not specify TERMINAL, the backup messages are sent only to the backup activity log, and the dump messages are sent to the dump activity log.

Examples of how to code the BACKVOL command for SMS-managed volumes

The following examples present different ways to code the BACKVOL command for SMS-managed volumes:

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Backing up control data sets

In this example, control data sets are backed up to DASD, using DFSMSdss as the datamover.

```
BACKVOL CONTROLDATASETS(BACKUPDEVICECATEGORY(DASD) DATAMOVER(DSS))
```

Nulling the journal

In this example, the journal is nulled and the control data sets are not backed up.

```
BACKVOL CONTROLDATASETS(NULLJOURNALONLY)
```

Backing up all the data sets on an SMS-managed volume

In this example, all the data sets on an SMS-managed volume are backed up if their management class attributes allow command backup. Because you did not specify TERMINAL, the data set backup messages go only to the backup activity log.

```
BACKVOL VOLUMES(SMS025) TOTAL
```

Backing up eligible data sets on an SMS-managed volume

In this example, the eligible data sets, as defined by their management-class attributes, are backed up. The backup versions of these data sets will reside on tape. The data set backup messages appear at the system console and in the backup activity log.

```
BACKVOL VOLUMES(VOL003) INCREMENTAL TERMINAL +  
BACKUPDEVICECATEGORY(TAPE)
```

Dumping an SMS-managed volume to a specified dump class and retention period

In this example, an SMS-managed volume, SMS13, is dumped to a specific class, EXTRA, and the dump copy is assigned a retention period of 10 days.

```
BACKVOL VOLUMES(SMS13) +  
DUMP(DUMPCCLASS(EXTRA) RETENTIONPERIOD(10))
```

Dumping an SMS-managed volume to a dump class

In this example, the volume SMS13 is dumped to a dump class called OLDCLASS. The retention period is taken from the definition of class OLDCLASS.

```
BACKVOL VOLUMES(SMS13) DUMP(DUMPCCLASS(OLDCLASS))
```

In this example, the volume SMS13 is dumped to the dump classes associated with its storage group definition.

```
BACKVOL VOLUMES(SMS13) DUMP
```

In this example, five dump copies are made of volume SMS13. The retention periods for the first three dump copies are the retention periods from the corresponding dump classes. The retention period for the fourth dump copy is 60 days. The retention period for the fifth dump class is unlimited.

```
BACKVOL VOLUMES(SMS13) +  
        DUMP(DUMPCCLASS(WK,MNTH,DLY,VITREC,SPEC) +  
            RETENTIONPERIOD(*,*,*,60,NOLIMIT))
```

Backing up all defined control data sets

The following example shows how to code the BACKVOL command to back up all defined control data sets.

```
BACKVOL CONTROLDATASETS
```

Backing up data sets in several storage groups

In this example, all the supported data sets on the volumes in the storage groups: HSMONE, HSMTWO, and HSMFOUR are to be backed up by DFSMSHsm.

```
BACKVOL STORAGEGROUP(HSMONE,HSMTWO,HSMFOUR) TOTAL
```

Dumping all volumes of a storage group to a specific dump class

In this example, DFSMSHsm dumps all volumes in storage group, SGSMALL. The dump stacking and retention options are obtained from the definition of dump class, SPECIAL.

```
BACKVOL STORAGEGROUP(SGSMALL) DUMP(DUMPCCLASS(SPECIAL))
```

Backing up data sets from one or more non-SMS-managed volumes or from all primary volumes or dumping non-SMS-managed volumes

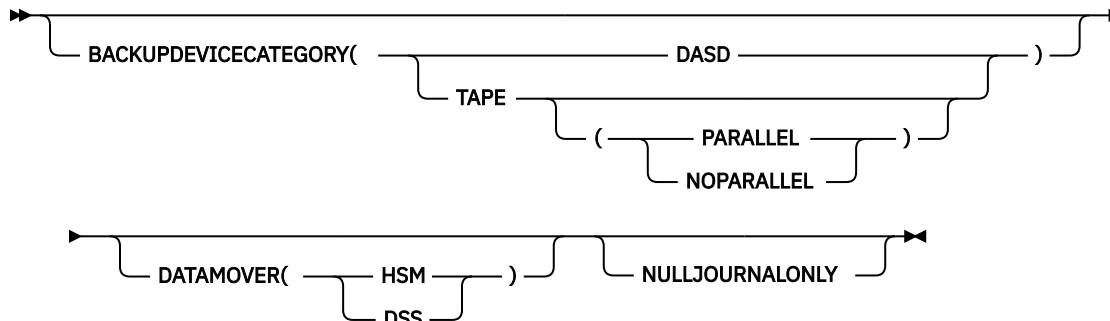

The BACKVOL command can be used to request that DFSMSHsm back up eligible data sets from specific volumes or from all primary volumes, or that it dumps all the data sets from the specified volumes. When backing up non-SMS-managed volumes, you can specify, on the command, the type of backup to be done. You can choose to back up the following:

- Data sets that have not been backed up for a specified number of days (FREQUENCY)
- Data sets that have changed since the last backup (INCREMENTAL)
- All data sets on a volume (TOTAL).

Syntax of the BACKVOL command with non-SMS-managed volumes

A: CONTROLDATASETS optional parameters

B: VOLUMES optional parameters

C: PRIMARY and VOLUMES optional parameters

D: DUMP optional parameters

Notes:

¹ The UNIT parameter is ignored if you specify the PRIMARY parameter.

Summary of parameters

The following table is a summary of the combination of parameters you can specify to back up eligible data sets, using the BACKVOL command:

Parameter	Related Parameters
BACKUPDEVICECATEGORY	None
CONTROLDATASETS	None
FREQUENCY	INCREMENTAL
INCREMENTAL	None
PRIMARY	None
TOTAL	None
TERMINAL	None
UNIT	VOLUMES(<i>volser</i>)
VOLUMES(<i>volser</i>)	UNIT (volume not managed or owned by DFSMSHsm)

The following table is a summary of the combination of parameters you can specify to dump all data sets from a volume, using the BACKVOL command:

Parameter	Related Parameters
DUMP	VOLUMES(<i>volser</i>)
DUMPClass	DUMP
RETENTIONPERIOD	DUMPClass
STACK	DUMPClass
TERMINAL	None
UNIT	VOLUMES(<i>volser</i>)
VOLUMES(<i>volser</i>)	UNIT (volume not managed or owned by DFSMSHsm)

Required parameters for non-SMS-managed volumes or all primary volumes

This topic describes the required parameters of the BACKVOL command.

CONTROLDATASETS: Specifying the control data sets to be backed up

The description of this parameter is the same in both the SMS-environment and in the non-SMS-environment, refer to [“CONTROLDATASETS: Specifying the control data sets to be backed up”](#) on page 781 for a description of this parameter.

PRIMARY and VOLUMES: Specifying the volumes to be backed up or dumped

Explanation: PRIMARY and VOLUMES(*volser*,...) are mutually exclusive, required parameters specifying whether DFSMSHsm backs up the eligible data sets on the specified volumes or all primary volumes, or whether DFSMSHsm dumps all data sets on the specified volumes.

PRIMARY specifies that DFSMSHsm back up the eligible data sets on all primary volumes, not just those with the primary-volume attribute of automatic backup.

VOLUMES(*volser*,...) specifies that DFSMSHsm is to back up the eligible data sets on the specified volumes or dump all data sets on those volumes. For *volser*, substitute the volume serial number of the volumes to be backed up or dumped. (A volume serial number appearing more than once in the list is backed up or dumped only once.)

Defaults: None.

Note:

1. A volume list can include both SMS-managed volumes and non-SMS-managed volumes.
2. If you specify the VOLUMES parameter with more than 80 volumes, DFSMSHsm processes only the first 80 volumes.
3. If DUMP is specified with DUMPCCLASS, and at least one of the specified dump classes (or the optional STACK subparameter) specifies a stacking value greater than one, DFSMSHsm attempts to stack the dumps of the volumes in the order specified.
4. All stacking to a given dump volume is done while that tape is mounted. DFSMSHsm always selects empty dump volumes as targets for DUMP.
5. When you use BACKVOL to dump one or more specific volumes, DFSMSHsm treats all volumes being dumped as having affinity to the host issuing the command which means that they are all processed on the single host where the command is submitted.

The following notes apply if you have not specified the optional parameter DUMP with the BACKVOL command:

- The FREQUENCY and INCREMENTAL parameters set up the eligibility criteria for data sets.
- You are not required to specify UNIT if you specify a volume managed or owned by DFSMSHsm. If, however, you specify a volume not managed by DFSMSHsm, you must also specify the UNIT parameter. If the list of volumes contains any not managed by DFSMSHsm, each volume must be capable of being allocated on the *unittype* specified with UNIT.
- If you request that DFSMSHsm back up more than one volume (you specified the PRIMARY parameter or the VOLUMES parameter by specifying a list of volume serial numbers), DFSMSHsm starts a separate volume backup task for each primary volume until it reaches the maximum number of backup tasks specified with the MAXBACKUPTASKS parameter of the SETSYS command.

The following notes apply only if you have specified the optional parameter DUMP with the BACKVOL command:

- The DUMP optional parameter is allowed only if you specify VOLUMES(*volser*,...), and *volser* can be for any DASD volume, including DFSMSHsm-owned volumes.
- You are not required to specify UNIT if you specify a volume managed or owned by DFSMSHsm.

Optional parameters for non-SMS-managed control data sets

This topic describes the optional parameters of the BACKVOL command.

BACKUPDEVICECATEGORY: Specifying the backup device for the control data sets and journal

The description of this parameter is the same in both the SMS-environment and in the non-SMS-environment, refer to [“BACKUPDEVICECATEGORY: Specifying the backup device for the control data sets and journal” on page 783](#) for a description of this parameter.

DATAMOVER: Specifying the type of data movement used when backing up the control data sets

The description of this parameter is the same in both the SMS-environment and in the non-SMS-environment, refer to [“DATAMOVER: Specifying the type of data movement used when backing up the control data sets” on page 783](#) for a description of this parameter.

NULLJOURNALONLY: Specifying that DFSMSHsm null the journal

The description of this parameter is the same in both the SMS-environment and in the non-SMS-environment, refer to [“NULLJOURNALONLY: Specifying that DFSMSHsm null the journal” on page 784](#) for a description of this parameter.

Optional parameters for non-SMS-managed volumes or all primary volumes

This topic describes the optional parameters of the BACKVOL command.

BACKUPDEVICECATEGORY: Specifying where the backup versions reside

Explanation: BACKUPDEVICECATEGORY is an optional parameter of PRIMARY and VOLUME specifying the type of device, tape or DASD, that receives the backup versions of the data sets when they are backed up. When using the BACKUPDEVICECATEGORY parameter, one of the following subparameters must be specified:

Subparameter	Explanation
TAPE	BACKUPDEVICECATEGORY(TAPE) specifies that the backup versions of the data sets on the volume reside on a tape daily backup volume when the data sets are backed up.
DASD	BACKUPDEVICECATEGORY(DASD) specifies that the backup versions of the data sets on the volume reside on a DASD daily backup volume when the data sets are backed up.

Defaults: If you do not specify BACKUPDEVICECATEGORY and the volume has been added with the ADDVOL command, the default is the backup device category specified in the ADDVOL command.

Note:

1. When you specify BACKUPDEVICECATEGORY, you can specify either TAPE or DASD, but not both.
2. The BACKUPDEVICECATEGORY parameter does not apply when you specify the DUMP parameter.
3. The BACKUPDEVICECATEGORY parameter will override the UNIT parameter when the specified backup device category does not match the specified unit type. For example, if the specified backup device category is DASD and the specified unit type is 3490 (tape) the volumes will be backed up to DASD.
4. If you are attempting to backup to tape, ensure that you have previously issued the SETSYS CDSVERSIONBACKUP (BACKUPDEVICECATEGORY(TAPE (UNITNAME(*unit*))) command to properly configure the CDSVERSIONBACKUP parameter table.

DUMP, INCREMENTAL, and TOTAL: Specifying which data sets are backed up

Explanation: DUMP, INCREMENTAL, and TOTAL are mutually exclusive optional parameters of the VOLUME parameter specifying which data sets are to be backed up.

DUMP

specifies that a DFSMSdss full-volume dump be performed for a single volume. All subparameters specified are used to process the volume, overriding the dump classes associated with the volume.

Note: The DUMP subparameters DUMPCCLASS, RETENTIONPERIOD, and STACK are described separately.

INCREMENTAL

specifies that only those data sets that have never been backed up or have been changed since their last backup version was created are eligible for backup. If a data set is a changed data set, the frequency requirement as defined in the data set's management class must be met before DFSMSHsm backs up the data set.

TOTAL

specifies that all the data sets on the volume or volumes are backed up by DFSMSHsm if it supports the data set organization. DFSMSHsm backs up all other data sets on the volume, except for data sets that have been excluded by an ALTERDS or HALTERDS VERSIONS(0) command, not just changed data sets that have met the frequency of backup.

Defaults: The default is INCREMENTAL.

DUMPCCLASS: Specifying that each dump copy be targeted to a particular dump class

Explanation: DUMPCCLASS(*class*) is an optional parameter of DUMP requesting that each dump copy be targeted to a particular dump class. Dump classes, *class*, must be predefined with the DUMPCCLASS optional parameter of the DEFINE command.

DUMPCCLASS *is required* unless the specified volume is a primary volume with a dump class specified for it with its ADDVOL command. At least one *class* and no more than five *classes* must be specified if DUMPCCLASS is specified.

Defaults: If the DUMPCCLASS parameter is not specified and the volume is a primary volume with DUMPCCLASS specified with its ADDVOL command, the dump classes specified with the ADDVOL command are used.

Note:

1. DUMPCCLASS is applicable only when the DUMP parameter is used.
2. Do not specify the same dump class more than once.
3. Do not specify more than one dump class if it targets cloud object storage. Creating multiple dump copies concurrently for a storage group or volume during one BACKVOL DUMP command or automatic dump session is not supported if one or more of the dump classes (copies) designate cloud object storage.

FREQUENCY: Specifying the frequency of backup for data sets

Explanation: FREQUENCY(*days*) is an optional parameter of VOLUME specifying the number of days required between backup versions of a data set. DFSMSHsm does not back up the data set unless the specified number of days has elapsed since the last back up of the data set. For *days*, substitute a decimal number from 0 to 999. For example, if *days* is specified as 5, only those data sets that have not been backed up in the last five days are eligible for backup. When you specify 0, DFSMSHsm backs up changed data sets no matter how recently they were backed up.

Defaults: If you do not specify the FREQUENCY parameter with the BACKVOL command or have not specified the FREQUENCY parameter with an ALTERDS command, the value for FREQUENCY previously specified on the SETSYS command or the DFSMSHsm default for FREQUENCY is used.

Note:

1. If you specify FREQUENCY when it does not apply, DFSMSHsm ignores it.
2. The frequency specified with this command does not override the frequency specified with the ALTERDS command; however, it overrides the frequency specified with the SETSYS command and the DFSMSHsm default. DFSMSHsm determines the frequency of backup in the following order:
 - a. ALTERDS
 - b. BACKVOL
 - c. SETSYS
 - d. DFSMSHsm default

RETENTIONPERIOD: Requesting a specific retention period for the dump copy

The description of this parameter is the same in both the SMS-environment and in the non-SMS-environment, refer to [“RETENTIONPERIOD: Requesting a specific retention period for the dump copy”](#) on page 786 for a description of this parameter.

STACK/MAXSTACK and MINSTACK: Specifying the maximum and minimum number of dump copies to be stacked for the specified dump classes

The description of this parameter is the same in both the SMS-environment and in the non-SMS-environment, refer to [“STACK/MAXSTACK and MINSTACK: Specifying the maximum and minimum number of dump copies to be stacked for the specified dump classes” on page 786](#) for a description of this parameter.

TERMINAL: Requesting that backup or dump messages appear at the terminal

The description of this parameter is the same in both the SMS-environment and in the non-SMS-environment, refer to [“TERMINAL: Requesting that backup or dump messages appear at the terminal” on page 788](#) for a description of this parameter.

UNIT: Specifying the type of device

Explanation: UNIT(*unittype*) is an optional parameter of PRIMARY and VOLUME specifying the type of unit where the volume being backed up can be allocated.

For *unittype*, substitute the type of unit where the volume can be allocated.

The following are valid types of DASD units:

- 3380
- 3390
- 9345

Defaults: None.

Note:

1. You need not specify UNIT if you specify a volume that DFSMSHsm manages or owns. If, however, you specify a volume DFSMSHsm does not manage, you must also specify the UNIT parameter.
2. The BACKUPDEVICECATEGORY parameter will override the UNIT parameter when the specified backup device category does not match the specified unit type. For example, if the specified backup device category is DASD and the specified unit type is 3490 (tape) the volumes will be backed up to DASD.
3. If you specify the UNIT parameter for a volume that DFSMSHsm owns or manages, DFSMSHsm uses the specified unit type rather than the one in its volume record.

Examples of how to code the BACKVOL command for non-SMS-managed volumes

The following examples present different ways to code the BACKVOL command for non-SMS-managed volumes:

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Backing up control data sets

In this example, control data sets are backed up to DASD, using DFSMSdss as the datamover.

```
BACKVOL CONTROLDATASETS(BACKUPDEVICECATEGORY(DASD) DATAMOVER(DSS))
```

The following example shows how to code the BACKVOL command to back up all defined control data sets according to options specified by the SETSYS CDSVERSIONBACKUP parameter or its defaults.

```
BACKVOL CONTROLDATASETS
```

Nulling the journal

In this example, the journal is nulled and the control data sets are not backed up.

```
BACKVOL CONTROLDATASETS(NULLJOURNALONLY)
```

Backing up all the data sets on a volume

In this example, all the data sets on a volume not managed by DFSMSHsm are backed up. Because you have not specified **TERMINAL**, the data set backup messages go only to the backup activity log.

```
BACKVOL VOLUMES(PUB025) UNIT(3390) TOTAL
```

Backing up eligible data sets on DFSMSHsm-managed volumes

In this example, only two kinds of data sets are backed up:

- Data sets that have never been backed up.
- Data sets that have been changed since the last backup version was created and that meet the specified frequency of two days since the last backup version was created.

The backup versions of these data sets will reside on tape. The data set backup messages appear at the console and in the backup activity log.

```
BACKVOL VOLUMES(VOL003,VOL004,VOL005) INCREMENTAL FREQUENCY(2) +
        BACKUPDEVICECATEGORY(TAPE) TERMINAL
```

Dumping a primary volume to a dump class

In this example, a primary volume, PRIM13, is dumped to a specific class, **EXTRA**, and assigns the dump copy a retention period of 10 days.

```
BACKVOL VOLUMES(PRIM13) +
        DUMP(DUMPCLASS(EXTRA) RETENTIONPERIOD(10))
```

In this example, the volume PRIM13 is dumped to a dump class called **OLDCLASS**. The retention period is the retention period of **OLDCLASS**.

```
BACKVOL VOLUMES(PRIM13) DUMP(DUMPCLASS(OLDCLASS))
```

In this example, the volume PRIM13 is a primary volume dumped to the classes associated with it by the previous **ADDVOL** command with the **AUTODUMP** parameter.

```
ADDVOL PRIM13 PRIMARY(AD(WEEKLY,MONTHLY)) +
        UNIT(3390)
```

```
BACKVOL VOLUMES(PRIM13) DUMP
```

In this example, five dump copies are made of volume PRIM13. The retention periods for the first three dump copies are the retention periods for the corresponding dump classes. The retention period for the fourth dump copy is 60 days. The fifth dump class has an unlimited retention period.

```
BACKVOL VOLUMES(PRIM13) +
        DUMP(DUMPCLASS(WK,MNTH,DLY,VITREC,SPEC) +
        RETENTIONPERIOD(*,*,*,60,NOLIMIT))
```

Chapter 37. BDELETE command: Deleting backup versions of a data set

The BDELETE command deletes all the backup versions of a specific data set or UNIX file or deletes specific backup versions by version number or date. You can specify multiple data set or UNIX file names with the BDELETE command.

If you have cataloged and uncataloged data sets with the same name, DFSMSHsm deletes the backup versions of either the cataloged or uncataloged data sets, not the backup versions of both. See note “2” on page 799.

To delete retired versions, you must use the BDELETE command and must specify the version number or date and time of the retired version.

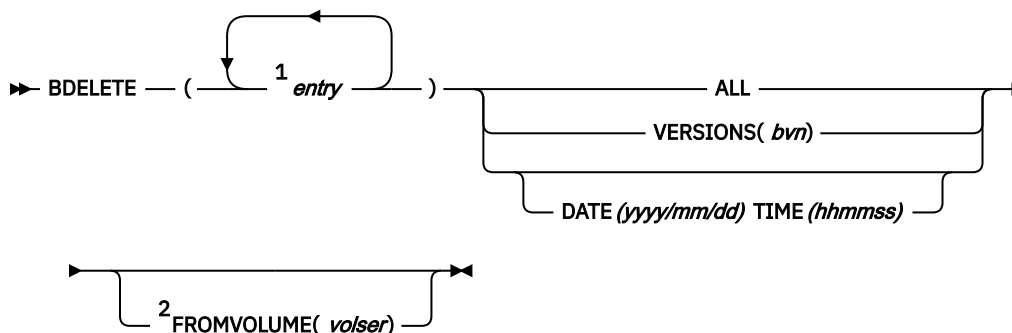

To delete all backup versions of a data set or UNIX file, both active and retained, you must use the ALL parameter on the BDELETE command.

If all backup versions of a data set or UNIX file are deleted, parameters previously specified with the ALTERDS command are no longer in effect.

When the BDELETE command is submitted from a batch environment, no messages indicating the success of this function are issued. You can use the LIST command to obtain information on existing backup versions.

When backup versions of a UNIX file are deleted, the last backup date in the UNIX file metadata is set to the most recent version in the DFSMSHsm inventory. If all backup versions are deleted, the last backup date is reset to January 1, 1970 UTC.

Syntax of the BDELETE command

Notes:

¹ *entry* may be either *dsname* or '*pathname*'.

² The FROMVOLUME parameter does not apply to SMS-managed data sets, cataloged data sets, or UNIX files.

Required parameters of the BDELETE command

This topic describes the required parameters of the BDELETE command.

dsname: Specifying the name of the data set whose backup versions are to be deleted

Explanation: (*dsname*) is a required positional parameter specifying the name of the data set or list of data set names whose backup versions you want to delete. Each data set name you specify must be fully

qualified. For *dsname*, substitute the fully qualified name or list of names of the data sets whose backup versions are to be deleted.

Defaults: None.

Note: Because *dsname* is a required positional parameter, you must specify it immediately after BDELETE.

pathname: Specifying the name of the UNIX file whose backup versions are to be deleted

Explanation: (*'pathname'*) is a required positional parameter specifying the name of the UNIX file or list of UNIX file names whose backup versions that you want to delete. UNIX path names must be an absolute path, starting with the forward slash character, enclosed in single quotation marks. If the UNIX file name has a single quotation mark character as part of the file name, specify two single quotation marks in the *'pathname'* instead of one.

Some special characters that are allowed by the UNIX cannot be processed by the HBDELETE command. Instead, the UNIX shell command, *hbdelete*, can be used to delete backup versions of files with these characters by using the backslash character. For more information, see [unix-hdel](#) in *z/OS DFSMSHsm Managing Your Own Data*. Note the *-o* option for the UNIX *hbdelete* program is equivalent to issuing the BDELETE storage administrator command.

Defaults: None.

Notes:

1. Because *'pathname'* is a required positional parameter, you must specify it immediately after BDELETE.
2. A mixture of UNIX file names and data set names can be specified on one BDELETE request.

ALL, DATE and TIME, and VERSIONS: Specifying which backup versions to delete

Explanation: ALL, DATE and TIME, and VERSIONS are mutually exclusive parameters that specify which backup versions are to be deleted. Specify one (and only one) of the following:

ALL: Deleting all backup versions

Explanation: ALL specifies that all active and retained backup versions of a data set or UNIX file are to be deleted.

Defaults: None.

Note: If you want to delete a retired version, you must specify either VERSIONS or DATE and TIME. A retired version is the backup version DFSMSHsm creates before it scratches a data set during data set retirement. DFSMSHsm does not automatically delete retired versions.

DATE and TIME: Specifying the date and time of the backup version to delete

Explanation: DATE(*yyyy/mm/dd*) is used together to delete any active or retained backup version. They must be used to delete NEWNAME backup copies. For *yyyy/mm/dd*, substitute the date when the backup version to be deleted was created. For *hhmmss*, substitute the time when the backup version to be deleted was created.

DATE and TIME apply to SMS and non-SMS-managed data sets and UNIX files.

Defaults: None.

Restrictions

- DATE and TIME must be specified together.

- FROMVOLUME is mutually exclusive with DATE and TIME.

VERSIONS: Specifying the backup versions to delete

Explanation: VERSIONS(*bvn*) specifies which of the active backup versions of a data set or UNIX file to delete. You can specify multiple version numbers. For *bvn*, substitute the one-to-three-digit decimal number of a particular backup version to be deleted. You can get the backup version number by issuing a LIST command and specifying the data set or UNIX file name and the BACKUPCONTROLDATASET parameter.

A list of backup version numbers applies to the backup versions of any data sets or UNIX file you specify. For example, assume that you specify the following command:

```
BDELETE (VLS6492.PQR.CLIST, VLS6493.STU.CLIST) +
VERSIONS(115,118,120)
```

DFSMSHsm deletes backup version numbers 115, 118, and 120 for data sets VLS6492.PQR.CLIST and VLS6493.STU.CLIST.

This command fails if VERSIONS(0) is specified. Instead, DATE and TIME must be used to uniquely identify a retained backup copy or a backup copy that was created with the NEWNAME keyword.

Note:

1. If you want to delete a retired version, you must specify VERSIONS or DATE and TIME. A retired version is the backup version DFSMSHsm creates before it scratches a data set during data set retirement. DFSMSHsm does not automatically delete retired versions.
2. You cannot use VERSIONS to delete an individual retained backup version.

Defaults: None.

Optional parameters of the BDELETE command

This topic describes the optional parameters of the BDELETE command.

FROMVOLUME: Specifying the volume where the data set resided when the backup versions were created

Explanation: FROMVOLUME(*volser*) is an optional parameter specifying the volume where the uncataloged data set or data sets resided when DFSMSHsm backed up the data sets. You specify this parameter only if the data set was uncataloged. For *volser*, substitute the serial number of the volume where the uncataloged data set or data sets resided when the backup versions were created.

Defaults: None.

Note:

1. The data sets you specified should have been either all cataloged or all uncataloged when DFSMSHsm created the backup versions. If the data sets were all uncataloged, they should have been on the same volume. If the backup versions were not created from the same volume, the backup versions of the data sets are not deleted.
2. If you have cataloged and uncataloged data sets with the same name, DFSMSHsm deletes the backup versions of the cataloged data set unless you specify the FROMVOLUME parameter. If you specify the FROMVOLUME parameter, only the backup version of the uncataloged data set is deleted.
3. FROMVOLUME does not apply to SMS-managed data sets.
4. FROMVOLUME does not apply to cataloged data sets.

Examples of how to code the BDELETE command

The following examples present different ways to code the BDELETE command:

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Deleting specific backup versions of two SMS-managed data sets

In this example, the specified backup versions of the two SMS-managed data sets are to be deleted.

```
BDELETE AMS6607.PDS.CLIST VERSIONS(3,8)
BDELETE AMS6609.PDS.CLIST VERSIONS(16,17)
```

Deleting all backup versions of two cataloged data sets

In this example, all the backup versions of the two data sets are deleted if all the data sets except for the retired version have been cataloged prior to backup.

```
BDELETE (AMS6607.A.CLIST, AMS6608.B.CLIST) ALL
```

Deleting particular backup versions of an uncataloged data set

In this example, backup versions numbered 9, 11, 13, and 15 of an uncataloged data set backed up from volume VOL001 are deleted.

```
BDELETE AMS6607.UNC.CLIST FROMVOLUME(VOL001) +
VERSIONS(9,11,13,15)
```

Chapter 38. CANCEL command: Canceling a queued or active DFSMSHsm request

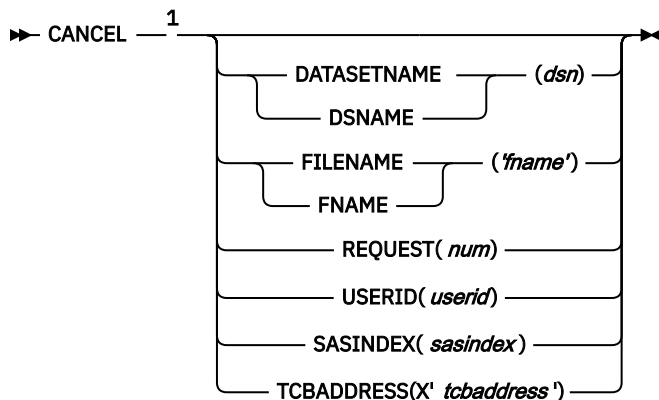

The CANCEL command cancels an active or queued DFSMSHsm data movement request. You can cancel a specific request, all requests for a particular data set or UNIX file, or all requests for a particular user.

Active requests can be canceled by using either the SASINDEX or TCBADDRESS parameters. Queued requests can be canceled by using the DATASETNAME, FILENAME, REQUEST, or USERID parameters.

Note:

1. The CANCEL command can be controlled using a RACF FACILITY class.
2. The CANCEL and QUERY commands have the highest processing priority. Therefore, the CANCEL and QUERY commands cannot be canceled.
3. In a CVQ environment, recall requests can be canceled only from the host that originated the request.
4. Canceling requests running in the CDQ or CVQ will complete for queued requests that originate on the host that issues the CANCEL command for a request number or user ID that matches the parameters on the CANCEL command. Canceling active requests with the TCBADDRESS must be done on the host that is processing the request. A single CANCEL by USERID will affect requests in both common queues. You can use the QUERY COMMONQUEUE(RECOVER) command or QUERY COMMONQUEUE(DUMP) command to determine the requests running in their respective common queues. These commands will identify the host ID of the originating host for the request and determines the host from which a corresponding CANCEL should be issued. For a host that is connected to a CDQ or CVQ, and is *not* the master scheduler, the local queue, and the master scheduler member group queue are searched. For a host that is the master scheduler, only the local queue is searched.

Syntax of the CANCEL command

Notes:

- ¹ The CANCEL command has no required parameters. Issuing the CANCEL command with no parameters results in no action taken and no output.

Related information

[“Syntax of the CANCEL command” on page 801](#)

Optional parameters of the CANCEL command

This topic describes the optional parameters of the CANCEL command.

DATASETNAME: Canceling a queued request by data set name

Explanation: DATASETNAME is a mutually exclusive, optional parameter, specifying which queued DFSMSHsm requests to cancel. All requests for the specified data set name will be canceled.

The following variable is required when using the DATASETNAME parameter:

dsn

Is the fully-qualified data set name for which all requests should be canceled.

Defaults: None.

FILENAME: Canceling a queued request by UNIX file name

Explanation: FILENAME is a mutually exclusive, optional parameter, specifying which queued DFSMSHsm requests to cancel. All requests for the specified UNIX file name will be canceled.

The following variable is required when if you are using the FILENAME parameter. If the CANCEL command is issued from the console, *fname* will need to be enclosed in single quotation marks.

fname

For *fname*, substitute the absolute path and file name for the file for which you want to cancel requests.

If the CANCEL command is issued from the console, *fname* will need to be enclosed in single quotation marks.

Defaults: None.

REQUEST: Canceling a queued request by request number

Explanation: REQUEST is a mutually exclusive, optional parameter, specifying which queued DFSMSHsm request to cancel. The request corresponding to the specified request number will be canceled.

The following variable is required when using the REQUEST parameter:

num

Is the DFSMSHsm request number of the request you want to cancel. Use the QUERY REQUEST command to determine the request number of a queued request.

REQUEST(*num*) can also be used to cancel an entire group of file backups that were requested via a partial path or UNIX file name.

Note:

1. If you issue the CANCEL REQUEST command for requests created by the following commands, all queued requests associated with the specified request number are canceled. This is because these commands spin-off multiple requests with the same request number.
 - A single volume recovery from incrementals
 - BACKVOL volumes list
 - BACKVOL STORAGEGROUP
 - FRBACKUP DUMP
 - FRBACKUP DUMPPONLY
 - FRRECOV COPYPOOL FROMDUMP
 - FRRECOV DSNNAME

Defaults: None.

USERID: Canceling a queued request by user ID

Explanation: USERID is a mutually exclusive, optional parameter, specifying which queued DFSMSHsm requests to cancel. All requests by the specified user ID will be canceled.

The following variable is required when using the USERID parameter:

userid

Is an 8-character alphanumeric user ID for which all requests can be canceled.

Defaults: None.

SASINDEX: Canceling an active request by ABARS secondary address space

Explanation: SASINDEX is a mutually exclusive, optional parameter, specifying which active DFSMSHsm request to cancel. The request corresponding to the specified ABARS secondary address space will be canceled.

The following variable is required when using the SASINDEX parameter:

sasindex

Is the integer value between 1 and 64 returned by the QUERY ACTIVE(TCBADDRESS) command for which the corresponding request should be canceled.

Defaults: None.

TCBADDRESS: Canceling an active request by TCB address

Explanation: TCBADDRESS is a mutually exclusive, optional parameter, specifying which active DFSMSHsm request to cancel. The request corresponding to the specified TCB address will be canceled.

The following variable is required when using the TCBADDRESS parameter:

X'tcbaddress'

Is the 8 digit hexadecimal value returned by the QUERY ACTIVE(TCBADDRESS) command for which the corresponding request should be canceled.

Note: This command should be used with caution.

CANCEL TCBADDR(*nnnnnn*) is not like the CANCEL USERID or CANCEL REQ commands. This command cancels a task that is doing work where a user suspects DFSMSHsm is hung. It should only be used if a problem is suspected and a user does not want to have to cancel DFSMSHsm.

Users canceling a TCBADDR must remember that they are canceling a DFSMSHsm task that is actively doing work. The task is abnormally terminated with an ABEND7D0 which will then cause abnormal termination routines to get control. Cascading errors after the ABEND 7D0 may occur.

Users should issue a HOLD for ALL functions prior to canceling the task. The HOLD will prevent other tasks from being started until the cancel has completed.

Defaults: None.

Examples of how to code the CANCEL command

The following examples present how to code the CANCEL command:

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Canceling all requests for a specified user ID

In this example, all requests submitted by the specified *userid* are canceled.

```
CANCEL USERID(L541563)
```

Canceling all requests issued from the system console

In this example, all requests submitted from the system console are canceled. Note that ****OPER*** in the example below is a pseudo *userid* representing the system operator.

```
CANCEL USERID(**0PER*)
```

Canceling all requests for a specified data set name

In this example, all requests for a specified data set name are canceled.

```
CANCEL DATASETNAME(L541563.PSU.N.F230EP03.DSET1)
```

Canceling a particular request

In this example, request number 0015 is canceled.

```
CANCEL REQUEST(15)
```

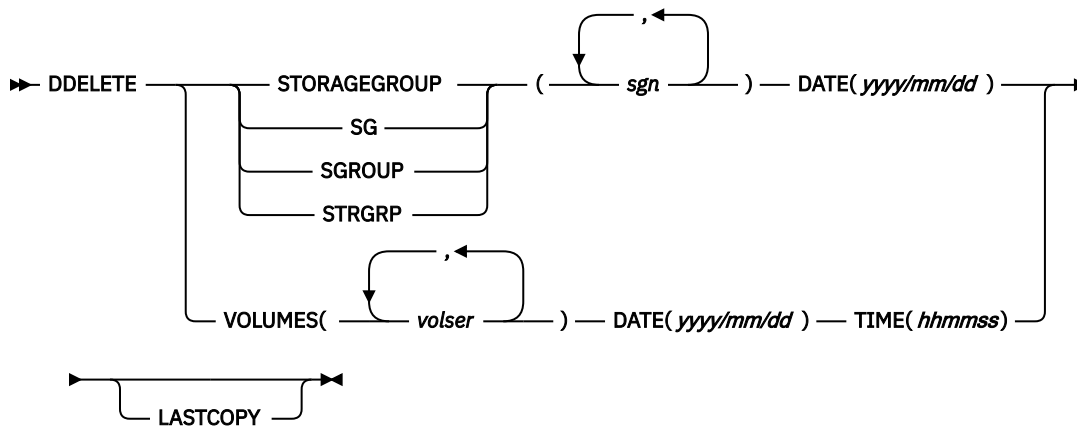

Chapter 39. DDELETE Command – Deleting cloud dump copies

The DDELETE command deletes dump copies residing in the cloud object storage that are associated with the specified storage groups or volumes. The command is intended for occasional cloud dump copy deletion and is not designed for bulk deletion. Use of automatic dump expiration to manage dumps and empty dump container deletion is recommended.

Note:

- DDELETE cannot be used to delete TAPE dump copies or copy pool dump copies. Use the FRDELETE command to delete copy pool dump copies.
- DDELETE does not delete the only valid dump copy of a volume unless the LASTCOPY parameter is specified.
- Do not issue DDELETE command when automatic dump is active.

Syntax of the DDELETE command

Required parameters of the DDELETE command

This topic describes the required parameter of the DDELETE command. The required STORAGEGROUP and VOLUMES parameters are mutually exclusive.

STORAGEGROUP: Specifying the storage group whose dump copies are to be deleted

Explanation: STORAGEGROUP(*sgn*,...) is a required parameter specifying that DFSMSHsm deletes the associated dump copies residing in the cloud object storage. For *sgn*, substitute the names of the storage groups containing volumes from where the dump copies are created. (A storage group name appearing more than one time in the list is a processed once.)

Defaults: None.

Notes:

1. If DFSMSHsm is running in a non-SMS environment, a message is issued, and the dump copies are not processed.
2. If you specify STORAGEGROUP without *sgn*, the command fails. If you specify STORAGEGROUP with more than 30 storage groups, the first 30 are processed.

3. If a batch job issues the WAIT DDELETE STORAGEGROUP command, DFSMSHsm processes the command, but does not ensure that the action completes before returning control to the caller. As a result, it is possible for the batch job to complete with return code zero before all of the dump copies are processed.

VOLUMES: Specifying the volumes whose dump copies are to be deleted

Explanation: VOLUMES(*volser*,...) is a required parameter specifying that DFSMSHsm is to delete the associated dump copies that reside in the cloud object storage. For *volser*, substitute the serial number of the volumes from which the dump copies were created. (A volume serial number appearing more than once in the list is processed only once.)

Defaults: None.

Notes:

1. A volume list can include both SMS-managed volumes and non-SMS-managed volumes.
2. If you specify the VOLUMES parameter with more than 80 volumes, DFSMSHsm processes only the first 80 volumes.

DATE and TIME: Specifying the particular cloud dump copy to delete

Explanation: DATE and TIME(*yyyy/mm/dd*) are used to delete the cloud dump copies of specified STORAGEGROUP volumes. DATE(*yyyy/mm/dd*) and TIME(*hhmmss*) are used together to delete the cloud dump copies of specified VOLUMES.

DATE(*yyyy/mm/dd*)

For *yyyy/mm/dd*, substitute the date when the dump copy to be deleted is created. The oldest generation that is made on the date is deleted.

TIME(*hhmmss*)

For *hhmmss*, substitute the time when the dump copy to be deleted is created. DATE and TIME apply to SMS and non-SMS managed volumes.

Defaults: None.

Restrictions: DATE and TIME are required when VOLUMES parameter is specified. TIME cannot be specified when STORAGEGROUP parameter is specified.

Usage notes: The DATE and TIME parameter formats are different from the formats in the dump copy name. The LIST PRIMARYVOLUME(*volser*) ALLDUMPS BCDS command can be used to display information on dump copies associated with the specified source volume. The DUMPED DATE *yy/mm/dd* and TIME *hh:mm:ss* in the LIST output can be used to determine the date and time values to use in the DDELETE command.

Related reading: For more information about LIST PRIMARYVOLUME ALLDUMPS BCDS command, see Chapter 76 Using LIST command.

Optional parameters of the DDELETE command

This topic describes the optional parameter of the DDELETE command.

LASTCOPY: Invalidating the only valid dump copy of a source volume

Explanation: LASTCOPY is an optional parameter that must be specified to delete a dump copy that is part of the only valid dump copy of a source volume. LASTCOPY is ignored if it is not part of the only copy.

Defaults: None.

Examples of how to code the DDELETE command

The following examples present different ways to code the DDELETE command:

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Deleting dump copies of volumes in a storage group

In this example, DFSMSHsm processes dump copies of volumes in the specified storage group. DFSMSHsm attempts to delete the oldest dump copy made on the specified date for the volumes in the storage group.

```
DDELETE STORAGEGROUP(sg1) DATE(2021/10/26)
```

Deleting a dump copy of a specified volume

In this example, DFSMSHsm processes dump copies of the specified volume. DFSMSHsm attempts to delete the dump copy made on the specified date and time. LASTCOPY allows DFSMSHsm to delete the only valid dump copy of a source volume.

```
DDELETE VOLUME(src001) DATE(2021/10/26) TIME(020041) LASTCOPY
```

Chapter 40. DEFINE command: Defining control structures for use by DFSMSHsm

The DEFINE command allows you to specify the following control structures that are used by DFSMSHsm:

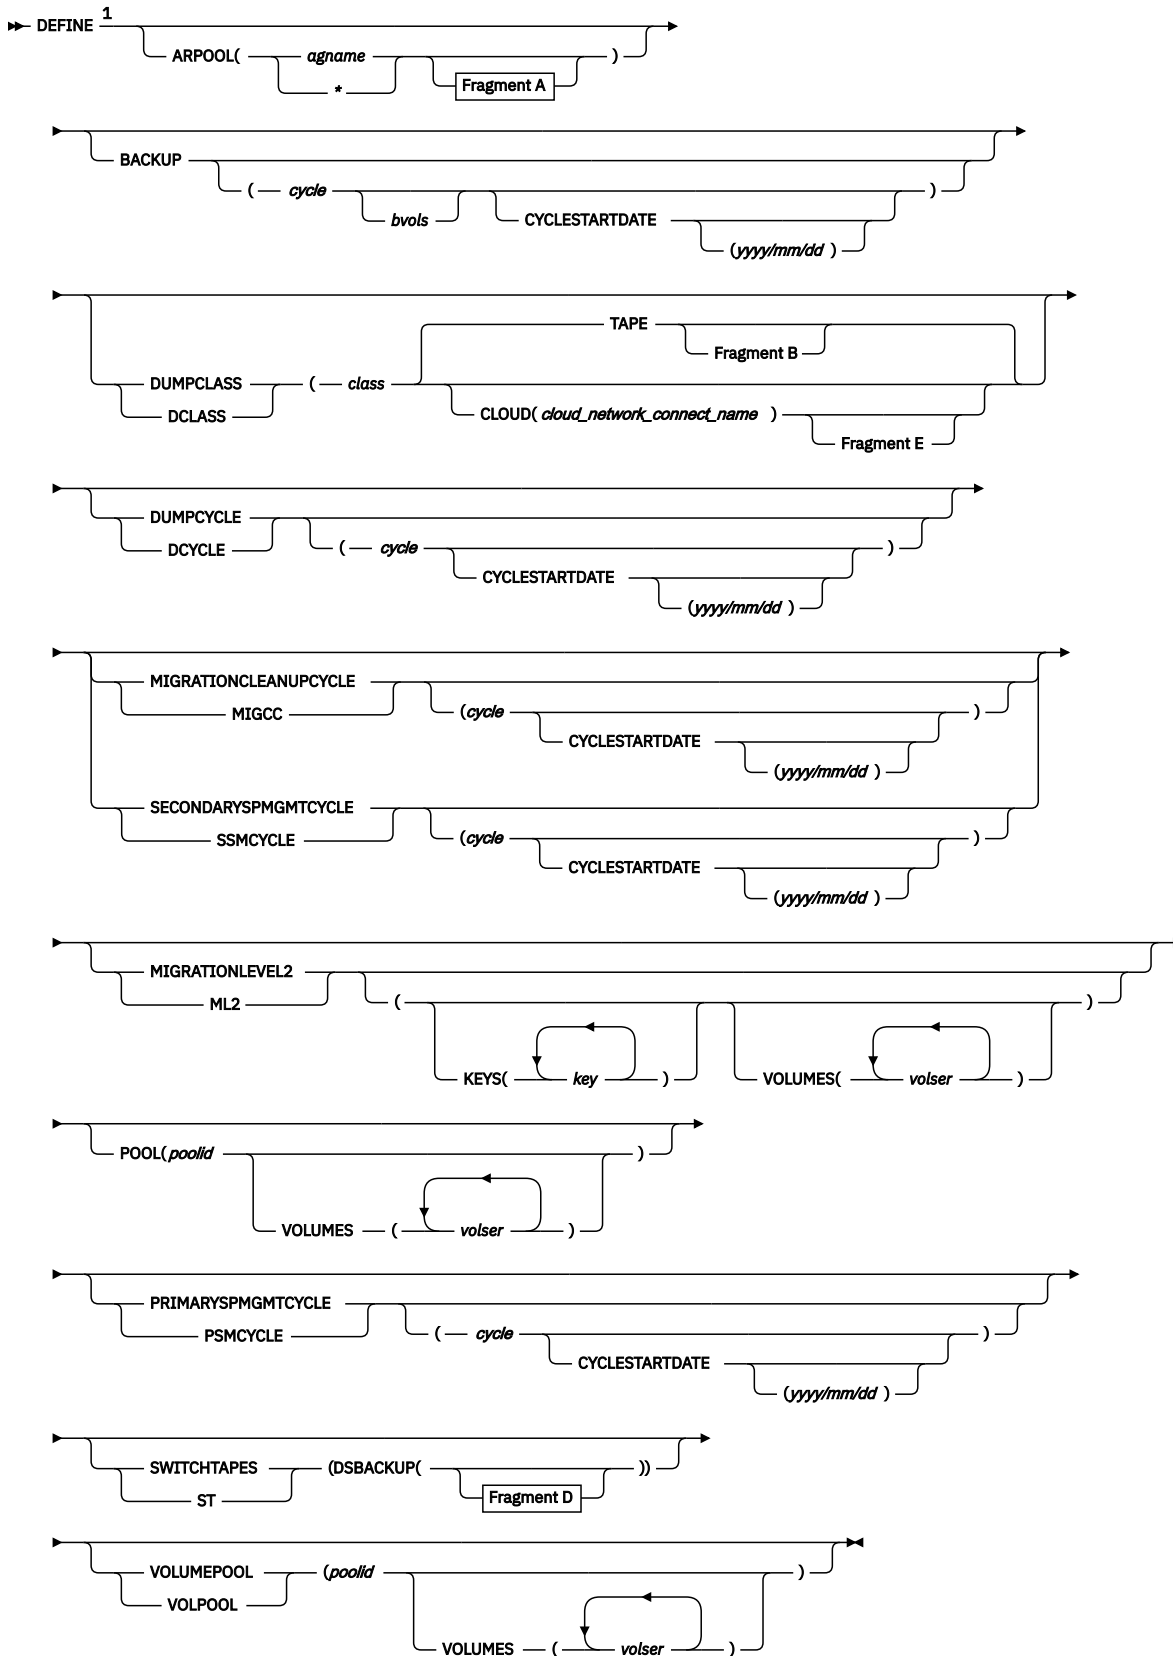

- Backup cycle, start date for the backup cycle, and the number of daily backup volumes to be used for each day in the backup cycle
- Dump class attributes
- Dump cycle and start date for the dump cycle
- Automatic primary space management cycle
- Automatic secondary space management cycle
- Key ranges for DASD migration level 2 volumes
- Pool of volumes to which non-SMS-managed data sets with the same set of initial characters are recalled
- Pool of volumes, that together can be used as a target for recalling a data set migrated from one of the volumes
- Pool of volumes to which backed-up aggregated data sets will be restored during aggregate recovery
- When to release a data set backup tape that is mounted to process data set backup commands and the status of the released tape.

When you use JES3, you must use the ADDVOL command to add primary volumes to DFSMSHsm before you can specify the volumes with the POOL or the VOLUMEPOOL parameter of the DEFINE command.

If an SMS-managed volume is specified as part of a data set pool, a message is issued indicating that the volume has not been added to the data set pool. Processing continues for the DEFINE command. If, however, only SMS-managed volumes are specified for the definition of the data set pool, the data set pool definition is rejected, and the DEFINE command fails.

With the exception of the ARPOOL, POOL and VOLUMEPOOL parameters, you do not have to redefine any optional parameters each time you start DFSMSHsm.

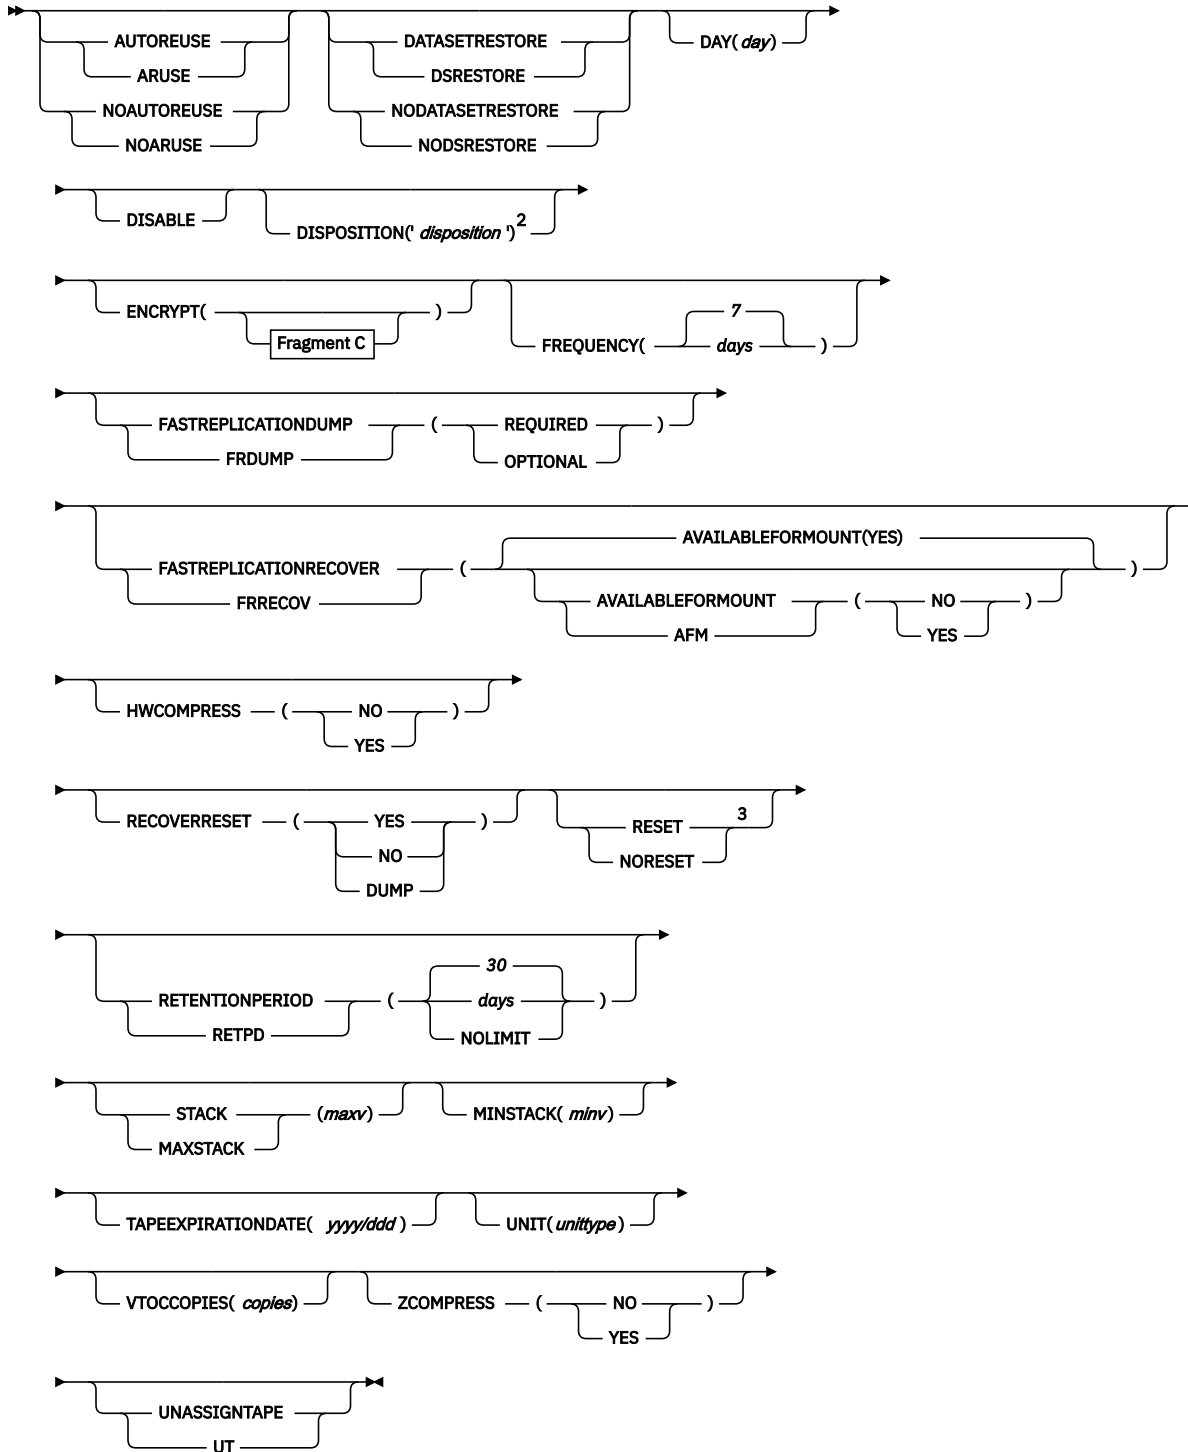

Syntax of the DEFINE command

A: ARPOOL optional parameters

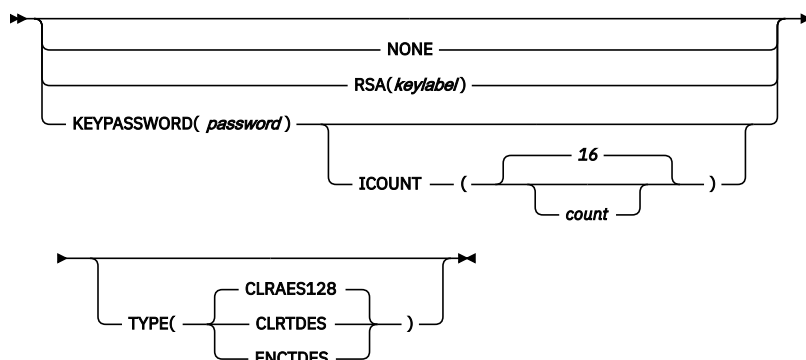

B: DUMPCCLASS optional parameters

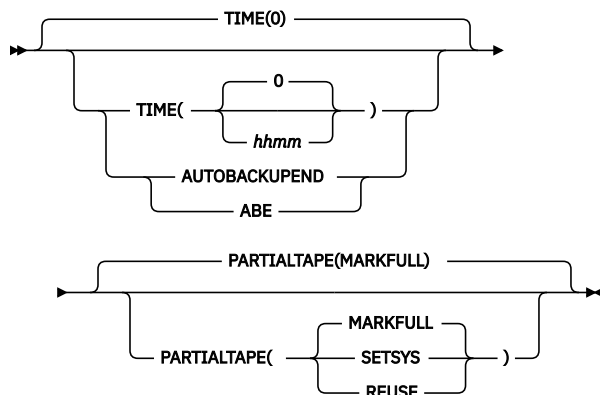

C: ENCRYPT optional parameters

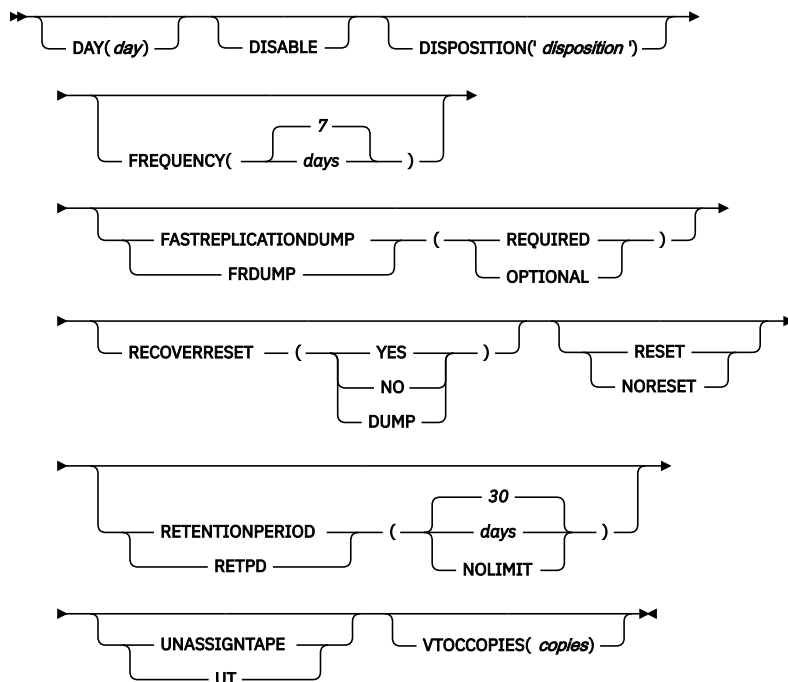

DEFINE command for DFSMSHsm

D: SWITCHTAPES optional parameters

E: DUMPCCLASS optional parameters with CLOUD parameter specified

Notes:

- ¹ You must specify at least one parameter with each DEFINE command.
- ² The single quotation marks (' ') are required if *disposition* is more than one word or if it contains a special character.
- ³ Do not specify the RESET parameter with the FASTREPLICATIONDUMP parameter because the RESET parameter does not apply to copy pool processing.

Optional parameters of the DEFINE command

This topic describes the optional parameters of the DEFINE command.

ARPOOL: Identifying the volumes for aggregate recovery

Explanation: **ARPOOL** is an optional parameter specifying a pool of volumes to be used as target volumes during an aggregate recovery.

Subparameter	Explanation
<i>agname</i>	ARPOOL(<i>agname</i>) specifies the name of the aggregate group. For <i>agname</i> substitute an aggregate group name that has been defined. The defined pool will be used for recovery of that aggregate group's data sets. If no <i>agname</i> is specified, the command fails.
*	ARPOOL(*) specifies that the volumes are assigned to a general pool of aggregate recovery volumes. The general pool of volumes is used when recovering an aggregate group that does not have a specific ARPOOL defined.

You can use the following optional subparameters with the ARPOOL parameter.

Subparameter	Explanation
ALL	ALL specifies that all currently mounted ADDVOL ML1 and primary volumes be defined as the respective volume pools for aggregate recovery. Specifying the ALL parameter is equivalent to specifying the LOVOLS(*) and ML1VOLS(*) parameters. ALL is mutually exclusive with the LOVOLS and ML1VOLS parameters.
LOVOLS	LOVOLS(<i>volser</i> ...) specifies the list of volumes used as target volumes during recovery of nonmigrated non-SMS-managed data sets. If you specify a parameter of LOVOLS(*), all currently mounted ADDVOL primary volumes (up to 59) will be used as the primary volume pool for aggregate recovery. LOVOLS is mutually exclusive with the ALL subparameter. You can use LOVOLS with ML1VOLS.
ML1VOLS	ML1VOLS(<i>volser</i> ...) specifies the list of volumes as target volumes during recovery of migrated data sets to ML1 volumes. If you specify a parameter of ML1VOLS(*), all currently mounted ADDVOL ML1 volumes will be used as the ML1 volume pool for aggregate recovery. ML1VOLS is mutually exclusive with the ALL subparameter. You can use ML1VOLS with LOVOLS.

Defaults: None.

Note:

1. If the DEFINE ARPOOL is issued without the ALL, ML1VOLS, and LOVOLS parameters, the aggregate recovery pool specified by *agname* is deleted. If an aggregate group name of * is issued without the ALL, M1VOLS, and LOVOLS parameters, the general pool of aggregate recovery volumes is deleted.
2. If a DEFINE ARPOOL command has not been issued when an ARECOVER command is issued, DFSMSHsm uses all currently mounted ADDVOL primary and ML1 volumes as a temporary ARPOOL.
3. The LOVOLS in an ARPOOL are used to recover non-SMS-managed data sets. In an SMS environment, allocation is directed by the ACS routines. LOVOLS are used only in an SMS environment if the ACS routines do not direct allocation to any other volume.
4. You cannot define the same volume as both LOVOLS and ML1VOLS within a pool or between pools.

5. You cannot define SMS-managed volumes to an ARPOOL.
6. A volume previously added to DFSMSHsm with the PRIMARY parameter of the ADDVOL command can subsequently be defined to the ARPOOL only by using the LOVOLS optional parameter.
7. A volume previously added to DFSMSHsm with the ML1 parameter of the ADDVOL command can subsequently be defined to the ARPOOL only by using the ML1VOLS optional parameter.
8. Since the DEFINE ARPOOL command is only in effect for the duration of DFSMSHsm startup, it is recommended that you add this command to the DFSMSHsm parmlib member (ARCCMDxx) on the system that is the target of the aggregate recovery.
9. Do not allow the DEFINE ARPOOL to default to the current ADDVOL volumes for all aggregates. If you allow this, all aggregate recoveries will choose the same volume as target volumes, causing contention for those volumes. To reduce volume contention and to improve performance, it is more beneficial to define a unique set of volumes to each aggregate being recovered, especially if more than 1 ABARS address space is active simultaneously.

BACKUP: Specifying the backup cycle

Explanation: **BACKUP** is an optional parameter specifying the days in a backup cycle when automatic backup is done and the number of backup volumes DFSMSHsm uses each day that volume backup runs.

BACKUP(*cycle*): For *cycle*, substitute a string of alphabetic Ys and Ns. Each Y represents a day in the cycle when you want automatic backup done and each N represents a day in the cycle when you do not want automatic backup done. You can represent up to 31 days with the Ys and Ns. When you specify BACKUP, the current day is the first day of a cycle unless you specify the cycle start date.

BACKUP(*cycle bvol*s): For *bvol*s, substitute a decimal number from 1 to 9999 to represent the number of DASD backup volumes DFSMSHsm assigns to a given day in the backup cycle before initiating spill or cleanup processing on full DASD daily backup volumes. This value is called the *daily limit*.

CYCLESTARTDATE can be used with this parameter and is listed alphabetically after this discussion.

Defaults: If you specify BACKUP without *cycle*, the backup cycle defaults to a seven-day cycle with automatic backup every day. If you do not specify a minimum number of backup volumes with *bvol*, the number defaults to one.

Note:

1. You must specify BACKUP if you want to use DFSMSHsm backup.
2. For DASD backup, ensure that the number of backup cycle days is greater than the number of SETSYS VERSIONS. (For example, if you specify SETSYS VERSIONS(3), then BACKUP cycle days must be 4 or greater.)

CYCLESTARTDATE: Specifying the start date of a cycle

Explanation: **CYCLESTARTDATE** is an optional subparameter specifying the start date or reset date of a cycle. It can be used with the following parameters:

- DEFINE BACKUP
- DEFINE DUMPCYCLE
- DEFINE MIGRATIONCLEANUPCYCLE
- DEFINE PRIMARYSPMGMTCYCLE
- DEFINE SECONDARYSPMGMTCYCLE

A leading zero is not required for a one-digit month or day. For a start date, specify *yyyy/mm/dd*.

Defaults: If CYCLESTARTDATE is specified without a start date or if CYCLESTARTDATE is not specified at all, then:

- If a date is not already stored, DFSMSHsm sets the start date to the current date.

- Or, if a date is already stored and the cycle length is changed, DFSMSHsm sets the start date to the current date.
- Or, if a date is already stored and the cycle length is unchanged, DFSMSHsm does not change the cycle start date.

Note:

1. The cycle start date is saved between DFSMSHsm startups.
2. The start date specified with the CYCLESTARTDATE parameter cannot be a date in the future. The date must be a date prior to or equal to the date when the DEFINE command is issued.
3. Understanding the difference between cycle days and calendar days is important. The first cycle day, DAY 1, begins at the start time of the function. The second cycle day, DAY 2, begins when this start time has again been reached, regardless of when the new calendar day begins. Third and subsequent days follow the same pattern. For instance, if the cycle start time for a function is 1100 (11 a.m.) on Monday, DAY 1 is from 11 a.m. on Monday to 10:59 a.m. on Tuesday. DAY 2 begins after 11 a.m. on Tuesday and continues until 10:59 a.m. on Wednesday.
4. If you specify CYCLESTARTDATE, you must also specify *cycle*; otherwise, the command will fail.

DUMPCLASS: Adding or changing a volume dump class

Explanation: DUMPCLASS is an optional parameter specifying a volume dump class to be added or changed.

Subparameter	Explanation
class	DUMPCLASS(class): For <i>class</i> , substitute from one to eight characters for the class name to be defined. The first character must be an alphabetic or national (# @ \$) character. The remaining characters can be alphabetic, national, or numeric characters. Only one class can be specified on a single DEFINE command.

Tape Library Relationship: A unit name can be used for filtering in the ACS routines. If you specify the unittype for this command, it will be sent to the ACS routines in SMS for the DEFINE function.

If the class has not been defined previously, a new backup control data set (BCDS) record is created describing the dump class. Unspecified parameters will have their DFSMSHsm defaults supplied.

A previously defined class will have its existing BCDS record. Unspecified parameters remain unchanged from the previous definition, unless either the DATASETRESTORE or AUTOREUSE subparameters, or both, have been specified and the RETENTIONPERIOD is specified as NOLIMIT. In this case, the DATASETRESTORE and AUTOREUSE subparameters are set to NODATASETRESTORE and NOAUTOREUSE.

For SMS-managed volumes, you must use the DUMPCLASS parameter to define dump classes referred to by storage groups.

The subparameters of the DUMPCLASS parameter are listed in alphabetical order and can be found at the following locations:

Subparameter	For more information, see
AUTOREUSE NOAUTOREUSE	“DUMPCLASS(AUTOREUSE and NOAUTOREUSE): Specifies whether DUMP volumes are automatically available for reuse when invalidated” on page 816
CLOUD TAPE	“DUMPCLASS(CLOUD TAPE): Specifying where the dump copies to reside” on page 817
DATASETRESTORE NODATASETRESTORE	“DUMPCLASS(DATASETRESTORE and NODATASETRESTORE): Data set restore is allowed from a full-volume dump copy in this dump class” on page 818

Subparameter	For more information, see
DAY	“DUMPCLASS(DAY): Specifying the target day of the dump cycle for this class” on page 819
DISABLE	“DUMPCLASS(DISABLE): Specifying the volume dump class and making it unavailable as a target of any full-volume dump” on page 820
DISPOSITION	“DUMPCLASS(DISPOSITION): Specifying the disposition of dump volumes” on page 820
ENCRYPT	“DUMPCLASS(ENCRYPT): Specifying whether to encrypt the dump data with host based encryption” on page 820
FASTREPLICATIONDUMP	“DUMPCLASS(FASTREPLICATIONDUMP): Specifying whether a dump class is required or optional” on page 821
FASTREPLICATIONRECOVER	“DUMPCLASS(FASTREPLICATIONRECOVER): Specifying whether a dump class copy is immediately available to be mounted for recovery” on page 822
FREQUENCY	“DUMPCLASS(FREQUENCY): Specifying the minimum number of days that must elapse between volume dumps of a volume to this class” on page 822
HWCOMPRESS	“DUMPCLASS(HWCOMPRESS): Specifying whether to compress the data to be encrypted” on page 823
RECOVERRESET	“DUMPCLASS(RECOVERRESET): Specifying whether to reset the data-set-changed indicator in the VTOC entry” on page 823
RESET NORESET	“DUMPCLASS(RESET and NORESET): Specifying whether DFSMSdss resets the change bit for each data set following a full-volume dump” on page 824
RETENTIONPERIOD	“DUMPCLASS(RETENTIONPERIOD): Specifying the enforcement of retention periods for the dump copies in this class” on page 824
STACK	“DUMPCLASS(STACK/MAXSTACK) and DUMPCLASS(MINSTACK): Specifying the maximum and minimum number of dump copies that are stacked for this dump class” on page 825
TAPEEXPIRATIONDATE	“DUMPCLASS(TAPEEXPIRATIONDATE): Specifying a unique expiration date for all dump copies created in a dump” on page 827
UNIT	“DUMPCLASS(UNIT): Specifying a default tape unit name” on page 827
VTOCCOPIES	“DUMPCLASS(VTOCCOPIES): Specifying the number of dump VTOC copy data sets to keep for dump copies created in this class” on page 828
ZCOMPRESS	“DUMPCLASS(ZCOMPRESS): Specifying whether to use zEDC Services on the dump data” on page 829

DUMPCLASS(AUTOREUSE and NOAUTOREUSE): Specifies whether DUMP volumes are automatically available for reuse when invalidated

Explanation: **AUTOREUSE** and **NOAUTOREUSE** are mutually exclusive, optional subparameters of **DUMPCLASS**, specifying whether dump volumes with retention periods in the defined class are automatically available for reuse when automatically invalidated.

Subparameter	Explanation
AUTOREUSE	DUMPClass(AUTOREUSE) specifies that when DFSMSHsm initiates the invalidation of a dump copy, the dump volumes are automatically made available for reuse.
NOAUTOREUSE	DUMPClass(NOAUTOREUSE) specifies that when DFSMSHsm initiates the invalidation of a dump copy, the dump volumes are marked unavailable for selection by DFSMSHsm. The ADDVOL command can be used to identify to DFSMSHsm that the volume is available for reuse. The use of NOAUTOREUSE is dependent upon using the SETSYS TAPEDELETION option of HSM TAPE for the dump category.

Defaults: If AUTOREUSE or NOAUTOREUSE are specified, the default is NOAUTOREUSE when a dump class is being defined for the first time.

If a dump class is already defined and certain characteristics are being changed, and if AUTOREUSE or NOAUTOREUSE are specified, then the previous specification remains unchanged unless the retention period is NOLIMIT. In this case, the dump class is set for NOAUTOREUSE.

Note:

1. You can use the DELVOL command with the PURGE parameter to invalidate the only valid dump copy.
2. NOAUTOREUSE must be specified if volumes for this dump class are to leave the confines of the data processing center and the SETSYS TAPEDELETION option of HSM TAPE has been specified for this dump class. The NOAUTOREUSE parameter prevents mount requests for volumes that are not immediately available. These volumes must be identified to DFSMSHsm by issuing the ADDVOL command, but not until they are returned from their off-site storage location. If AUTOREUSE is used in this environment, then DFSMSHsm might call for a specific mount for output of a recently released tape before the tape is again physically present in the data processing center.
3. The disposition of tapes automatically made available for reuse depends on the TAPEDELETION parameter of the SETSYS command. If you are using the TAPEDELETION option of SCRATCH, then the tape is released from DFSMSHsm when invalidated and DFSMSHsm does not know of it to consider it for subsequent use.
4. If you use NOLIMIT, you can use only the NOAUTOREUSE subparameter.
5. AUTOREUSE and NOAUTOREUSE are not applicable when CLOUD subparameter is also designated.

DUMPClass(CLOUD | TAPE): Specifying where the dump copies to reside

Explanation: **CLOUD(*cloud_network_connection_name*) | TAPE** is an optional parameter of DUMPClass specifying the device category where the dump copies are to be stored.

Subparameter	Explanation
CLOUD(<i>cloud_network_connection_name</i>)	DUMPClass(CLOUD(<i>cloud_network_connection_name</i>)) specifies the associated volumes are to be dumped directly to the specified cloud object storage. The <i>cloud_network_connection_name</i> is the name of the SMS network connection construct or the CDA provider file. If the specified name does not match what is in the SMS construct or the CDA provider file, the DEFINE DUMPClass fails. To remove DUMPClass(CLOUD) designation for the dump class, ensure all associated dump copies have been deleted, then specify DUMPClass(TAPE) .
TAPE	DUMPClass(TAPE) specifies that the associated primary volumes are to be dumped to tape volumes.

Defaults: If you do not specify this parameter, the default is TAPE for a new dump class, or the previous dump device category for an existing dump class.

The following DEFINE DUMPCLASS parameters are not applicable when the dump copy is to reside in the cloud object storage.

AUTOREUSE | NOAUTOREUSE

These settings apply to dump tape volumes.

DATASETRESTORE | NODATASETRESTORE

Neither parameter settings are applicable to dump copies residing in cloud storage. Data set recovery from full volume dump copy residing in cloud object storage is not supported at this time.

ENCRYPTION

These settings are not applicable in transparent cloud tiering.

FRRECOV(AFM(NO | YES))

These settings apply to dump tape volumes.

HWCOMPRESS(NO | YES)

These settings are not applicable in transparent cloud tiering.

STACK | MAXSTACK, MINSTACK

These settings apply to dump tape volumes.

TAPEEXPIRATIONDATE

These settings apply to dump tape volumes.

UNIT(*unitname*)

These settings apply to dump tape volumes.

When the CLOUD(*cloud_network_connection_name*) parameter is specified to an existing dump class, DFSMSHsm will do the following:

- Fail the DEFINE DUMPCLASS command if one or more dump tape volumes assigned to the class contained part of a valid dump copy. Any dump volumes containing valid data in the class remain unchanged. Any dump volumes that did not contain part of a valid dump copy may become unassigned.
- Unspecified *applicable* parameters remain unchanged from the previous definition.
- Unspecified *inapplicable* parameters are ignored or reset to a default value compatible to the CLOUD(*cloud_network_connection_name*) option.

DUMPCLASS(DATASETRESTORE and NODATASETRESTORE): Data set restore is allowed from a full-volume dump copy in this dump class

Explanation: DATASETRESTORE and NODATASETRESTORE are mutually exclusive, optional subparameters of DUMPCLASS, specifying whether to allow a physical data set restore from a full-volume dump copy in this dump class. This support applies to the RECOVER or HRECOVER commands that are issued for a single data set.

Subparameter	Explanation
DATASETRESTORE	DUMPCLASS(DATASETRESTORE) specifies that physical restores of individual data sets from dump volumes in this class are allowed. The dump volumes must remain available to satisfy mount requests. A physical data set restore requires the mounting of one or more tapes to complete the request. DFSMSHsm or DFSMSdss do not keep track of exactly where the data set is on the dump tapes. A dump VTOC copy data set is needed for data set restores.
NODATASETRESTORE	DUMPCLASS(NODATASETRESTORE) specifies that dump volumes in this class are not available to do individual physical data set restores. All data set recoveries are from incremental backup versions unless a dump volume is explicitly requested on the RECOVER command.

Defaults: If neither DATASETRESTORE nor NODATASETRESTORE is specified, the default is NODATASETRESTORE when a dump class is being defined for the first time.

If a dump class is already defined and certain characteristics are changed, and if neither DATASETRESTORE nor NODATASETRESTORE is specified, the previous specification remains unchanged unless the retention period is NOLIMIT. In this case, the dump class is set for NODATASETRESTORE.

Note:

1. If DATASETRESTORE is selected and the data set resides or has resided on a volume that was dumped to this class, DFSMSHsm determines whether the most current backup has been done by the incremental backup process or by the full-volume process. When the most current version is on a dump volume, DFSMSDss performs a physical data set restore from the copy. When the most current version is an incremental backup version or if the backup version cannot be determined, DFSMSHsm performs a data set recovery of an incremental version. If there are no records in BCDS and there is no catalog entry for the data set on the volume from which the dump copy has been made, the recovery fails unless you specify the RECOVER command with the FROMDUMP parameter.
2. If NODATASETRESTORE is selected and the request was explicitly from a dump copy (FROMDUMP keyword), DFSMSHsm fails the recovery request unless the dump volume was specified (DUMPVOLUME(valid)).
3. If NODATASETRESTORE is selected and the request was not explicitly from a dump copy, DFSMSHsm always performs a data set recovery of an incremental backup version.
4. A RETENTIONPERIOD(NOLIMIT) for the class overrides the DATASETRESTORE option and prevents physical data set restores from a dump volume in this class.
5. If you use NOLIMIT, you can use only the NODATASETRESTORE subparameter.
6. Neither DATASETRESTORE nor NODATASETRESTORE are applicable to data set recovery from a copy pool.
7. AUTOREUSE or NOAUTOREUSE is not applicable to data set recovery from a CLOUD dump class.

DUMPCCLASS(DAY): Specifying the target day of the dump cycle for this class

Explanation: **DAY** is an optional subparameter of DUMPCCLASS specifying the target day of the dump cycle for this class. DAY restricts that this class be targeted during automatic dump processing only on the specified day of the cycle.

DUMPCCLASS(DAY(*day*)): For *day*, substitute a decimal number to specify the target day of the dump cycle. A value of zero indicates that a previous association with a day in the dump cycle should be removed. Any other numeric value must be from one to a value less than or equal to the number of days specified in the dump cycle. *day* must be a 'Y' day specified in the DUMPCYCLE parameter. If a frequency is also specified, the frequency must be satisfied before the class is chosen. Full-volume dumps requested by command, however, are processed independently of the DAY specified.

DAY can be used instead of the FREQUENCY parameter, if you desire to dump to this class every cycle repeat. DAY allows a subset of the primary volumes to be dumped on one day and another subset to be dumped on another day. For example, if the primary volume subsets are defined by two dump classes and the dump classes are identical except for the DAY parameter, one subset of primary volumes can be dumped on one day and the other subset of primary volumes can be dumped on another day. The primary volumes can retain the same frequency and retention characteristics.

DUMPCCLASS Defaults: If the DAY parameter is not specified for the DUMPCCLASS, determination of whether to dump a volume is based on other parameters. If the FREQUENCY parameter criterion is met, a volume will be dumped on each 'Y' day specified in the DEFINE DUMPCYCLE.

Note: The FREQUENCY parameter defaults to seven days. However, in some cases, you may want to specify FREQUENCY(1). If for some reason autodump does not run during its normally scheduled time and manual dumps are requested later, and if the DAY specified in this parameter occurs sooner in the cycle than the FREQUENCY days specified, autodump does not run on the day specified. This problem can be avoided by specifying FREQUENCY(1).

DUMPCLASS(DISABLE): Specifying the volume dump class and making it unavailable as a target of any full-volume dump

Explanation: **DISABLE** is an optional subparameter of DUMPCLASS specifying that a dump class be unavailable as the target of any full-volume dumps. When you specify **DISABLE**, DFSMSHsm automatically unassigns any dump volumes that are empty and currently added to this class. The unassigned dump volumes are available for selection to any other class that uses the same unit type. Information about valid dumps remains in the BCDS, but no further dumps to this class are allowed, and no more dump volumes can be added to this class. The definition of the dump class also remains in the BCDS and the dump class definition will be shown in the LIST DUMPCLASS output.

Defaults: None.

Note:

1. You can enable a disabled dump class by issuing a DEFINE command without specifying the **DISABLE** subparameter.
2. Any other parameters specified on the same command are ignored.
3. Use the LIST command to find any volumes that are currently assigned to a particular class.

DUMPCLASS(DISPOSITION): Specifying the disposition of dump volumes

Explanation: **DISPOSITION** is an optional subparameter of DUMPCLASS specifying the disposition of the dump volumes after they have received part of a dump copy.

DUMPCLASS(DISPOSITION('disposition')): For *disposition*, substitute a character string from 1 to 20 characters describing the intended disposition of the dump volumes. The *disposition* is inserted into message ARC0637I, which is issued for each dump copy successfully created for a source volume. If *disposition* is not specified, message ARC0637I is sent to the dump activity log, but not to the system console.

Defaults: None.

Restriction: The single quotation marks (' ') are required if *disposition* is more than one word or if it contains a special character.

DUMPCLASS(ENCRYPT): Specifying whether to encrypt the dump data with host based encryption

Explanation: **ENCRYPT** is an optional parameter that allows you to specify whether the data to be dumped will be encrypted with host based encryption. Indicate the method of host based encryption through the **NONE**, **RSA**, or **KEYPASSWORD** parameters. To have data encrypted, you must specify either **RSA** or **PASSWORD** (but not both) in the dump class. Do not use the **ENCRYPT** parameter to specify tape hardware encryption. You can use the SMS data class to specify tape hardware encryption.

The following are parameters of the **ENCRYPT** parameter:

NONE

specifies that data encryption is not performed for this dump class. This option overrides the encryption settings, if any, in the existing dump class.

RSA

specifies the RSA key label to be used when secure cryptographic hardware is used to encrypt the data to be dumped. *keylabel* identifies the key label that is to be used to encrypt the data. The key label is 1-64 characters long, and the first character must be an alphabetic or special character.

KEYPASSWORD

specifies that the data is to be encrypted without secure cryptographic hardware. The password, which is used to generate a key for the data encryption, is 8-32 characters long.

ICOUNT

specifies the number of hash iterations to be performed on the password when the PKCS #12 algorithm is used to generate the key. For the iteration count (*count*), specify an integer between 1 and 10000.

TYPE

specifies the type of encryption to be performed on the data.

CLRAES128

encrypts the dumped data with a clear 128-bit AES key.

CLRTDES

encrypts the dumped data with a clear, triple-length DES key

ENCTDES

encrypts the dumped data with a secure triple-length DES key.

Defaults

- If you specify the KEYPASSWORD keyword without specifying ICOUNT (and ICOUNT was not previously set in the dump class definition), the default value for ICOUNT is 16.
- If you do not specify the TYPE keyword (and TYPE was not previously set in the dump class definition), CLRAES128 encryption is used by default.

Note:

1. Before using the DUMPCLASS(ENCRYPT) parameter, review the topic about considerations for host-based encryption in [z/OS DFSMSdss Storage Administration](#).
2. The ICSF address space must be started successfully, regardless of the processor you are running, to use the DUMPCLASS(ENCRYPT) parameter.
3. The set of dump classes that constitute a dump generation (that is, the set of dump classes specified on the BACKVOL command or in the storage group definition) must have the same encryption and HWCOMPRESS settings, or the dump operation will fail.
4. If you specify the KEYPASSWORD keyword, you cannot specify the ENCTDES parameter with the TYPE keyword.

DUMPCLASS(FASTREPLICATIONDUMP): Specifying whether a dump class is required or optional

Explanation: FASTREPLICATIONDUMP is an optional keyword and is applicable only to dump classes associated with copy pools.

Subparameter	Explanation
REQUIRED	DUMPCLASS(FASTREPLICATIONDUMP(REQUIRED)) indicates that every volume in a copy pool must have a successful dump copy to represent this dump class before the DASD backup version that is being dumped is replaced with a more recent DASD backup copy. After a DASD backup copy is replaced, you can no longer attempt to create dump copies from it.
OPTIONAL	DUMPCLASS(FASTREPLICATIONDUMP(OPTIONAL)) indicates that even though every volume in the copy pool might not have a successful dump copy to represent this dump class, if an FRBACKUP request is submitted to replace the DASD backup copy, the command is allowed to proceed.

Example: In a particular environment, assume that two dump classes are defined to create two dump copies. One dump class is named ONSITE and the other OFFSITE. The dump copies created for ONSITE are the primary dump copies used for recovery and have the specification of FASTREPLICATIONDUMP(REQUIRED). The dump copies for dump class OFFSITE are secondary dump copies and have the specification of FASTREPLICATIONDUMP(OPTIONAL).

The FASTREPLICATIONDUMP keyword is mutually exclusive with the RESET keyword. Any attempts to define a dump class with both RESET and FASTREPLICATIONDUMP will fail.

DUMPCCLASS(FASTREPLICATIONRECOVER): Specifying whether a dump class copy is immediately available to be mounted for recovery

Explanation: **DUMPCCLASS(FASTREPLICATIONRECOVER)** is an optional keyword. When specified, the AVAILABLEFORMOUNT parameter must also be specified as YES or NO, as follows:

AVAILABLEFORMOUNT(YES)

Specifies that a dump class copy is available for recovery and does not need to be specified on the FRRECOV command to be used.

AVAILABLEFORMOUNT(NO)

Specifies that a dump class copy is not available for immediate recovery and must be specifically specified on the FRRECOV command to be used.

If multiple dump copies are created for a backup version and AVAILABLEFORMOUNT(YES) is specified for more than one of the dump classes, the first dump copy found with YES specified will be used.

If AVAILABLEFORMOUNT(NO) is specified for all dump classes, you must specify DUMPCCLASS or DUMPVOLUME on the FRRECOV command, otherwise the command will fail. The DUMPCCLASS and DUMPVOLUME keywords of the FRRECOV command override the DUMPCCLASS FASTREPLICATIONRECOVER setting.

The FASTREPLICATIONRECOVER dump class setting applies to tape processing at the data set and volume level.

Defaults: If FASTREPLICATIONRECOVER is not specified for a dump class, the default value is AVAILABLEFORMOUNT(YES).

DUMPCCLASS(FREQUENCY): Specifying the minimum number of days that must elapse between volume dumps of a volume to this class

Explanation: **FREQUENCY** is an optional subparameter of DUMPCCLASS specifying the minimum number of days that must elapse from the last volume dump of the volume to this class before the volume can be automatically dumped again.

DUMPCCLASS(FREQUENCY(days)): For *days*, substitute a decimal number from 0 to 999.

Automatic full-volume dumps are included in the test for satisfying the requirement defined by the FREQUENCY parameter. Full-volume dumps requested by command, however, are processed independently of the FREQUENCY specified with the DEFINE command. The frequency for the class is considered met if DFSMSHsm has no record of dumping the volume in question to this class. Therefore, the frequency is met for each volume dumped to the class for the first time. DFSMSHsm keeps track of only the last five distinct dump classes to which a volume has been dumped.

Defaults: If you do not specify FREQUENCY, the default for *days* is 7.

Note:

1. Coordinate the FREQUENCY parameter with DUMPCYCLE parameter days to ensure that schedules for automatic dumps do not conflict. **Example:** The following example shows an apparent conflict:

```
DEFINE DUMPCYCLE(NNNNNNY CYCLESTARTDATE(84/01/01)) +
      DUMPCCLASS(A FREQ(8))
```

In this example, DUMPCYCLE specifies a 7-day cycle, with the dumps taken on a Saturday. The dump frequency, FREQ, specifies an 8-day elapsed time. The dumps to class A would be performed every other Saturday, beginning with the second Saturday, because the dump frequency would not have elapsed by the time the dump cycle had completed. If, however, the volume had never been dumped by DFSMSHsm, the initial dump would be on the first Saturday, and then every other Saturday.

To be more consistent with the dump cycle, choose the following value: `FREQ(7)`. This causes the required number of days to elapse before the next 'Y' day in the processing of automatic dump.

2. The `DUMPCLASS` parameter `FREQUENCY` is calculated from the last date that the level 0 volume was dumped while not in debug mode. The date that the level 0 volume was last dumped is not updated when DFSMSHsm is running in debug mode because the dump prevents volume dumps from processing on schedule when no debug is specified. In debug mode, if the date last dumped is zeros, and if the frequency value is not calculated, then the level 0 volume is eligible to be dumped, and the date last dumped is not updated.

DUMPCLASS(HWCOMPRESS): Specifying whether to compress the data to be encrypted

Explanation: `HWCOMPRESS` is an optional parameter specifying whether DFSMSdss is to perform hardware-assisted compression on the dump data. Typically you can use it in conjunction with host based encryption specified in the `DUMPCLASS`, but not in conjunction with tape hardware encryption.

Subparameter	Explanation
HWCOMPRESS(YES)	DUMPCLASS(HWCOMPRESS(YES)) When YES is specified, hardware-assisted compression will be performed. Specify this option only when encryption is being used; it specifies that the data should be compressed before it is encrypted.
HWCOMPRESS(NO)	DUMPCLASS(HWCOMPRESS(NO)) When NO is specified, hardware-assisted compression will not be performed. <code>HWCOMPRESS(NO)</code> can be specified to override an existing setting of <code>HWCOMPRESS(YES)</code> . If the data is not being encrypted, specify <code>HWCOMPRESS(NO)</code> so that tape hardware compression is used.

Defaults: When `HWCOMPRESS` is not specified and was not previously set in the existing dump class definition, NO is used by default.

DUMPCLASS(RECOVERRESET): Specifying whether to reset the data-set-changed indicator in the VTOC entry

Explanation: `RECOVERRESET` is an optional parameter specifying whether or not the data-set-changed indicator in the VTOC entry should be reset for all data sets that are restored during full volume recover processing.

Subparameter	Explanation
RECOVERRESET(YES)	DUMPCLASS(RECOVERRESET(YES)) When YES is specified, the data-set-changed indicator in the VTOC (DS1DSCHA) is reset (set to OFF) for all data sets on the volume being recovered.
RECOVERRESET(NO)	DUMPCLASS(RECOVERRESET(NO)) When NO is specified, the data-set-changed indicator in the VTOC is not reset for any of the data sets on the volume being recovered. This action indicates that the data-set-changed setting retains the value the data sets had the dump was created.

Subparameter	Explanation
RECOVERRESET(DUMP)	DUMPCLASS(RECOVERRESET(DUMP)) When DUMP is specified, and the RESET keyword was specified in the dump class at the time the dump was created, the data-set-changed indicator in the VTOC is reset for all data on the volume being recovered. If RESET was not specified, or NORESET was specified, or the dump copy was created prior to z/OS V2R1 DFSMSHsm, then the data-set-changed indicator is not reset and retains the value it had when the dump copy was created. Note that this parameter is not applicable for FRRECOV (fast replication recovery) because RESET cannot be specified in dump classes associated with the FRBACKUP function. For dump classes used during FRRECOV processing, specify either YES or NO.

Defaults: When RECOVERRESET is not specified and was not previously set in the existing dump class definition, YES is used by default.

DUMPCLASS(RESET and NORESET): Specifying whether DFSMSdss resets the change bit for each data set following a full-volume dump

Explanation: **RESET** and **NORESET** are mutually exclusive, optional subparameters of **DUMPCLASS** specifying whether DFSMSdss resets the change bit for each data set after a full-volume dump is successfully performed.

Subparameter	Explanation
RESET	DUMPCLASS(RESET) specifies that the change bit for each data set should be reset.
NORESET	DUMPCLASS(NORESET) specifies that the change bit for each data set should not be reset.

The specified option affects whether DFSMSHsm makes an incremental backup version of the data sets the next time the volume is processed by incremental backup with the BACKVOL command and whether the data sets have not been changed since the full-volume dump.

If multiple dump copies are made concurrently, each copy is associated with a different dump class. If RESET is specified for any of these dump classes, then the RESET option is specified on the command to DFSMSdss.

Defaults: If neither RESET nor NORESET is specified, the default is NORESET when a dump class is defined for the first time.

Note:

1. If a dump class is already defined (certain characteristics are changed) and neither RESET nor NORESET is specified, the previous specification remains unchanged.
2. If you use the APPLYINCREMENTAL subparameter with the FROMDUMP parameter of the RECOVER command, specify the NORESET subparameter.
3. Do not specify RESET for a dump class that is used for creating fast replication dump copies.

DUMPCLASS(RETENTIONPERIOD): Specifying the enforcement of retention periods for the dump copies in this class

Explanation: **RETENTIONPERIOD** is an optional subparameter of **DUMPCLASS** specifying whether you want DFSMSHsm to enforce retention periods for the dump copies in this class.

Subparameter	Explanation
<i>days</i>	DUMPClass(RETENTIONPERIOD(<i>days</i>)) specifies that DFSMSHsm enforces retention periods for the dump copies in this dump class and then automatically invalidates them when the retention period has been met. After the number of <i>days</i> has elapsed, the dump volumes are automatically reused if the AUTOREUSE subparameter is specified for the class. If AUTOREUSE is not specified, <i>days</i> may be used to specify an expected date to delete the volumes. If the maximum number of dump generations is reached, another dump is performed. If the oldest generation contains a dump copy with an explicit retention period that has not been reached, DFSMSHsm invalidates the oldest dump generation and issues a message reporting this action. The maximum number of dump generations is 100 generations. For <i>days</i> , enter a decimal number between 1 and 9999.
NOLIMIT	DUMPClass(RETENTIONPERIOD(NOLIMIT)) specifies that there is no predetermined expiration date for the dump copies in this DUMPClass. DFSMSHsm does not automatically enforce an expiration date. The dump copy can be invalidated only by an explicit request using the DELVOL command. If the maximum number of dump generations is reached, another dump will be performed. The oldest generation contains a dump copy with RETENTIONPERIOD(NOLIMIT). The maximum number of dump generations is 100 generations. If DFSMSHsm must invalidate a dump copy without a retention period, a message is issued reporting this action.

Defaults: If you do not specify RETENTIONPERIOD, the default is 30 days.

Note:

1. If you use NOLIMIT, also use the NOAUTOREUSE and the NODATASETRESTORE subparameters. If you use AUTOREUSE or DATASETRESTORE, the NOLIMIT parameter overrides the values. The values become NOAUTOREUSE and NODATASETRESTORE respectively.
2. DFSMSHsm does not automatically delete the last and only copy of a source volume, regardless of the RETENTIONPERIOD set. To delete the dump volumes in this copy, issue the DELVOL command with the LASTCOPY option for one of the dump volumes. All of the volumes in the copy are deleted.

DUMPClass(STACK/MAXSTACK) and DUMPClass(MINSTACK): Specifying the maximum and minimum number of dump copies that are stacked for this dump class

Explanation

STACK/MAXSTACK and MINSTACK are optional parameters of the DEFINE DUMPClass command, specifying how many dump copies DFSMSHsm should place on a dump volume (assigned to the specified dump class) during one invocation of automatic dump or BACKVOL dump.

Dump volumes from multiple copy pools with the same dump class will be stacked on the same tape volume as allowed by the values specified for MAXSTACK and MINSTACK.

Subparameter	Explanation
<i>maxv</i>	<p data-bbox="513 191 1476 405">DUMPClass(STACK(<i>maxv</i>)) or DUMPClass(MAXSTACK(<i>maxv</i>)) specifies the preferred maximum number of dump copies that the system should place on a tape volume. In some cases, the available MAXDUMPTASKS tasks may be under utilized if <i>maxv</i> is too large. This could occur when the number of dump copies are not large enough to fill a tape volume to the maximum number of dump copies defined for every available dump task. For <i>maxv</i>, specify a value from 1 to 255.</p> <p data-bbox="513 428 1476 516">When defining a new DUMPClass, if the STACK or MAXSTACK parameter is not specified and the MINSTACK parameter is specified, the MINSTACK value will be used for MAXSTACK. If neither is specified, the default value of 1 will be used.</p> <p data-bbox="513 539 1476 659">When modifying an existing DUMPClass and the MINSTACK parameter is not specified and the STACK or MAXSTACK parameter is specified, then the specified STACK or MAXSTACK parameter must be greater than or equal to the previously defined MINSTACK value for the existing DUMPClass.</p>
<i>minv</i>	<p data-bbox="513 695 1476 1035">DUMPClass(MINSTACK(<i>minv</i>)) specifies the preferred minimum number of dump copies that the system should place on a tape volume. If not specified, the value used by the system will be <i>maxv</i>. The minimum value will be used by the system to determine the number of available MAXDUMPTASKS tasks to use for the dump copies. The effect is that the system could utilize more available dump tasks for the dump copies as compared to using <i>maxv</i>, but could also have less dump copies on the tape volume. <i>minv</i> could be used in conjunction with the common queue dump group to maximize the use of available dump tasks in all the group members in the HSMplex. The system will place dump copies on a tape volume until the <i>maxv</i> is reached. If a value is specified, it must not be greater than <i>maxv</i>.</p> <p data-bbox="513 1058 1476 1146">When defining a new DUMPClass, if the MINSTACK parameter is not specified and the STACK or MAXSTACK parameter is specified, the MAXSTACK value will be used for MINSTACK. If neither is specified, the default value of 1 will be used.</p> <p data-bbox="513 1169 1476 1289">When modifying an existing DUMPClass and the STACK or MAXSTACK parameter is not specified and the MINSTACK parameter is specified, then the specified MINSTACK parameter must be less than or equal to the previously defined STACK or MAXSTACK value for the existing DUMPClass.</p>

All stacking to a given tape is done while that tape is mounted. DFSMSHsm selects empty dump volumes as targets for auto or command dump. Each dump copy is written in its own file, with a unique data set name. As dump generations are rolled off when new dumps are created, a dump volume may contain a combination of valid and not valid dump copies.

A given dump volume:

- Regardless of the STACK/MAXSTACK and MINSTACK value that is used to write to it, is associated with only one dump class.
- Never contains more than one dump copy of the same source volume.
- Can contain dump copies of both SMS-managed volumes and non-SMS-managed volumes.
- Contains dump copies of only source volumes with affinity to the autodump host, or source volumes without such affinity, not a combination of both. System affinity can only be specified for SMS-managed volumes.

Defaults

If you do not specify STACK/MAXSTACK and MINSTACK for a new dump class, DFSMSHsm uses the value of 1. If you do not specify STACK/MAXSTACK and MINSTACK for a dump class that is already defined, the previous value remains unchanged.

Usage notes:

1. If you specify a stack value greater than 99, verify the BCDS maximum record size is 6544 bytes. If it is not, redefine the BCDS with a maximum record size of 6544 bytes. For more information about redefining the BCDS and maximum record size requirements, see [z/OS DFSMSHsm Implementation and Customization Guide](#).
2. DFSMSHsm ignores any STACK/MAXSTACK and MINSTACK value from DEFINE during a BACKVOL DUMP command for a list of volumes, unless you specify the dump class with the DUMPCLASS parameter on the BACKVOL command.
3. VTOCCOPIES are created or not created in the same manner for all volumes dumped to the same dump class.
4. Any RETENTIONPERIOD or EXPIRATIONDATE for the dump class applies to all the dump copies that are written to its dump volumes (all dump copies stacked on a dump volume expire on the same day).

DUMPCLASS(TAPEEXPIRATIONDATE): Specifying a unique expiration date for all dump copies created in a dump

Explanation: **TAPEEXPIRATIONDATE** is an optional subparameter of DUMPCLASS specifying a unique expiration date for the dump tape header labels of all dump copies created in this dump class.

DUMPCLASS(TAPEEXPIRATIONDATE(yyyyddd)): For *yyyyddd*, specify a 7-digit number in the format of *yyyyddd*. The *yyyy* value and the *ddd* value are the year and day of the year for the expiration date of the dump copies. For *yyyy*, specify a year between the current year and 2155. For *ddd*, specify a day between 001 and 366.

Defaults: None.

Note:

1. For TAPEEXPIRATIONDATE to be effective, the security options in effect, as established with a SETSYS command, must include EXPIRATION or EXPIRATIONINCLUDE.
2. Values for *yyyyddd* of 1999365 and 1999366 are recognized as “never expire” dates. Values of 1998000 and 1999000 are recognized as meaningful to certain tape management systems.
3. If you do not specify TAPEEXPIRATIONDATE for a dump class and a tape security option of EXPIRATION or EXPIRATIONINCLUDE is in effect, DFSMSHsm provides an expiration date of 1999 for 365 days for dump volumes written for this class.
4. Past dates are not recognized as expiration dates.

DUMPCLASS(UNIT): Specifying a default tape unit name

Explanation: **UNIT** is an optional subparameter of DUMPCLASS specifying the default unit name for allocation when no volumes are added to the class and when the class has been selected as the target of a dump copy.

DUMPCLASS(UNIT(*unittype*)): For *unittype*, substitute a valid esoteric name or a valid unit type.

The following are valid types of tape units:

- 3480
- 3480X
- 3490
- 3590-1

You can substitute an esoteric tape unit defined with the SETSYS USERUNITTABLE command. If you specify an esoteric tape unit name that does not exist in the user unit table, the command fails. If you specify:

- 3480 or 3480X, you use all the functions of the 3480 Magnetic Tape Subsystem.
- 3490, you use all the functions of the 3490 Magnetic Tape Subsystem.
- 3590-1, you use all the functions of the 3590 Magnetic Tape Subsystem.

If you define both 3592-E05 and 3592-J1A to the same esoteric group, the E05 must use the EFMT1 recording format.

You can define a 3592-E05 or 3592-J1A to the 3590-1 generic group. If so, you must ensure drive compatibility or segmentation when using the 3590-1 in a non-SMS environment.

Defaults: If you do not specify UNIT when you define a dump class for the first time, the unit type specified with the SETSYS UNITNAME parameter is the default.

If a dump class is already defined and certain characteristics are being changed, and if UNIT is not specified, the previous specification remains unchanged.

Attention: If UNIT is **not** specified on either the DEFINE or the SETSYS command, the default unit name that is used for allocation is a 3590-1 unit type.

DUMPCCLASS(UNASSIGNTAPEUNIT): Specifying unassigning empty dump volumes

Explanation: **UNASSIGNTAPE** is an optional subparameter of DUMPCCLASS specifying that DFSMSHsm unassigns any dump volumes that are empty and currently added to this class. The unassigned dump volumes are available for selection to any other class that uses the unit type.

Defaults: None.

Note:

- UNASSIGNTAPE can be specified with TAPE or CLOUD dump classes.
- UNASSIGNTAPE is ignored if DISABLE is also specified.
- Use the LIST command to find any dump volumes that are currently assigned to a particular class.

DUMPCCLASS(VTOCCOPIES): Specifying the number of dump VTOC copy data sets to keep for dump copies created in this class

Explanation: **VTOCCOPIES** is an optional subparameter of DUMPCCLASS specifying the number of dump VTOC data sets to keep for dump copies created in this class.

DUMPCCLASS(VTOCCOPIES(*copies*)): For *copies*, substitute a number from 0 to 100. The value indicates how many of the existing dump copies of a given volume dumped to this class should have dump VTOC copy data sets kept associated with them. For example, use 3 as a value for *copies*. If there are six generations of dumps for a given volume and generations 0, 2, and 4 have copies in a class with VTOCCOPIES(3), then all of these generations have VTOC copy data sets kept for them. This happens regardless of what other dump copies might exist in the same dump generations, or whether generations 1, 3, and 5 have dump VTOC copies. If a new dump copy is created in the same class for the same volume, the oldest dump copy in this dump class no longer requires the dump VTOC copy data set. The dump VTOC copy data set is deleted if no other dump copy in the same generation requires it to be kept.

VTOCCOPIES is also used to determine if a dump VTOC copy data set should be created when a volume is dumped. If *copies* is greater than 0, a dump VTOC copy data set is created. If *copies* is 0 and the volume is not dumped to multiple dump classes concurrently, a dump VTOC copy data set is not created. If *copies* is 0 and the volume is dumped to multiple dump classes concurrently, a dump VTOC copy data set is created if any of the dump classes being dumped to has VTOCCOPIES(*copies*) greater than 0.

The dump VTOC copy data sets are written to migration level 1 volumes. Space required for these data sets varies with the size of the original VTOC. Only part of the data set VTOC entry for each data set from

the original VTOC is contained in the VTOC copy data set. When a dump generation no longer has a dump VTOC copy data set associated with it, or when the number of dump VTOC copies kept is zero, DFSMSHsm cannot provide the following:

- Physical data set restore support from the associated dump copies
- Listing capabilities for the dump copy using the DUMPCONTENTS parameter with the LIST DUMPVOLUME command
- Physical data set restore from dump copies in cloud object storage is not supported, therefore, specify VTOCCOPIES(0) for CLOUD dump classes is recommended.
- VTOCCOPIES are not needed for data set recovery from copy pools, so specifying VTOCCOPIES(0) for dump classes used for copy pool dump is recommended.

Dump VTOC copy data sets are not created for or maintained for dumps of DFSMSHsm-owned volumes. When the number of dump VTOC copies kept is zero, DFSMSHsm cannot provide listing capability for the dump copy using the DUMPCONTENTS parameter with the LIST DUMPVOLUME command.

Defaults: If you do not specify VTOCCOPIES when a dump class is defined for the first time, a default of 2 is used for non-copy pool volumes, and a default of 0 is used for copy pool volumes and volumes to be dumped to cloud object storage.

If a dump class is already defined and certain characteristics are changed, and if VTOCCOPIES is not specified, the previous specification remains unchanged.

DUMPCCLASS(ZCOMPRESS): Specifying whether to use zEDC Services on the dump data

Explanation: **ZCOMPRESS** is an optional subparameter specifying whether DFSMSdss is to use zEDC Services on the dump data.

Subparameter	Explanation
ZCOMPRESS(YES)	<p>DUMPCCLASS(ZCOMPRESS(YES)) When YES is specified, compression with zEDC will be performed, if this function is supported by the system. If zEDC Services are <i>not</i> available, the other compression type will be used.</p> <p>For a CLOUD dump class, CDA compression with zEDC Services will be used when a DIRECT cloud provider is specified in the CLOUD parameter.</p>
ZCOMPRESS(NO)	<p>DUMPCCLASS(ZCOMPRESS(NO)) When NO is specified, compression with zEDC will <i>not</i> be performed. ZCOMPRESS(NO) can be specified to override an existing setting of ZCOMPRESS(YES).</p> <p>For a CLOUD dump class, CDA compression will not be used when a DIRECT cloud provider is specified in the CLOUD parameter.</p>

Defaults: When ZCOMPRESS is not specified and was not previously set in the existing dump class definition, NO is used by default.

DUMPCYCLE: Specifying the automatic dump cycle

Explanation: **DUMPCYCLE** is an optional parameter specifying the days in a cycle when the automatic dump process should run.

DUMPCYCLE(*cycle*): For *cycle*, substitute a string of alphabetic Ys and Ns. Each Y represents a day in the cycle when automatic dump is to run, and each N represents a day in the cycle when automatic dump is not to run. You can represent up to 31 days with the Ys and Ns. When you specify *cycle*, the current day is the first day of the cycle unless you specify the cycle start date.

CYCLESTARTDATE can be used with this parameter and is covered separately under [“CYCLESTARTDATE: Specifying the start date of a cycle” on page 814.](#)

Defaults: None.

Note:

1. *Cycle* must be defined sometime before the automatic dump process is permitted to run.
2. *Cycle* is ignored if a volume dump is requested with the BACKVOL command.
3. *Cycle* has no meaning unless the AUTODUMPSTART and BACKUP parameters of the SETSYS command are specified for the DFSMSHsm startup.
4. Dump cleanup also runs on an 'N' day in the dump cycle. Cleanup functions include expiration of expired dump copies and deletion of excess dump VTOC copy data sets and deletion of empty dump containers.

Note: The deletion of excess dump VTOC copy data sets occur on both 'Y' and 'N' days of the dump cycle. Empty dump container deletion only occurs on an 'N' day in the dump cycle.

MIGRATIONCLEANUPCYCLE and SECONDARYSPMGMTCYCLE: Specifying the cycle for automatic secondary space management functions

Explanation: **MIGRATIONCLEANUPCYCLE** and **SECONDARYSPMGMTCYCLE** are mutually exclusive, optional parameters that apply to all secondary space management functions, including migration cleanup and ML1 to ML2 migration.

Both of these parameters allow you to specify the days in a cycle when migration cleanup and ML1 to ML2 migration run.

These two parameters have identical function. The parameter name **MIGRATIONCLEANUPCYCLE** has been retained in order to maintain compatibility, but the parameter name **SECONDARYSPMGMTCYCLE** has been selected as the preferred name, because it more accurately describes the function.

MIGRATIONCLEANUPCYCLE(*cycle*) or **SECONDARYSPMGMTCYCLE(*cycle*)**: For *cycle*, substitute a string of alphabetic Ys and Ns. Each Y represents a day in the cycle when migration cleanup and level 1 to level 2 migration run. Each N represents a day in the cycle when migration cleanup and level 1 to level 2 migration do not run. You can represent up to 31 days with the Ys and Ns. When you specify **MIGRATIONCLEANUPCYCLE** or **SECONDARYSPMGMTCYCLE**, the current day is the first day of the cycle, unless you specify a cycle start date.

Note: In either of the above environments, if **MAXSSMTASKS(EMPTYCONTAINERDELETION(Y))** is specified or defaulted to, the empty container deletion will run every day as every day is considered as the first day of the secondary space management cycle.

CYCLESTARTDATE can be used with either parameter and is covered separately under [“CYCLESTARTDATE: Specifying the start date of a cycle” on page 814.](#)

Defaults: If you do not specify **MIGRATIONCLEANUPCYCLE** or **SECONDARYSPMGMTCYCLE**, *cycle* defaults to a one-day cycle. Therefore, if a start time has been specified by a SETSYS **SECONDARYSPMGMTSTART** command, automatic secondary space management functions will run every day.

If you do not specify both *cycle* and **CYCLESTARTDATE**, DFSMSHsm sets *cycle* to a one-day cycle and **CYCLESTARTDATE** to the current date. Therefore, if a start time has been specified by a SETSYS **SECONDARYSPMGMTSTART** command, automatic secondary space management functions run every day.

Note: It is important to understand the difference between cycle days and calendar days. The first cycle day, DAY 1, begins at the start time of the function. The second cycle day, DAY 2, begins when this start time has again been reached, regardless of when the new calendar day begins. Third and subsequent days follow the same pattern. For instance, if the cycle start time for a function is 1100 (11 a.m.) on Monday, DAY 1 runs from 11 a.m. on Monday to 10:59 a.m. on Tuesday. DAY 2 begins after 11 a.m. on Tuesday and continues until 10:59 a.m. on Wednesday.

MIGRATIONLEVEL2: Specifying DASD level 2 volumes and their associated key range structure

Explanation: **MIGRATIONLEVEL2** is an optional parameter specifying the division of key ranges for DASD migration level 2 volumes. When you specify **MIGRATIONLEVEL2**, you can also specify **KEYS** to indicate how data sets are assigned to the available DASD migration level 2 volumes.

Subparameter	Explanation
KEYS	<p>MIGRATIONLEVEL2(KEYS(<i>key</i> ...)) specifies an ascending alphanumeric sequence of lower key-range boundaries, where the set of initial characters of the data set name is compared against the key. Any data set having the set of initial characters within the specified alphanumeric range migrates to the volume associated with that range. You specify only the lower boundary of the key range for a volume. The maximum number of key ranges you can define is 61.</p> <p>You specify one key less than the number of key ranges being defined because the lower boundary for the first key range defaults to the lowest key possible. For example, KEYS(L T) identifies three key ranges: the first key range begins with A and ends with K9999999, the second key range begins with L and ends with S9999999, and the third key range begins with T and ends with Z9999999.</p> <p>For <i>key</i> ..., substitute one or more strings of 1 to 8 characters, starting with an alphabetic or \$, #, or @. The remaining characters can be alphanumeric and \$, #, or @.</p>
VOLUMES	<p>MIGRATIONLEVEL2(VOLUMES(<i>volser</i> ...)) VOLUMES is an optional subparameter specifying a list of DASD migration level 2 volumes, assigned to the specified key ranges. If you specify fewer volumes than key ranges, DFSMSHsm assigns an available DASD migration level 2 volume to the key range when it needs another volume. An available DASD migration level 2 volume is one that is not associated with a key range and has not been associated with a key range since the last ADDVOL or DELVOL command was issued. If you specify more volumes than key ranges, the extra volumes are not associated with any key range. Before you can specify any DASD migration level 2 volumes with the DEFINE command, you must add the volumes to DFSMSHsm control by using the ADDVOL command.</p> <p>For <i>volser</i> ..., substitute the serial numbers of the DASD migration level 2 volumes, assigned to the corresponding specified key ranges. Only one volume is associated with each key range at a time.</p> <p>When the specified volume for a key range is full, DFSMSHsm assigns an available DASD migration level 2 volume to that key range. To cover all specified key ranges, you must specify one more volume than you specify keys.</p>

Defaults: If you do not specify **KEYS**, DFSMSHsm assumes that you are defining one key range for all possible keys.

Note:

1. You must issue a **DEFINE** command with the **MIGRATIONLEVEL2** parameter before DFSMSHsm can process level 1 to level 2 migration.
2. If you want to reuse the DASD migration level 2 volume after it has been removed from a key range, you must use the **DELVOL** command with the **UNASSIGN** parameter.
3. DFSMSHsm does not process a change to the key range definition while migration to DASD migration level 2 volumes is occurring.

POOL: Identifying the non-SMS-managed volumes where the data sets with the same first qualifier are recalled

Explanation: **POOL** is an optional parameter specifying the set of initial characters of the data set name for a group of data sets and the set of non-SMS-managed volumes where the group of data sets is to be recalled. Each *poolid* and associated volume list is a user-defined pool. When recall occurs, the set of initial characters of the data set name forces the recall of those data sets to one of the specific volumes identified with the **VOLUMES** subparameter. To remove the association between a pool ID and its associated volumes from pool control, you omit the **VOLUMES** subparameter when you specify **POOL**.

POOL(poolid): For *poolid*, substitute the set of initial characters of the data set name of those data sets you want recalled to the specified volume or volumes. The *poolid* can end with a period if **POOL** is the first keyword on the command.

Subparameter	Explanation
VOLUMES	<p>POOL(poolid VOLUMES(volser ...)) specifies the volumes where the data sets with the set of initial characters specified with the POOL parameter are recalled. When you specify multiple volumes for a pool ID, DFSMSHsm tries to recall data sets to the volume with the most space. If there is not enough space on the volume, DFSMSHsm can try recalling the data set to up to four different volumes from the same pool.</p> <p>For <i>volser ...</i>, substitute the serial numbers of the volumes where the group of data sets is to be recalled.</p>

Defaults: None.

Note:

1. When DFSMSHsm checks whether a data set belongs to a pool, it checks the pools in the order you defined them and chooses a pool whose ID matches the initial characters of the data set name. If you define pools, so one is a subset of the other such as MYDSN and MYDSNAME, define the more restrictive pool first (in this case, MYDSNAME) as shown in the following example:

```
DEFINE POOL(MYDSNAME VOLUMES(VOL001))
DEFINE POOL(MYDSN VOLUMES(VOL002 VOL004))
```

- If you do not define the pools in the order shown in the example, as soon as DFSMSHsm sees the MYDSN part of MYDSNAME, it finds a match, and chooses VOL002 even if you wanted to use VOL001.
2. The “JES3 considerations” on page 102 contains detailed information about defining pools in a JES3 environment.
3. You can specify up to 140 volumes.
4. If an SMS-managed volume is specified as part of a data set pool, a message is issued indicating that the volume was not added to the data set pool. Processing continues for the **DEFINE** command. If, however, only SMS-managed volumes are specified for the definition of the data set pool, the data set pool definition is rejected and the **DEFINE** command fails.
5. Volumes specified in the **DEFINE POOL** command must also be added as primary volumes. To do this, use of the **ADDVOL** command.

PRIMARYSPMGMTCYCLE: Specifying the cycle for automatic primary space management

Explanation: **PRIMARYSPMGMTCYCLE** is an optional parameter specifying the days in a cycle when automatic primary space management runs.

PRIMARYSPMGMTCYCLE(cycle): For *cycle*, substitute a string of alphabetic Ys and Ns. Each Y represents a day in the cycle when automatic primary space management is to run. Each N represents a day in the

cycle when automatic primary space management is not to run. You can represent up to 31 days with the Ys and Ns. The current day is the first day of the cycle, unless you specify the cycle start date.

CYCLESTARTDATE can be used with this parameter and is covered separately under [“CYCLESTARTDATE: Specifying the start date of a cycle”](#) on page 814.

Defaults: If you do not specify PRIMARYSPMGMTCYCLE or if you specify PRIMARYSPMGMTCYCLE without specifying *cycle*, automatic primary space management will default to a one-day cycle. Therefore, if a start time has been specified by a SETSYS PRIMARYSPMGMTSTART or AUTOMIGRATIONSTART command, automatic primary space management functions run every day.

If you do not specify both *cycle* and CYCLESTARTDATE, DFSMSHsm will set the cycle to a one-day cycle. Therefore, if a start time has been specified by a SETSYS PRIMARYSPMGMTSTART or AUTOMIGRATIONSTART command, automatic primary space management functions will run every day.

Note:

1. If you specify CYCLESTARTDATE, you must also specify *cycle*; otherwise, the DEFINE PRIMARYSPMGMTCYCLE command will fail.
2. The first day of the cycle is DAY 1. The second day in the cycle is DAY 1 until the start time for the function is reached; then it becomes DAY 2. Third and subsequent days follow the same pattern.

SWITCHTAPES: Releasing mounted tapes for command data set backup

Explanation: SWITCHTAPES is an optional parameter that defines when to release those tapes mounted to process data set backup commands.

Subparameter	Explanation
DSBACKUP	SWITCHTAPES(DSBACKUP) is a required subparameter that specifies that the data set backup function performs a demount of all mounted data set backup tapes.

You can use the following optional parameters with the SWITCHTAPES parameter.

Subparameter	Explanation
TIME	<p>SWITCHTAPES(DSBACKUP(TIME(<i>hhmm</i>))) specifies the time of day to demount mounted data set backup tapes. For <i>hhmm</i>, specify the planned demount time. If you specify TIME with <i>hhmm</i> as zero, DFSMSHsm does not demount any mounted tapes. If the tape is mounted but not actively processing a data set, the demount occurs at the time indicated by TIME. If a tape is actively processing a data set, DFSMSHsm demounts the tape at the end of the current data set.</p> <p>Note: The <i>hhmm</i> format expresses time as a four-digit decimal number that is based on the 24-hour clock. The <i>hh</i> specifies the hour and <i>mm</i> specifies the minutes. For example, you can specify 1:15 p.m. as 1315, and you can specify midnight as 2400. The maximum value you can specify for <i>hh</i> is 24, the maximum value you can specify for <i>mm</i> is 59, and the maximum value you can specify for <i>hhmm</i> is 2400.</p>
AUTOBACKUPEND	SWITCHTAPES(DSBACKUP(AUTOBACKUPEND)) specifies that DFSMSHsm demounts all tapes that were mounted for data set backup at the end of the autobackup cycle. Before the autobackup cycle ends, all retries (data sets that were in use when the initial attempt to backup occurred) complete.
PARTIALTAPE	SWITCHTAPES(DSBACKUP(PARTIALTAPE)) specifies the method that DFSMSHsm uses to mark a single-file format output tape as full or available for reuse when a switch tape event occurs.

Subparameter	Explanation
SETSYS	SWICHTAPES(DSBACKUP(PARTIALTAPE(SETSYS))) specifies that the SETSYS PARTIALTAPE value is used.
REUSE	SWICHTAPES(DSBACKUP(PARTIALTAPE(REUSE))) specifies that all partial tapes demounted with the SWICHTAPES option remain selectable in the DFSMSHsm inventory as partial tapes.
MARKFULL	SWICHTAPES(DSBACKUP(PARTIALTAPE(MARKFULL))) specifies that DFSMSHsm marks full all partial tapes demounted with the SWICHTAPES option. If backups are going to the IBM Virtual Tape Server (VTS) subsystem, refer to the SETSYS PARTIALTAPE parameter description for performance considerations.

Defaults: TIME(0) is the default if you specify the SWICHTAPES(DSBACKUP) command without specifying the TIME or AUTOBACKUPEND parameters. MARKFULL is the default if you specify the SWICHTAPES(DSBACKUP) command without specifying the PARTIALTAPE parameter.

Note: If you specify the MARKFULL parameter of the SWICHTAPES(DSBACKUP) command, DFSMSHsm marks full the tapes that are released from command data set backup. Any other partial tapes in the DFSMSHsm backup inventory are unaffected, and those partials remain as selection candidates and can be immediately selected and mounted for new output processing.

VOLUMEPOOL: Identifying groups of volumes where data sets are recalled

Explanation: **VOLUMEPOOL** is an optional parameter specifying a set of volumes where a data set is recalled based on the volume from which the data set migrated. A data set that migrates from a volume in the volume pool is recalled to a volume in the volume pool.

VOLUMEPOOL(poolid): For *poolid*, substitute from 1 to 8 alphanumeric characters for the name of the volume pool.

Subparameter	Explanation
VOLUMES	<p>VOLUMEPOOL(poolid VOLUMES(volser)) specifies the volumes belonging to the volume pool where the data sets are recalled. When you specify multiple volumes for a pool ID, DFSMSHsm tries to recall data sets to the volume with the most space. If there is not enough space on the volume, DFSMSHsm tries recalling the data set to up to four different volumes in the volume pool.</p> <p>For <i>volser</i>, substitute the serial number of the primary volume or volumes making up the volume pool where data sets are recalled.</p>

Defaults: None.

Note:

1. In a JES3 environment, at least one of the volumes in the volume pool must be added by the ADDVOL command. This JES3 requirement prevents the user from defining a volume pool that cannot be changed and fails the recall every time it is selected. It fails the recall because a volume cannot be selected for recall unless it has been added by the ADDVOL command. It cannot be changed, except at DFSMSHsm startup, because the DEFINE and ADDVOL commands can be used only at DFSMSHsm startup.
2. In a JES2 environment, no volume in the volume pool needs to be added with the ADDVOL command or mounted for the DEFINE command. The RECALL command, however, still requires a volume added by the ADDVOL command before the volume can be selected for the recall. After DFSMSHsm startup, the ADDVOL command can be issued to add a volume, or the DEFINE command can be reissued with a new combination of volumes to change the association between volumes within a volume pool.

3. No checking is done to see if a volume is SMS-managed. A data set migrated from a volume that has been converted to SMS is recalled (if it is to be recalled as non-SMS) to a non-SMS-managed volume in the volume pool. The pool is not used for data sets recalled as SMS.
4. If *poolid* is specified without VOLUMES being specified, the volume pool becomes empty.
5. The hierarchy of selecting a candidate volume for recall is as follows:
 - A limit of 140 volumes can be defined to a volume pool.
 - If a data set being recalled is associated with a data set pool, the candidate volumes are selected from the data set pool.
 - If the volume from which the data set migrated is part of a volume pool, the candidate volume is selected from the volume pool.
 - If a volume is defined in multiple volume pools, the first definition is used. For example, if a data set was migrated from volume VP0001 and is recalled, it is recalled to volume pool SAMPLE1:

```
DEFINE VOLUMEPOOL(SAMPLE1 VOLUMES(VP0001 VP0003))
DEFINE VOLUMEPOOL(SAMPLE2 VOLUMES(VP0001 VP0002 VP0003))
```

- If the volume from which the data set migrated is not part of a volume pool, the candidate volumes are selected based upon the SETSYS RECALL values of ANYSTORAGEVOLUME or PRIVATEVOLUME.

DUMPCCLASS(TAPE | CLOUD): Specifying where the dump copies to reside

Explanation: **TAPE | CLOUD(*cloud_network_connection_name*)** is an optional parameter of DUMPCCLASS that specifies the device category where the dump copies are stored.

Subparameter	Explanation
TAPE	DUMPCCLASS(TAPE) specifies that the associated primary volumes are dumped to tape volumes.
CLOUD(<i>cloud_network_connection_name</i>)	<p>DUMPCCLASS(CLOUD(<i>cloud_network_connection_name</i>)) specifies that the associated volumes are dumped directly to the specified cloud object storage. The <i>cloud_network_connection_name</i> is the name of the SMS network connection construct or the CDA provider file (when OA66197 enabled). If the specified name does not match what is in the SMS construct or the CDA provider file (when OA66197 enabled), the DEFINE DUMPCCLASS fails.</p> <p>To remove the DUMPCCLASS(CLOUD) designation for the dump class, ensure that all associated dump copies are deleted, then specify DUMPCCLASS(TAPE).</p>

Defaults: If you do not specify this parameter, the default is TAPE for a new dump class, or the previous dump device category for an existing dump class.

Note: The following DEFINE DUMPCCLASS parameters are not applicable when the dump copy is resides in the cloud object storage:

- AUTOREUSE | NOAUTOREUSE - These settings apply to dump tape volumes.
- DATASETRESTORE | NODATASETRESTORE - Neither parameter settings are applicable to dump copies residing in cloud storage. Data set recovery from full volume dump copy residing in cloud object storage is not supported as of z/OS V2R5.
- ENCRYPTION - These settings are not applicable in transparent cloud tiering.
- FRRECOV(AFM(NO | YES)) - These settings apply to dump tape volumes.
- HWCOMPRESS(NO | YES) - These settings are not applicable in transparent cloud tiering.
- STACK | MAXSTACK, MINSTACK - These settings apply to dump tape volumes.
- TAPEEXPIRATIONDATE - These settings apply to dump tape volumes.

UNIT(*unitname*) - These settings apply to dump tape volumes.

Examples of how to code the DEFINE command

The following examples present different ways to code the DEFINE command:

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Specifying key ranges for DASD migration level 2 volumes

In this example, key ranges are assigned to the specified migration level 2 volumes. Data sets with the set of initial characters of the data set name within key range A through F9999999 migrate to the level 2 volume with volume serial number VOL002. Data sets with the set of initial characters of the data set name within key range G through L9999999 migrate to the level 2 volume with volume serial number VOL005. Data sets with the set of initial characters of the data set name within key range M through R9999999 migrate to the level 2 volume with volume serial number VOL007. Data sets with the set of initial characters of the data set name within key range S through Z9999999 migrate to the level 2 volume with volume serial number VOL009.

```
DEFINE MIGRATIONLEVEL2(KEYS(G M S) VOLUMES(VOL002 VOL005 +
VOL007 VOL009))
```

Specifying a pool of volumes

In this example, two volumes are specified as the pool used when data sets with the pool ID FE.T3322 are recalled.

```
DEFINE POOL(FE.T3322 VOLUMES(FET001 FET002))
```

Specifying the automatic primary space management cycle

In this example, an automatic primary space management cycle of five days is defined. The automatic primary space management functions are to run on the fifth day of the cycle. CYCLESTARTDATE without a date specified is redefined to today's date.

```
DEFINE PRIMARYSPMGMTCYCLE(NNNNY CYCLESTARTDATE)
```

Specifying the automatic secondary space management cycle

In this example, an automatic secondary space management cycle of seven days is defined. The automatic secondary space management functions are to run on the seventh day of the cycle. CYCLESTARTDATE without a date specified is redefined to today's date.

```
DEFINE SECONDARYSPMGMTCYCLE(NNNNNY CYCLESTARTDATE)
```

Specifying a backup cycle

In this example, a backup cycle of seven days is defined, with two volumes used for each day in the cycle when volume backup is processed. The example specifies that the automatic backup function is processed on the second and fifth days of the cycle. The starting date for the backup cycle is October 1, 1997.

```
DEFINE BACKUP(NYNNYNN 2 CYCLESTARTDATE(1997/10/01))
```

Specifying a dump cycle

In this example, a dump cycle of seven days is defined, with a cycle start date of 96/12/29. If the cycle start date is a Sunday, the specified dump cycle results in the automatic dump function running Monday through Friday, but not running on Saturday or Sunday.

```
DEFINE DUMPCYCLE(NYYYYYN +
  CYCLESTARTDATE(1996/12/29))
```

Specifying the number of VTOC copy data sets to keep for each volume dumped

In this example, 12 copies of the VTOC copy data sets are to be kept for a dumped volume.

```
DEFINE DUMPCCLASS(class VTOCCOPIES(12))
```

Specifying a dump class for a volume

In this example, a dump class for a 3590-1 type volume with a class name of *weekly* is defined. The other parameters used in our example are:

- DFSMSdss resets the change bit for each data set.
- A physical data set restore is allowed.
- The volume can be automatically reused when invalidated by the retention period of 15 days.
- The target day of the dump for this dump class is the sixth day of the dump cycle.
- The dump volume is to be dumped every Friday night.
- A maximum of ten dump copies can be placed on this volume.

```
DEFINE DUMPCCLASS(WEEKLY UNIT(3590-1) +
  RESET DATASETRESTORE AUTOREUSE +
  RETENTIONPERIOD(15) DAY(6) +
  DISPOSITION('DUMP EVERY FRI NITE.') +
  (STACK(10)))
```

Specifying a pool of volumes to be used for recovering an aggregate group

In this example, four volumes are specified to be used for recovery of the aggregate group *PAY1*. Two volumes are for recovery of level 0 non-SMS-managed data sets, and two volumes are for recovery of migrated data sets.

```
DEFINE ARPOOL(PAY1 ML1VOLS(MPAY1 MPAY2) +
  L0VOLS(PAY001 PAY002))
```

Specifying when to demount and deallocate output tapes that are used by command data set backup

In this example, output tapes that are used by command data set backup are demounted at the end of the autobackup cycle, and the devices are deallocated. Single-file format output tapes are not available for reuse when a switch tape event occurs.

```
DEFINE SWICTAPES(DSBACKUP(AUTOBACKUPEND PARTIALTAPE(MARKFULL)))
```

Specifying encryption and HWCOMPRESS settings

In this example, the data will be compressed with hardware-assisted compression and then encrypted prior to being dumped.

DEFINE command for DFSMSHsm

```
DEFINE DUMPCCLASS(ENCRYPT(RSA(CCA.CRT08.INT.ENC.1024S0F)  
TYPE(CLRTHDES)) HWCMPRESS(YES))
```

Chapter 41. DELETE Command: Deleting a migrated data set from a migration volume

The DELETE command deletes a migrated data set without recalling the data set. When you specify the DELETE command, DFSMSHsm deletes the MCDS data set record and the migrated data set. DFSMSHsm does not delete backup versions of the data set. If you want to delete the backup versions of a deleted data set, you must use the BDELETE command. See [Chapter 37, “BDELETE command: Deleting backup versions of a data set,” on page 797](#) for information about the BDELETE command.

Syntax of the DELETE command

► DELETE — *dsname* — 

Required parameters of the DELETE command

This topic describes the required parameter of the DELETE command.

dsname: Specifying the data set to be deleted

Explanation

dsname is a required parameter specifying the fully qualified name of the migrated data set that you want to delete. DFSMSHsm deletes the data set without recalling it.

Defaults

None.

Usages notes:

1. You cannot specify an alias for *dsname*. If you do, DFSMSHsm does not delete the data set.
2. DFSMSHsm fails any DFSMSHsm delete command that specifies a member name of a partitioned data set.
3. DFSMSHsm will not uncatalog an original data set unless the cataloged volume serial is MIGRAT. This prevents DFSMSHsm from inadvertently scratching a newly cataloged data set of the same name.
4. The command fails for both SMS-managed and non-SMS-managed data sets if the *dsname* specified on the command is determined by DFSMSHsm to be one of the following:
 - An associated part of a VSAM data set (for example, a data component name, index component name, path name) rather than the base cluster name.
 - The name of a migration copy data set.

Optional parameters of the DELETE command

This topic describes the optional parameter of the DELETE command.

PURGE: Specifying deletion of a data set

Explanation

PURGE is an optional parameter specifying deletion of the data set *dsname* even if the data set is still within its retention period.

Defaults

If PURGE is not specified, DFSMSHsm deletes data set *dsname* only if it has exceeded its retention period.

Examples of how to code the DELETE command

The following examples present different ways to code the DELETE command.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Deleting a migrated data set

In this example, a migrated data set (SMS or non-SMS) is deleted from a migration volume without recalling the data set.

```
DELETE WIN3357.PLAN.PLI
```

Deleting a migrated data set within its retention period

In this example, a migrated data set (SMS or non-SMS) is deleted from a migration volume even if it is within its retention period.

```
DELETE L541563.PSF.N.F230EP03.DSET1 PURGE
```

Chapter 42. DELVOL command: Removing a volume from DFSMSHsm management

The DELVOL command reassigns the volume as not managed or owned by DFSMSHsm. You can remove a primary volume (in this instance, PRIMARY includes both volumes added using the ADDVOL command and SMS-managed volumes), migration volume, dump volume, dump version of a copy pool, or backup volume from the list by specifying the serial number and the category of the volume you want to remove. If a DELVOL command is entered for an SMS-managed volume, the MCV record for the volume, if it exists, is deleted. You can remove only one volume each time you issue the DELVOL command unless the volume specified is part of a valid dump copy, then all volumes containing part of the same dump copy are removed from DFSMSHsm.

Although you can respecify a deleted non-SMS-managed volume with the ADDVOL command, historical information about the deleted volume is lost. This information is included in the MCDS and BCDS volume records. If you use ADDVOL to respecify the volume, DFSMSHsm recreates the volume record without the historical information.

Note: The DELVOL command must be issued on each system in the DFSMSHsm plex where this volume is to be used.

Syntax of the DELVOL command

A: BACKUP and MIGRATION optional parameters

B: DUMP optional parameters

Note:

1. If you specify the COPYPOOLCOPY, LASTCOPY, MARKFULL, PURGE, REASSIGN, or UNASSIGN subparameter of the BACKUP, DUMP, or MIGRATION parameter, you must put parentheses around the subparameter.
2. If the volume serial number is for an SMS-managed volume, only the PRIMARY parameter applies.
3. If a DELVOL MIGRATION command is used to delete a migration volume while the automatic secondary space management function is running, the DELVOL MIGRATION command fails.
4. If SMS storage groups change, use the DELVOL command to remove from DFSMSHsm control those volumes that were removed from the SMS storage groups before daily automatic functions started.

Remove those volumes on all DFSMSHsm systems that know about them so that the MVT entries are no longer present.

Required parameters of the DELVOL command

This topic describes the required parameters of the DELVOL command.

volser: Specifying the volume you are deleting

Explanation: *volser* is a required positional parameter for which you substitute the serial number of the volume you want to delete.

Defaults: None.

Note:

1. Because *volser* is a required positional parameter, you must specify it immediately after the command name.
2. Intermittent DELVOLs of active SMS-managed volumes have little effect, because the list of volumes is obtained prior to each automatic function, and MVT and MCV records for the volumes are built at that time.

BACKUP, DUMP, MIGRATION, and PRIMARY: Specifying the type of volume

Explanation: **BACKUP, DUMP, MIGRATION, and PRIMARY** are mutually exclusive, required parameters specifying what type of volume to delete.

BACKUP specifies that a backup volume is reassigned as an unassigned volume or, if the PURGE subparameter is specified, deleted from DFSMSHsm control.

DUMP specifies that a dump volume is disassociated from the dump class to which it is currently assigned and all record of its contents is discarded. In addition, the PURGE or REASSIGN subparameters can be specified to remove the volume from the control of DFSMSHsm or to retain the associated dump class respectively. If the volume specified is part of a valid dump copy, all volumes containing part of the same dump copy are treated similarly.

MIGRATION specifies that a migration volume is changed as follows:

- In the case of a migration level 1 volume, the volume is deleted from DFSMSHsm control.
- In the case of a DASD migration level 2 volume, the volume is no longer associated with its key range and is available for selection. If the optional PURGE subparameter is specified, the volume is removed from the control of DFSMSHsm.
- In the case of a tape migration level 2 volume, the volume is marked as not selected and is therefore available unless full. If the optional PURGE subparameter is specified, the volume is removed from the control of DFSMSHsm if no valid data exists on the volume.

Note: In the preceding cases, DFSMSHsm determines from the serial number whether the volume you have identified with the *volser* positional parameter is a migration level 1 volume or a migration level 2 volume.

PRIMARY specifies that a primary volume (a volume added using the ADDVOL command or an SMS-managed volume) is deleted from DFSMSHsm control. DFSMSHsm removes the record of the deleted volume from the MCDS.

Defaults: None.

Note:

1. If you issue the BACKUP parameter of the DELVOL command while the backup volume is in use, the command fails.
2. If you issue the MIGRATION parameter of the DELVOL command while automatic volume space management or automatic secondary space management is running, the command fails.

3. If you issue the PRIMARY parameter of the DELVOL command while that volume is being processed by automatic space management, automatic backup, or automatic dump, the command fails.
4. If you issue the DUMP parameter of the DELVOL command while automatic dump is running, the command fails.
5. If you use the MIGRATION parameter of the DELVOL command to delete a migration level 2 tape volume that has incomplete data set information saved in the OCDS TTOC record, the command fails.

Optional parameters of the DELVOL command

This topic describes the optional parameters of the DELVOL command.

COPYPOOLCOPY: Deleting a copy pool dump volume

Explanation: **COPYPOOLCOPY** is an optional subparameter that must be specified to delete a dump volume that contains one or more copy pool dump copies. During DELVOL processing, a REQUIRED COMPLETE or ALL COMPLETE dump version of a copy pool is marked as a partial so that dump processing for that version can be resumed at a later time if the DASD copy is still valid.

Defaults: None.

LASTCOPY: Invalidating the only valid dump copy of a source volume

Explanation: **LASTCOPY** is an optional subparameter that must be specified to delete a dump volume that is part of the only valid dump copy of a source volume. LASTCOPY is ignored if it is not part of the only copy.

Defaults: None.

MARKFULL, PURGE, REASSIGN, and UNASSIGN: Specifying the options for deleting a backup, dump, or ML2 volume

Explanation: **MARKFULL**, **PURGE**, **REASSIGN**, and **UNASSIGN** are mutually exclusive, optional subparameters of the BACKUP, DUMP, and MIGRATION parameters specifying whether the volume is deleted, reassigned, or marked full.

Note:

1. MARKFULL applies only to tape backup and migration volumes.
2. These subparameters do not apply to primary or migration level 1 volumes.

MARKFULL with BACKUP or MIGRATION

When you specify MARKFULL with the BACKUP or MIGRATION parameters, MARKFULL specifies that the requested backup or migration volumes be marked full. No other processing will be performed. This subparameter allows you to make a tape volume available for RECYCLE or TAPECOPY processing by marking the volume full. It can also be used to prevent a volume from being selected for further output processing.

PURGE with BACKUP

When you specify PURGE with the BACKUP parameter, PURGE specifies that DFSMSHsm delete all volume information, including the tape table of contents (TTOC) for a tape backup volume. DFSMSHsm removes the record of the deleted volume from the BCDS. In addition, DFSMSHsm deletes any association with a day in the backup cycle or with a set of spill backup volumes.

If the volume is a tape volume, all valid backup versions that exist on the tape volume are deleted, and the data on the tape is no longer usable. If an error occurs in deleting a valid backup version, DFSMSHsm continues deleting all other backup versions but does not delete the backup volume in which the error has occurred.

PURGE with DUMP

When you specify PURGE with the DUMP parameter, PURGE specifies that DFSMSHsm delete all volume information for a dump volume. DFSMSHsm removes the record of the deleted volume from the BCDS. In addition, DFSMSHsm deletes any association with the day in the dump cycle or with the dump class. DFSMSHsm also deletes any valid dump copies. The dump volume then becomes a scratch tape.

Depending upon the tape security option used for protection by DFSMSHsm, the volume may have to be reinitialized before being reused by another user or job.

PURGE with MIGRATION

When you specify PURGE with the MIGRATION parameter, PURGE specifies that DFSMSHsm delete all volume information for a non-SMS migration level 2 volume, including the TTOC for a tape non-SMS migration level 2 volume. Before DFSMSHsm removes a tape migration level 2 volume from its control, DFSMSHsm checks whether the volume still contains valid data. If it does, DFSMSHsm fails the DELVOL command and issues message ARC0260I.

If the PURGE parameter has been used because the ML2 tape was lost or destroyed and if the command fails and message ARC0260I is displayed, perform the following steps:

1. Issue the MIGRATE VOLUME (*volser* DBA(0)) command to remove all record of valid data. Only non-SMS data sets whose expiration dates have been reached are scratched. If the ML2 tape volume contains SMS data, the volume is not eligible for DELVOL processing.
2. Reissue the DELVOL PURGE command.

Note: Do this only if the tape is totally unusable because the DELVOL PURGE command removes what may be the only copy of the data. If backup copies are available, recover the data sets that the MIGRATE command deleted. If the volume is DASD or if the volume is a tape that does not contain valid data, DFSMSHsm removes the record of the deleted volume from the MCDS.

REASSIGN with DUMP

When you specify the REASSIGN subparameter with the dump parameters, REASSIGN specifies that the contents of that volume are to be discarded. The volume is also made available and is associated with its original dump class. The original dump class is the class specified with the ADDVOL command. If no class is specified with ADDVOL, then there is no associated dump class after the DELVOL REASSIGN. DFSMSHsm can reuse the reassigned volume without reinitialization. REASSIGN is applicable only for dump volumes.

UNASSIGN with BACKUP

When you specify the UNASSIGN subparameter with the BACKUP parameter, UNASSIGN specifies that the volume is no longer associated with the day in the backup cycle or with the set of spill volumes. The volume becomes an unassigned backup volume. All volume and data set information is kept in the BCDS and, for tape backup volumes, in the OCDS. The unassigned volume can be selected as a daily or spill backup volume.

UNASSIGN with DUMP

When you specify UNASSIGN with the DUMP parameter, UNASSIGN specifies that the volume is to remain known to DFSMSHsm but must be removed from its current use. The volume is also disassociated from the dump class to which it is currently assigned. All records of the volume's contents must be discarded. DFSMSHsm can reuse the volume without reinitialization. If the volume is available for reuse, it is available to any dump class requiring a volume of the same unit type.

UNASSIGN with MIGRATION

When you specify UNASSIGN with the MIGRATION parameter, UNASSIGN specifies that the DASD migration level 2 volume is no longer associated with its key range and is available for selection. If the

volume is a tape migration level 2 volume, DFSMSHsm marks the volume as not selected. Therefore, the tape migration level 2 volume is available unless it is full.

Defaults: If you do not specify PURGE, REASSIGN, or UNASSIGN, the default is UNASSIGN.

Note:

1. You can delete valid data from a tape backup volume or dump volume if you specify the PURGE parameter. DFSMSHsm deletes all control data set information associated with each valid backup version dump copy on the purged tape backup volume or dump volume. As a result, DFSMSHsm can no longer recover backup versions from the tape volume.
2. You specify only a migration level 2 volume when you use the PURGE or UNASSIGN subparameter with the MIGRATION parameter. If you specify a migration level 1 volume, DFSMSHsm ignores the parameter and a purge is performed.
3. If you use the PURGE parameter to remove a tape volume from control of DFSMSHsm and the tape volume is protected by a password or expiration date, reinitialize the tape volume. You reinitialize the tape volume with the IEHINITT utility. If you do not reinitialize the purged tape volume and another program tries to write on the tape volume, message IEC512I is issued and the tape volume is unloaded.
4. If you do not reinitialize the purged tape volume, and if DFSMSHsm protected the tape volume with an expiration date, and another program tried to write on the tape volume, the following occurs:
 - Message IEC507D is issued.
 - The operator is prompted to approve or disapprove the attempt to write over an expiration-date-protected data set whose expiration date has not been reached. If the operator disapproves the use of the tape volume, the tape volume is unloaded and removed from the inventory of backup or migration volumes.
5. Messages IEC512I and IEC507D occur only if the program trying to write on the tape volume is not using the volume verification exit to override the password or expiration date protection on the first file on the tape volume.
6. If you use the ADDVOL command to add a purged tape volume to the list of tape volumes owned by DFSMSHsm and the purged tape volume was previously protected by a password or expiration date, reinitialize the tape volume. If you do not reinitialize the purged tape volume and another program tries to write on the tape volume, message IEC512I is issued, the tape volume is unloaded, and the tape volume is removed from the inventory of backup, dump, and migration volumes.
7. If a dump volume has more than one dump copy stacked on it, you must use the PURGE parameter to delete the volume.

Examples of how to code the DELVOL command

The following examples present different ways to code the DELVOL command.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Deleting a primary volume

In this example, a primary volume (added using the ADDVOL command or SMS-managed) is deleted from DFSMSHsm control.

```
DELVOL VOL005 PRIMARY
```

Deleting a migration level 1 volume

In this example, a migration level 1 volume is deleted from DFSMSHsm control.

```
DELVOL MIG003 MIGRATION
```

Marking a migration level 2 tape volume full

In this example, a migration level 2 tape volume is marked full. The MARKFULL parameter does not delete the volume.

```
DELVOL MIG003 MIGRATION(MARKFULL)
```

Unassigning a backup volume

In this example, a backup volume becomes an unassigned backup volume of DFSMSHsm.

```
DELVOL BAC001 BACKUP(UNASSIGN)
```

Deleting a tape migration level 2 volume

In this example, a tape migration level 2 volume is purged from DFSMSHsm if it does not contain any valid data.

```
DELVOL TML203 MIGRATION(PURGE)
```

Deleting a DASD migration level 2 volume

In this example, a DASD migration level 2 volume is purged from DFSMSHsm.

```
DELVOL DML201 MIGRATION(PURGE)
```

Deleting a tape backup volume

In this example, a tape backup volume is deleted from DFSMSHsm's control. All record of any valid backup versions on the tape is also deleted.

```
DELVOL TAPE01 BACKUP(PURGE)
```

Deleting a dump volume

In this example, a dump volume is deleted and its contents are discarded. The volume is made available and is associated with its original dump class.

```
DELVOL DUPT01 DUMP(REASSIGN)
```

Deleting a dump volume that is part of the only valid dump copy of a source volume

In this example, a dump volume is part of the only valid dump copy of a source volume. The volume is made available but is not associated with any dump class.

```
DELVOL DUPT02 DUMP(UNASSIGN LASTCOPY)
```

Purging the records for a dump volume that is part of the only valid dump copy of a source volume

In this example, a dump volume is part of the only valid dump copy of a source volume. The volume is purged from DFSMSHsm.

```
DELVOL DUPT02 DUMP(PURGE LASTCOPY)
```

Deleting a copy pool dump volume

In this example, an unneeded dump volume that contains one or more copy pool dump copies is deleted from DFSMSHsm control.

```
DELVOL DUPT03 DUMP(COPYPOOLCOPY)
```

Chapter 43. DISPLAY command: Displaying DFSMSHsm storage locations

The DISPLAY command is used for maintenance purposes only; for information, see [*z/OS DFSMSHsm Diagnosis*](#).

Chapter 44. EXPIREBV command: Deleting unwanted backup versions of data sets and UNIX files

The EXPIREBV command is used to delete unwanted backup and expired ABARS versions of SMS-managed and non-SMS-managed data sets and unwanted backup versions of UNIX files from DFSMShsm-owned storage. The optional parameters of the EXPIREBV command determine the deletion of the backup versions of non-SMS-managed data sets and UNIX files. The management class attributes determine the deletion of backup versions of SMS-managed data sets. The management class fields **Retain Extra Versions** and **Retain Only Version** determine which ABARS versions or incremental backup versions are deleted. The RETAIN DAYS value that is provided during the data set or UNIX file backup request determines how long a data set backup copy is kept for both SMS-managed and non-SMS-managed data sets and UNIX files.

A detailed description of eligibility considerations for both SMS-managed and non-SMS-managed data sets is provided in the [Chapter 8, “Aggregate backup and recovery support \(ABARS\),” on page 319](#).

EXPIREBV determines if a backed-up data set should be considered SMS-managed (and thus whether to apply management-class attributes or EXPIREBV command parameters in expiring cataloged backup versions) by the most recent status of the data set:

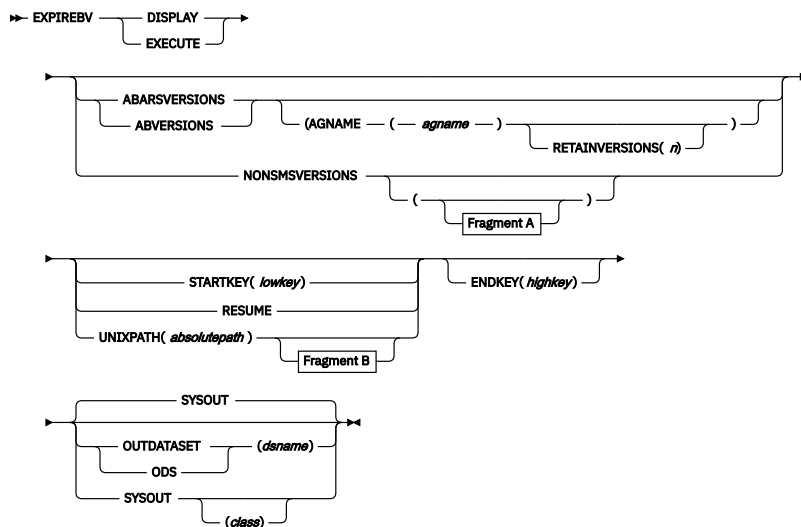

- If the data set is still cataloged, SMS-managed status is taken from the data set’s current catalog entry.
- If the data set has been deleted (that is, if it is no longer cataloged), SMS-managed status is the same as it was the last time the data set was backed up.

The SMS Management class of the zFS data set that contains the UNIX file system will apply to the UNIX file. Specifically, the number of backup versions attribute in the management class will apply to backup versions of the UNIX file. If the zFS that contains the UNIX file is non-SMS managed, then the value of SETSYS VERSIONS will apply.

When the EXPIREBV command is processing a backup of a UNIX file, the management class of the zFS data set containing the UNIX file is used to determine the expiration criteria for the backup. If the zFS data set that contained the UNIX file does not exist, the management class that was associated with the file when the last backup version was made is used. If the UNIX file is determined to be non-SMS-managed, then the DELETEIFBACKEDUP or CATALOGEDDATA sub-parameters of the NONSMSVERSIONS parameter criteria is used.

Note: The EXPIREBV command processes a backup of a UNIX file only if the containing file system is mounted. If the file system is unmounted, the backup version processing is skipped.

Syntax of the EXPIREBV command

A: NONSMSVERSIONS Optional Parameters

B: UNIXPATH Optional Parameters

Note: The NONSMSVERSIONS parameter does not apply to SMS-managed data sets.

Required parameters of the EXPIREBV command

This topic describes the required parameters of the EXPIREBV command.

DISPLAY and EXECUTE: Specifying whether to delete the backup versions

Explanation

DISPLAY and EXECUTE are mutually exclusive, required parameters specifying whether to delete the ABARS or backup versions or just to produce a listing of the ABARS or backup versions eligible for deletion.

DISPLAY

produces a line in the listing for every ABARS or backup version eligible for deletion based on the appropriate input parameters or management class attributes. The listing is written to a particular output class or DASD data set, depending on the value of the OUTDATASET | SYSOUT parameter.

EXECUTE

specifies that the ABARS or backup versions should be deleted based on the input parameters and management class attributes. The output consists of an ARC0734I message for each backup version eligible for deletion. The messages are written to the backup activity log, depending on the values specified by SETSYS ACTLOGMSGLVL:

- FULL specifies that all ARC0734I messages are produced.
- EXCEPTIONONLY specifies that an ARC0734I message is produced only when there is a failure.
- REDUCED has the same effect as EXCEPTIONONLY.

Defaults

None.

Usage notes:

1. If the DISPLAY parameter is specified, no backup versions are deleted. If, however, any backed up, cataloged data sets have been scratched and do not already have a scratch date recorded, the current date is recorded as the scratch date for those data sets. This scratch date is used by subsequent EXPIREBV commands to determine whether active backup versions of these cataloged data sets are eligible for deletion.
2. When EXPIREBV is invoked and it detects a scratched data set, it creates a scratch date for that data set. The date is stored in the BCDS MCB record in a 4-byte field MCBSCDR (offset X'48', packed decimal). The date can be displayed using the FIXCDS command. When EXPIREBV is again invoked and it encounters the same data set—which now has an established scratch date—it deletes the data set (when the data set meets the criteria for deletion). Thus, if you are running EXPIREBV for the first time, you do not get a list of deleted data sets. On subsequent occurrences, you will get a list, as long as the data sets meet the criteria for deletion.

Optional parameters of the EXPIREBV command

This topic describes the optional parameters of the EXPIREBV command.

ABARSVERSIONS: Specifying that only aggregate group versions are to be processed

Explanation

ABARSVERSIONS is an optional parameter specifying that only ABARS activity records (ABR) in the BCDS are processed by the EXPIREBV command. This parameter is mutually exclusive with the NONSMSVERSIONS parameter and is functionally exclusive to processing backup versions of SMS data sets. This parameter can be used to delete old ABR records.

The following are optional parameters of the ABARSVERSIONS parameter:

AGNAME(*agname*)

Process only the activity records associated with the specified aggregate group (*agname*).

RETAINVERSIONS(*n*)

Retain a specific number (*n*) of ABR versions. This parameter is used with the AGNAME parameter when EXECUTE is specified. If you do not want to retain any versions of a particular aggregate group's ABR record, specify zero. Specifying zero allows you to clean up the ABR records for aggregate groups no longer being processed.

Defaults

None.

Usage notes:

1. Running EXPIREBV for ABARS should only be needed if you have an aggregate that you no longer use and you need to clean up old records. For more information, see [“Expiring ABR records in the BCDS” on page 354](#).

NONSMSVERSIONS: Specifying expiration criteria for backup versions of data sets not managed by SMS

Explanation

NONSMSVERSIONS is an optional parameter specifying that you want backup versions of non-SMS-managed data sets processed during processing of the EXPIREBV command.

The following are optional parameters of the NONSMSVERSIONS parameter:

DELETEIFBACKEDUP

Controls the deletion of retired versions. If the age of a retired version exceeds *days*, the retired version is deleted along with all other backup versions that were made for the same cataloged non-SMS-managed data set.

CATALOGEDDATA

Controls the deletion of backup versions (other than the retired version) of non-SMS-managed data sets that were cataloged when they were backed up. If the difference between the scratch date recorded by a prior EXPIREBV command and the current date exceeds *days*, all backup versions of the cataloged data set, except the retired version, are deleted. If the cataloged data set has not been deleted, the *days* parameter is ignored and all excess backup versions (as a result of an (H)ALTERDS command) are deleted.

UNCATALOGEDDATA

Controls the deletion of backup versions made of non-SMS-managed data sets that were uncataloged when they were backed up. If the age of a backup version exceeds *days*, the backup version is deleted.

days

Number of days (0–9999) to keep a retired version (DELETEIFBACKUP), a backup version of a cataloged data set after the EXPIREBV command determines the data set has been deleted (CATALOGDDATA), or a backup version of an uncataloged data set (UNCATALOGEDDATA).

Defaults

If RETAINDDAYS is specified at the time of data set backup, the RETAINDDAYS value takes precedence over NONSMSVERSION. If RETAINDDAYS is not specified and you do not specify NONSMSVERSIONS on the command, backup versions of non-SMS-managed data sets are not processed.

If you specify DELETEIFBACKEDUP with no *days* value, the DFSMSHsm default is 150 days. If you do not specify DELETEIFBACKEDUP on the command, retired versions are not processed.

If you specify CATALOGEDDATA with no *days* value, the default for *days* is 60. If you do not specify CATALOGEDDATA on the command, backup versions of cataloged, non-SMS-managed data sets are not processed.

If you specify UNCATALOGEDDATA, you must specify *days*. If you do not specify UNCATALOGEDDATA on the command, backup versions of uncataloged, non-SMS-managed data sets are not processed.

Usage notes:

1. The result of the CATALOGEDDATA and UNCATALOGEDDATA subparameters is based on whether a data set was cataloged or uncataloged when a given backup version was created, not its current status.
2. Eligibility for deletion of a backup version under the CATALOGEDDATA criterion is based on the number of days that have passed since a prior EXPIREBV command determined that a cataloged data set has been scratched. This means that you must issue the EXPIREBV command a minimum of two times: once to record that the cataloged data set has been scratched and once to calculate whether the difference between the current date and the recorded scratch date exceeds the specified number of days.
3. At least one of the optional subparameters of NONSMSVERSIONS must be specified.

4. The EXPIREBV command examines only the latest backup version for a data set name to determine the existence of a retired version, and it treats all backup versions older than the latest version (and all versions of data sets uncataloged at the time of backup) as nonretired versions. (A retired version is the backup version DFSMSHsm creates before it scratches a data set during data set retirement. DFSMSHsm does not automatically delete retired versions.)
5. If the SETSYS versions parameter is decreased and the EXPIREBV command is executed prior to the time the next backup version is created, all excess versions—whether cataloged or uncataloged—are deleted.
6. Eligibility for deletion of a backup version under the CATALOGEDDATA criterion for existing cataloged data sets is based on the current version limit.

STARTKEY and RESUME: Determining the starting point for BCDS processing during command execution

Explanation

STARTKEY and RESUME are mutually exclusive, optional parameters that you specify to control from which BCDS record the processing is started during command execution.

STARTKEY

Specifies a start key.

lowkey

Provides a starting point for processing in the BCDS. The value of *lowkey* can be up to 44 alphanumeric characters that identify the data set for which you want the deletion of backup versions to begin. Numbers are higher in the range (they follow Z) than letters. The value specified cannot end in a period. If fewer than 44 characters are entered, the value specified is appended with X'00' to make 44 characters.

RESUME

Starts processing at the point the EXPIREBV command left off the last time an EXPIREBV command was processed on this host.

Defaults

If you do not specify STARTKEY or RESUME, processing begins at the beginning of the BCDS. If you specify RESUME and the most recent EXPIREBV command processed on this DFSMSHsm host did not end early, processing begins at the beginning of the BCDS.

Usage notes:

1. During processing of the EXPIREBV command, the current key (data set name) is saved periodically.

UNIXPATH: Specifying the UNIX file, empty directory, or nonempty directory to analyze for backup

Explanation

UNIXPATH is used to specify an absolute path (that is, starting from the '/' [root] directory) to a UNIX file, empty directory, or nonempty directory to analyze for backup expiration. If a UNIX file or empty directory is specified, then only that is analyzed. If a nonempty UNIX directory is specified, then the directory node itself is checked (in the case it was backed up when it was an empty directory) and then all direct children.

The following are optional parameters of the UNIXPATH parameter:

absolute path

Absolute UNIX path starting from the root (that is, '/') directory. The absolute path might contain one of the following:

1. Absolute UNIX path to a file (for example, '/absolute/path/myfile.json')

2. Absolute UNIX path to an empty directory (for example, '/absolute/path/emptydir/').
3. Absolute UNIX path to a nonempty directory (for example, '/absolute/path/nonemptydir/')

Note: When a directory (whether empty or nonempty) is specified a trailing '/' must be included. For example:

Incorrect '/absolute/path/mydir'

Correct '/absolute/path/mydir/'

Defaults

None.

Usage notes:

1. Specifying UNIXPATH alone does not cause DFSMSHsm to recurse into subdirectories unless the RECURSE option is explicitly specified also.
2. The RESUME option, as it relates to the UNIXPATH('absolute/path') being the most recent EXPIREBV command run but was CANCELED for whatever reason, is targeted as follows:
 - If UNIXPATH only was specified (for example, without RECURSE) and when processing it is CANCELED and later RESUME was specified (caveat is no other EXPIREBV commands are run in between that CANCELED instance and trying to RESUME), DFSMSHsm continues as follows:
 - When a UNIX file is specified in this scenario, RESUME causes DFSMSHsm to continue processing siblings within the same containing directory as the original UNIX file (DFSMSHsm does not recurse into subdirectories).
 - When an empty UNIX directory is specified in this scenario, RESUME causes DFSMSHsm to continue processing siblings within the same containing directory as the original UNIX file (DFSMSHsm does not recurse into subdirectories).
 - When a nonempty UNIX directory is specified in this scenario, RESUME causes DFSMSHsm to continue traversing the sibling linked list of the given directory from that last saved key in the BCR (Recall that EXPIREBV processing state is periodically saved in the BCR record). Note that this continuation in processing looks at siblings that are UNIX files or empty UNIX directories, it does not recurse into subdirectories when they are found.
3. Issuing the RESUME option after a successful completion of an EXPIREBV UNIXPATH (+- any other optional parameters) causes EXPIREBV to begin from the first record in the BCDS, as is the case with other combinations that finish successfully and then are RESUMEd (for example, STARTKEY). It is important to note is that DFSMSHsm does not continue processing from within the UNIX file tree if RESUME is issued after a successful EXPIREBV UNIXPATH run.

RECURSE : Used with UNIXPATH to recurse into subdirectories of the directory specified with UNIXPATH

Explanation

RECURSE is an optional keyword exclusive to UNIXPATH, that when used with UNIXPATH causes DFSMSHsm to recurse into subdirectories of the specified directory with UNIXPATH. This allows logically related subtrees within the file system to be checked together.

The following are optional parameters of the UNIXPATH parameter:

NOCROSSMOUNTS

Indicates that, during recursion into subdirectories of the containing parent directory, DFSMSHsm should not recurse into subdirectories belonging to a different mount than the containing parent.

CROSSMOUNTS

Indicates that, during recursion into subdirectories of the containing parent directory, DFSMSHsm should recurse into subdirectories belonging to a different mount than the containing parent.

Defaults

If nothing is specified with the RECURSE option, then NOCROSSMOUNTS is assumed by default.

Usage notes:

1. If the absolute path specified with UNIXPATH is to a file or empty directory, RECURSE is ignored.
2. The RESUME option, as it relates to the UNIXPATH('absolutepath') + RECURSE(CROSSMOUNTS | NOCROSSMOUNTS) being the most recent EXPIREBV command run but was CANCELED for whatever reason, is targeted as follows:
 - If UNIXPATH('absolutepath') + RECURSE(CROSSMOUNTS | NOCROSSMOUNTS) is specified, and at some point during processing it is CANCELED and later RESUME is specified, it is considered an error and processing stops with message ARC0685I issued.

RETAINDAYONLYBACKUP: Optional keyword used in conjunction with UNIXPATH to override the RETAINDAYONLYBACKUP value assigned from the Management Class

Explanation

User may need the ability to override the RETAINDAYONLYBACKUP value assigned from the Management Class on an individual Unix file(s) or [sub]directory basis.

Defaults

None.

Usage notes: If not specified, the RETAINDAYONLYBACKUP value from the Management Class is used.

RETAINDAYSEXTRABACKUPS: Optional keyword used in conjunction with UNIXPATH to override the RETAINDAYSEXTRABACKUPS value assigned from the Management Class

Explanation

User may need the ability to override the RETAINDAYSEXTRABACKUPS value assigned from the Management Class on an individual Unix file(s) or [sub]directory basis.

Defaults

None.

Usage notes: If not specified, the RETAINDAYSEXTRABACKUPS value from the Management Class is used.

ENDKEY: Determining the ending point for BCDS processing during command execution

Explanation

ENDKEY is an optional parameter that you specify to control on which BCDS record the processing is completed during command execution.

The following is a required parameter of the ENDKEY parameter:

highkey

Provides an ending point for processing in the BCDS. The value of *highkey* can be up to 44 alphanumeric characters that identify the data set for which you want the deletion of backup versions

to end. Numbers are higher in the range (they follow Z) than letters. The value specified cannot end in a period. If fewer than 44 characters are entered, the value specified is appended with X'FF' to make 44 characters.

Defaults

If the ENDKEY subparameter is not specified, the planned end key is different, depending upon whether you specify RESUME. If the RESUME parameter is specified without ENDKEY, processing continues until the last specified planned end key, saved from the last EXPIREBV command issued for this host. If RESUME is specified without ENDKEY and the most recent EXPIREBV command processed in this host did not end early, processing continues to the end of the BCDS. If neither RESUME nor ENDKEY is specified, processing continues to the end of the BCDS.

Usage notes:

1. When processing is started for the EXPIREBV command, the planned ending key is saved.
2. If the value of *highkey* is equal to the value of *lowkey*, DFSMSHsm attempts to process only the data set (MCB) records with those initial characters. If the value of *highkey* is less than the value of *lowkey*, DFSMSHsm fails the command with an error message.

OUTDATASET and SYSOUT: Specifying the output location for EXPIREBV DISPLAY listing

Explanation

OUTDATASET and SYSOUT are mutually exclusive, optional parameters specifying the output location for the listing produced while running the EXPIREBV command with the DISPLAY option.

OUTDATASET

Directs output to a data set.

If the data set does not exist, DFSMSHsm dynamically allocates and catalogs an output data set with the following characteristics:

- Data set name specified (*dsname*)
- Record format of fixed-blocked with ANSI control characters (FBA)
- Logical record length of 121
- Data set is system reblockable
- Primary allocation of 20 tracks (see note)
- Secondary allocation of 50 tracks (see note)
- Unit of SYSALLDA (see note)

If the data set already exists, DFSMSHsm will use the data set. The data set must have the following characteristics:

- The data set must be cataloged and on DASD.
- The data set record format must be FBA and the logical record length must be 121.
- The data set is system reblockable.
- The user can choose the primary space allocation.
- If DFSMSHsm needs additional extents after the primary space allocation, DFSMSHsm uses a secondary space allocation of 50 tracks. (see note)
- If the data set does not contain data, DFSMSHsm starts writing output data at the beginning of the data set.
- If the data set contains data, DFSMSHsm writes the output data after the existing data.

dsname

Name of the data set to which DFSMSHsm writes the output data. For *dsname*, substitute the fully qualified name of the data set that receives the EXPIREBV output.

SYSOUT

Directs output to a specified output class. This is the default.

class

Alphanumeric character representing the output class. The default class is A, unless otherwise specified by the SETSYS command.

Defaults

The default is SYSOUT, and the default for *class* is the value specified with the SETSYS command. If you do not use the SYSOUT parameter of the SETSYS command to specify the output location, the default is class A.

Usage notes:

1. These parameters do not apply when the EXECUTE option is specified. If either of these parameters is entered when it does not apply, it is ignored.
2. If you select the OUTDATASET option, you can use the PATCH command to change the unit name, primary allocation, and secondary allocation. If you select the SYSOUT option, you can use the PATCH command to change whether, and how, DFSMSHsm limits the lines of SYSOUT output. Refer to the *z/OS DFSMSHsm Implementation and Customization Guide* for a list of the available PATCH commands.

Examples of how to code the EXPIREBV command

The following examples present different ways to code the EXPIREBV command.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Displaying backup versions within a key range that qualify for deletion

In this example, a starting message is issued to the user. An output line is directed to SYSOUT class H for every SMS backup version that qualifies for deletion. All SMS backup versions with key ranges from A000 to L888 are processed. Deletion qualification is determined by the SMS management class attributes for each data set as they are defined for that data set. No deletions are performed and no non-SMS processing is done. An ending message is issued to the user.

```
EXPIREBV DISPLAY STARTKEY(A000) ENDKEY(L888) SYSOUT(H)
```

Deleting SMS backup versions and specific non-SMS versions that qualify for deletion

In this example, a starting message is directed to the backup activity log and to the user. DFSMSHsm attempts to delete all SMS backup versions that qualify for deletion. An ARC0734I message is directed to the backup activity log under the control of the SETSYS ACTLOGMSGLVL. Deletion is determined by the SMS management class attributes as they are defined for each data set.

DFSMSHsm processes all retired versions of non-SMS data sets. DFSMSHsm attempts to delete all retired versions and associated cataloged backup versions which are over 100 days old. An ARC0734I message is written to the backup activity log under control of the SETSYS ACTLOGMSGLVL command. An ending message is directed to the backup activity log and to the user.

```
EXPIREBV EXECUTE NONSMSVERSIONS(DBU(100))
```

Displaying SMS backup versions and non-SMS cataloged versions that qualify for deletion

In this example, a starting message is directed to the user. DFSMSHsm processes all SMS backup versions. An output line is directed to SYSOUT class A for each backup version that qualifies for deletion. Deletion is determined by the SMS management class attributes as they are defined for each data set.

An output line is directed to SYSOUT class A for all non-SMS backup versions of deleted data sets that have been cataloged and more than five days have elapsed since EXPIREBV determined that the data set was deleted. DFSMSHsm does not perform any deletions. An ending message is directed to the user.

```
EXPIREBV DISPLAY NONSMSVERSIONS(CATALOGEDDATA(5))
```

Displaying, in an output dataset, the SMS backup versions and non-SMS uncataloged versions that qualify for deletion

In this example, a starting message is directed to the user. DFSMSHsm processes all SMS backup versions. An output line is directed to the output dataset for each backup version that qualifies for deletion. Deletion is determined by the SMS management class attributes as they are defined for each data set.

DFSMSHsm processes all uncataloged backup versions, and an output line is directed to the output dataset for each uncataloged backup version that is over 10 days old, thereby qualifying for deletion. DFSMSHsm does not perform any deletions. An ending message is directed to the user.

```
EXPIREBV DISPLAY NONSMSVERSIONS(UNCATALOGEDDATA(10)) ODS(DSNAME)
```

Resuming deletion of SMS backup versions that qualify following release of a previously held EXPIREBV command

In this example, EXPIREBV processing had been held, with the HOLD EXPIREBV command, before a prior EXPIREBV command had finished. Later, EXPIREBV processing was released by issuing the RELEASE EXPIREBV command and then resumed by issuing the EXPIREBV RESUME EXECUTE command.

```
EXPIREBV RESUME EXECUTE
```

A starting message is directed to the backup activity log and the user. Processing begins where the prior EXPIREBV command left off and continues to the ENDKEY specified in the prior command. If no ENDKEY is specified, processing continues to the end of the BCDS.

DFSMSHsm attempts to delete all SMS backup versions that qualify for deletion. An ARC0734I message is directed to the backup activity log under the control of the SETSYS ACTLOGMSGVLVL. Deletion is determined by the SMS management class attributes as they are defined for each data set.

No non-SMS backup versions are processed. An ending message is directed to the backup activity log and the user.

Sample of a printer listing when you specify EXPIREBV ABARSVERSIONS with the DISPLAY parameter

Figure 94 on page 861 is a sample of a printer listing when you specify EXPIREBV ABARSVERSION with the DISPLAY parameter.

```

DISPLAY OF ABARS VERSIONS ELIGIBLE FOR EXPIRATION AT 18:21:50 ON 1992/08/25 FOR 381A

END OF DISPLAY - 00000002 ABARS  VERSIONS ELIGIBLE FOR EXPIRATION

```

Figure 94. Sample Printer List of Data Sets When You Specify EXPIREBV ABARSVERSIONS and DISPLAY

Sample of a printer listing when you specify EXPIREBV with the DISPLAY parameter

Table 57 on page 861 presents the header information when you specify EXPIREBV and DISPLAY.

Table 57. Headings of Output When You Specify EXPIREBV and DISPLAY	
Printer Output Heading	Description
SYS CAT	YES indicates that the backup version was made from a cataloged data set.
GEN NMBR	This field contains the generation number of the backup version. The most recent backup version is 0, the next most recent is 1, and so forth.
AGE	This is the number of days between the creation of the backup version and the execution of the EXPIREBV command.
RET VERS	YES indicates that the version being listed is a retired version. NO indicates that the version is not a retired version.
BACK PROF	YES indicates that a RACF discrete backup profile exists. NO indicates that a RACF discrete backup profile does not exist.

Figure 95 on page 861 is a sample of a printer listing when you specify EXPIREBV with the DISPLAY parameter. Each data set listed is deleted if the same EXPIREBV command is issued with the EXECUTE parameter.

```

Figure 95. Sample Printer List of Data Sets When You Specify EXPIREBV and DISPLAY

Chapter 45. FIXCDS command: Displaying or modifying MCDS, BCDS, and OCDS records

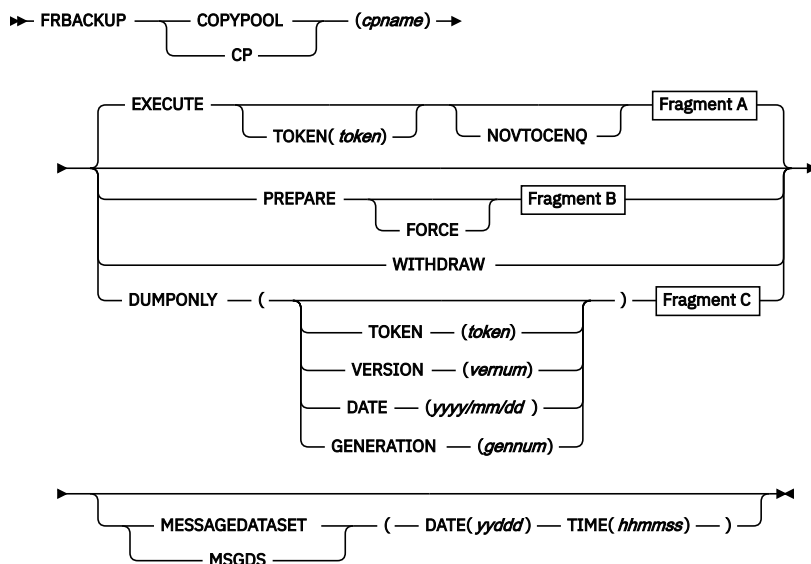

The FIXCDS command is used for maintenance purposes only; for more information, see [*z/OS DFSMSHsm Diagnosis*](#).

Chapter 46. FRBACKUP command: Requesting a fast replication backup or dump version

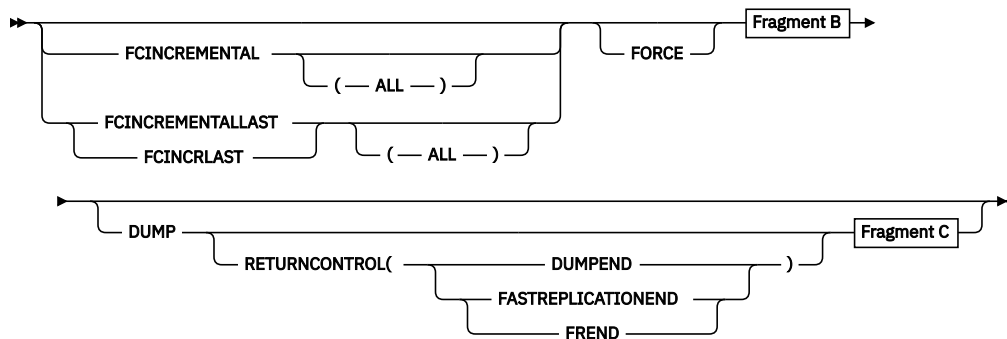

The FRBACKUP command enables you to create a fast replication backup version for sets of storage groups followed by a dump of each fast replication target volume. A set of storage groups is defined through the SMS construct termed 'copy pool'. Storage groups are defined to a copy pool and all of the volumes in those storage groups are backed up or dumped by the fast replication function. For a discussion of the copy pool construct, see [z/OS DFSMSdfp Storage Administration](#).

Note: Because fast replication can be used to make volume-level recoveries, there are important factors to consider to ensure that the backup and recovery process restores your data to a usable state. Before using the fast replication function, see “Managing volume backups with fast replication” on page 254.

Syntax of the FRBACKUP command

A: EXECUTE Optional Parameters

B: EXECUTE and PREPARE Optional Parameters

C: DUMP and DUMPONLY Optional Parameters

Note: The RETURNCONTROL parameter only applies to the DUMP parameter. It does not apply to the DUMPONLY parameter.

Required parameter of the FRBACKUP command

This topic describes the required parameter of the FRBACKUP command.

COPYPOOL: Specifying the name of the copy pool for backup

Explanation: **COPYPOOL**(*cpname*) is a required parameter that is used to identify the copy pool for backup. For *cpname*, substitute the name of the copy pool for which to create a backup version.

Defaults: None.

Optional parameters of the FRBACKUP command

This topic describes the optional parameters of the FRBACKUP command.

BACKUPSTORAGEGROUP: Overriding the copy pool backup storage group with an alternate storage group

Explanation: **BACKUPSTORAGEGROUP** is an optional keyword that can be used with the EXECUTE and PREPARE keywords. It is a copy pool backup storage group that is defined within the pool storage group.

You can use the **BACKUPSTORAGEGROUP** parameter to override the copy pool backup storage group with an alternate storage group. Only one alternate copy pool backup storage group may be used at a time. If more than one alternate copy pool backup storage group is specified on the command, the other copypool backup storage group is ignored and no error message is issued.

When **BACKUPSTORAGEGROUP** is specified with an alternate copy pool backup storage group (CPBSG) name, DFSMSHsm will attempt to override the existing CPBSG specifications in the copy pool with the alternate. When **BACKUPSTORAGEGROUP** is specified without a storage group name, DFSMSHsm will attempt to use the CPBSG defined in the pool type storage group(s). For more information, see [Chapter 6, “Availability management of SMS-managed storage,”](#) on page 165.

DUMP: Creating a fast replication DASD version followed by a dump

Explanation: **DUMP** is an optional parameter that first causes DFSMSHsm to establish a Fast Replication relationship between the source and target volumes. When all relationships are successfully established, DFSMSHsm starts dumping the target DASD copies to tape. If the copy pool is defined with **VERSIONS=0**, DFSMSHsm withdraws the source and target relationship after creating the dump copies for the source volume. For a copy pool defined with **VERSIONS** not equal to zero, the hardware automatically withdraws the relationship as the background DASD copies finish.

Subparameter	Explanation
RETURNCONTROL	DUMP RETURNCONTROL specifies when DFSMSHsm is to return control to the application or user for WAIT type requests.

The following subparameters are mutually exclusive, required parameters that you must use with the **RETURNCONTROL** parameter.

Subparameter	Explanation
DUMPEND	RETURNCONTROL(DUMPEND) specifies to DFSMSHsm to return control after all volumes are dumped.
FASTREPLICATIONEND	RETURNCONTROL(FASTREPLICATIONEND) specifies to DFSMSHsm to return control just before the dumping processing starts.

Defaults: DUMPEND is the default for the RETURNCONTROL parameter.

DUMPCCLASS: Specifying unique dump classes for fast replication dump processing

Explanation: **DUMPCCLASS** is an optional parameter that allows you to specify up to five unique dump classes per copy pool. Fast Replication dump processing produces one dump copy of each volume for each dump class. You can mark a dump class as required or optional in the dump class definition. If all required dump classes successfully complete, DFSMSHsm marks the dump version as complete.

On the FRBACKUP DUMP command, for *dclass1*, ... *dclass5*, up to five dump class names, each separated by a comma. If a dump class name is listed multiple times, DFSMSHsm fails the command.

Note: If DUMPCCLASS is specified on the FRBACKUP command that initiated a dump for that version, that dump class is marked as required, by default, and all other dump classes associated with the copy pool are ignored.

Defaults: None.

EXECUTE, PREPARE, WITHDRAW, and DUMPONLY: Specifying the backup or dump action

Explanation: **EXECUTE**, **PREPARE**, **WITHDRAW**, and **DUMPONLY** are mutually exclusive, optional parameters that indicate to DFSMSHsm the type of backup or dump action that you are initiating.

EXECUTE: The EXECUTE parameter indicates that DFSMSHsm is to create a fast replication backup for each volume defined in the specified copy pool. EXECUTE is the default action.

PREPARE: When you use this parameter, DFSMSHsm assigns specific target volumes to each source volume for each version of the copy pool.

This parameter does not verify that there is a sufficient amount of tape volumes to successfully dump the version. If you specified VERSIONS=0 for the copy pool, DFSMSHsm does not preassign DASD backup volumes to the copy pool source volumes but PREPARE processing checks that sufficient target volumes are available.

This PREPARE processing enables validation of the fast replication environment outside the backup window. The PREPARE processing does not create a backup of the copy pool.

WITHDRAW: The WITHDRAW parameter indicates that all outstanding FlashCopy relationships are withdrawn for the most recent valid version. DFSMSHsm marks that DASD version invalid if any FlashCopy relationships are withdrawn.

Any successful dump copies for the withdrawn version will remain but any incomplete dumps for the version are not resumable.

You should use the WITHDRAW parameter when it is necessary to withdraw one or more relationships established by FRBACKUP. If a version other than the most recent is invalidated, then that version is also deleted because it is no longer usable. Withdraw of a relationship can only be performed at the copy pool level. If any part of a copy pool backup version is invalidated, then the entire version is invalidated.

Note: If you withdraw the only backup version, recovery cannot be performed. Use the LIST COPYPOOL command or the ARCXTRCT macro to ensure that the backup version you wish to withdraw is not the only backup version.

If you specify the WITHDRAW parameter for a version that is being dumped, DFSMSHsm will not process any volumes that have not yet been dumped. For those volumes that are actively being dumped, after the dump completes, DFSMSHsm marks the dump as a failure. The dump copy for the withdrawn version will be marked as being partially complete. Since the DASD copy has been withdrawn, the dump version cannot be completed.

DUMPONLY: You can use the DUMPONLY parameter when a valid DASD backup version exists and you need to create or complete a dump copy for that version. The DUMPONLY parameter does not initiate a DASD copy.

The following special considerations exist between the DUMPONLY and DUMPCLASS parameters:

- If you specify the DUMPONLY parameter for a version that has an incomplete dump and you have not specified the DUMPCLASS parameter, DFSMSHsm resumes the dump process for any dump classes not successfully dumped.
- If you specify the DUMPONLY parameter and the DUMPCLASS parameter for a dump class that previously failed the dump process, DFSMSHsm resumes the dump process for that dump class.
- If you specify the DUMPONLY parameter and the DUMPCLASS parameter and the dump of a dump class was not previously attempted and less than five dump classes exist for the version, DFSMSHsm creates a new dump copy.

Note: If five successful dump versions already exist, DFSMSHsm fails the dump.

- If you specify the DUMPONLY parameter without the DUMPCLASS parameter and successful dump copies already exist for that version, DFSMSHsm fails the command.

The following subparameters are mutually exclusive, optional parameters that you can use with the DUMPONLY parameter to indicate to DFSMSHsm which specific DASD backup version to dump.

Subparameter	Explanation
DATE	DUMPONLY(DATE (<i>yyyy/mm/dd</i>)) indicates that you want to dump a backup version from a particular date. For <i>yyyy/mm/dd</i> , substitute the creation date for the backup version.
GENERATION	DUMPONLY(GENERATION (<i>gennum</i>)) indicates that you want to dump a particular generation of a backup version. For <i>gennum</i> , substitute the generation number of the backup version.
TOKEN	DUMPONLY(TOKEN (<i>token</i>)) indicates that you want to dump a backup version with a particular token. For <i>token</i> , specify the token for the backup version.
VERSION	DUMPONLY(VERSION (<i>vernum</i>)) indicates that you want to dump a particular version of a backup version. For <i>vernum</i> , specify the specific version number.

Defaults: If you do not specify any of these optional parameters with the FRBACKUP command, the default is EXECUTE. If you do not specify any optional subparameters with the DUMPONLY parameter, the default is GENERATION(0).

FCINCREMENTAL: Requesting DFSMSHsm to create a copy pool version using incremental FlashCopy

Explanation: FCINCREMENTAL is an optional keyword that can be used with EXECUTE. It can be specified with the optional subparameter ALL.

Volumes in an incremental backup version have persistent relationships.

FCINCREMENTAL(ALL) indicates that an incremental copy pool version is to be created, and all subsequent copy pool backup copies should also be incremental.

FCINCREMENTAL without the ALL subparameter indicates the version that is created is an incremental version.

Note:

1. Creating and maintaining multiple incremental backup versions causes each source volume in the copy pool to have multiple incremental targets. Each volume is allowed to have up to 12 incremental targets. That is, when you specify FCINCREMENTAL(ALL), the copy pool VERSIONS must be set to a value between 1 and 12.
2. You can specify the FCINCREMENTAL keyword (without the ALL subparameter) to designate multiple incremental copies. When a version designated as incremental is deleted, the indication of that copy as incremental is lost and the FCINCREMENTAL keyword must be re-specified on a future FRBACKUP command to create a replacement incremental backup copy.
3. If an incremental copy is desired for each copy pool backup, it is recommended that the FCINCREMENTAL(ALL) keyword (instead of multiple FCINCREMENTAL requests) be used. If all backup copies of the copy pool are deleted (both disk and tape copies), the FCINCREMENTAL(ALL) parameter must be reissued when creating the first new backup.
4. The Multiple Incremental FlashCopy target function must be enabled when attempting to create multiple incremental copy pool copies or to recover a backup version created with the Multiple Incremental FlashCopy target support. Otherwise, the FRBACKUP or FRRECOV command will fail. The Multiple Incremental FlashCopy target function can be disabled with MULTINCRFLC=NO in the DEVSUPxx member of parmlib.

FCINCREMENTALLAST: Requesting a FlashCopy incremental copy with a subsequent withdraw

Explanation: FCINCREMENTALLAST is an optional keyword that can be used with EXECUTE. It can be specified with the optional subparameter ALL.

FCINCREMENTALLAST(ALL) causes a new incremental of the oldest copy to be taken and the persistent relationships of that copy to be withdrawn. Relationships of all other backup copies are withdrawn after the next increment is taken of each of those copies. Relationships of any new incremental copies created subsequent to the command being issued are persistent, that is, they are not impacted by the previous FCINCREMENTALLAST(ALL) request.

FCINCREMENTALLAST without the ALL subparameter causes a new increment to be taken of the oldest backup copy, and then the persistent relationships of only that copy to be withdrawn. If the FCINCREMENTAL(ALL) keyword was previously specified for the same copy pool then when this copy rolls off, it is replaced with a new incremental copy.

FORCE: Replacing a DASD backup copy that has an incomplete dump copy

Explanation:

Usually, if a new DASD copy replaces an existing DASD copy that has an incomplete dump copy, the creation of the new DASD copy is failed. FORCE is an optional parameter that allows you to force a DASD copy with an incomplete dump copy to be rolled-off and replaced with a new DASD copy.

The FORCE parameter is required when the creation of a new dump version causes the roll of a DASD backup version before a dump completes.

Defaults: None.

MESSAGEDATASET: Specifying the date and time used in the message data set name

Explanation: MESSAGEDATASET is an optional parameter that allows you to specify the date and time used in the name of the fast replication command message data set. Specifying the date and time ensures that you can identify the message data set that corresponds with the FRBACKUP request. If you don't specify the date and time with the MESSAGEDATASET parameter, DFSMSHsm uses the date and time when the message data set name is generated.

The value for the DATE parameter must be a five-digit numeric value, *yyddd*.

The value for the TIME parameter must be a six-digit numeric value, *hhmmss*.

If a duplicate message data set already exists with the specified date and time, DFSMSShsm issues message ARC1873I and continues without capturing the fast replication messages in a message data set.

Use of the message data set is controlled with the MESSAGEDATASET parameter of the SETSYS FASTREPLICATION command. Refer to [Chapter 65, “SETSYS command: Establishing or changing the values of DFSMSShsm control parameters,”](#) on page 1057 for more information.

Defaults: None.

NOVTOCENQ: Requesting DFSMSShsm to not serialize the VTOC of processed volumes

Explanation: **NOVTOCENQ** is an optional parameter that you use to request DFSMSShsm to not serialize on the VTOCs of the volumes being processed. Do not use this parameter unless you have taken specific action to ensure that no update activity will occur to the volumes being processed.

Defaults: None.

TOKEN: Specifying an identifier for each copy pool backup version

Explanation: **TOKEN(token)** is an optional parameter that is a string (up to 40 bytes) that DFSMSShsm maintains with each backup version of the copy pool. The token may be used to identify a specific backup version to dump or recover. The token is returned as part of the LIST and ARCXTRCT data for the copy pool backup version. If the value specified for TOKEN is less than 40 bytes, the TOKEN value is left justified and binary zeros fill the remainder of the positions to fill the 40 byte space. If TOKEN is not specified, binary zeros are returned with the data.

Defaults: None.

Examples of how to code the FRBACKUP command

The following examples present different ways to code the FRBACKUP command.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Creating a fast replication dump copy

In this example, DFSMSShsm will initiate a fast replication DASD copy for each volume and subsequently dump the target DASD volumes to a onsite dump class and an offsite dump class.

```
FRBACKUP COPYPOOL(CPDATABAS4) DUMP DCLASS(ONSITE,OFFSITE)
```

Dumping an existing valid DASD version

In this example, DFSMSShsm will initiate dump processing for an existing DASD version.

```
FRBACKUP COPYPOOL(CPDATABAS5) DUMPONLY
```

Validating the current environment

In this example, DFSMSShsm submits a request for validation of the current environment. DFSMSShsm assigns specific target volumes to each source volume for each version.

```
FRBACKUP COPYPOOL(CPDATABASE3) PREPARE
```

Creating a fast replication backup for each volume in the copy pool's storage groups

In this example, DFSMSHsm creates a fast replication backup version.

```
FRBACKUP COPYPOOL(CPDATABASE2) EXECUTE TOKEN(FRBACKUP_JULYDATA)
```

Withdrawing copy pool relationships

In this example, DFSMSHsm submits a request to withdraw outstanding FlashCopy relationships that were established for the previous backup version. This invalidates the previous backup version.

```
FRBACKUP COPYPOOL(CPDATABASE1) WITHDRAW
```

Chapter 47. FRDELETE command: Deleting fast replication backup or dump versions

The FRDELETE command enables you to delete one or more fast replication backup or dump versions. This is useful when you rename a copy pool, when you no longer need a copy pool, or when you no longer need an individual backup or dump version. Before a version is deleted, any outstanding FlashCopy relationships are withdrawn.

Syntax of the FRDELETE command

A: DUMPONLY Optional Parameters

Note: You must specify either ALL, TOKEN, or VERSIONS with each FRDELETE command.

Required parameters of the FRDELETE command

This topic describes the required parameters of the FRDELETE command.

COPYPOOL: Specifying the name of the copy pool for deletion

Explanation

COPYPOOL(*cpname*) is used to identify the copy pool for which backup versions are deleted. For *cpname*, substitute the name of the copy pool for which to delete the backup version.

Defaults

None

ALL, TOKEN, and VERSIONS: Specifying the delete action

Explanation

ALL, TOKEN, and VERSIONS are mutually exclusive parameters that indicate to DFSMSHsm the type of delete action that you are initiating.

ALL

DFSMSHsm is to delete all fast replication backup versions.

TOKEN(*token*)

The token of the backup version to delete. If the token is not unique, then DFSMSHsm deletes the most recent backup version with the specified token.

token

Alphanumeric or hexadecimal token.

VERSIONS(*bvn,bvn,...*)

The backup versions to delete.

bvn,bvn,...

Number of the backup versions.

Defaults

None.

Optional parameters of the FRDELETE command

This topic describes the optional parameters of the FRDELETE command.

DASDONLY, DUMPONLY, and BOTH: Specifying which copies to delete

Explanation

DASDONLY, DUMPONLY, and BOTH are mutually exclusive, optional parameters that indicate to DFSMSHsm which copies to delete.

DASDONLY

DFSMSHsm is to delete only the DASD copies for the specified copy pool.

DUMPONLY

DFSMSHsm is to delete only the dump copies for the specified copy pool.

DUMPCCLASS**DCLASS**

Optional parameter that specifies to DFSMSHsm which specific dump classes to delete.

dclass1, ... dclass5

Up to five dump class names, each separated by a comma. If a dump class name is listed multiple times, DFSMSHsm fails the command.

BOTH

DFSMSHsm is to delete both DASD and dump copies for the specified copy pool.

Defaults

If you do not specify DUMPONLY, DASDONLY, or BOTH, the default is DASDONLY.

Usage notes:

1. Unlike autodump expiration, the FRDELETE command does not keep the last indicated version.
2. If the DUMPCCLASS parameter is not specified, DFSMSHsm deletes all dump copies associated with the specification of the VERSIONS, TOKEN, or ALL parameters.

Examples of how to code the FRDELETE command

The following examples present different ways to code the FRDELETE command.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Deleting all versions of a fast replication backup

In this example, DFSMSHsm deletes all fast replication backup versions for both DASD and dump copies for the specified copy pool.

```
FRDELETE COPYPOOL(CPDATABASE1) ALL BOTH
```

Deleting one version of a fast replication backup by version number

In this example, DFSMSHsm deletes one fast replication backup version for a copy pool. The specific version number is specified.

```
FRDELETE COPYPOOL(CPDATABASE1) VERSIONS(2)
```

Deleting one version of a fast replication backup by token

In this example, DFSMSHsm deletes the fast replication backup version for a copy pool. The specific token is specified.

```
FRDELETE COPYPOOL(CPDATABASE1) TOKEN(53800)
```

Deleting a dump class from a copy pool dump version

In this example a single dump class is removed from a copy pool dump version.

```
FRDELETE COPYPOOL(CPDATABAS1) TOKEN(53801) DUMPNLY(DUMPCCLASS(DCL1))
```

Deleting only the DASD version for two copy pool versions

In this example, version 5 and 6 DASD copy of a copy pool will be deleted

```
FRDELETE COPYPOOL(CPDATABAS1) VERSIONS(5,6) DASDONLY
```

Chapter 48. FREEVOL command: Freeing DFSMSHsm-owned volumes

The FREEVOL command allows you to empty a migration or backup DASD volume in preparation for new equipment or to replace old or partially damaged volumes. If the intended use is to make more space available on an ML1 volume, use the MIGRATE ML1 command instead. In addition, FREEVOL removes selected data sets from a volume based on management class attributes or age. FREEVOL moves valid backup versions and migration copies from DFSMSHsm-owned DASD volumes to either tape or DASD.

The FREEVOL command moves migration copies of SMS-managed data sets from:

- A migration level 1 volume based on each data set's management class attribute values
- A migration level 2 volume based on the age specified on the AGE parameter of the FREEVOL command.

The FREEVOL command moves all migration copies of non-SMS-managed data sets meeting a specified age criterion from DFSMSHsm migration volumes. Migration copies meeting the specified age criterion are:

- Moved from a specified migration level 1 volume to other migration level 1 or level 2 volumes
- Moved from a specified migration level 2 DASD volume to other migration level 2 volumes.

The FREEVOL command moves all backup versions of SMS-managed and non-SMS-managed data sets meeting a specified age criterion from DFSMSHsm daily backup volumes. Backup versions are moved from a specified backup volume to spill DASD or tape volumes. A parameter can be specified to prevent the movement of the most recent backup version for each data set.

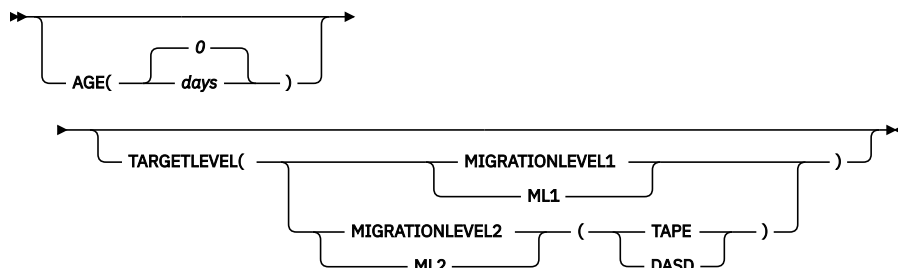

Note:

1. FREEVOL can be used to move migration copies from one unit type to another unit type.
2. Each time automatic backup processing runs, backup copies are moved off migration level 1 volumes. FREEVOL ML1BACKUPVERSIONS provides this same function. However, FREEVOL of a single migration volume does not move backup versions.
3. FREEVOL does not move user data sets, SYS1.VVDS, or the VTOC index data set or user catalogs.
4. FREEVOL moves catalog information data sets to another ML1 volume, regardless of the target level of the FREEVOL command.
5. FREEVOL of a migration level 1 volume moves VTOC copy data sets on the freed volume to other migration level 1 volumes, regardless of the target level of the FREEVOL command.
6. Unless you want DFSMSHsm to continue to use the freed *migration* volume as a target for migration, you should either delete the volume or add it again with the DRAIN attribute.
7. Unless you want DFSMSHsm to continue to use the freed *backup* volume as a target for backup, you should delete the volume.
8. For migrated SMS data sets, the values specified for the management class attribute of *COMMAND-OR-AUTO-MIGRATE* are ignored.
9. FREEVOL does not move any SDSP data sets, although it can move or delete any data sets that are in an SDSP data set. Small data sets that move to another ML1 volume may go into an SDSP data set. Refer to [“Managing SDSP data sets” on page 555](#) for removing an SDSP.
10. When FREEVOL AGE(0) is specified, BACKDS backup versions and data sets that have migrated but are awaiting automatic backup are not moved off the volume. Running automatic backup on the DFSMSHsm primary host performs this function. When you are planning to remove an ML1 volume, run autobackup on the primary host shortly before running the FREEVOL function with the AGE(0) parameter.

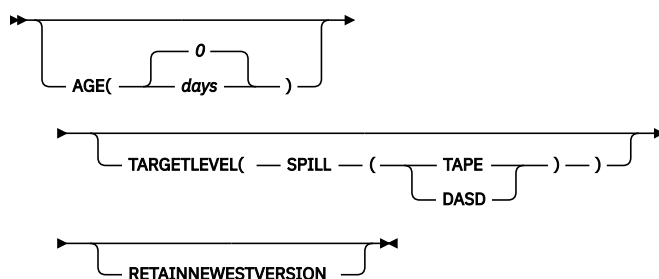

Syntax of the FREEVOL command

A: MIGRATIONVOLUME optional parameters

B: BACKUPVOLUME optional parameters

Required parameters of the FREEVOL command

This topic describes the required parameters of the FREEVOL command.

MIGRATIONVOLUME and BACKUPVOLUME: Specifying a volume to free

Explanation: **MIGRATIONVOLUME(volser)** | **BACKUPVOLUME(volser)** are mutually exclusive, required parameters. Issue one or the other with the FREEVOL command when a volume serial number is specified. For (volser), substitute the serial number of the migration or daily backup volume you want processed.

Defaults: None.

Note:

1. When you are using MIGRATIONVOLUME, all data set movement statistics appear as SUBSEQUENT MIGS on the REPORT summary.
2. When you are using BACKUPVOLUME, all data set movement statistics appear as SUBSEQUENT BACKUP on the REPORT summary.

ML1BACKUPVERSIONS: Moving backup versions off migration volumes

Explanation: **ML1BACKUPVERSIONS** is mutually exclusive with the MIGRATIONVOLUME and BACKUPVOLUME parameters. There are no subparameters specified with this parameter.

When this parameter is specified, backup versions are moved from all migration level 1 volumes to daily backup volumes. This processing occurs on a primary or secondary host, but does not allow processing from two hosts concurrently. While this processing occurs, volume backups are not permitted to start

on this host. This parameter does not support wait processing in the HSEND CMD command or the ARCHSEND invocation macro.

All data set movement statistics appear as SUBSEQUENT BACKUP on the report summary.

Defaults: None.

Optional parameters of the FREEVOL command

This topic describes the optional parameters of the FREEVOL command.

AGE: Specifying data set use

Explanation: **AGE(days)** is an optional parameter specifying the age criterion for moving data sets.

- When processing a migration volume, substitute a decimal value from 0 to 999 for the number of days since data sets were last referred to.
- When processing a backup volume, substitute a decimal value from 0 to 999 for the number of days since the backup version was created. If the RETAINNEWESTVERSION subparameter is specified, the newest versions created are retained on the volume independent of the age criterion specified.

If AGE(0) is entered for a migration level 1 volume, migration copies of all SMS-managed data sets are moved from the volume and placed on other migration level 1 volumes or migration level 2 volumes, depending on each data set's management class. If the management class has a value specified for the LEVEL-1-DAYS-NONUSAGE and the age is met, the data set migrates to a migration level 2 volume. If the management class has a value specified for LEVEL-1-DAYS-NONUSAGE and the data set age does not meet the criterion or if the data set has an attribute of NOLIMIT, the data set migrates to another migration level 1 volume.

If an AGE other than zero is specified for migration level 1 volumes, the management class for each SMS data set is used to determine whether the migration copy is moved to another volume.

If AGE (0–999) is entered for a migration level 2 volume, the age specified applies to all of the data sets on the volume, because there are no management class attributes that apply to SMS data sets on migration level 2 volumes.

If AGE (0–999) is entered for a backup volume, the age specified applies to all of the data sets on the volume. Expiration processing of backup versions is not performed during FREEVOL.

Defaults: If you do not specify AGE, the default is zero. A default of zero clears the volume of all migrated data except the ones in need of backup, or it clears the backup volume if the RETAINNEWESTVERSION subparameter is not specified.

TARGETLEVEL: Specifying the target to which data sets are moved

Explanation: **TARGETLEVEL** specifies the level and the unit type for migration copies that are eligible to be moved.

For SMS-Managed Migrated Data Sets: The target levels of MIGRATIONLEVEL1 and MIGRATIONLEVEL2 do not apply because their target levels are determined by management class as described in the AGE parameter description. The device category of DASD or TAPE applies only to those SMS-managed data sets migrating to ML2:

Subparameter	Explanation
DASD	TARGETLEVEL (MIGRATIONLEVEL2 (DASD)) specifies that the eligible data sets migrate from MIGRATIONVOLUME(<i>volser</i>) to DASD migration level 2 volumes.
TAPE	TARGETLEVEL (MIGRATIONLEVEL2 (TAPE)) specifies that the eligible data sets migrate from MIGRATIONVOLUME(<i>volser</i>) to tape migration level 2 volumes.

For Non-SMS-Managed Migrated Data Sets: The **TARGETLEVEL (MIGRATIONLEVEL1 | MIGRATIONLEVEL2 (TAPE | DASD))** parameters apply to these migrated data sets.

Subparameter	Explanation
MIGRATIONLEVEL1	TARGETLEVEL (MIGRATIONLEVEL1) specifies that volumes defined as migration level 1 receive migrated data sets from <code>MIGRATIONVOLUME(volser)</code> .
MIGRATIONLEVEL2	<p>TARGETLEVEL (MIGRATIONLEVEL2) specifies that volumes defined for migration level 2 receive migrated data sets from <code>MIGRATIONVOLUME(volser)</code>.</p> <p>TARGETLEVEL (MIGRATIONLEVEL2 (DASD)) specifies that the eligible data sets migrate from <code>MIGRATIONVOLUME(volser)</code> to DASD migration level 2 volumes.</p> <p>TARGETLEVEL (MIGRATIONLEVEL2 (TAPE)) specifies that the eligible data sets migrate from <code>MIGRATIONVOLUME(volser)</code> to tape migration level 2 volumes.</p>

For BACKUP Data Sets: The **TARGETLEVEL(SPILL(TAPE | DASD))** parameters are used to specify the level and the unit type for backup versions eligible to be moved. The device category applies to all data sets moving to SPILL backup volumes:

Subparameter	Explanation
DASD	TARGETLEVEL(SPILL(DASD)) specifies that the eligible data sets move from <code>BACKUPVOLUME(volser)</code> to DASD spill backup volumes.
TAPE	TARGETLEVEL(SPILL(TAPE)) specifies that the eligible data sets move from <code>BACKUPVOLUME(volser)</code> to tape spill backup volumes.

Defaults: If you do not specify either DASD or TAPE, the default is the type of migration set up by the SETSYS command. For migration volumes, the TAPEMIGRATION parameter is used to set up this default. For backup volumes, the SPILL parameter is used.

Note:

1. If `MIGRATIONVOLUME` and `TARGETLEVEL` are the same level, the current source volume (`MIGRATIONVOLUME(volser)`) is excluded from the target volume selection process.
2. If the source volume you specified is a migration level 2 volume, the specification of a target level migration level 1 volume is invalid.
3. If you do not specify `TARGETLEVEL`, migration copies of non-SMS-managed data sets are moved to migration level 2 volumes.
4. If you specify either DASD or TAPE, the one selected overrides the environment specified with the SETSYS TAPEMIGRATION command or the SETSYS SPILL command.
5. After a FREEVOL command has been processed against a migration level 2 volume with an associated key range, that volume must be further processed by a DELVOL and an ADDVOL command in order to become eligible again as a target volume for that key range.

RETAINNEWESTVERSION: Preventing movement of backup versions

Explanation: **RETAINNEWESTVERSION** specifies that the FREEVOL process not move the most recent backup version of a data set from the volume.

If both AGE and RETAINNEWESTVERSION are specified, the most recent backup versions are retained on the current volume, regardless of the age criterion.

Defaults: If you do not specify this parameter, all backup versions are selected by the number of days specified by the AGE parameter.

Examples of how to code the FREEVOL command

Coding of the FREEVOL command is demonstrated in the examples that follow.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Moving migration copies from one migration volume to other migration volumes

In this example, migration copies of SMS-managed data sets are moved from a specific migration volume to migration level 1 or migration level 2 DASD volumes based on their management class attributes. Non-SMS-managed data sets are moved from a specific migration volume to migration level 2 DASD volumes.

```
FREEVOL MIGRATIONVOL(MIG100) TARGETLEVEL(ML2(DASD))
```

Moving backup versions from one backup volume to tape

In this example, backup versions are moved from a specific backup volume to spill tape volumes.

```
FREEVOL BACKUPVOL(BACK01) TARGETLEVEL(SPILL(TAPE))
```

Moving backup versions selectively

In this example, backup versions are moved from a specific backup volume to the type of volumes set up by the SETSYS SPILL parameter. Backup versions are moved if they were created 30 or more days ago. Backup versions that are the most recently created copies of their source data sets remain on the volume and are not affected by the AGE parameter.

```
FREEVOL BACKUPVOL(BACK02) AGE(30) RETAINNEWEST
```

Moving backup versions from ML1 volumes

In this example, backup versions are moved from all ML1 volumes to daily backup volumes.

```
FREEVOL ML1BACKUPVERSIONS
```

Chapter 49. FRRECOV command: Requesting a fast replication recovery

The FRRECOV command can be used to recover a copy pool or individual volumes and data sets from the managed copy pool copies. The backup copy to be recovered can reside on either DASD or tape. If the backup copy resides on both DASD and tape, the default is to use the DASD backup copy.

To restrict the recovery to only backup copy versions residing on DASD or tape, use the FROMDASD or FROMDUMP options, respectively. If the backup copy version is not found on either DASD or tape, the recovery request will fail.

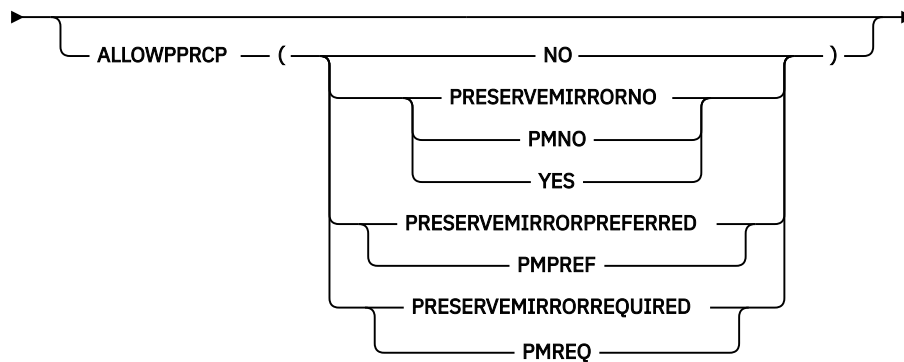

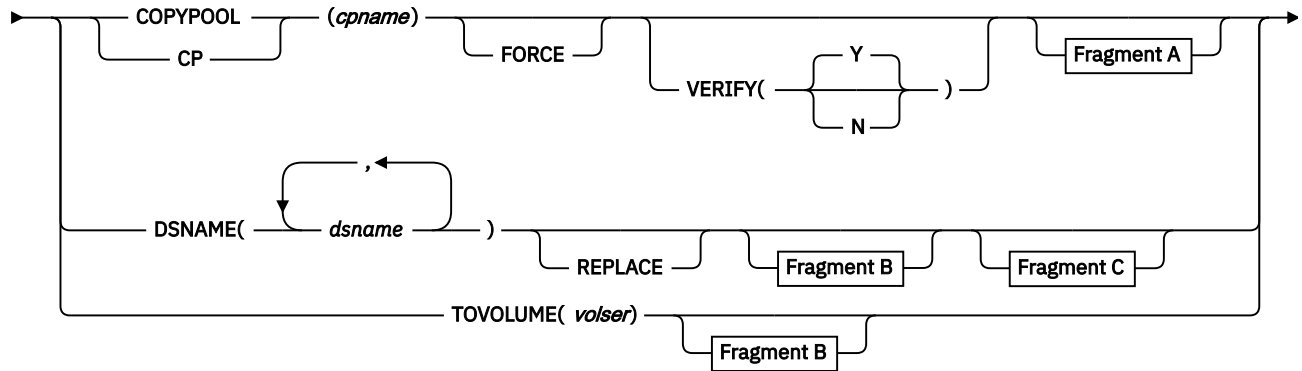

When DATE, GENERATION, TOKEN, or VERSION is specified, the corresponding backup copy will be recovered. If no specific backup copy is specified, an attempt to recover generation zero will occur. If no valid backup copy (either the indicated or implicit) is found, on DASD or tape, the recovery request will fail.

A specific dump class to recover the version from can be specified when recovering from a dump copy on tape. When recovery is performed at the copy pool level, and the dump copy to recover is a partial dump, the recovery request will fail unless the PARTIALOK option is specified.

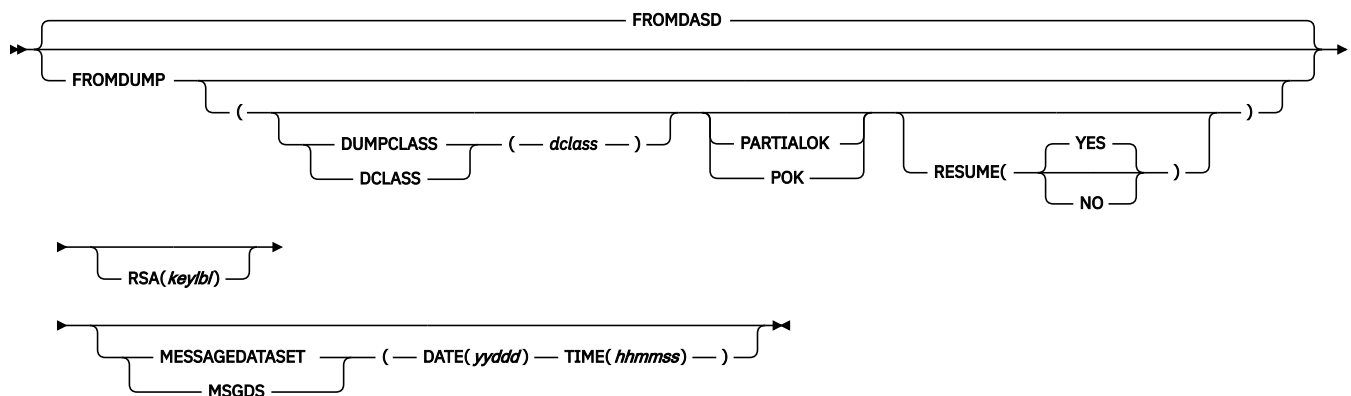

Note: Because fast replication can be used to make volume-level recoveries, there are important factors to consider to ensure that the backup and recovery process restores your data to a usable state. Before using the fast replication function, see [“Managing volume backups with fast replication”](#) on page 254.

Syntax of the FRRECOV command

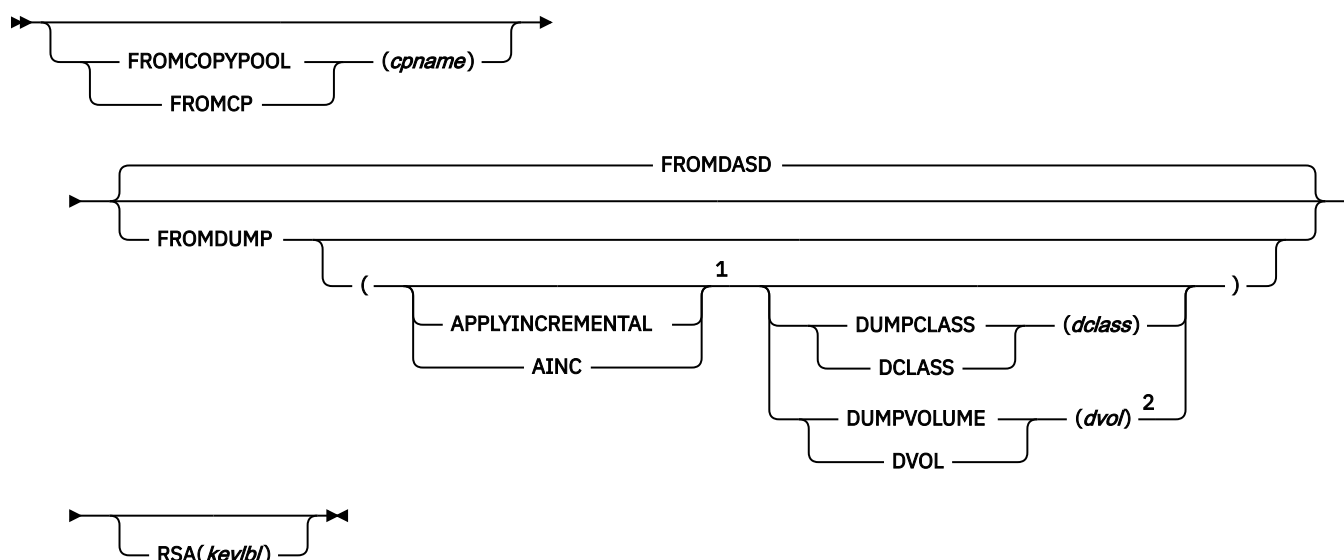

➤ FRRECOV ➤

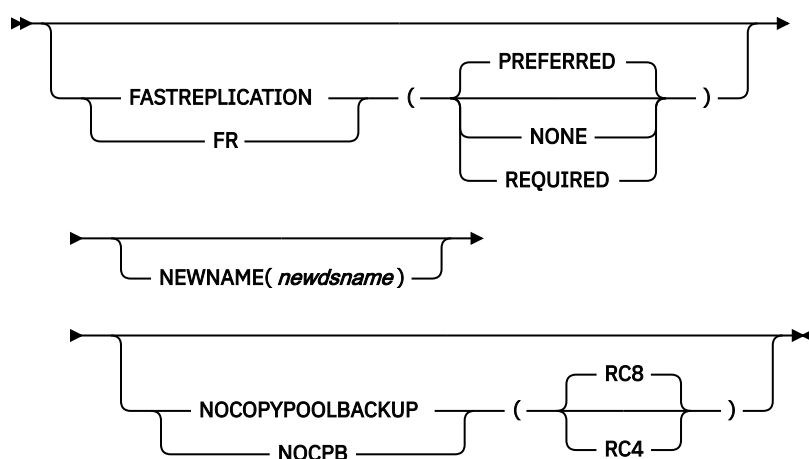

A: COPYPOOL and TOVOLUME optional parameters

B: DSNAME and TOVOLUME optional parameters

C: DSNAME only optional parameters

Notes:

¹ APPLYINCREMENTAL is valid only with the TOVOLUME keyword and is applicable only when the recovery is from a dump volume.

² FROMDUMP(DUMPVOLUME(dvol)) is mutually exclusive with the DATE, GENERATION, TOKEN, and VERSION parameters.

Required parameters of the FRRECOV command

This topic describes the required parameters of the FRRECOV command.

COPYPOOL: Specifying the copy pool for which to recover all backup volumes

Explanation: COPYPOOL is a required parameter that is mutually exclusive with the DSNAME and TOVOLUME parameters. The COPYPOOL parameter indicates to DFSMSHsm to recover all source volumes associated with the named copy pool.

For *cpname*, substitute the name of the copy pool that you want to recover. DFSMSHsm recovers all volumes that are associated with this copy pool.

Defaults: None.

DSNAME: Specifying the data sets to recover from a copy pool backup version

Explanation: DSNAME is a required parameter that is mutually exclusive with the COPYPOOL and TOVOLUME parameters. The DSNAME parameter indicates to DFSMSHsm to recover individual data sets from a copy pool backup version.

For *dsname*, substitute one or more fully-qualified or partially-qualified names of data sets you want to recover (separate each name with a comma). Deleted data sets must be fully-qualified. If you specify a partially-qualified data set name, every cataloged data set in the standard search order that matches the filtering criteria is processed. If one or more data sets are not found, processing continues.

The high-level qualifier of the specified data set name must be fully-qualified or partially-qualified. A double wildcard ("**") is used in place of a full qualifier and a single wildcard ("*") is used within a qualifier. You cannot specify a double wildcard as the high-level qualifier or as the only qualifier. You can specify a single wildcard in the high-level qualifier position if it is not the first character specified. These restrictions help to prevent an unmanageable number of data sets from being processed. The remainder of the data set name can include any arrangement of wildcard characters.

When the optional NEWNAME(*newdsname*) parameter is specified, *dsname* must be a single, fully-qualified data set name.

When GDG data sets are recovered, their bases are serialized. When using a wildcard to recover multiple GDG generations with the same base, they will fail due to serialization errors. It is recommended that multiple GDG generation data sets are recovered individually.

Defaults: None.

TOVOLUME: Specifying a single volume within a copy pool to recover

Explanation: TOVOLUME is a required parameter that is mutually exclusive with the DSNAME and COPYPOOL parameters. The TOVOLUME parameter indicates to DFSMSHsm to recover a single volume within a copy pool.

For *volser*, specify the name of the source volume to be recovered. If you specify a source volume that is contained within a storage group that is defined within multiple copy pools, then you must also specify FROMCOPYPOOL(*cpname*).

You can use the LIST PRIMARYVOLUME BCDS command to determine which copy pools a volume is contained within. You can then use the LIST COPYPOOL(*cpname*) command to determine which of those copy pools contains the version that you want recovered.

Note: Do not use the TOVOLUME operation to recover individual volumes in a copy pool that are defined with fast reverse restore capability.

Defaults: None.

Optional parameters of the FRRECOV command

This topic describes the optional parameters of the FRRECOV command.

ALLOWPPRCP: Specifying Metro Mirror and Global Mirror primary volumes and preserve mirror options for a FlashCopy operation

Explanation: ALLOWPPRCP is an optional parameter that specifies whether a Metro Mirror or Global Mirror primary volume is allowed to become a target of a FlashCopy operation, and whether a preserve mirror operation is required, preferred, or not desired when the target volume is a Metro Mirror primary volume during fast replication recovery. When you specify ALLOWPPRCP, you must specify one of the following options:

NO

Specifies that a Metro Mirror or Global Mirror primary volume is not to become a FlashCopy target. This is the default.

PRESERVEMIRRORNO**YES**

Specifies that a Metro Mirror or Global Mirror primary volume is allowed to become a FlashCopy target, and the FlashCopy is to be performed without considering a preserve mirror operation. If the target volume is not a Metro Mirror or Global Mirror primary volume, this parameter has no effect.

PRESERVEMIRRORPREFERRED

Specifies that a Metro Mirror or Global Mirror primary volume is allowed to become a FlashCopy target and it would be preferable that the Metro Mirror pair does not go into a duplex pending state as a result of the FlashCopy operation when the target volume is a Metro Mirror primary volume. If the preserve mirror operation cannot be accomplished, the FlashCopy operation is still to be attempted. If the intended FlashCopy target volume is not a Metro Mirror primary volume, this parameter has no effect.

The IBM DS8880 series and newer IBM storage systems do not support the Preserve Mirror Preferred option for Metro Mirror. If you are using one of those storage systems, and you want to preserve your disk mirror or copy, specify PRESERVEMIRRORREQUIRED.

PRESERVEMIRRORREQUIRED

Specifies that a Metro Mirror or Global Mirror primary volume is allowed to become a FlashCopy target. If the FlashCopy target volume is a Metro Mirror primary device, a Preserve Mirror option is required when performing FlashCopy recovery. If the target volume is not a Metro Mirror or Global Mirror primary volume, this parameter has no effect.

Note:

1. ALLOWPPRCP overrides the stored preserve mirror indicator for the copy pool. The change is not persistent and applies to one invocation of the FRRECOV command only.
2. ALLOWPPRCP is ignored when recovering from a tape.
3. The combined use of fast reverse restore and the preserve mirror operation is not supported. When a copy pool is defined allowing fast reverse restore, and the ALLOWPPRCP(PMREQ) or ALLOWPPRCP(PMPREF) parameter is specified, the FRRECOV command is failed.
4. ALLOWPPRCP options PRESERVEMIRRORREQUIRED, PRESERVEMIRRORPREFERRED, PRESERVEMIRRORNO, and YES cannot be specified in combination with the FASTREPLICATION option of NONE for data set recoveries.

Defaults: If you do not specify ALLOWPPRCP on the FRRECOV command, DFSMSHsm uses the currently stored preserve mirror indicator for the copy pool. If no preserve mirror indicator has been set for the copy pool, the default is NO.

Related reading: For more information about IBM Remote Pair FlashCopy, Metro Mirror, also known as synchronous Peer-to-Peer Remote Copy (PPRC), and other copy services functions, see [z/OS DFSMS Advanced Copy Services](#).

ALLOWXRC: Specifying an extended remote copy primary volume option for a FlashCopy operation

Explanation:

ALLOWXRC is an optional parameter that specifies whether an extended remote copy (XRC) primary volume is allowed to become a target of a FlashCopy operation during fast replication recovery. When you specify ALLOWXRC, you must specify one of the following options:

NO

Specifies that an XRC primary volume is not to become a FlashCopy target. This is the default.

YES

Specifies that an XRC primary volume is allowed to become a FlashCopy target. If the target volume is not an XRC volume, this parameter has no effect.

Note:

1. The ALLOWXRCP parameter overrides the specified setting for the SMS copy pool. The override is not persistent and applies to the current invocation of the FRRECOV command only.
2. ALLOWXRCP is ignored when recovering from a tape.
3. ALLOWXRCP(YES) cannot be specified in combination with the FASTREPLICATION option of NONE for data set recoveries.
4. ALLOWXRCP(YES) cannot be specified in combination with the fast reverse restore option.

Defaults: If you do not specify ALLOWXRCP on the FRRECOV command, DFSMSHsm uses the currently specified option for the SMS copy pool. If no ALLOWXRCP option has been designated for the copy pool, the default is NO.

Related reading: For more information about IBM remote pair FlashCopy, XRC, and other copy services functions, see [z/OS DFSMS Advanced Copy Services](#).

DATE, GENERATION, TOKEN, VERSION: Specifying a specific backup version to recover

Explanation: DATE, GENERATION, TOKEN, and VERSION are mutually exclusive, optional parameters that indicate to DFSMSHsm a specific backup copy to recover.

DATE

Specify DATE(*yyyy/mm/dd*) to recover a backup copy from a particular date. If more than one copy exists for the specified date, then DFSMSHsm recovers the most recent copy from that date. The FRRECOV command fails if no copy exists for the specified date. A copy may not exist because either no valid backup copy exists or the copy exists, but it is invalid. You do not need to include a leading zero to specify single digit months and days.

GENERATION

Specify GENERATION(*gennum*) to recover a backup copy of a particular generation. The generation number can be from 0 to 84. The most recent copy is generation 0, the next is 1, and so on.

TOKEN

Specify TOKEN(*token*) to recover a backup copy with a particular token. If the token is not unique, then the most recent backup copy with the specified token is recovered. If the specified token is less than 40 characters, then the token is left justified and padded with binary zeroes before the backup copy search. You can specify a hexadecimal token using the X'...' syntax.

VERSION

Specify VERSION(*vernum*) to recover a backup of a particular copy. The copy number can be from 1 to 999.

Defaults: If you do not specify DATE, GENERATION, TOKEN, or VERSION, DFSMSHsm uses the most recent backup copy (generation zero) to perform the recovery.

FASTREPLICATION: Indicating a recovery preference

Explanation: FASTREPLICATION is an optional parameter that indicates whether the use of fast replication for data set recovery is required, preferred, or not desired.

The following are parameters of the FASTREPLICATION parameter:

PREFERRED

Indicates that fast replication should be used when possible. If fast replication cannot be used, the data set is recovered through traditional copy methods.

REQUIRED

Indicates that if fast replication cannot be used, the recovery is to fail.

NONE

Indicates that only traditional copy methods are to be used.

Defaults: None.

Notes:

1. Using the FASTREPLICATION parameter overrides the FASTREPLICATION value specified using the SETSYS FASTREPLICATION command. If not specified, the value of SETSYS FASTREPLICATION is used.
2. FASTREPLICATION is valid only for recovery from disk. If the recovery is from tape, the parameter is ignored.
3. FASTREPLICATION is valid with DSNAME only. It is not valid with the COPYPOOL or TOVOLUME parameters.
4. To recover data sets only when fast replication can be used, specify FROMDASD with FASTREPLICATION(REQUIRED).

FORCE: Allowing recovery from a DASD backup copy that has an incomplete dump copy

Explanation: FORCE is an optional parameter that allows you to force fast replication recovery of a copy pool from a DASD backup copy with an in-progress dump to tape or otherwise incomplete dump copy. Any in-progress dump to tape of the DASD backup copy is terminated. In addition, the FORCE parameter also allows the recovery of a copy pool to proceed when the recovery operation (such as fast reverse restore) will invalidate the DASD backup copy. In a situation where the DASD backup copy is invalidated, the incomplete dump cannot be resumed.

Defaults: None.

FROMCOPYPOOL: Recovering a volume or data set that belongs to multiple copy pools

Explanation: FROMCOPYPOOL(*cpname*) is an optional parameter that you must specify if the volume or data set you want DFSMSHsm to recover belongs to a storage group that is defined within multiple copy pools. For *cpname*, substitute the name of the copy pool that contains the volume. When performing a data set recovery, DFSMSHsm checks the catalog to determine the volumes on which the data set resides. Based on the first volume, DFSMSHsm determines which copy pool the volume belongs to. If the volume belongs to more than one copy pool, you must specify the FROMCOPYPOOL(*cpname*) keyword. The FROMCOPYPOOL is a required keyword for deleted data sets. If the data set is uncataloged, but exists on a volume, you must specify both FROMCOPYPOOL and REPLACE keywords in order to recover the data set.

Defaults: None.

FROMDASD: Recovering a volume from DASD

Explanation: FROMDASD is an optional parameter that indicates to DFSMSHsm to recover the specified volume from DASD.

Defaults: FROMDASD is the default. If a volume version exists both on DASD and tape, DFSMSHsm recovers the DASD copy.

FROMDUMP: Recovering a volume from a dump tape

Explanation: FROMDUMP is an optional parameter that indicates to DFSMSHsm to recover the specified volume from a dump tape.

The following options can be used with the FROMDUMP parameter:

APPLYINCREMENTAL

Specifies that an incremental volume recovery process is to follow immediately after the volume restore and is to be part of the single request to recover a specific volume.

DUMPCCLASS

Specifies which dump class to use for the volume recovery.

dclass

Is the name of the dump class to use for the volume recovery.

DUMPVOLUME

Specifies which specific dump copy to use for the volume recovery.

dvol

Is the name of the dump volume to use for volume recovery.

PARTIALOK

Allows recovery of a backup copy from a partial dump version. If the requested dump version is complete, that is, not a partial dump version, the PARTIALOK parameter is ignored.

RESUME

Specifies whether resuming a previously failed recovery is attempted. If the previous recovery was successful, the RESUME parameter is ignored.

NO

Specifies a previously failed recovery should not be resumed. A full recovery will be attempted instead.

YES

Specifies a previously failed recovery should be resumed. This is the default.

Note:

1. APPLYINCREMENTAL can be specified only when recovering a specific volume (TOVOLUME) from a dump tape copy.
2. PARTIALOK and RESUME can be specified only when recovering a copy pool from a dump tape copy.

Defaults: If the version to be recovered resides on a dump tape only, DFSMSHsm recovers the version from tape. If the version exists both on DASD and tape, DFSMSHsm recovers the DASD copy.

MESSAGEDATASET: Specifying the date and time used in the message data set name

Explanation: MESSAGEDATASET is an optional parameter that allows you to specify the date and time used in the name of the fast replication command message data set. Specifying the date and time ensures that you can identify the message data set that corresponds with the FRRECOV COPYPOOL or TOVOLUME command.

The value for the DATE parameter must be a five-digit numeric value, *yyddd*.

The value for the TIME parameter must be a six-digit numeric value, *hhmmss*.

When DATE and TIME are specified on the FRRECOV COPYPOOL or TOVOLUME command and a duplicate message data set already exists with the specified date and time, DFSMSHsm issues message ARC1873I and continues without capturing the fast replication messages in a message data set.

When the DATE and TIME keywords are not specified on the FRRECOV command, DFSMSHsm obtains the date and time that message data set name was generated.

Use of the message data set is controlled with the MESSAGEDATASET parameter of the SETSYS FASTREPLICATION command. Refer to [Chapter 65, “SETSYS command: Establishing or changing the values of DFSMSHsm control parameters,” on page 1057](#) for more information.

Defaults: None.

NEWNAME: Specifying a new data set name for the recovered data set

Explanation: NEWNAME(*newdsname*) is an optional parameter specifying a new, fully qualified data set name for the recovered backup version or dump copy. For *newdsname*, specify a new, fully-qualified data set name for the recovered data set. The originally-named data set will be preserved for analysis or other purposes.

If a cataloged data set exists with the same name as the new name you are specifying, you must specify the REPLACE parameter to replace the existing cataloged data set.

Note:

1. The NEWNAME parameter applies only to data set recovery. If you specify NEWNAME when it does not apply, DFSMSHsm ignores it.
2. You must specify NEWNAME when a data set exists with the same data set name as the data set that you are recovering, and you want to keep both versions of the data set.
3. A GDG base cannot be recovered using fast replication data set recovery. If you specify the NEWNAME keyword when you recover a generation data set (GDS) to a new name, the new GDG base name must have already been defined.
4. During FRRECOV, when NEWNAME is used, DFSMS ACS routines are not called. The data set will be recovered to a volume in the same storage group by using the source data set's DFSMS constructs.

Defaults: None.

NOCOPYPOOLBACKUP: Setting an alternate return code

Explanation: NOCOPYPOOLBACKUP is an optional parameter that indicates an alternate return code value for failed data set recovery requests.

If you specify a partially qualified data set name on DSNNAME and the copy pool backup version cannot be found for a data set that matches the filtering criteria, the default return code is eight. In this case, however, you might not expect all of the data sets to be found in a copy pool backup version. If so, you can specify NOCOPYPOOLBACKUP(RC4) to have a lower return code for this situation (return code four instead of eight).

NOCOPYPOOLBACKUP is valid with DSNNAME only. It is not valid with the COPYPOOL or TOVOLUME parameters.

Defaults: RC8.

REPLACE: Recovering a cataloged data set

Explanation: REPLACE is an optional parameter, but required for recovering cataloged data sets. If the data set is uncataloged, but exists on a volume, you must specify both the REPLACE and FROMCOPYPOOL parameters in order to recover the data set.

If you specify the NEWNAME(*newdsname*) parameter and the new name is the same as the name of an existing data set, you must specify the REPLACE parameter. If REPLACE is not specified, DFSMSHsm fails the FRRECOV DSNNAME command.

Defaults: None.

RSA: Overriding the RSA key label

Explanation: RSA is an optional parameter used to override the RSA key label that DFSMSdss would otherwise use to restore an encrypted dump.

The following variable is required when using the RSA parameter:

keylbl

Is the key label, up to 64 characters in length, used to restore an encrypted dump. The first character must be alphabetic or national.

Defaults: None.

VERIFY: Verifying that no unexpected FlashCopy relationship exists for a volume in a copy pool

Explanation: VERIFY is an optional parameter that specifies whether verification, of conditions which might prevent a successful fast replication recovery, is performed *before* starting a fast replication recovery operation. Performing verification reduces the risk of a fast replication recovery failure. The following condition is verified:

1. The copy pool is defined allowing fast reverse restore, but one or more DASD are in the process of being dumped to tape.

The following conditions are verified when the devices do not support cascaded FlashCopy:

1. The copy pool is not defined allowing fast reverse restore, but one or more volumes are in an existing FlashCopy relationship.
2. The copy pool is defined allowing fast reverse restore, but there are multiple FlashCopy targets, including non-DFSMSHsm managed targets, associated with a source volume in the copy pool. Additional FlashCopy targets need to be removed before attempting fast reverse restore when cascaded FlashCopy is not supported.
3. There are multiple FlashCopy Incremental FlashCopy targets associated with a source volume in the copy pool.

The following options can be used with the VERIFY parameter:

Y

specifies that source volumes require verification. This option is the default.

N

specifies that source volumes do not require verification. Use VERIFY(N) only when all volumes are SnapShot capable, or if the QUERY COPYPOOL command has been issued to verify that there are not any unexpected FlashCopy relationships.

Note:

1. VERIFY(N) cannot be specified when a copy pool is defined allowing fast reverse restore unless a previous FRRECOV COPYPOOL operation has determined the copy pool backup version is no longer eligible for fast reverse restore and regular fast replication recovery can be used.

Defaults: If you do not specify the VERIFY parameter, the default is Y (verification is performed).

Examples of how to code the FRRECOV command

The following examples present different ways to code the FRRECOV command.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Recovering a volume from a dump copy for dump class DCL1

In this example a single volume is recovered from dump class DCL1.

```
FRRECOV TOVOLUME(SRC001) FROMDUMP DUMPCLASS(DCL1) GENERATION(0)
```

Recovering a single volume is recovered from a specific dump tape

In this example, a specific volume from a specific copy pool from a specific dump volume is recovered.

```
FRRECOV TOVOLUME(SRC002) FROMCOPYPOOL(CPDATABASE1) FROMDUMP(DUMPVOLUME(TDUMP1))
```

Recovering all data sets for multiple users

In this example, DFSMSHsm requests a fast replication recovery of all data sets for three specific users.

```
FRRECOV DSNNAME(USER1.** ,USER2.** ,USER3.** ) REPLACE
```

Recovering each volume in a copy pool

In this example, DFSMSHsm requests a fast replication recovery for each volume in a copy pool named CPDATABASE1. The most recent versions are recovered since a specific version is not requested.

```
FRRECOV COPYPOOL(CPDATABASE1) VERIFY(Y)
```

Recovering each volume in a copy pool from a specific date

In this example, DFSMSHsm requests a fast replication recovery for each volume in a copy pool named CPDATABASE1 from a specific date.

```
FRRECOV COPYPOOL(CPDATABASE1) DATE(2002/1/15)
```

Recovering volumes in a copy pool with a specific token

In this example, DFSMSHsm requests a fast replication recovery of each volume in a copy pool named CPDATABASE1 with a specific token.

```
FRRECOV COPYPOOL(CPDATABASE1) TOKEN(FRBACKUP_JULYDATA)
```

Recovering a specific source volume

In this example, DFSMSHsm requests a fast replication recovery of the most recent fast replication backup version to a specific source volume.

```
FRRECOV TOVOLUME(VOL186)
```

Recovering a specific source volume from a specific copy pool

In this example, DFSMSHsm requests a fast replication recovery for a specific source volume from the copy pool named CPDATABASE1.

```
FRRECOV TOVOLUME(VOL186) FROMCOPYPOOL(CPDATABASE1)
```

Recovering a specific generation of a source volume from a specific copy pool

In this example, DFSMSHsm requests a fast replication recovery for a specific generation of a source volume from the copy pool named CPDATABASE1.

```
FRRECOV TOVOLUME(VOL186) FROMCOPYPOOL(CPDATABASE1) GENERATION(1)
```

Resuming a failed copy pool recovery from dump

In this example, the previous recovery of a copy pool named CPDATABASE1 from dump class DCL1 failed. The failed recovery is resumed.

```
FRRECOV COPYPOOL(CPDATABASE1) FROMDUMP(DUMPCCLASS(DCL1) RESUME(YES))
```

Chapter 50. HOLD command: Preventing DFSMSHsm functions from running

The HOLD command prevents all or some DFSMSHsm functions from running. For example, you specify HOLD when a temporary software or hardware problem occurs that can be compounded if data movement continues in DFSMSHsm.

Migration, backup, dump, recovery, and restore have an optional keyword related to stopping volume processing after the current data set (EOD) or delaying until the end of processing the user volume (EOV).

Note:

- HOLD ALL will hold the sub-function of AUTOEXPIRATION of data sets beginning with PTF UA99661 in 2.4 and above.
- HOLD MIGRATION or HOLD MIGRATION(AUTO) will not hold AUTOEXPIRATION. You must use HOLD AUTOEXPIRATION if you want this function held.

The WAIT and NOWAIT parameters of the HSEND CMD command have implications to HOLD command processing that are function specific. Refer to the specific processing function for an explanation.

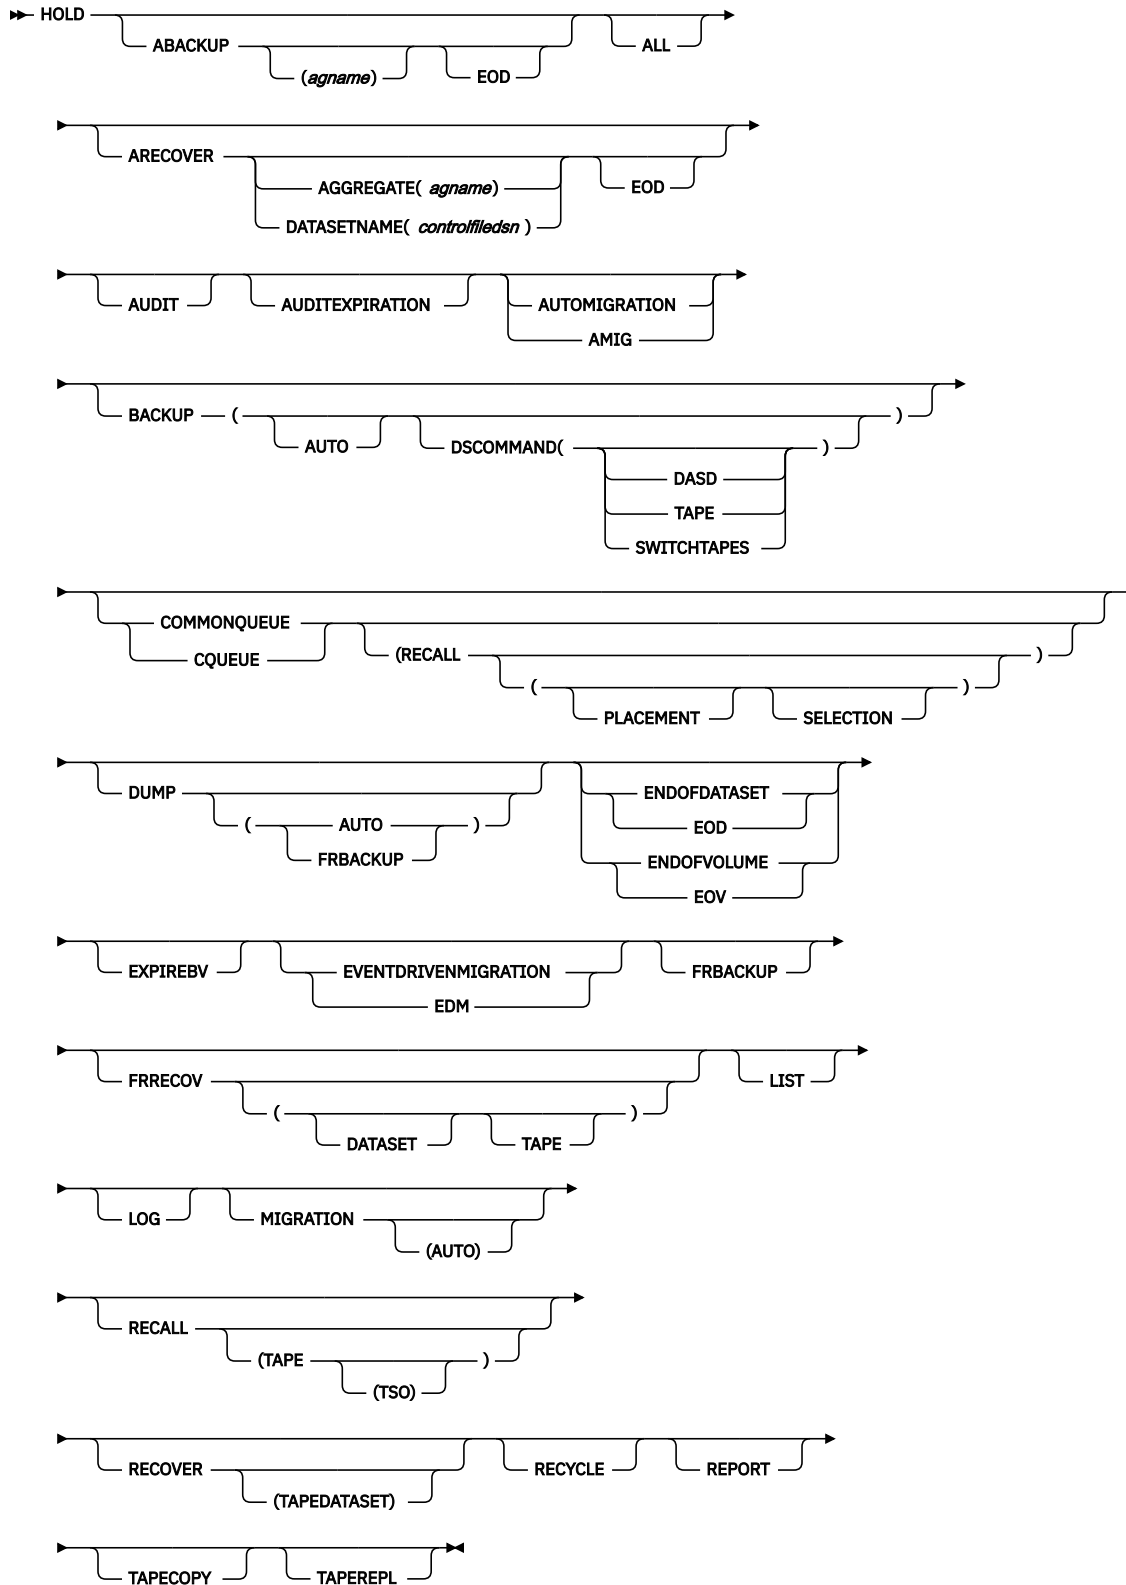

All nonWAIT-type requests remain on the processing queue when the appropriate HOLD command is in effect.

If the HOLD command is issued while the TAPECOPY or TAPER EPL commands are processing more than one volume, either from a volume list from the command or from an input data set, processing stops after the current volume.

You can issue the RELEASE command to release for processing all or some of the DFSMSHsm functions held with the HOLD command.

Functions held from processing by the HOLD command are no longer prevented from processing if DFSMSHsm is reinitialized.

Syntax of the HOLD command

Note:

1. The ENDOFDATASET and ENDOFVOLUME optional parameters affect the following optional parameters:

- AUTOMIGRATION
 - BACKUP
 - BACKUP(AUTO)
 - DUMP
 - DUMP(AUTO)
 - DUMP(FRBACKUP)
 - MIGRATION
 - MIGRATION(AUTO)
 - RECOVER
 - RECOVER(TAPEDATASET)
2. Although the HOLD command has no required parameters, you must specify at least one optional parameter if you want to prevent a DFSMSHsm function from processing.
 3. In a multiple address space for DFSMSHsm environment, ABARS commands, like HOLD ABACKUP or HOLD ARECOVER, can only be issued by the host identified as the main host. DFSMSHsm ignores the ABARS commands if directed to a host identified as HOSTMODE=AUX.

Optional parameters of the HOLD command

This topic describes the optional parameters of the HOLD command.

ABACKUP: Preventing aggregate backup

Explanation: **ABACKUP** is an optional parameter specifying that the process of backing up aggregated data sets stops after completion of any currently running aggregate backup. Any ABACKUP commands not processed remain in the queue until ABACKUP is released.

Subparameter	Explanation
<i>agname</i>	ABACKUP(<i>agname</i>) is an optional parameter specifying an aggregate group. For <i>agname</i> , substitute the name of the SMS aggregate group.

Subparameter	Explanation
EOD	<p>ABACKUP EOD If the EOD option is specified with a HOLD ABACKUP command, the currently executing aggregate backup is stopped at the end of the data set currently processing, and the ABACKUP command is purged from the queue. All open data sets and tapes are closed and all allocated data sets and tapes are deallocated before the termination. The ABACKUP output files are uncataloged and the tape volume serial numbers are removed from the HSMABR tape volume set if they were indicated to be protected. During ABACKUP processing, if the control file has already been written and a HOLD EOD is issued, ABACKUP is allowed to complete normally. However, if ABACKUP was issued with the MOVE option, ABACKUP will be held. If an aggregate group name was specified with the HOLD ABACKUP command, the above processing only occurs when the specified name matches a currently running or pending ABACKUP command.</p> <p>If the ABACKUP parameter is specified with the HOLD command and without the EOD option, the currently executing ABACKUP commands run to completion. If an aggregate group name has been specified, subsequent commands for that name are held. When an aggregate group name was specified, the above processing only occurs if the specified name matches a currently running or pending ABACKUP command.</p> <p>Notes:</p> <ol style="list-style-type: none"> 1. If you issue an ABACKUP command with a WAIT option when ABACKUP is held, that request fails and an error message is issued. 2. If you issue an ABACKUP command with a NOWAIT option when ABACKUP is held, that request is queued and processed when ABACKUP is released. 3. To ensure data integrity, you should HOLD ABACKUP from processing aggregated data sets whose data is being heavily used, or when automatic functions are running.

Defaults: None.

ALL: Preventing all DFSMSHsm functions

Explanation: **ALL** is an optional parameter specifying that all functions controlled by this command, except logging, are prevented.

If the EOD or EOV parameter is specified, then all functions (except ABACKUP, ARECOVER, FRBACKUP, and FRRECOV) are held using that parameter. If neither EOD nor EOV is specified, then each function is held according to its default: BACKUP, MIGRATION, and RECOVER are held as EOD, and DUMP is held as EOV. ABACKUP and ARECOVER ignore the EOD parameter.

Note: HOLD ALL will hold the sub-function of AUTOEXPIRATION of data sets during Auto Migration.

Defaults: None.

ARECOVER: Preventing aggregate recovery

Explanation: **ARECOVER** is an optional parameter specifying that the process of recovering aggregated data sets stop after completion of any currently running aggregate recovery. Any ARECOVER commands not processed remain in the queue until ARECOVER is released.

Subparameter	Explanation
AGGREGATE	<p>ARECOVER AGGREGATE(<i>agname</i>) is an optional parameter specifying an aggregate group. For <i>agname</i>, substitute the name of the SMS aggregate group against which you want DFSMSHsm to hold processing.</p>

Subparameter	Explanation
DATASETNAME	ARECOVER DATASETNAME(<i>controlfiledsn</i>) is an optional parameter specifying a control file name. For <i>controlfiledsn</i> , substitute the name of the control file against which you want DFSMSHsm to hold processing.
EOD	<p>ARECOVER EOD If the EOD option is specified with a HOLD ARECOVER command, the currently executing aggregate recovery is stopped at the end of the data set currently processing, and the ARECOVER command is purged from the queue. All open data sets and tapes are closed and all allocated data sets and tapes are deallocated before the termination. If an aggregate group name or control file data set name has been specified with the HOLD ARECOVER command, the above processing only occurs when the specified name matches a currently running or pending ARECOVER command. During ARECOVER processing, the restart data set is written when the HOLD EOD command is selected so that if the ARECOVER is reissued, data sets already processed are skipped.</p> <p>If the ARECOVER parameter is specified with the HOLD command and without the EOD option, the currently executing ARECOVER commands run to completion. If AGGREGATE(<i>agname</i>) or DATASETNAME(<i>controlfiledsn</i>) has been specified, subsequent commands for that name will be held. When AGGREGATE(<i>agname</i>) or DATASETNAME(<i>controlfiledsn</i>) has been specified, the above processing only occurs if the specified name matches a currently running or pending ARECOVER command.</p> <p>Note:</p> <ol style="list-style-type: none"> 1. If you issue an ARECOVER command with a WAIT option when ARECOVER is held, that request fails and an error message is issued. 2. If you issue an ARECOVER command with a NOWAIT option when ARECOVER is held, that request is queued and processed when ARECOVER is released.

Defaults: None.

AUDIT: Ending the audit function

Explanation: **AUDIT** is an optional parameter specifying that DFSMSHsm stop the audit function after it finishes processing the current data set. WAIT-type command requests fail, and NOWAIT-type command requests remain queued.

Defaults: None.

Note: When you issue the HOLD command, you lose any part of the AUDIT command that has not finished running.

AUTOEXPIRATION: Preventing data sets from expiring

Explanation: **AUTOEXPIRATION** is an optional parameter specifying that DFSMSHsm stop the automatic expiration of data sets during space management.

Defaults: None.

Note: Use caution with this command, as this can lead to volumes being filled to capacity. Short hand for the command is 'AEXP'.

AUTOMIGRATION: Preventing automatic volume and automatic secondary space management

Explanation: **AUTOMIGRATION** is an optional parameter specifying that automatic volume and automatic secondary space management are prevented. If automatic volume and automatic secondary space management are running when you issue the HOLD command, automatic volume and automatic secondary space management stop. The point at which processing stops is controlled by the ENDOFDATASET and ENDOFVOLUME parameters.

Defaults: None.

Note:

1. When you specify **AUTOMIGRATION**, DFSMSHsm does not prevent the running of any space management functions that were issued by command.
2. **HOLD AUTOMIGRATION** has the same meaning as **HOLD MIGRATION(AUTO)**.
3. **HOLD AUTOMIGRATION** will not **HOLD AUTOEXPIRATION**. You must use **HOLD AUTOEXPIRATION** if you want this function held.

BACKUP: Preventing backups

Explanation: **BACKUP** is an optional parameter that specifies whether you want DFSMSHsm to prevent all backup processing or to prevent only the following processing:

- All data set backup requests
- All data set backup requests to either DASD or tape
- Data set backups to DASD
- Data set backups to tape
- All automatic backups

The **BACKUP** parameter also specifies whether you want DFSMSHsm to demount tapes that are used by command backup.

The **BACKUP** parameter, without any subparameters, prevents all backup processing tasks and demounts all tapes mounted for command data set backup. No more tasks are started for backup processing. Any command requests that specified the **WAIT** keyword are failed.

Subparameter	Explanation
AUTO	<p>BACKUP(AUTO) specifies that automatic backup processing is prevented. No more automatic backup processing tasks are started. You can still perform command backup processing tasks.</p> <p>The ENDOFDATASET and ENDOFVOLUME parameters control volume backup processing. Data set processing is always ENDOFDATASET.</p>

Subparameter	Explanation
DSCOMMAND	<p>BACKUP(DSCOMMAND) specifies that all data set backups by command (BACKDS, HBACKDS, ARCHBACK, and ARCINBACK) and all INUSE RETRY backups from autobackup are prevented. All WAIT-type requests fail, and control returns to the requester.</p> <p>BACKUP(DSCOMMAND(DASD)) specifies that only data set backups by command that are directed to ML1 DASD are prevented. All WAIT-type requests fail that specifically target DASD, and the requester is returned control.</p> <p>BACKUP(DSCOMMAND(TAPE)) specifies that only data set backups by command that are directed to tape are prevented. All WAIT-type requests that specifically target tape or are too large for DASD fail, and the requester is returned control. Based on the setting used in the SETSYS DSBACKUP (DASDSELECTIONSIZE) parameter, DFSMSHsm directs some WAIT-type requests to tape. DFSMSHsm fails these WAIT-type requests when you specify DSCOMMAND(TAPE). To redirect these requests to DASD, you can do one of the following tasks:</p> <ul style="list-style-type: none"> • Issue SETSYS DSBACKUP(TAPE(TASKS(0))). This directs to DASD all but those requests that specifically target tape. DFSMSHsm fails those BACKDS requests that specifically target tape. • Increase the SETSYS DSBACKUP(DASDSELECTIONSIZE) settings. This directs to DASD all larger data sets. <p>BACKUP(DSCOMMAND(SWITCHTAPES)) specifies that command data set backup demounts any mounted tapes at the end of the current data set or immediately, if the mounted tape is waiting for additional work. When command data set backup has additional work, processing continues with new tapes. This SWITCHTAPES type of HOLD does not require the use of a RELEASE command.</p> <p>Use the SWITCHTAPES parameter for the following tasks:</p> <ul style="list-style-type: none"> • You have tapes that are continuously mounted, and the need arises to demount a tape so that it or its alternate tape can be taken to another site for disaster backup purposes • To introducing new tape devices to the installation, these continuously mounted tapes also need to be demounted and the drives deallocated <p>If you want to change the PARTIALTAPE options from what was originally defined in the DEFINE SWITCHTAPES(DSBACKUP) command, you must do so before you issue the HOLD command.</p>

Defaults: Issuing the HOLD BACKUP command with no parameters prevents all backup processing.

Note: If you are using the SETSYS BACKUP command or a data set backup installation exit to direct DFSMSHsm to retry backup requests that fail because data sets are in use, and if DFSMSHsm has scheduled any such retries during automatic backup, those backup retries will not be affected by the HOLD BACKUP(AUTO) command. You will need to use HOLD BACKUP or HOLD ALL.

COMMONQUEUE: Preventing common queue functions

Explanation: **COMMONQUEUE** is an optional parameter that specifies that DFSMSHsm prevent all common queue processing. If you specify COMMONQUEUE without any parameters, a host neither places recall requests in the CRQ, nor selects recall requests from the CRQ.

Subparameter	Explanation
RECALL	<p>COMMONQUEUE(RECALL) specifies that a host neither places recall requests in the CRQ, nor selects recall requests from the CRQ.</p> <p>COMMONQUEUE(RECALL(PLACEMENT)) specifies that the host does not place additional requests in the CRQ. All new requests will be placed on the host's local recall queue.</p> <p>COMMONQUEUE(RECALL(SELECTION)) specifies that the host does not select recall requests from the CRQ.</p>

Note: Specifying HOLD COMMONQUEUE without parameters does not affect the common dump queue or recover queue functions.

For more information about using HOLD COMMONQUEUE, see [“Preventing DFSMSHsm functions from running” on page 596.](#)

Defaults: None.

DUMP: Preventing dumps

Explanation: **DUMP** is an optional parameter specifying whether DFSMSHsm prevents all dump processing (command and automatic) or prevents only automatic dump processing. The **DUMP** parameter, without any subparameters, specifies that all dump processing tasks are prevented. No more dump processing tasks are started. Also, any command requests that specified the **WAIT** keyword are failed.

Subparameter	Explanation
AUTO	DUMP(AUTO) specifies that automatic dump processing is prevented. No additional automatic dump processing tasks are started. You can still perform command dump processing tasks. HOLD DUMP(AUTO) also prevents auto dump tasks for fast replication copy pool volumes from starting. This setting does not affect dump tasks started through the FRBACKUP command.
FRBACKUP	DUMP(FRBACKUP) specifies that dump processing of FRBACKUP target volumes is prevented. No additional FRBACKUP DUMP tasks or FRBACKUP DUMPONLY tasks are started.

The point at which DFSMSHsm stops dump processing is controlled by the **ENDOFDATASET** and **ENDOFVOLUME** parameters.

When a **HOLD** command is submitted that interrupts a dump of a copy pool, if it is a **NOWAIT** request, the MWE for the dump remains queued until canceled or the **HOLD** is released. All **WAIT** requests are purged and must be resubmitted once the **HOLD** is released for the dump to take place.

When the **HOLD** command is issued from a host that is connected to a common dump queue (CDQ), the effect is different than in a non-CDQ environment. The actions taken by this host include:

- A **HOLD DUMP** does not fail **WAIT** type requests if another host in the CDQ is not held. This is because this host's resources are those of the group.
- Requests submitted to the CDQ from this host that are active or queued are allowed to complete as long as work did not get assigned to the host issuing the **HOLD DUMP**.
- A **HOLD DUMP** on a CDQ host may cause the work currently on that host for processing to be failed, based on whether **EOD** or **EOV** is specified on the **HOLD**.
- If the **HOLD** was issued from the master scheduler host, the scheduling of CDQ work is prevented.

Consider using **SETSYS MAXDUMPTASKS(0)** from the master scheduler, instead of this **HOLD**, if you want the master scheduler to schedule CDQ work but not use its resources for CDQ dump processing.

When the **HOLD** command is issued from all hosts connected to a common dump queue, which changes the master scheduler status to **DISABLED**, the actions taken by each host include:

- New WAIT request types from this host are failed locally
- New NOWAIT request types from this host are queued locally as the master scheduler status is DISABLED
- If EOD is specified on the HOLD, all requests are failed. If EOVS is specified, the current volume in a stack is completed and the remaining are failed.
- Queued WAIT request types in the CDQ master scheduler host are failed

HOLD FRBACKUP, DUMP, and AUTODUMP all have the same impact in a common dump queue (CDQ) for selection of a host for dump processing. Any one of these being held prevents a host from being selected for all CDQ dump processing. HOLD of FRBACKUP, DUMP, and/or AUTODUMP also impact the master scheduler's ability to perform scheduling of CDQ work. Instead of the HOLD, consider using the SETSYS MAXDUMPTASKS(0) command from all of the hosts connected to a CDQ. This prevents the selection of a host's resources for CDQ dump processing. It allows the master scheduler to schedule CDQ work but not select its resources for CDQ dump processing. If a HOLD was used, any takeover of the master scheduler responsibilities by another system are impacted by a previously issued HOLD for DUMP. In this case the HOLD DUMP should only be used to prevent the selection of a host's resources, unless the host is defined to the group with a master scheduler candidate status of NO, with SETSYS COMMONQUEUE(DUMP(MSC(NO))).

In addition, when any variety of the HOLD command is issued from a host that is connected to a common dump queue, its host resources are prevented from being selected to process a request by the common queue, even if the requests did not originate from the system that issued the hold command.

Notes:

1. The MASTERSCHEDULER status for the dump group on this host is not changed by this command. It will continue to have a MASTERSCHEDULER status of ENABLED as long as one host in the group is not held. If all of the group hosts have been held, then no host is eligible to do the work and the MASTERSCHEDULER status will be changed to be DISABLED. In this state, the wait-type requests are failed and no-wait type requests are still placed on the common dump queue.
2. You can further refine the capabilities of a common dump queue host, as follows:
 - a. If you wish a dump common dump host to be able to submit command work, but *not* process dump work, issue the SETSYS MAXDUMPTASKS(0) command on that host. This can be either a master scheduler host or a non-master scheduler host. In the case of a master scheduler host, this does *not* impact the master scheduler duties.
 - b. If you wish to stop automatic dump processing in a common dump queue, issue the HOLD DUMP(AUTO) command on the host that originally requested the automatic dump processing.
 - c. If you wish to stop a host from performing master scheduler duties, issue a SETSYS COMMONQUEUE(DUMP(MSC(NO))) on that host. Another master scheduler candidate host, if available, will take on the master scheduler duties.
 - d. If you wish to prevent a host from running automatic dump processing, while still allowing it to submit command dumps and to process command and auto dumps using the common dump queue, simply do *not* provide an AUTODUMPSTART window for that host.

Defaults: If AUTO is not specified, command dump and automatic dump processing are prevented.

ENDOFDATASET: Specifying when aggregate group processing should stop

Explanation: ENDOFDATASET is an optional parameter that you can use with the ABACKUP and ARECOVER parameters to specify when processing stops during aggregate backup or aggregate recovery.

Refer to “ABACKUP: Preventing aggregate backup” on page 897 and “ARECOVER: Preventing aggregate recovery” on page 898 for a description of aggregate processing when using the ENDOFDATASET parameter with the ABACKUP or ARECOVER parameters.

Defaults: None.

ENDOFDATASET and ENDOFVOLUME: Specifying when volume processing should stop

Explanation: **ENDOFDATASET** and **ENDOFVOLUME** are optional parameters specifying when to stop volume processing of one of the following:

- Space management (automatic or command)
- Backup (automatic or command)
- Dump (automatic or command, including fast replication dump)
- Recover (including fast replication recovery from a dump volume)
- Restore

Note: This description does not apply to aggregate group processing or fast replication backup or recovery processing. See “[ENDOFDATASET: Specifying when aggregate group processing should stop](#)” on page 903 for information on holding aggregate group processing. See “[FRBACKUP: Preventing fast replication backup or dump processing](#)” on page 905 and “[FRRECOV: Preventing fast replication recovery processing](#)” on page 905 for information on holding fast replication backup or recovery processing.

ENDOFDATASET specifies that currently processing volume tasks stop after the current data set finishes processing. In the case of DUMP, FRBACKUP DUMP, FRBACKUP DUMPONLY, FRRECOV, or FRRECOV(TAPE), the current dump copies being written by each dump task are discarded; if any dump task is stacking output, any dump copies successfully completed by that task are preserved.

ENDOFVOLUME specifies that volume tasks stop after the current user volume finishes processing. In the case of DUMP, FRBACKUP DUMP, or FRBACKUP DUMPONLY, the current dump copies being written by each dump task are allowed to complete; if any dump task is stacking output, no further dump copies are stacked or processed.

When the level functions are running at the time a HOLD EOV command is issued, the command is interpreted to mean that the particular function runs to completion before the stop occurs. **Example:** If a HOLD EOV is entered while the movement of backup versions is running, the movement of the backup versions is allowed to complete all of its requests but the backup of migrated data sets does not start. In other words, HOLD EOV means stop processing a specific function at the end of a volume, or at the end of the movement of backup versions from a migration volume to a daily backup volume, or at the end of the movement of backup versions from one volume to another volume.

Either parameter prevents processing another user volume.

Defaults: If neither ENDOFDATASET nor ENDOFVOLUME is specified, the default is ENDOFDATASET. If the function being held is DUMP, FRBACKUP DUMP, or FRBACKUP DUMPONLY, the default is ENDOFVOLUME.

Note: If you hold dump processing with the ENDOFDATASET parameter while DFSMSHsm is automatically deleting expired dump copies or deleting excess dump VTOC copy data sets, processing is ended after DFSMSHsm finishes processing the current dump generation.

EVENTDRIVENMIGRATION: Preventing Interval and On-demand Migration

Explanation: **EVENTDRIVENMIGRATION** is an optional parameter specifying that DFSMSHsm stop both interval Migration and On-demand Migration. Other automatic migration functions may still run.

Defaults: None.

Note: When you issue the HOLD command, if Interval or On-demand migration have already been started they will run through to completion, and then will be held the next time they try to run.

Note: If automatic migration (HOLD AUTOMIGRATION) has been held, it will also cause Interval and On-demand migration to be held along with other automatic migration functions.

EXPIREBV: Ending the expire backup function

Explanation: **EXPIREBV** is an optional parameter specifying that DFSMSHsm stop the process of deleting old, unwanted backup versions from the BCDS at the end of the current data set and not allow an EXPIREBV command to be started. If the expire backup function is running at the time the HOLD command is entered, the key of the last data set processed is saved, which allows processing to continue from that point if the RESUME parameter is specified on the next EXPIREBV command processed by this host. WAIT-type command requests fail, and NOWAIT-type command requests remain queued.

Defaults: None.

FRBACKUP: Preventing fast replication backup or dump processing

Explanation: **FRBACKUP** is an optional parameter that you specify to prevent new FRBACKUP, FRBACKUP DUMP, or FRBACKUP DUMPONLY commands from processing. When you issue the HOLD FRBACKUP command, DFSMSHsm completes any FRBACKUP, FRBACKUP DUMP, or FRBACKUP DUMPONLY requests that have already started.

When a HOLD command is submitted that interrupts a dump of a copy pool, if it is a NOWAIT request, the MWE for the dump remains queued until canceled or the HOLD is released. All WAIT requests are purged and must be resubmitted once the HOLD is released for the dump to take place.

HOLD ALL prevents FRBACKUP, both dump of target volumes and backup of DASD, from starting. The auto dump of FRBACKUP target volumes is also held. Currently running target dumps and DASD copy pool backups are allowed to finish.

This command will also have the same effect if the system issuing the command is connected to a dump group in the HSMplex. The respective queue in this case is the dump group common queue.

Defaults: None.

Note: HOLD ALL does not control the hold level of the common recall queue (CRQ) placement and selection functions. To place a hold on CRQ placement and selection, specify HOLD COMMONQUEUE. To place a hold on only one of the two functions (placement or selection), specify the appropriate optional subparameter.

FRRECOV: Preventing fast replication recovery processing

Explanation: **FRRECOV** is an optional parameter that you specify to prevent new FRRECOV commands from processing. When you enter the HOLD FRRECOV command, DFSMSHsm completes any FRRECOV requests that have already started.

The description below applies to preventing fast replication recovery and recover processing when running in a common recover queue (CVQ).

When you issue the HOLD command (ALL, RECOVER, FRRECOV, or FRRECOV(TAPE)) from a host that is connected to a CVQ, the effect is different from in a non-CVQ environment. The actions taken by this host include:

- HOLD of any type (ALL, RECOVER, FRRECOV) will prevent a host being selected by the master scheduler as a processing host, even though the request may be for another type that the HOLD was specified for.
- HOLD of any type (ALL, RECOVER, FRRECOV) on a specific host will not prevent that host from submitting requests, including WAIT type requests, to the CVQ. This is because this host's resources are those of the group. It just won't be selected as a processing host (previous item).
- HOLD by the Master Scheduler host for a specific type will affect the assignment of that type by the Master Scheduler host. A HOLD on both (RECOVER, FRRECOV) on the CVQ MS will prevent it from performing its assignment duties. For example, a HOLD RECOVER on the Master Scheduler host will prevent the assignment of only RECOVER requests but will still assign FRR CP requests volumes to processing hosts. The Query Active command message ARC1560I response will indicate this status.
 - Requests submitted to the CVQ from this host that are active or queued are allowed to complete as long as work did not get assigned to the host issuing the HOLD

- A HOLD on a CVQ host may cause the work currently on that host for processing to be failed, based on whether EOD or EOVS is specified on the HOLD.
- Consider using SETSYS MAXDUMPRECOVERTASKS(0) from the master scheduler, instead of A HOLD, if you want the master scheduler to schedule CVQ work but not use its resources for CVQ volume restore processing.
- When the HOLD command (ALL, RECOVER, FRRECOV, or FRRECOV(TAPE)) is issued from all hosts connected to a common recover queue, which changes the master scheduler status to DISABLED, the actions taken by each host include:
 - New WAIT request types from this host are failed locally
 - New NOWAIT request types from this host are queued locally as the master scheduler status is DISABLED
 - If EOD is specified on the HOLD, all requests are failed. If EOVS is specified, the current volume in a stack is completed and the remaining are failed.
 - Queued WAIT request types in the CDQ master scheduler host are failed

When you select a host for volume restore processing, the HOLD ALL, RECOVER (any variety), and FRRECOV(TAPE) commands prevent a host from being selected for CVQ volume restore processing

These holds also impact the ability of the master scheduler to perform scheduling of CVQ work for the specific hold type. Instead of using the HOLD command, consider using the SETSYS MAXDUMPRECOVERTASKS(0) command from all of the hosts connected to a CVQ.

Using the SETSYS MAXDUMPRECOVERTASKS(0) command prevents the selection of host resources for CVQ volume restore processing, and allows volume restore requests to be submitted. It also allows the master scheduler to schedule CVQ work without selecting resources for processing. If a HOLD was used, any transfer of the master scheduler responsibilities to another system is impacted by a previously issued HOLD for RECOVER or FRRECOV(TAPE). In this case, the HOLD can be used only to select resources from a host, unless the host is defined to the group with a master scheduler candidate status of NO, with SETSYS COMMONQUEUE(DUMP(MSC(NO))).

In addition, when you issue any of the HOLD commands from a host that is connected to a CVQ, it prevents the selection of host resources to process a request, even when the requests did not originate from the system that issued the HOLD command.

Note:

The MASTERSCHEDULER status for the common recover group on this host remains ENABLED until one host in the group is not held. If all of the group hosts have been held, then no host is eligible to do the work, and the MASTERSCHEDULER status changes to DISABLED. In this state, the wait-type requests are failed and no-wait type requests are placed on the common recover queue.

You can further refine the capabilities of a common recover queue host, as follows:

- When you want a common recover queue host to be able to submit command work, but not process the work, issue the SETSYS MAXDUMPRECOVERTASKS(0) command on that host. This can be either a master scheduler host or a non-master scheduler host. When you issue the SETSYS MAXDUMPRECOVERTASKS(0) command on master scheduler host, it does not impact the master scheduler responsibilities.

Subparameter	Explanation
TAPE	FRRECOV(TAPE) specifies that recovery processing of FRBACKUP generated dump volumes is prevented. No more recoveries from FRBACKUP dump tasks are started. You can still recover DASD backups.
DATASET	FRRECOV(DATASET) is an optional parameter for HOLD FRRECOV. Data set recoveries are held when HOLD ALL, HOLD FRRECOV or HOLD FRRECOV(DATASET) are specified. The existing TAPE keyword will hold data set recoveries from tape.

Defaults: None.

LIST: Ending the list function

Explanation: **LIST** is an optional parameter specifying that DFSMSHsm stop the list function after it finishes processing the control data set record of the current request. WAIT-type command requests fail, and NOWAIT-type command requests remain queued.

Defaults: None.

Note: When you issue the HOLD command, you lose any part of the LIST command that did not finish running.

LOG: Preventing logging

Explanation: **LOG** is an optional parameter specifying that DFSMSHsm stop recording in the DFSMSHsm log. No records are written in the DFSMSHsm log for those DFSMSHsm functions that continue to run. DFSMSHsm continues recording information in the activity logs.

Defaults: None.

MIGRATION: Preventing space management

Explanation: **MIGRATION** is an optional parameter specifying whether DFSMSHsm should prevent all space management processing or prevent only automatic space management processing. The MIGRATION parameter, without any subparameters, specifies that all space management functions are prevented. No more space management tasks are started.

Subparameter	Explanation
AUTO	MIGRATION(AUTO) specifies that automatic volume and automatic secondary space management processing are prevented. No more automatic volume and automatic secondary space management processing tasks are started. You can still perform command space management.

The point at which DFSMSHsm stops space management processing is controlled by the ENDOFDATASET and ENDOFVOLUME parameters. WAIT-type command requests are failed, and NOWAIT command requests remain queued.

Defaults: If AUTO is not specified, automatic volume space management, automatic secondary space management, and command space management are prevented.

Note: HOLD MIGRATION(AUTO) will not HOLD AUTOEXPIRATION. You must use HOLD AUTOEXPIRATION if you want this function held.

RECALL: Preventing recall and deletion

Explanation: **RECALL** is an optional parameter specifying which recalls (automatic or command) and deletions of a migrated data set are prevented.

The RECALL parameter, without any subparameters, specifies that all recall and data set deletion tasks from all volumes are prevented. No more recall or data set deletion tasks are started.

Subparameter	Explanation
TAPE	<p>RECALL(TAPE) specifies that recall requests from all tape volumes do not process. If you specify RECALL(TAPE) for a host that is participating in a common recall queue, the host selects only recall requests that do not require tape.</p> <p>RECALL(TAPE(TSO)) specifies that TSO recall requests from migration level 2 tapes are prevented. Recall requests from tape submitted from a batch job and all nontape volumes are still processed.</p>

Defaults: None.

Note:

1. All nonWAIT requests remain queued when the appropriate function is held.
2. If TSO tape recalls are held, a WAIT-type recall from tape that was submitted through TSO is changed to a non-WAIT-type request. The user is told that the request remains on the queue to be processed when the function is released.
3. All WAIT recall or deletion requests from batch or from the storage administrator are failed when RECALL is held.
4. All WAIT recall requests from tape, from batch, or from the storage administrator are failed when tape recall is held.

RECOVER: Preventing recovery and restore

Explanation: **RECOVER** is an optional parameter specifying whether DFSMSHsm prevents all recovery and restore processing or prevents only tape data set recovery processing. The RECOVER parameter, without any subparameters, specifies that all recover and restore processing tasks are prevented. No additional recovery and restore processing tasks are started. The RECOVER parameter prevents any request for backup data sets on a mounted tape volume.

When you issue any HOLD (ALL, RECOVER, FRRECOV, or FRRECOV(TAPE)) command from a host that is connected to a common recover queue (CVQ), the HOLD command has a different effect than when it is issued from a non-CVQ environment. See [“FRRECOV: Preventing fast replication recovery processing”](#) on page 905 for details.

Subparameter	Explanation
TAPEDATASET	RECOVER(TAPEDATASET) specifies that tape recover and restore processing is prevented. No additional tape data set processing tasks are started. You can still perform recover processing tasks from DASD.

The point at which DFSMSHsm stops recovery processing is controlled by the ENDOFDATASET and END OFVOLUME parameters. WAIT-type command requests fail, and NOWAIT-type command requests remain queued.

Defaults: If TAPEDATASET is not specified, command recovery for both data sets and volumes is prevented.

Note: If a HOLD RECOVER(TAPEDATASET) has been issued, any request for backup data sets on a mounted backup tape volume is processed, and any requests for the new tape volume mounts are not processed.

RECYCLE: Ending the recycle function

Explanation: **RECYCLE** is an optional parameter specifying that the recycle function ends after DFSMSHsm processes the current backup version or migration copy on each volume being recycled. WAIT-type command requests fail, and NOWAIT-type command requests remain queued.

Defaults: None.

Note: When you issue the HOLD command, you lose any part of the RECYCLE command that has not finished running.

REPORT: Ending the report function

Explanation: **REPORT** is an optional parameter specifying that DFSMSHsm stop the report function after it has finished processing the control data set record for the current request. WAIT-type command requests fail, and NOWAIT-type command requests remain queued. When you issue the HOLD command, you lose any part of the REPORT command that has not finished running.

Defaults: None.

TAPECOPY: Preventing DFSMSHsm from copying a tape

Explanation: **TAPECOPY** is an optional parameter specifying that DFSMSHsm hold all tape copy processes. WAIT-type command requests fail, and NOWAIT-type command requests remain queued.

If DFSMSHsm was processing an explicit volume list when the HOLD command was issued, the remaining volumes in the list may not process when the TAPECOPY command is released.

Defaults: None.

TAPEREPL: Preventing DFSMSHsm from replacing an original tape volume with an alternate

Explanation: **TAPEREPL** is an optional parameter specifying that DFSMSHsm hold all tape replacement processes. WAIT-type command requests fail, and NOWAIT-type command requests remain queued.

Defaults: None.

Examples of how to code the HOLD command

The following examples present different ways to code the HOLD command.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Preventing space management and recall

In this example, DFSMSHsm prevents processing of automatic space management, space management by command, and recall and deletion of migrated data sets.

```
HOLD MIGRATION RECALL
```

Preventing all DFSMSHsm functions and logging

In this example, DFSMSHsm prevents processing of all DFSMSHsm functions, including logging.

```
HOLD ALL LOG
```

Ending the report function

In this example, DFSMSHsm stops the report function at the end of the current unit of work. No more REPORT commands are started.

```
HOLD REPORT
```

Ending all recalls from tape

In this example, DFSMSHsm stops all recalls from tape.

```
HOLD RECALL(TAPE)
```

Ending all recalls from tape submitted by an interactive TSO user

In this example, DFSMSHsm stops all recalls from tape submitted by an interactive TSO user. DFSMSHsm allows recalls from tape that are submitted from a batch job to process.

```
HOLD RECALL(TAPE(TSO))
```

Preventing placement and selection of recall requests in the CRQ

In this example, DFSMSHsm prevents the host from placing recall requests in the common recall queue (CRQ) and selecting recall requests from the CRQ.

```
HOLD COMMONQUEUE(RECALL)
```

Preventing placement of recall requests in the CRQ

In this example, DFSMSHsm prevents the host from placing recall requests in the CRQ, but the host selects recall requests for processing from the CRQ.

```
HOLD COMMONQUEUE(RECALL(PLACEMENT))
```

Preventing selection of recall requests from the CRQ

In this example, DFSMSHsm prevents the host from selecting recall requests for processing from the CRQ, but the host places recall requests in the CRQ.

```
HOLD COMMONQUEUE(RECALL(SELECTION))
```

Ending all tape copying

In this example, DFSMSHsm stops all tape copying.

```
HOLD TAPECOPY
```

Ending all tape replacement

In this example, DFSMSHsm stops all tape replacement.

```
HOLD TAPEREPL
```

Preventing backup function from running

In this example, DFSMSHsm prevents the backup function from running.

```
HOLD BACKUP
```

Preventing the fast replication backup function from running

In this example, DFSMSHsm prevents new FRBACKUP commands from processing. When you issue this command, DFSMSHsm completes any FRBACKUP requests that have already started.

```
HOLD FRBACKUP
```

Preventing the fast replication recovery function from running

In this example, DFSMSHsm prevents new FRRECOV commands from processing. When you issue this command, DFSMSHsm completes any FRRECOV requests that have already started.

```
HOLD FRRECOV
```

Preventing the automatic volume and automatic secondary space management functions from running

In this example, DFSMSHsm prevents the automatic volume and automatic secondary space management functions from running. Command migration can still run.

```
HOLD MIGRATION(AUTO)
```

Preventing processing of a specific function at the end of the data set

In this example, DFSMSHsm stops backup processing at the end of the data set currently being processed.

```
HOLD BACKUP ENDOFDATASET
```

Preventing dump processing

In this example, DFSMSHsm prevents the dump function from running. Dumps currently in progress complete.

```
HOLD DUMP
```

Note: This is equivalent to HOLD DUMP ENDOFVOLUME.

Ending dump processing

In this example, DFSMSHsm stops all dumps the next time DFSMSdss reads or writes a record. Dumps in progress are stopped and invalidated.

```
HOLD DUMP ENDOFDATASET
```

Preventing automatic dump processing

In this example, DFSMSHsm prevents the automatic dump function from running. Any automatic dumps currently in progress complete, but no new automatic dumps start. Command dumps can still run.

```
HOLD DUMP(AUTO)
```

Preventing the expire backup versions function from running

In this example, DFSMSHsm stops deleting backup versions at the end of the current data set.

```
HOLD EXPIREBV
```

Preventing aggregate backup

In this example, DFSMSHsm stops backing up aggregated data sets after completion of any currently running aggregate backup.

```
HOLD ABACKUP(PAY1) EOD
```

Preventing aggregate recovery

In this example, DFSMSHsm stops recovering aggregated data sets after completion of any currently running aggregate recovery.

```
HOLD ARECOVER(PAY1.C.C01V0001)
```

Preventing automatic backup and command data set backups to DASD

In this example, DFSMSHsm holds automatic backups and command data set backups directed to ML1 DASD. Command data set backups to tape continue processing.

```
HOLD BACKUP(AUTO DSCOMMAND(DASD))
```

Preventing automatic backup and command data set backups to tape

In this example, DFSMSHsm holds automatic backups and command data set backups directed to tape. Command data set backups to ML1 DASD continue processing.

```
HOLD BACKUP(AUTO DSCOMMAND(TAPE))
```

Interrupting command data set backup to change output tapes

In this example, you have tapes that are scheduled to be taken offsite for disaster backup and you need to switch the output tapes used by command data set backup.

```
HOLD BACKUP(DSCOMMAND(SWITCHTAPES))
```

Chapter 51. HSEND CMD command: Issuing DFSMSHsm authorized-user commands from a TSO terminal

In a RACF FACILITY class environment, permission to issue the HSEND CMD is not checked by DFSMSHsm. Instead, permission to issue the command submitted by HSEND CMD is checked by DFSMSHsm using RACF FACILITY class checking.

In an AUTH environment, if you are an authorized user, you can use the HSEND CMD command to issue any DFSMSHsm operator, storage administrator, or system programmer commands from a TSO terminal, instead of from the system console.

In this AUTH environment, DFSMSHsm allows an unauthorized user to use the HSEND CMD to issue the ALTERDS, BDELETE, and the QUERY commands. The subcommands ALTERDS and BDELETE are processed in the same manner as the HALTERDS and HBDELETE.

In a RACF FACILITY class environment, an unauthorized user can only use the HQUERY, HCANCEL, HBDELETE, and HALTERDS commands. Users no longer have access to any storage administrator commands unless the security administrator has given them access to those command profiles.

Syntax of the HSEND CMD command

Required parameters of the HSEND CMD command

This topic describes the required parameter of the HSEND CMD command.

command: Specifying DFSMSHsm authorized command

Explanation

command is a required positional parameter specifying the authorized command from a TSO terminal. For *command*, substitute the DFSMSHsm command you want and its associated parameters. You cannot use more than 1024 bytes. The command and its associated parameters are treated as a group of parameters.

Optional parameters of the HSEND CMD command

This topic describes the optional parameters of the HSEND CMD command.

WAIT and NOWAIT: Specifying whether to wait for command completion

Explanation: WAIT and NOWAIT are mutually exclusive, optional parameters to specify whether you want to wait for the HSEND CMD requested function command to complete before control is returned to the user. If WAIT or NOWAIT is used, it must immediately follow HSEND CMD and precede command.

WAIT

Wait for the HSEND CMD requested function command to complete before control is returned to the user. The following DFSMSHsm commands (when used with the HSEND CMD WAIT) cannot ensure that the action will have completed at the time control is returned to the requester, because the processing of the command merely sets a flag or builds a request that is subsequently processed by another task.

- LOG
- QUERY SPACE
- STOP
- SWAPLOG

When you use the WAIT parameter with a command that processes a single item (such as one data set) or a volume as a single unit (such as DUMP), an ARC1000I message is issued if the process is successful, or an ARC1001I message is issued if the process is not successful. The following is a list of these commands:

- ABACKUP
- ARECOVER
- BACKDS
- BACKVOL with DUMP parameter
- DELETE of a migrated data set
- MIGRATE of a data set
- RECALL
- RECOVER of a data set
- RECOVER of a volume from a DFSMSdss physical full-volume copy

Other commands, when issued with the WAIT parameter, do not issue a successful termination message or set an HSEND CMD failing return code; however, they do issue explicit error messages for failing conditions.

If you press the TSO attention key when the WAIT parameter has been specified on a command request, and you confirm your intention to "attention out" of the request, an ARC1800I message is issued. This action makes your terminal available for use but does not cause DFSMSHsm to discontinue processing the request. If the request is for recalling or recovering a data set, a volume mount request (ARC0612I) message can be issued.

NOWAIT

Do not want to wait for the HSEND CMD requested function command to complete before control is returned to the user. The completion message does not occur until the requested function is complete. If the NOWAIT option is being used with the ABACKUP, ARECOVER, BACKDS, BACKVOL, DELETE, MIGRATE, RECALL, or RECOVER commands, an ARC1007I message is issued after the command has been communicated to DFSMSHsm. After DFSMSHsm has processed the request, a completion message (ARC1000I or ARC1001I) is written, indicating respectively success or failure of the request. If the request is for recalling or recovering a data set, a volume mount request (ARC0612I) message is issued.

Defaults: The default is NOWAIT.

HOST: Specifying the DFSMSHsm host that is to receive the command

Explanation: HOST(*hostid*) is an optional parameter to specify the host where the command needs to be issued. The parameter variable is explained:

hostid

The *hostid* is a one-character host identifier that is used to distinguish which active DFSMSHsm (main or auxiliary) host is to receive the command. The specified host ID must match one of the currently active DFSMSHsm host IDs. For requirements of the *hostid* value, see the topic about startup procedure keywords in *z/OS DFSMSHsm Implementation and Customization Guide*.

Defaults If the host parameter is not specified, the command is directed to the main host.

Usage notes:

1. The following are HSEND CMD return codes and their meanings:

Return code**Meaning****0**

With the WAIT option, communication with DFSMSHsm is successful and the function is successful.

With the NOWAIT option, communication with DFSMSHsm is successful. It is not known if the function is or is not successful.

4

With the WAIT option, the function has encountered an error.

8

With the WAIT or NOWAIT option, communication with DFSMSHsm has failed.

2. The HSEND CMD command name must precede each authorized command you issue from a TSO terminal.
3. An HSEND CMD return code of 4 indicates that a functional error occurred during processing when one of the previously identified commands was being performed. Specific errors can be determined by the ARC1001I message and the DFSMSHsm messages accompanying it. However, if the command was BACKVOL CDS, then specific errors can be determined by the ARC0741I, ARC0744E, and ARC0747E messages. Return code 4 means a functional error only when one of these specifically identified commands is issued.

Note: A return code of 4 will be returned from any request when DFSMSHsm cannot recognize the command or all of its parameters.
4. These HSEND CMD return codes are set in Register 15. They can be tested in a CLIST using as variables &LASTCC or &MAXCC; They can also be tested with the COND parameter within JCL when the commands are issued in the TSO batch environment.
5. If you issue multiple HSEND CMD commands at the same time, some specifying the WAIT parameter and others the NOWAIT parameter, all of the commands with the WAIT parameter are processed first, regardless of the order in which the commands were received.
6. The WAIT and NOWAIT parameters of the HSEND CMD command have implications for HOLD command processing that are function specific. Refer to the specific processing function for an explanation.
7. When a command is issued to an inactive host with NOWAIT specified, then the command is queued and ARC1004I message is issued. The command is executed when the host is started. When a command is issued to an inactive host with WAIT specified, then the request is rejected and ARC1005I is issued.

Examples of how to code the HSEND CMD command

The following examples present different ways to code the HSEND CMD command.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Sending an authorized command with WAIT from a TSO terminal

In this example, the ADDVOL command is issued from a TSO terminal. Control returns to the user when the command is completed. The syntax of the ADDVOL command does not change when it is used with the HSEND CMD command.

```
HSEND CMD WAIT ADDVOL VOL004 UNIT(3390) +  
PRIMARY(NOAUTOMIGRATION AUTOBACKUP NOAUTORECALL)
```

Sending an authorized command from a TSO terminal

In this example, the ADDVOL command is issued from a TSO terminal. Control is returned to the user before the command completes. The syntax of the ADDVOL command does not change when it is used with the HSEND CMD command.

```
HSEND CMD ADDVOL VOL004 UNIT(3390) +  
PRIMARY(NOAUTOMIGRATION AUTOBACKUP NOAUTORECALL)
```

Sending an authorized command with HOST from TSO terminal

In this example, ADDVOL command is issued to host with *hostid* 2. Control returns to the user before the command completes. The syntax of the ADDVOL command does not change when it is used with the HSEND CMD command.

```
HSEND CMD HOST(2) ADDVOL VOL004 UNIT(3390) +  
PRIMARY(NOAUTOMIGRATION AUTOBACKUP NOAUTORECALL)
```

Chapter 52. HSENDU command: Issuing DFSMSHsm authorized user commands to a Filemode DFSMSHsm host

The HSENDU command is an alias to the HSENCMD command. All parameters valid on the HSENCMD command are acceptable on the HSENDU command. When this command is used, the request is directed to the DFSMSHsm Filemode host. If only a Full Support DFSMSHsm host exists, the request is directed to the Full Support DFSMSHsm host.

Chapter 53. LIST command: Listing information from the MCDS, BCDS, and OCDS

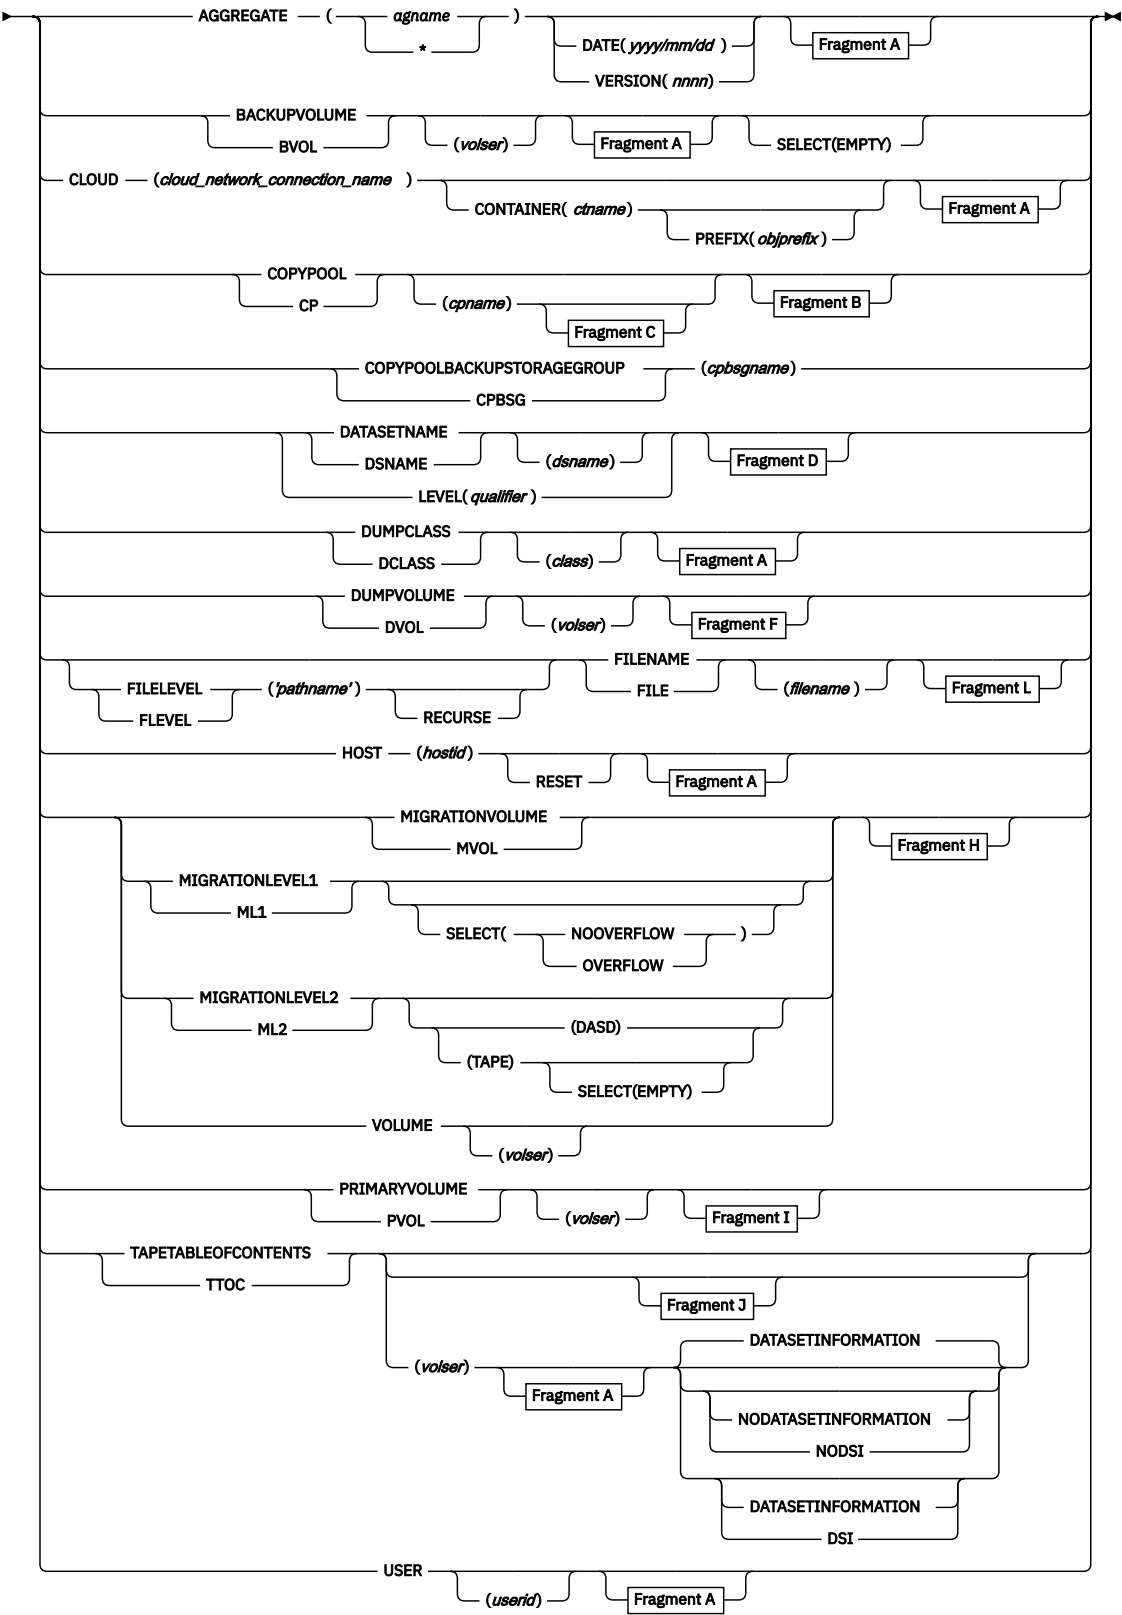

The LIST command lists selected data set, aggregate, user, DFSMSHsm host serialization, and volume information from the MCDS, BCDS, and OCDS. You can list the following categories of information:

Category of Information	See
Aggregate backup and recovery activity information	“AGGREGATE: Listing the aggregate backup and recovery activity information” on page 925
Backup volume information	“BACKUPVOLUME: Listing backup volume entries” on page 925
Cloud container and object information	Cloud storage
Copy pool information	“COPYPOOL: Listing information for each version of a copy pool” on page 926
Copy pool backup storage group information	“COPYPOOLBACKUPSTORAGEGROUP: Listing copy pool information for each volume in the specified copy pool backup storage group” on page 926
Data set information	“DATASETNAME and LEVEL: Listing data set entries” on page 926
Dump class information	“DUMPCCLASS: Listing dump class profiles” on page 927
Dump volume information	“DUMPVOLUME: Listing information about a single dump volume or a set of dump volumes” on page 927
Host information	“HOST: Listing all control data sets serialized by the DFSMSHsm host” on page 928
Migration information	“MIGRATIONVOLUME, MIGRATIONLEVEL1, MIGRATIONLEVEL2, and VOLUME: Listing migration volumes” on page 929
Primary volume information	“PRIMARYVOLUME: Listing primary volumes” on page 929
Tape volume information	“TAPETABLEOFCONTENTS: Listing tape volume information from the OCDS” on page 930
UNIX file information	“FILENAME and FILELEVEL: Listing UNIX file entries” on page 928
User authorization information	“USER: Listing user entries” on page 931

For examples of LIST command output, see [Chapter 76, “Using the LIST command,” on page 1341](#).

Syntax of the LIST command

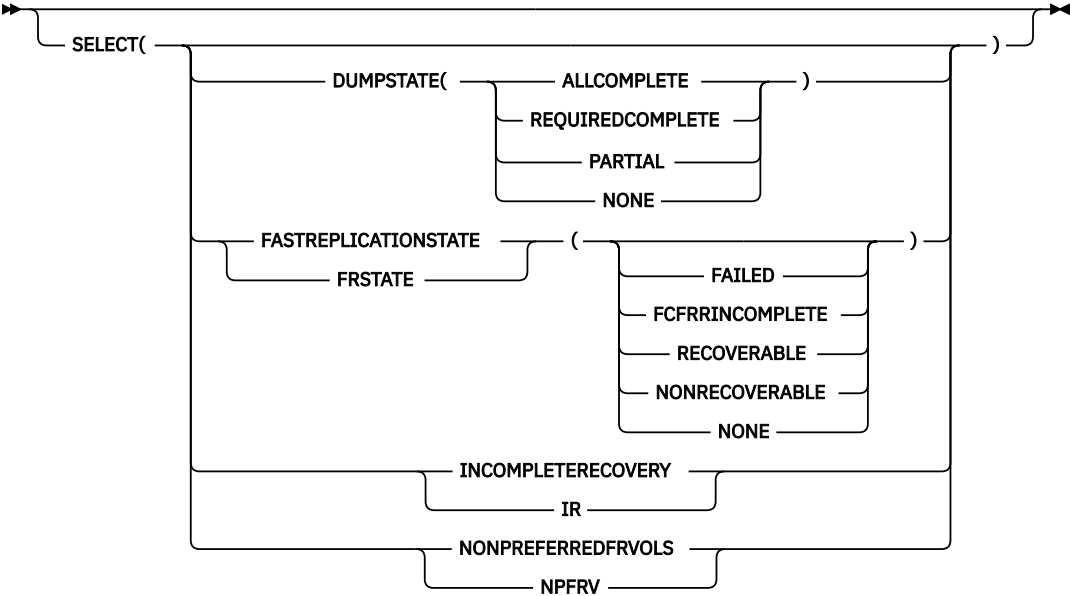

➤ LIST ➔

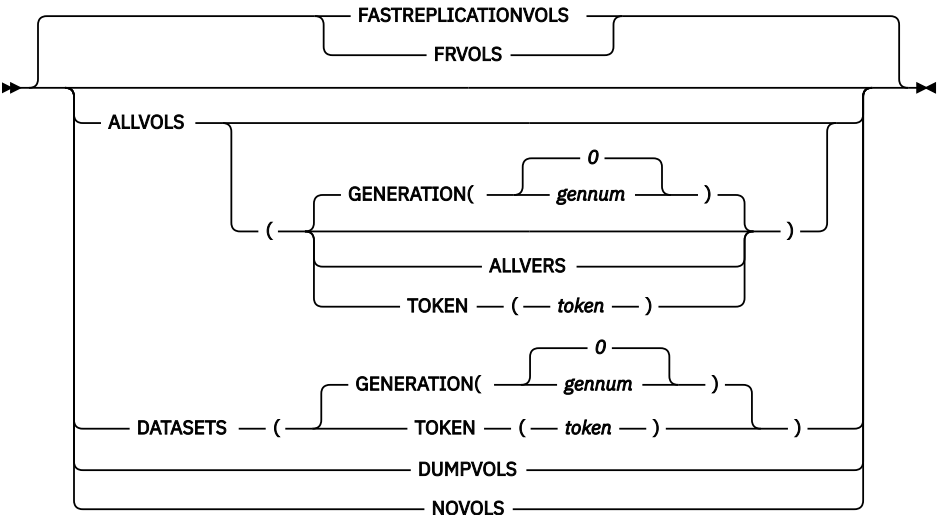

A: LIST optional parameters

B: COPYPOOL optional parameters

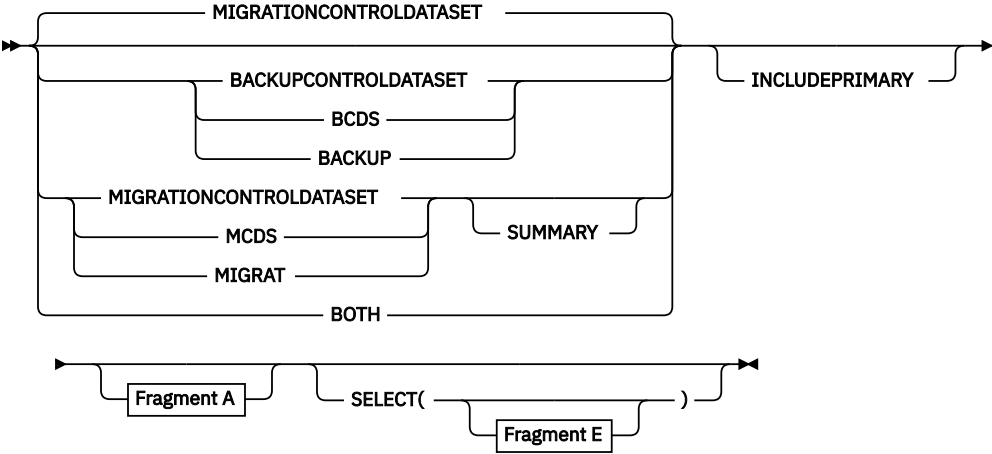

C: COPYPOOL(cpname) optional parameters

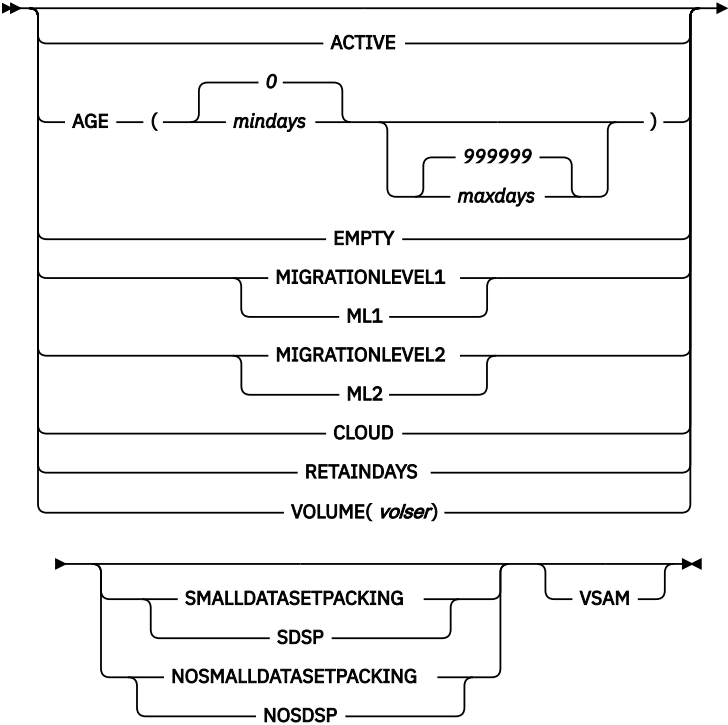

D: DATASETNAME optional parameters

LIST command for DFSMSShsm

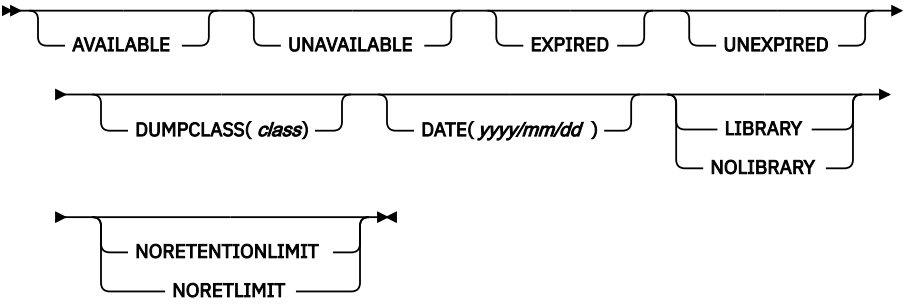

E: DATASETNAME SELECT optional parameters

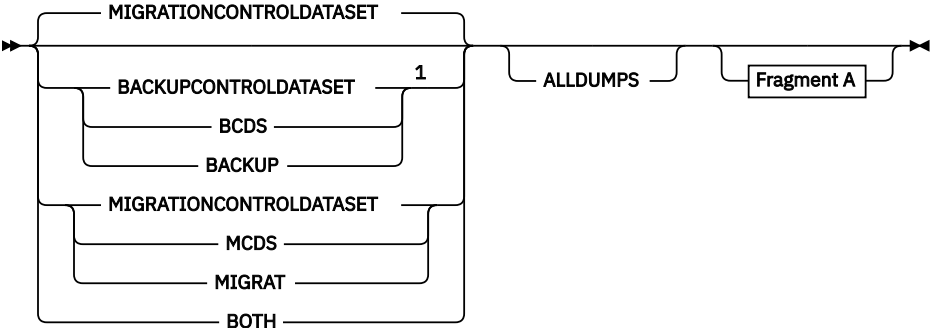

F: DUMPVOLUME optional parameters

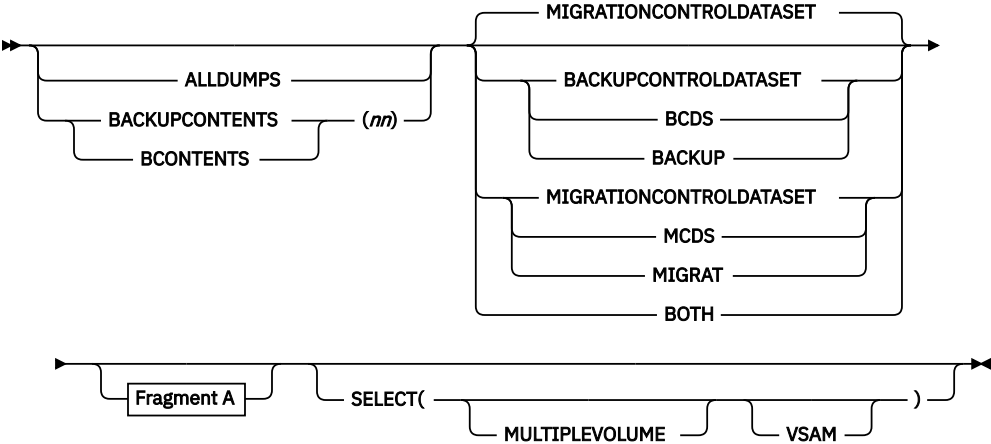

G: DUMPVOLUME SELECT optional parameters

H: MVOL, ML1, ML2, and VOLUME optional parameters

I: PRIMARYVOLUME optional parameters

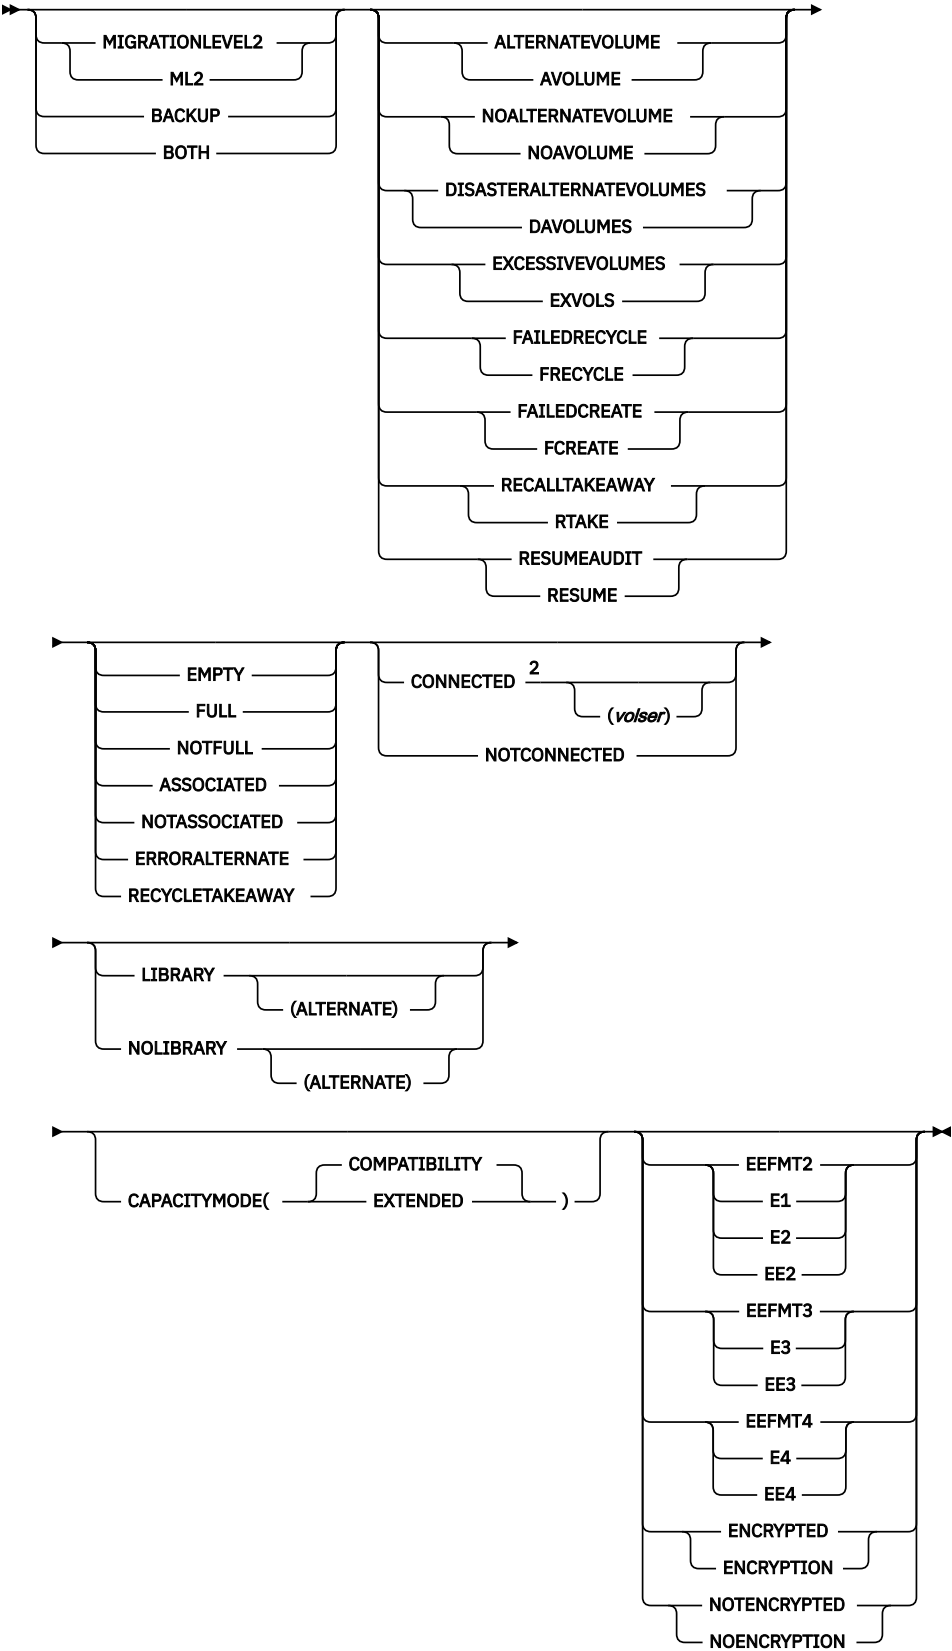

J: TTOC optional parameters

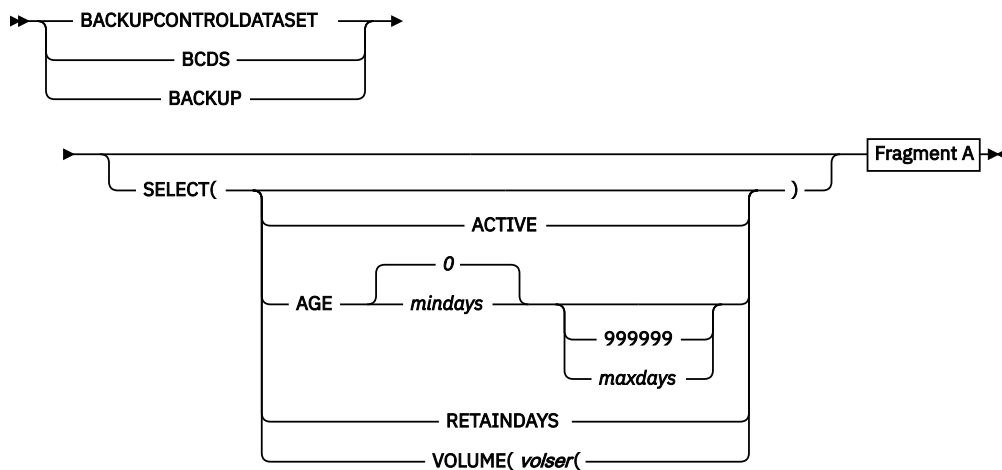

K: TTOC SELECT optional parameters

LIST command for DFSMSHsm

L: FILENAME and FILELEVEL optional parameters

Notes:

- ¹ The BACKUPCONTROLDATASET or BCDS parameter and the BACKUP parameter are not valid with the LIST ML2(TAPE) SELECT(EMPTY) command.
- ² The SELECT(CONNECTED) subparameter of the LIST TTOC command cannot be specified with the SELECT(ML2), SELECT(BACKUP), or SELECT(BOTH) subparameters.

Required parameters of the LIST command

This topic describes the required parameters of the LIST command.

AGGREGATE: Listing the aggregate backup and recovery activity information

Explanation: AGGREGATE is a required parameter you specify to request a list of information for selected backed up and recovered aggregates. This information is contained in the BCDS. The values specified when using the AGGREGATE parameter are explained:

agname

specifies the name of the specific aggregate group whose records are listed.

*

specifies that all records for all aggregate groups are listed.

Defaults: None.

BACKUPVOLUME: Listing backup volume entries

Explanation: BACKUPVOLUME is a required parameter you specify to request a list of selected information from backup volume entries contained in the BCDS.

BACKUPVOLUME specifies that you want a list of all backup volumes.

For *volser*, substitute the serial number of the specific backup volume you want listed.

Defaults: If you specify BACKUPVOLUME without (*volser*), DFSMSHsm lists all backup volume entries contained in the BCDS.

Note:

1. If you specify this parameter, you get a list, but you do not get any additional information about the data sets on the backup volume.

CLOUD: Listing information from cloud storage

Explanation: CLOUD is a required parameter that you specify to retrieve information about containers, and objects in cloud storage. Only containers created using the current HSMplex name will be surfaced in the output.

CLOUD(*cloud_network_connection_name*)

specifies the name of an SMS construct, or a CDA provider file that describes cloud storage to list the DFSMSHsm containers currently existing in the specified cloud.

CONTAINER(*ctname*)

specifies a particular container name within the cloud storage to list the pseudo-directories or prefixes that are found within the requested container. A pseudo-directory is the first part of the object name ending with a forward-slash character (/).

PREFIX(*objprefix*)

specifies to list all of the objects found under a specific prefix or pseudo-directory. It is a maximum 44-byte prefix that can match to specific objects contained within the specified container. Fragment A indicates that output can be written to SYSOUT, OUTDATASET, and TERMINAL.

COPYPOOL: Listing information for each version of a copy pool

Explanation: COPYPOOL is a mutually exclusive required parameter in which you can specify a single copy pool name (*cpname*) or no copy pool name, for a list containing all copy pools.

COPYPOOL

Specify COPYPOOL to request a list of information for each version of each copy pool that has at least one fast replication backup or dump version.

COPYPOOL(*cpname*)

Specify COPYPOOL(*cpname*) to request detailed information for each version of the specified copy pool. This information includes source volume to target volume pairings, DASD versions, dump versions, and catalog information.

Defaults: None.

COPYPOOLBACKUPSTORAGEGROUP: Listing copy pool information for each volume in the specified copy pool backup storage group

Explanation: COPYPOOLBACKUPSTORAGEGROUP is a mutually exclusive required parameter that you specify to request copy pool information for each volume in the specified copy pool backup storage group.

Specify COPYPOOLBACKUPSTORAGEGROUP(*cpbsgname*) to request a list of volumes in the copy pool backup storage group that DFSMSHsm has assigned as a target volume. The corresponding source volumes are also listed.

Defaults: None.

DATASETNAME and LEVEL: Listing data set entries

Explanation: DATASETNAME and LEVEL are mutually exclusive, required parameters that you specify to request a list of data set entries.

DATASETNAME(*dsname*)

is specified to request a data set entry with a specific data set name. For *dsname*, substitute the fully qualified name of the particular data set you want listed. You can specify a data set name of up to 44 characters.

LEVEL(*qualifier*)

is specified to request a list of all data set entries that have the same set of initial characters of the data set name. For *qualifier*, substitute the set of initial characters of the data set name for the data sets you want listed. The set of initial characters can contain imbedded periods. The *qualifier* can end with a period if LEVEL is the first keyword on the command. You can specify a *qualifier* of up to 44 characters.

Defaults: If you specify DATASETNAME without *dsname*, DFSMSHsm lists all data set entries.

Note:

1. If you used the SETMIG command to prevent a data set from migrating, DFSMSHsm does not list the data set.
2. DFSMSHsm does not handle partitioned data set members individually. If you specify a member name of a partitioned data set, DFSMSHsm lists the entire partitioned data set.
3. You can specify DATASETNAME or LEVEL with a LIST COMMAND, but not both. If you specify both parameters, the last parameter specified overrides the previous one.

DUMPCLASS: Listing dump class profiles

Explanation: DUMPCLASS is a mutually exclusive required parameter you specify to request a list of one or more dump-class profiles. For *class*, substitute from 1 to 8 alphanumeric characters for the class to be listed.

The following information is listed for each dump class:

- Class name
- Class disposition
- Retention period
- Required (Y/N)
- Available (Y/N)
- Frequency and/or day
- Automatic reuse option (Y/N)
- Data set restore option (Y/N)
- Change bit reset option (Y/N)
- Unit type
- Class disable (Y/N)
- Maximum stack value
- Minimum stack value
- FRRECOV(AVAILABLEFORMOUNT(Y|N))
- FRDUMP(REQUIRED|OPTIONAL)
- HWCOMPRESS(Y|N)
- Encryption values

Defaults: If you specify DUMPCLASS without *class*, profiles for all dump classes are listed.

DUMPVOLUME: Listing information about a single dump volume or a set of dump volumes

Explanation: DUMPVOLUME is a required parameter you specify to request a list of information about a single dump volume or a set of dump volumes. For *volser*, substitute any *volser* from a set of volumes that collectively represents a dump of a user volume. The following information is listed first about the dump volume:

- Dump volume serial number
- Copy pool (Y|N)
- Volume status
- Dump volume unit type
- Dump class
- Dump expiration date
- IDRC status
- Physical percent full

- Library status
- HWCOMPRESS(Y|N)
- Encryption value
- Tape hardware encryption

The following information is then listed about each valid dump copy that is stacked on the dump volume:

- File sequence number
- Source volume serial number
- SMS status
- Dump creation date and time
- Set of dump volume serial numbers

See [Figure 136 on page 1366](#) for an example of the listed information.

Defaults: None.

Note:

1. If the *volser* specified is not part of a valid dump copy, only the dump class, volume serial, and volume unit type of the specified *volser* is listed.
2. If host based encryption is specified and the SMS data class is set up for tape hardware encryption, the host based encryption is ignored in favor of doing tape hardware encryption. If more than one DUMPCLASS is specified (creating more than one dump copy) and they are set up for host based encryption, but the associated SMS data classes do not agree in their tape hardware encryption settings, the dump function fails.
3. When %CLOUD is specified as the DUMPVOLUME *volser*, the DUMPCONTENTS(*srcvol*) parameter is mandatory for LIST DUMPVOLUME(%CLOUD). SELECT(DDMMYY(*yyyy/mm/dd*)) is optional.

FILENAME and FILELEVEL: Listing UNIX file entries

Explanation: FILENAME and FILELEVEL are mutually exclusive, required parameters that you specify to request a list of UNIX file entries.

FILENAME('filename')

Requests information about an entry with a specific UNIX file name. It allows you to list information about backups for a specific UNIX file. If a UNIX directory is specified, 0 entries are returned. FILE is an acceptable abbreviation. Single quotation marks are required to enclose the absolute UNIX path name.

FILELEVEL('pathname')

Lists information about backups for all files under a specific UNIX directory. If the path is not for a directory, 0 entries are returned. FLEVEL is an acceptable abbreviation. Single quotes are required to enclose the absolute UNIX path name.

HOST: Listing all control data sets serialized by the DFSMSHsm host

Explanation: HOST is a required parameter you use in a multiple-DFSMSHsm-host environment to request a list of all control data set records currently serialized by the specified DFSMSHsm host. The serialized control data set records are:

- Backup cycle volume record (BVR)
- Copy pool dump version record (FRD)
- MCDS data set record (MCD)
- MCDS volume record (MCV)
- Tape table of contents record (TTOC)

You can issue the LIST HOST command to receive information about SMS-managed volumes that have MCV records serialized with a host-ID. For *hostid*, substitute the identification character of the DFSMSHsm host whose serialization information you want listed.

Defaults: None

MIGRATIONVOLUME, MIGRATIONLEVEL1, MIGRATIONLEVEL2, and VOLUME: Listing migration volumes

Explanation: MIGRATIONVOLUME, MIGRATIONLEVEL1, MIGRATIONLEVEL2, and VOLUME are mutually exclusive, required parameters you specify to request a list of selected information for migration volumes. These parameters can also be used as subparameters of the SELECT parameter.

MIGRATIONVOLUME

specifies that you want a list of the volume entries for all migration volumes.

MIGRATIONLEVEL1

specifies that you want a list of volume entries for migration level 1 volumes.

You can narrow down the kind of migration level 1 volumes you list using the optional SELECT parameter:

SELECT(NOOVERFLOW)

lists the volume entries for all NOOVERFLOW ML1 volumes.

SELECT(OVERFLOW)

lists the volume entries for all OVERFLOW ML1 volumes.

Defaults: If you specify MIGRATIONLEVEL1 alone (without the SELECT subparameter), which is the default, you will get a list of all migration level 1 volumes.

MIGRATIONLEVEL2

specifies that you want a list of the volume entries for all migration level 2 volumes.

DASD

lists the volume entries for all DASD migration level 2 volumes is generated.

TAPE

lists the volume entries for all tape migration level 2 volumes is generated.

VOLUME

specifies that you want a list of all primary and migration volumes. VOLUME(*volser*) specifies that you want a list of a particular primary or migration volume. For *volser*, substitute the serial number of the specific volume you want listed. Both SMS and non-SMS volumes can be listed.

When using VOLUME(*volser*) as a subparameter of SELECT and when *volser* is specified as a backup volume, the output contains a list of the latest backup versions on the volumes.

Defaults: If you specify VOLUME without *volser*, DFSMSHsm lists all the primary and migration volumes it owns or manages. If you specify PRIMARYVOLUME without *volser*, DFSMSHsm lists all primary volumes it owns or manages.

Note:

1. When you specify any of these parameters, DFSMSHsm does not list information about the data sets on the primary or migration volume, and DFSMSHsm does not give you any information about the amount of space left on the volume. To find out how much space is left on a primary or migration level 1 volume, use the SPACE parameter of the QUERY command.

PRIMARYVOLUME: Listing primary volumes

Explanation: PRIMARYVOLUME is a required parameter you can specify to list selected information for primary volumes.

PRIMARYVOLUME

specifies that you want a list of the volume entries for all primary volumes.

PRIMARYVOLUME(*volser*)

specifies that you want a list for a particular primary volume. For *volser*, substitute the serial number of the specific volume you want listed. Both SMS and non-SMS volumes can be listed.

Defaults: If you specify PRIMARYVOLUME without *volser*, DFSMSHsm lists all primary volumes it owns or manages except when the optional ALLDUMPS parameter is specified.

Note:

1. The PRIMARYVOLUME parameter returns a list of copy pools that the volume is a part of when BCDS or BOTH are specified.
2. The PRIMARYVOLUME(*volser*) parameter returns a list of copy pool dump generations that the volume is a part of when ALLDUMPS and BCDS are both specified.
3. When you specify PRIMARYVOLUME, DFSMSHsm does not list information about the data sets on the primary volume, and DFSMSHsm does not give you any information about the amount of space left on the volume. To find out how much space is left on a primary volume, use the SPACE parameter of the QUERY command.

TAPETABLEOFCONTENTS: Listing tape volume information from the OCDS

Explanation: TAPETABLEOFCONTENTS is a required parameter you can specify to list tape volume information from an OCDS, without listing all the data-set-related information for the volume.

You can direct the output of the list command using the optional parameters OUTDATASET(*dsname*) | SYSOUT(*class*) | TERMINAL.

Defaults: LIST TAPETABLEOFCONTENTS defaults to a condition of NODATASETINFORMATION. When you require data set information, use the LIST TAPETABLEOFCONTENTS(*volser*) command, which is discussed in the following topic.

TAPETABLEOFCONTENTS(*volser*): Listing tape volume information and data set names from the TTOC

Explanation: TAPETABLEOFCONTENTS(*volser*) is a required parameter that can be specified to list migration level 2 or backup tape volume information from the OCDS. At your option, you can choose whether or not to list data set information for the volume. For *volser*, substitute the serial number of the specific tape volume you want listed. If you specify a *volser* shorter than 6 characters, you must enclose it in quotes and pad it to the right with blanks.

If the volume specified in the LIST command is added to DFSMSHsm's control (ADDVOL) as an esoteric unit, the field, UNIT NAME, that appears in the LIST output, contains the esoteric unit name until DFSMSHsm uses the volume. Once DFSMSHsm has used the volume, this UNIT NAME field will contain the generic unit name.

You can direct the output of the list command using the optional parameters OUTDATASET(*dsname*) | SYSOUT(*class*) | TERMINAL.

You can specify NODATASETINFORMATION | DATASETINFORMATION. When you specify NODATASETINFORMATION, you will get a list of volume information, without data set information. When you specify DATASETINFORMATION, you will get a list of volume information and data set information for the volume.

If you use extended TTOCs at your installation and you do not use 3390s for SYSALLDA, consider patching MCVTODS_SECONDARY(PATCH .MCVT.+4b2) to a be X'A0' (160 tracks).

Defaults: LIST TAPETABLEOFCONTENTS(*volser*) defaults to DATASETINFORMATION. You can change this to NODATASETINFORMATION when you do not require data set information for the volume.

USER: Listing user entries

Explanation: USER is a required parameter you specify to request a list of DFSMSHsm authorized users. For *userid*, substitute a string of 1-8 alphanumeric characters for the identification of the user whom you want listed.

Defaults: If you specify USER without *userid*, all user entries are listed from the MCDS.

Note:

1. The USER list does not include any information about data sets associated with specified users.

Optional parameters of the LIST command

When you issue the LIST command, you may specify one or more of the optional parameters. Refer to the syntax diagrams at the beginning of this topic for the recommended use of the LIST command and its sub-parameters.

ALLDUMPS and BACKUPCONTENTS: Determining existence of dumps or listing incremental backup contents

Explanation: ALLDUMPS and BACKUPCONTENTS(*nn*) are optional parameters you specify to determine the existence of all full-volume dumps and to determine the contents of the user volume at the time of incremental backup.

ALLDUMPS

is specified to determine the existence of all volume dumps and on which dump volumes the dumps exist for a single level 0 or migration level 1 volume. The following information is provided for each selected dump:

- Source volume serial number
- Copy pool dump generations
- Dump class
- Dump date
- Dump time
- Dump relative generation number
- Dump expiration date
- Volume serial numbers of the set of volumes containing the dump

BACKUPCONTENTS(*nn*)

when used with the PRIMARYVOLUME(*volser*) parameter, is specified to list the contents of the user volume when the latest or next-to-latest backup of (*volser*) was made. For *nn*, substitute a 0 or 1 to indicate whether the latest or the next to latest backup volume table of contents (VTOC) is listed. A 0 (zero) indicates the latest. A 1 (one) indicates the next latest.

The listing is from the requested VTOC data set. If 0 is specified, the listing represents the contents of the user volume at the time when the last incremental backup was done.

BACKUPCONTENTS, when used with the PRIMARYVOLUME(*volser*) parameter, is not processed for volumes that have not been incrementally backed up by DFHSM 2.3.0 or a subsequent release. This happens because the VTOC copy data set is not on a migration level 1 volume for incremental volume backups performed by previous releases of DFSMSHsm. With the PRIMARYVOLUME, the listing can include data sets that are not eligible for incremental backup by DFSMSHsm. In addition to information provided for this variation of the command, the following information is provided:

- Data set name
- Data set organization
- Date of last reference to data set

- Data set creation date

Defaults: If you do not specify a 0 or 1 for *nn*, the default is 0 (list the latest backup VTOC copy data set). If you specify any value other than 0 or 1, the default is 0.

Note:

1. BACKUPCONTENTS is meaningful only when *volser* is specified with the PRIMARYVOLUME parameter.
2. The BACKUPCONTENTS parameter is not equivalent to the DUMPCONTENTS parameter.
3. BACKUPCONTENTS is ignored when DUMPVOLUME is specified.
4. ALLDUMPS is valid with PRIMARYVOLUME and VOLUME when specified with *volser* and with BCDS.
5. Since DFSMSHsm does not handle partitioned data set members individually, the entire partitioned data set will be listed.

ALLVOLS, DATASETS, DUMPVOLS, FASTREPLICATIONVOLS, and NOVOLS: Listing a specific type of copy pool information

Explanation: ALLVOLS, DATASETS, DUMPVOLS, FASTREPLICATIONVOLS, and NOVOLS are mutually exclusive, optional parameters that you can use to obtain specific information about copy pools, as follows:

ALLVOLS

requests a list of DASD source and target pairs, and all dump volume information.

ALLVERS

specifies that DFSMSHsm is to list all DASD and dump versions.

GENERATION(*gennum*)

specifies that DFSMSHsm is to list a particular generation.

The default with ALLVOLS is GENERATION(0). It lists only the most recent DASD and dump copies.

TOKEN(*token*)

specifies that DFSMSHsm is to list the version with the specified token.

DATASETS

requests a list of data sets associated with a given version, including the data sets that were backed up, but have been deleted. DATASETS returns information only if the catalog information about a backup version is captured at the time of backup.

GENERATION(*gennum*)

specifies that DFSMSHsm is to list data sets associated with a particular generation. The default, DATASETS GENERATION(0), lists only the most recent DASD and dump copies.

TOKEN(*token*)

specifies that DFSMSHsm is to list the data sets associated with the version with the specified token.

Note: You must specify either GENERATION or TOKEN to identify the version.

DUMPVOLS

requests a list of source and dump volume serial numbers for all dump versions.

FASTREPLICATIONVOLS

FRVOLS

requests a list of source and target pairs.

NOVOLS

requests a list of dump class information, if a dump copy version exists. This parameter does not list any data for volume pairs.

Defaults: FASTREPLICATIONVOLS is the default. The default when ALLVOLS or DATASETS is specified is GENERATION(0).

BACKUPCONTROLDATASET, MIGRATIONCONTROLDATASET, and BOTH: Controlling the source of information

Explanation: BACKUPCONTROLDATASET, MIGRATIONCONTROLDATASET, and BOTH are mutually exclusive, optional parameters. When the information to be listed can exist in the MCDS and BCDS, you can tell DFSMSHsm where to look for the information. These parameters apply to data set entries, UNIX file entries, primary volume entries, and migration volume entries.

BACKUPCONTROLDATASET

is specified to request a list of the BCDS entries for a specific data set, level, UNIX file, UNIX directory, or volume, or for migration volumes, or primary volumes. BACKUP is allowed as an alias for BACKUPCONTROLDATASET. Currently information for UNIX files exists in the BCDS only. If MCDS is specified or defaulted to, 0 entries will be returned and ARC0138I will be issued.

MIGRATIONCONTROLDATASET

is specified to request a list of the MCDS entries for a specific data set, level, or volume, or for migration volumes, or primary volumes. MIGRAT is allowed as an alias for MIGRATIONCONTROLDATASET.

BOTH

is specified to request a list of the MCDS and BCDS data set entries.

Defaults: The default is MIGRATIONCONTROLDATASET.

DATASETINFORMATION and NODATASETINFORMATION: Including or not including data set information

Explanation: DATASETINFORMATION and NODATASETINFORMATION are mutually exclusive, optional parameters that can be used only when you specify LIST TAPETABLEOFCONTENTS(*volser*).

DATASETINFORMATION

When you specify DATASETINFORMATION, you get a list of volume-related information and data set information for the volume.

NODATASETINFORMATION

When you specify NODATASETINFORMATION, you get a list of only volume-related information. Data set information for the volume is not included.

Defaults: LIST TAPETABLEOFCONTENTS(*volser*) defaults to DATASETINFORMATION.

DATE and VERSION: Specifying the date or version of the aggregate group

Explanation: DATE and VERSION are optional parameters of AGGREGATE.

DATE(*yyyy/mm/dd*)

specifies that all versions of the aggregate group created on that date are listed:

- *yyyy* is the 4-digit year (1992)
- *mm* is the month (01-12)
- *dd* is the day of the month (01-31)

VERSION(*nnnn*)

specifies the version number of a specific aggregate group version to be listed. VERSION is not valid when AGGREGATE(*) is specified.

Defaults: If you do not specify either DATE or VERSION with the LIST AGGREGATE command, you receive a listing of all active versions of an aggregate.

DUMPCONTENTS: Listing contents of a set of dump volumes

Explanation: DUMPCONTENTS is an optional parameter. You can specify a contents list for a set of dump volumes. The listing is from a full-volume dump VTOC copy data set and represents the contents of the user volume at the time the dump was done.

For any dump volume that is stacked with more than one valid dump copy, you must specify the *srcvol* subparameter to indicate which dump contents you desire.

The following information is listed for each data set on the source volume:

- Data set name
- Data set organization
- Multivolume or single volume
- Data set creation date
- Date data set was last referred to
- Data set expiration date
- RACF indicated
- Password protected
- Change indicated

Defaults: None.

Note:

1. DUMPCONTENTS is meaningful only when *volser* is specified with the DUMPVOLUME parameter.
2. The DUMPCONTENTS parameter is not equivalent to the BACKUPCONTENTS parameter.
3. DUMPCONTENTS is ignored when PRIMARYVOLUME is specified.
4. DUMPCONTENTS applies only to dumps made from level 0 volumes. VTOC copies are not made for migration level 1 volumes. If this parameter is specified for a migration level 1 dump copy, it is ignored.
5. When %CLOUD is specified as the DUMPVOLUME *volser*. The DUMPCONTENTS(*srcvol*) parameter is mandatory for LIST DUMPVOLUME(%CLOUD). SELECT(DDNAME(%CLOUD)) is optional.

INCLUDEPRIMARY: Listing entries for any data set that has migrated

Explanation: INCLUDEPRIMARY is an optional parameter requesting that a list of data set entries include data set entries from the MCDS, even though DFSMSHsm might have already recalled the data sets. A recalled data set can still have an entry in the MCDS.

Defaults: If you do not specify INCLUDEPRIMARY, DFSMSHsm does not list entries for recalled data sets.

Note:

1. The INCLUDEPRIMARY parameter applies only to the DATASETNAME and LEVEL parameters and only when DFSMSHsm lists information from the MCDS. If you specify INCLUDEPRIMARY when it does not apply, DFSMSHsm ignores it.

OUTDATASET, SYSOUT, and TERMINAL: Specifying the location of output for the list

Explanation: OUTDATASET, SYSOUT, and TERMINAL are mutually exclusive, optional parameters specifying the output location for the list.

OUTDATASET(*dsname*)

specifies the name of the data set where DFSMSHsm is to write the output data. For *dsname*, substitute the fully qualified name of the data set to receive the LIST command output.

If the data set does not exist, DFSMSHsm dynamically allocates and catalogs an output data set with the following characteristics:

- Data set name specified (*dsname*)
- Record format of fixed-blocked with ANSI control characters (FBA)
- Logical record length of 121
- Data set is system reblockable
- Primary allocation of 20 tracks (see third note)
- Secondary allocation of 50 tracks (see third note)
- Unit of SYSALLDA (see third note)

If the data set already exists, DFSMSHsm will use the data set. The data set must have the following characteristics:

- The data set must be cataloged and on DASD.
- The data set record format must be FBA, and the logical record length must be 121.
- The data set must be system reblockable.
- The user chooses the primary space allocation.
- DFSMSHsm uses a secondary space allocation of 50 tracks, if DFSMSHsm needs additional extents after the primary space allocation. (See third note.)
- If the data set does not contain data, DFSMSHsm starts writing output data at the beginning of the data set.
- If the data set contains data, DFSMSHsm writes the output data after the existing data.

SYSOUT(class)

specifies that the list is printed to the specified system output class. For *class*, substitute the alphanumeric character for the system output class you want.

TERMINAL

specifies that the list is printed at your terminal.

Defaults: The default is SYSOUT, and *class* defaults to the class specified with the SETSYS SYSOUT command. If you did not specify the type of class with the SETSYS command, the default is class A.

Note:

1. DFSMSHsm does not handle partitioned data set members individually. If you specify a partitioned data set with a member name as the output data set, the list can be written over existing data.
2. If you specify an output data set that does not have the required characteristics, I/O errors can occur in your output data set.
3. If you select the OUTDATASET option, you can use the PATCH command to change the unit name, primary allocation, and secondary allocation. If you select the SYSOUT option, you can use the PATCH command to change whether, and how, DFSMSHsm limits the lines of SYSOUT output. See [*z/OS DFSMSHsm Implementation and Customization Guide*](#) for a description of the PATCH commands available.

RECURSE: Examine subdirectories of the specified UNIX file path

Explanation: RECURSE is optional parameter accepted with the FILELEVEL parameter that requests that subdirectories in the DFSMSHsm inventory be traversed recursively to list backup versions of UNIX files.

Defaults: DFSMSHsm does not use RECURSE.

RESET: Requesting that the host ID field indicate no serialization

Explanation: RESET is an optional parameter specifying that DFSMSHsm reset the host ID field in the records to indicate no serialization by the DFSMSHsm host specified on the command. You use this parameter in a multiple-DFSMSHsm-host environment. Then, if one of the DFSMSHsm hosts becomes inoperative, the serialization done by that DFSMSHsm host remains in the control data set records. No

other DFSMSHsm host can access the serialized resource. DFSMSHsm issues message ARC0817I to show whether the record is reset successfully.

Defaults: None.

Note:

1. The RESET parameter applies only to the HOST parameter. If you do not specify HOST, DFSMSHsm ignores the RESET parameter.

SELECT: Listing only those data set or volume entries that meet selection criteria

Explanation: SELECT, along with its subparameters, is used to specify that only selected entries are listed. SELECT and each of its subparameters is optional. Refer to the syntax diagrams at the beginning of this topic for the recommended use of SELECT and its subparameters.

The optional subparameters of the SELECT parameter are listed in alphabetical order and can be found at the following locations:

Subparameter	See
ACTIVE and RETAIN_DAYS	“SELECT (ACTIVE and RETAIN_DAYS): Displaying information about active and retained backup copies” on page 938
AGE	“SELECT (AGE): Specifying data set use by age” on page 938
ALTERNATEVOLUME and NOALTERNATEVOLUME	“SELECT (ALTERNATEVOLUME and NOALTERNATEVOLUME): Listing tape volumes that have alternate tape volumes” on page 938
AVAILABLE	“SELECT (AVAILABLE): Listing available dump volumes for dump output” on page 939
CAPACITYMODE	“SELECT (CAPACITYMODE): Identifying tape volumes by their ability to use available tape capacity” on page 939
CONNECTED and NOTCONNECTED	“SELECT (CONNECTED and NOTCONNECTED): List volumes that contain spanning data sets ” on page 939
DISASTERALTERNATEVOLUMES	“SELECT (DISASTERALTERNATEVOLUMES): Listing tape volumes that have disaster alternate volumes” on page 940
DUMPCLASS	“SELECT (DUMPCLASS)” on page 940
EFMT1, EFMT2, EEFMT2, EFMT3, EEFMT3, EFMT4, EEFMT4, ENCRYPTED, and NOTENCRYPTED	“SELECT (EFMT1, EFMT2, EEFMT2, EFMT3, EEFMT3, EFMT4, EEFMT4, ENCRYPTED, and NOTENCRYPTED): Recording format” on page 941
EMPTY, FULL, NOTFULL, ASSOCIATED, NOTASSOCIATED, and RECYCLETAKEAWAY	“SELECT (EMPTY, FULL, NOTFULL, ASSOCIATED, NOTASSOCIATED, ERRORALTERNATE, and RECYCLETAKEAWAY): Identifying tape volume capacity” on page 941
ERRORALTERNATE	“SELECT (EMPTY, FULL, NOTFULL, ASSOCIATED, NOTASSOCIATED, ERRORALTERNATE, and RECYCLETAKEAWAY): Identifying tape volume capacity” on page 941

Subparameter	See
EXCESSIVEVOLUMES	“SELECT (EXCESSIVEVOLUMES): Listing volumes with data sets spanning four or more volumes” on page 942
EXPIRED	“SELECT (EXPIRED): Listing expired dump volumes” on page 942
FAILEDCREATE	“SELECT (FAILEDCREATE): Listing all tape volumes that have incomplete data set information saved in the OCDS TTOC record” on page 943
FAILEDRECYCLE	“SELECT (FAILEDRECYCLE): Listing only those volumes that have failed recycle” on page 943
FASTREPLICATIONSTATE, DUMPSTATE, INCOMPLETERECOVERY and NONPREFERREDFRVOLS	“SELECT (DUMPSTATE, FASTREPLICATIONSTATE, INCOMPLETERECOVERY, and NONPREFERREDFRVOLS): Listing specific information about copy pools” on page 940
LIBRARY and NOLIBRARY	“SELECT (LIBRARY and NOLIBRARY): Listing tape volume library status” on page 943
MIGRATIONLEVEL1, MIGRATIONLEVEL2, VOLUME, BACKUP, and BOTH	“SELECT (MIGRATIONLEVEL1, MIGRATIONLEVEL2, VOLUME(volser), BACKUP, and BOTH): Requesting specific information for volumes” on page 944
MULTIPLEVOLUME	“SELECT (MULTIPLEVOLUME): Listing multiple-volume non-VSAM data sets from backup or dump VTOC copy data sets” on page 944
NORETENTIONLIMIT	“SELECT (NORETENTIONLIMIT): List dump volumes with no retention period” on page 945
OVERFLOW and NOOVERFLOW	“SELECT (OVERFLOW and NOOVERFLOW): List overflow or non-overflow ML1 volumes” on page 945
RECALLTAKEAWAY	“SELECT (RECALLTAKEAWAY): Listing ML2 volumes taken away by recall or ABACKUP functions” on page 945
RESUMEAUDIT	“SELECT (RESUMEAUDIT): Listing tape volumes that are capable of being resumed after AUDIT MEDIACONTROLS was interrupted” on page 945
SMALLDATASETPACKING and NOSMALLDATASETPACKING	“SELECT (SMALLDATASETPACKING and NOSMALLDATASETPACKING): Specifying whether data sets have migrated to SDSP” on page 946
UNAVAILABLE	“SELECT (UNAVAILABLE): Listing dump volumes with invalid contents” on page 946
UNEXPIRED	“SELECT (UNEXPIRED): Listing dump volumes that have not reached their expiration date” on page 946
VSAM	“SELECT (VSAM): Specifying the data set organization” on page 947

Defaults: None.

SELECT (ACTIVE and RETAIN_DAYS): Displaying information about active and retained backup copies

Explanation: ACTIVE and RETAIN_DAYS are optional subparameters of SELECT that specify what information is to be displayed about active and retained backup copies

ACTIVE

displays the backup information about the active copies of the data set or UNIX files and the total number of backup copies.

RETAIN_DAYS

displays the backup information about the active and retained backup copies that have RETAIN_DAYS specified at the time of backup. Version and generation number do not apply to retained backup copies, and therefore are not displayed in the LIST output.

Defaults: If you specify SELECT without specifying either RETAIN_DAYS or ACTIVE, DFSMSHsm displays information about both active and retained backup copies. The output contains zeros for generation and version numbers for retained copies, and "*****" in the field of the RETAIN_DAYS value for copies that do not have RETAIN_DAYS specified during backup.

SELECT (AGE): Specifying data set use by age

Explanation: AGE is an optional subparameter of SELECT, specifying a list of entries for those data sets in the MCDS that have been referred to within the specified range of days. AGE is also used for those data sets in the BCDS that have been backed up within the specified range of days. The values to specify when using the AGE parameter are explained:

mindays

specifies the minimum number of days since the data sets have been referred to or backed up. For *mindays*, substitute a decimal number from 0 to 999999.

maxdays

specifies the maximum number of days since the data sets have been referred to or backed up. Specify a *maxdays* value greater than or equal to the *mindays* value. For *maxdays*, substitute a decimal number from 0 to 999999.

Defaults: The default for *mindays* is 0. The default for *maxdays* is 999999. The default range causes entries to be listed for all data sets that meet the data set or volume-selection criteria. If *maxdays* is less than *mindays*, *maxdays* defaults to the same value as *mindays*.

Note:

1. AGE applies to information from the MCDS and BCDS.

SELECT (ALTERNATEVOLUME and NOALTERNATEVOLUME): Listing tape volumes that have alternate tape volumes

Explanation: ALTERNATEVOLUME and NOALTERNATEVOLUME are mutually exclusive optional subparameters used with LIST TAPETABLEOFCONTENTS when *volser* is not specified.

ALTERNATEVOLUME

lists only those tape volumes that are marked full or partially full and that have alternate tape volumes. This list provides you with the capability to identify the full or partially full backup and migration tape volumes that have alternate tapes. In a duplex tape environment, you want to keep those alternate tapes in the library because they can be extended. In a nonduplex tape environment, you may want to EJECT those alternate tapes from the library or initially not put them in the library.

NOALTERNATEVOLUME

lists only those tape volumes that are marked full or partially full and have neither alternate tape volumes nor DISASTERALTERNATEVOLUMES.

Defaults: None.

SELECT (AVAILABLE): Listing available dump volumes for dump output

Explanation: AVAILABLE is an optional subparameter of SELECT specifying a list of each dump volume that is available for dump output use. An available volume is one that has been added to DFSMSHsm's inventory but never used or that has been used but has since been invalidated and remains under DFSMSHsm ownership. The following information is listed for each available dump volume:

- Volume serial number
- Unit type
- Dump class

Defaults: None.

SELECT (CAPACITYMODE): Identifying tape volumes by their ability to use available tape capacity

Explanation: CAPACITYMODE is an optional subparameter of SELECT. The parameters of the CAPACITYMODE parameter are explained:

COMPATIBILITY

lists all nonempty tape volumes that are written by an IBM 3590 in 3490 emulation mode that are not written in CAPACITYMODE(EXTENDED) mode. Data on these tapes is accessible to IBM 3590 drives emulating 3490 drives, regardless of CAPACITYMODE switching support.

EXTENDED

lists all nonempty tape volumes that are written by an IBM 3590 in 3490 emulation mode that were written in CAPACITYMODE(EXTENDED) mode. Data on these tapes is accessible only to tape units capable of CAPACITYMODE switching. On input, DFSMSHsm dynamically switches temporarily to CAPACITYMODE(EXTENDED) to read the tape even if the unit name is in CAPACITYMODE(COMPATIBILITY).

Defaults: None.

SELECT (CONNECTED and NOTCONNECTED): List volumes that contain spanning data sets

Explanation: CONNECTED and NOTCONNECTED are mutually exclusive optional subparameters of SELECT.

CONNECTED

specifies a list of tape volumes that contain spanning data sets. The tapes are grouped based on which volumes are associated with their spanning data sets. CONNECTED lists all connected sets where each set is shown in the connected order. The order of the sets is in collating order of the first tape volser in each set. The collection of sets lists all tapes that contain spanning, valid data sets.

CONNECTED(volser)

specifies that the tape volume set that is associated with *volser* be listed. All tapes in the connected set associated with this *volser* are listed.

NOTCONNECTED

specifies a list of tape volumes that excludes all that contain spanning data sets. Any tape in this list can be moved into or out of a library without having to find a tape containing another part of a spanning data set. Tapes that are not connected can be full or partially full (empty tapes are not included). The SELECT subparameters FULL or NOTFULL may be used to further restrict the listing. Output from the NOTCONNECTED subparameter identifies those tape volumes that can be individually inserted into or ejected from a tape library.

Defaults: None.

Note:

1. Output from the CONNECTED subparameter identifies which tape volumes should be inserted or ejected from a tape library at the same time.
2. Do not use any other subparameters on SELECT when specifying CONNECTED(*volser*).
3. Do not use the EMPTY, FULL, NOTFULL, ALTERNATE, NOALTERNATE, or DIASSTERALTERNATEVOLUMES subparameters when specifying CONNECTED.

SELECT (DIASSTERALTERNATEVOLUMES): Listing tape volumes that have disaster alternate volumes

Explanation: DIASSTERALTERNATEVOLUMES is an optional subparameter of SELECT to list TAPETABLEOFCONTENTS. DIASSTERALTERNATEVOLUMES will list only tape volumes whose TTOCs have been flagged as having a disaster alternate volume.

Defaults: None.

SELECT (DUMPCLASS)

DUMPCLASS can be used as an optional parameter of the LIST command and as a subparameter of SELECT. DUMPCLASS is explained in [“DUMPCLASS: Listing dump class profiles”](#) on page 927.

SELECT (DUMPSTATE, FASTREPLICATIONSTATE, INCOMPLETERECOVERY, and NONPREFERREDFRVOLS): Listing specific information about copy pools

Explanation: DUMPSTATE, FASTREPLICATIONSTATE, INCOMPLETERECOVERY, and NONPREFERREDFRVOLS are mutually exclusive optional subparameters of SELECT.

DUMPSTATE

requests information about the FRBACKUP DUMP.

The following parameters are mutually exclusive, optional parameters with the DUMPSTATE parameter.

ALLCOMPLETE

indicates that all volumes have been successfully dumped to the dump classes specified.

REQUIREDCOMPLETE

indicates that all volumes have been successfully dumped to at least the required dump classes.

PARTIAL

indicates that some volumes of a copy pool have been successfully dumped.

NONE

indicates that no dumps are associated with the copy pool.

FASTREPLICATIONSTATE

requests information about the FRBACKUP DASD copy.

The following parameters are mutually exclusive, optional parameters of the FASTREPLICATIONSTATE parameter.

FAILED

indicates the DASD version is not recoverable due to one of the following reasons:

- a failure occurred during an FRBACKUP or WITHDRAW operation before all volumes in the copy pool were successfully copied.
- the backup version was invalidated during an FRRECOV operation following a successful fast reverse restore.

FCFRRINCOMPLETE

indicates that the copy pool has a DASD version that was not completely recovered using fast reverse restore. Some volumes have been recovered while other volumes have remained unrecovered. This state typically indicates that either the recovery is in process or ended without recovering all volumes.

RECOVERABLE

indicates that the copy pool has a DASD copy that can be recovered.

NONRECOVERABLE

indicates that the copy pool has a DASD version that was created with the VERSIONS=0 and ALLOWFCFRR=N copy pool values.

NONE

indicates a DASD copy does not exist.

INCOMPLETERECOVERY

requests information about copy pool FRBACKUP versions that have not been recovered completely. This refers to either DASD recovery using fast reverse restore or recovery from tape.

NONPREFERREDFRVOLS

requests information about DASD source and target pairs that are recognized by DFSMSHsm as non-preferred.

During fast replication environment setup, DFSMSHsm assigns eligible copy pool backup storage group volumes to the source volumes and prefers target volumes that are in the same cluster as the source volumes on applicable devices. When such a volume is not available, any volumes eligible for fast replication are assigned.

With NONPREFERREDFRVOLS, DFSMSHsm lists only the non-preferred source and target volume pairs. The preferred pairs are omitted. Volume pairs that were assigned without enabling the volume preferencing function are not listed. Information for non-preferred pairs is available when all of the following conditions are met:

- Volume preferencing function was used when the fast replication environment was set up and one or more pairs are non-preferred
- ALLVOLS or FRVOLS is specified, or FRVOLS is in effect by default
- A specific copy pool name is specified to request detailed information
- The specified copy pool is defined with one or more backup versions.

Defaults: None.

SELECT (EFMT1, EFMT2, EEFMT2, EFMT3, EEFMT3, EFMT4, EEFMT4, ENCRYPTED, and NOTENCRYPTED): Recording format

Explanation: EFMT1, EFMT2, EEFMT2, EFMT3, EEFMT3, EFMT4, EEFMT4, ENCRYPTED, and NOTENCRYPTED are mutually exclusive optional subparameters of SELECT.

Defaults: None.

SELECT (EMPTY, FULL, NOTFULL, ASSOCIATED, NOTASSOCIATED, ERRORALTERNATE, and RECYCLETAKEAWAY): Identifying tape volume capacity

Explanation: EMPTY, FULL, NOTFULL, ASSOCIATED, NOTASSOCIATED, ERRORALTERNATE, and RECYCLETAKEAWAY are mutually exclusive optional subparameters of SELECT. The FULL, NOTFULL, ASSOCIATED, NOTASSOCIATED, ERRORALTERNATE, and RECYCLETAKEAWAY subparameters apply only to the LIST TTOC command. The EMPTY subparameter applies to the following commands:

- LIST BACKUPVOLUME
- LIST DATASETNAME
- LIST MIGRATIONLEVEL2(TAPE)
- LIST TTOC

EMPTY

specifies a list of empty tape backup volumes or empty tape level 2 migration volumes. If you specify SELECT(EMPTY) with LIST DATASETNAME MCDS, then DFSMSHsm will list only those migrated data sets that were empty when they were migrated.

FULL

specifies a list of tape volumes that are not available for selection (marked full). This subparameter provides a means of identifying the full backup and migration tape volumes.

NOTFULL

specifies a list of tape volumes that are available for output selection including those that are empty, as well as those that have some data but are not marked full. By using NOTFULL, you have the capability of identifying those tapes that could be the first ones added to a library and made available for backup or migration.

ASSOCIATED

specifies a listing of only those ML2 partial (not empty and not full) tape volumes currently associated for output by specific migration or recycle tasks.

NOTASSOCIATED

specifies a listing of only those ML2 partial tape volumes available for an initial allocation and not currently associated for output by any migration or recycle task.

ERRORALTERNATE

displays the volumes that encountered errors and were subsequently marked full when the SETSYS DUPLEX (MIGRATION(Y (ERRORALTERNATE(MARKFULL) environment was specified.

RECYCLETAKEAWAY

displays the volumes that were not completely recycled because they were taken away.

Defaults: None.

Note:

1. These subparameters cannot be used when *volser* is part of the command.
2. The FULL and NOTFULL subparameters are ignored when used with the RECALLTAKEAWAY subparameter of SELECT.
3. When EMPTY is specified with the BACKUPVOLUME parameter, DASD backup volumes are not listed. EMPTY is ignored when it is specified with MIGRATIONLEVEL2(DASD). You must use the TAPE parameter for the EMPTY subparameter to work.
4. When EMPTY is specified with the DATASETNAME MIGRATIONCONTROLDATASET parameter, the list excludes PDS and PDSE data sets.
5. The ASSOCIATED and NOTASSOCIATED subparameters are ignored when listing TTOCs for backup tape volumes.

SELECT (EXCESSIVEVOLUMES): Listing volumes with data sets spanning four or more volumes

Explanation: EXCESSIVEVOLUMES is an optional parameter used with the LIST TAPETABLEOFCONTENTS command when no *volser* is specified. The EXCESSIVEVOLUMES parameter lists only the volumes that contain a data set that spans four or more volumes.

Defaults: None.

SELECT (EXPIRED): Listing expired dump volumes

Explanation: EXPIRED is an optional subparameter of SELECT specifying a list of each dump volume that is part of a valid dump copy and has reached or passed its expiration date. The following information is listed for each dump volume:

- Source volume serial number
- Dump volume serial number

- Unit type
- Expiration date
- Dump class

Defaults: None.

Note:

1. If DUMPCCLASS(*class*) is also specified in the set of SELECT options, only dump volumes assigned to the specified *class* are listed.
2. The EXPIRED subparameter of the SELECT parameter is relevant when *volser* is not specified with the DUMPVOLUME parameter. The EXPIRED subparameter can be used in combination with the subparameters AVAILABLE, DUMPCCLASS, NORETENTIONLIMIT, UNAVAILABLE, or UNEXPIRED to get a list of volumes that satisfies all the selection criteria.

SELECT (FAILEDCREATE): Listing all tape volumes that have incomplete data set information saved in the OCDS TTOC record

Explanation: FAILEDCREATE is an optional parameter used when you specify LIST TAPETABLEOFCONTENTS without the *volser*.

FAILEDCREATE lists only the volumes that have not been created.

If DFSMSHsm issues message ARC0378I, it indicates the TTOC for a volume is incomplete. Use LIST TAPETABLEOFCONTENTS SELECT(FAILEDCREATE) to list all volumes that have incomplete data set information saved in the OCDS TTOC record.

Defaults: None.

Note:

1. Multihost Consideration: As an example, consider two hosts, 'A' and 'B'. If host 'A' has experienced an outage and has not been restarted, you *cannot* use host 'B' to issue the FAILEDCREATE parameter to list all tape volumes that have incomplete data set information saved in the OCDS TTOC record.
2. If DFSMSHsm has issued message ARC0378I, indicating that there is a mismatch between the OCDS TTOC and the tape media, we recommend using the AUDIT MEDIACONTROLS FIX command to resolve the problem. See [“MEDIACONTROLS VOLUMES, MEDIACONTROLS\(SDSP\) VOLUMES and MEDIACONTROLS\(CLOUD\): Requesting an audit of control information” on page 748](#) for more information. Also see Chapter 75, “Using the AUDIT command,” on page 1255 for more information on using AUDIT MEDIACONTROLS. An explanation of how to correct the mismatch can be found in the [“How to handle inconsistencies between tape media contents and OCDS TTOC records” on page 550](#).

SELECT (FAILEDRECYCLE): Listing only those volumes that have failed recycle

Explanation: FAILEDRECYCLE is an optional parameter used when you specify LIST TAPETABLEOFCONTENTS without the *volser*.

FAILEDRECYCLE lists only the volumes that have failed recycle and which are not selected for processing by a generic RECYCLE command.

Defaults: None.

Note:

1. Input tapes are marked in error when one of the following occurs: an I/O error on the input tape or an OPEN failure for the input tape. These errors prevent a successful recycle of the tape.

SELECT (LIBRARY and NOLIBRARY): Listing tape volume library status

Explanation: LIBRARY and NOLIBRARY are mutually exclusive optional subparameters of SELECT.

LIBRARY

lists only the tape volumes that are in a tape library. LIBRARY(ALTERNATE) lists only the tape volumes that have alternate tape volumes.

NOLIBRARY

lists only the tape volumes that are *not* in a tape library. NOLIBRARY(ALTERNATE) lists only the tape volumes that have alternate tape volumes not in a library.

When using the ALTERNATE subparameter, the listing is independent of whether the ORIGINAL volume is in a library and applies to both BACKUP and ML2 volumes. The field under the heading, LIB, applies to the alternate volume not the original volume. If you specify SELECT(NOALTERNATEVOLUME), the specification of LIBRARY(ALTERNATE) or NOLIBRARY(ALTERNATE) is ignored.

Defaults: None.

Note:

1. If you select LIBRARY with no other parameter, all volumes in your library will be listed. To reduce the run time of the LIST command, narrow the scope of the command with other parameters.

SELECT (MIGRATIONLEVEL1, MIGRATIONLEVEL2, VOLUME(*volser*), BACKUP, and BOTH): Requesting specific information for volumes

Explanation: MIGRATIONLEVEL1, MIGRATIONLEVEL2, VOLUME(*volser*), BACKUP, and BOTH are mutually exclusive, optional parameters you specify to request a list of selected information for migration or backup volumes.

MIGRATIONLEVEL1

specifies that you want a list of the volume entries for all migration level 1 volumes. This parameter is used only with DATASETNAME and LEVEL.

MIGRATIONLEVEL2

specifies that you want a list of the volume entries for all migration level 2 volumes.

VOLUME

specifies that you want a list for a particular volume. For *volser*, substitute the serial number of the specific volume you want listed. When you specify VOLUME(*volser*) to list a backup volume, the output contains a list of the latest backup versions on the volume.

BACKUP

is used only with the LIST TAPETABLEOFCONTENTS with no *volser* specified. You specify BACKUP to list all backup volumes.

BOTH

is specified to list both migration and backup volumes.

Defaults: If the SELECT subparameters RECALLTAKEAWAY, ASSOCIATED, or NOTASSOCIATED is specified, the default is MIGRATIONLEVEL2. Otherwise, the default is BOTH.

SELECT (MULTIPLEVOLUME): Listing multiple-volume non-VSAM data sets from backup or dump VTOC copy data sets

Explanation: MULTIPLEVOLUME is an optional subparameter of SELECT, specifying a list of only multiple-volume non-VSAM data sets. DFSMSHsm treats a non-VSAM data set as multiple-volume if the data set VTOC entry indicates that the data resides on more than one volume. DFSMSHsm does not use the catalog in determining if a non-VSAM data set resides on multiple volumes.

Defaults: None.

Note:

1. If both the MULTIPLEVOLUME subparameter and the VSAM subparameter are specified as SELECT options, all VSAM data sets and all multiple-volume non-VSAM data sets are listed.

SELECT (NORETENTIONLIMIT): List dump volumes with no retention period

Explanation: NORETENTIONLIMIT is an optional subparameter of SELECT specifying a list of each dump volume that is part of a valid dump copy and has no retention date. These dump volumes contain dump copies that DFSMSHsm invalidates automatically only if the dump copy is the 100th generation and a new dump is performed. The following information is listed for each dump volume:

- Source volume serial number
- Dump volume serial number
- Unit type
- Dump class

Defaults: None.

Note:

1. If DUMPCLASS(*class*) is also specified in the set of SELECT options, only dump volumes assigned to the specified *class* are listed.
2. The NORETENTIONLIMIT subparameter of SELECT is relevant only when *volser* is not specified with the DUMPVOLUME parameter. The NORETENTIONLIMIT subparameter can be used in combination with the subparameters AVAILABLE, DUMPCLASS, EXPIRED, UNAVAILABLE, or UNEXPIRED to get a list of volumes that satisfy all the selection criteria.

SELECT (OVERFLOW and NOOVERFLOW): List overflow or non-overflow ML1 volumes

Explanation: OVERFLOW and NOOVERFLOW are mutually exclusive optional subparameters of SELECT used with LIST MIGRATIONLEVEL1 specifying a list of NOOVERFLOW or OVERFLOW ML1 volumes.

NOOVERFLOW

specifies a list of all NOOVERFLOW ML1 volumes.

OVERFLOW

specifies a list of all OVERFLOW ML1 volumes.

Defaults: None.

Note:

1. If OVERFLOW or NOOVERFLOW is not specified, all ML1 volumes are listed.

SELECT (RECALLTAKEAWAY): Listing ML2 volumes taken away by recall or ABACKUP functions

Explanation: RECALLTAKEAWAY is an optional subparameter of SELECT that specifies a list of all ML2 volumes taken away from use as migration tape output because either RECALL or ABACKUP needed a data set on the volume.

Defaults: None.

SELECT (RESUMEAUDIT): Listing tape volumes that are capable of being resumed after AUDIT MEDIACONTROLS was interrupted

Explanation: RESUMEAUDIT is an optional subparameter used when you specify LIST TAPETABLEOFCONTENTS without the *volser*.

RESUMEAUDIT lists only the volumes that were interrupted during AUDIT MEDIACONTROLS and are capable of being resumed.

Defaults: None.

Notes:

1. LIST TTOC SELECT(RESUMEAUDIT) only lists volumes that were previously interrupted during AUDIT MEDIACONTROLS because the volume was held. DFSMSHsm was stopped or emergency mode was specified. RESUME can be specified on the AUDIT MEDCTLVOLUMES(*tape volser*) FIX command to resume audit of a volume at the point it was interrupted.

SELECT (SMALLDATASETPACKING and NOSMALLDATASETPACKING): Specifying whether data sets have migrated to SDSP

Explanation: SMALLDATASETPACKING and NOSMALLDATASETPACKING are mutually exclusive, optional subparameters of SELECT specifying a list of those data sets that have migrated to small-data-set-packing data sets or a list of those data sets that have not migrated to small-data-set-packing data sets. If you do not specify either subparameter, the list contains entries for all migrated data sets.

SMALLDATASETPACKING

specifies a list of entries for those data sets that have migrated to small-data-set-packing data sets.

NOSMALLDATASETPACKING

specifies a list of entries for those data sets that have not migrated to small-data-set-packing data sets.

Defaults: None.

Note:

1. Small-data-set-packing data sets can exist only on migration level 1 volumes. You can specify the MIGRATIONLEVEL1 subparameter of the SELECT parameter and the SMALLDATASETPACKING or NOSMALLDATASETPACKING subparameter of the SELECT parameter in the same LIST command.

Do not specify MIGRATIONLEVEL2 and SMALLDATASETPACKING in the same LIST command. Also, do not specify a migration level 1 volume (VOLUME) and SMALLDATASETPACKING in the same LIST command.

2. These parameters apply only to information in the MCDS.

SELECT (UNAVAILABLE): Listing dump volumes with invalid contents

Explanation: UNAVAILABLE is an optional subparameter of SELECT specifying a list of each dump volume that has had its contents invalidated, but was not eligible to be automatically reused. The following information is listed for each dump volume:

- Dump volume serial number
- Unit type
- Dump class

Defaults: None.

Note:

1. If DUMPCLASS(*class*) is also specified in the set of SELECT options, only dump volumes assigned to the specified *class* are listed.
2. The UNAVAILABLE subparameter of the SELECT parameter is relevant when *volser* is not specified with the DUMPVOLUME parameter. The UNAVAILABLE subparameter can be used in combination with the subparameters AVAILABLE, DUMPCLASS, EXPIRED, NORETENTIONLIMIT, or UNEXPIRED to get a list of volumes that satisfy all the selection criteria.

SELECT (UNEXPIRED): Listing dump volumes that have not reached their expiration date

Explanation: UNEXPIRED is an optional subparameter of SELECT specifying a list of each dump volume that is part of a valid dump copy and has not reached or passed its expiration date. Dump volumes with a retention period of NONE are not included. The following information is listed for each dump volume:

- Source volume serial number for each valid dump copy
- Dump volume serial number
- Unit type
- Expiration date
- Dump class

Defaults: None.

Note:

1. If DUMPCCLASS(*class*) is also specified in the set of SELECT options, only dump volumes assigned to the specified *class* are listed.
2. The UNEXPIRED subparameter of the SELECT parameter is relevant only when *volser* is not specified with the DUMPVOLUME parameter. The UNEXPIRED subparameter can be used in combination with the subparameters AVAILABLE, DUMPCCLASS, EXPIRED, NORETENTIONLIMIT, or UNAVAILABLE to get a list of volumes that satisfy all the selection criteria.

SELECT (VSAM): Specifying the data set organization

Explanation: VSAM is an optional subparameter of SELECT specifying a list of only migrated VSAM data sets. The list contains standard data set information for the MCDS data set records and any VSAM object names that you can use to automatically recall the data set.

Defaults: None.

Note:

1. The VSAM subparameter applies only to data set information from the MCDS.

SUMMARY: Requesting a summary

Explanation: SUMMARY is an optional parameter specifying a count of data sets, tracks, and bytes of the selected data sets.

Defaults: None.

Note:

1. When you specify this parameter, DFSMSHsm does not list information about each data set. This parameter applies only to information from the MCDS.
2. The SUMMARY information is issued when you specify the LEVEL parameter or the DATASETNAME parameter (with no data set name specified) and the MCDS information is requested and available. The SUMMARY parameter applies only to the DATASETNAME parameter (with no data set name specified) and the LEVEL parameter.

Examples of how to code commonly used list requests

The examples as presented below show how to use the LIST command to request various types of commonly desired information. Chapter 76, “Using the LIST command,” on page 1341 contains examples of output produced by the LIST command.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Listing migrated data sets contained in the SDSP

In this example, you issued the DATASETNAME command to list the migrated data sets contained in the SDSP data set on a particular migration level 1 (ML1) volume and the results of the request are written to an output data set.

```
LIST DATASETNAME MIGRATIONCONTROLDATASET SELECT(VOLUME(L1VOLA) SDSP)
OUTDATASET(fully.qualified.dsn)
```

Listing migrated data sets using abbreviations

In this example, you used the standard abbreviations to list the migrated data sets.

```
LIST DSN MCDS SEL(VOL(L1VOLA) SDSP)
```

Listing the number and total space of migrated data sets

This example shows you how to list the number and total space of the migrated data sets contained in the SDSP data set on a particular ML1 volume.

```
LIST DATASETNAME MIGRATIONCONTROLDATASET SELECT(VOLUME(L1VOLA) SDSP) SUMMARY
```

Listing migrated data sets not referenced in 180 days

This example shows you how to list the migrated data sets, not referenced in 180 days, on an ML1 volume and how to write the results of the request to the terminal.

```
LIST DSN MCDS SEL(VOL(L1VOLA) AGE(180)) TERM
```

Listing migrated data sets with a high-level qualifier

This example shows you how to list on ML1 volumes the migrated data sets having a common high-level qualifier that have not been referenced in 180 days.

```
LIST LEVEL(L364204) MCDS SELECT(ML1 AGE(180))
```

Listing specific migrated data sets

This example shows you how to request a specific ML1 volume and how to write the results of the request to the terminal.

```
LIST LEVEL(L364204) MCDS SELECT(VOLUME(L1VOLB) AGE(180)) TERM
```

Listing migrated data sets with a high-level and a common secondary qualifier

This example shows you how to list on ML1 volume the migrated data sets with a common high-level qualifier and a common secondary qualifier and how to write the results of the request to the terminal.

```
LIST LEVEL(L364204.TEST) MCDS SELECT(VOLUME(L1VOLB)) TERM
```

Listing copy pool information for all copy pools

In this example, DFSMSHsm lists information for all copy pools..

```
LIST COPYPOOL
```

See [Figure 116 on page 1350](#) for an example of the output.

Listing copy pool information for a specific copy pool

In this example, DFSMSHsm lists detailed information for each backup version of the CPDATABASE1 copy pool.

```
LIST COPYPOOL(CPDATABASE1)
```

See [Figure 116 on page 1350](#) for an example of the output.

Listing specified copy pool storage group information

In this example, DFSMSHsm lists information for each volume in the CPBSGDATABASE4 storage group and the corresponding source volume for each volume in that copy pool backup storage group. This list only returns those volumes that DFSMSHsm has selected as target volumes. For those target volumes that are listed, the source volume is also listed.

```
LIST COPYPOOLBACKUPSTORAGEGROUP(CPBSGDATABASE4)
```

See [Figure 120 on page 1352](#) for an example of the output.

Listing information about data sets backed up as part of a copy pool backup version

In this example, DFSMSHsm lists all data sets backed up as part of a copy pool backup version, including those that have been deleted. The data sets are listed in alphabetical order by catalog.

```
LIST COPYPOOL(CP1) DATASETS(GENERATION(1))
```

Note: DATASETS only returns information related to a copy pool backup version if the catalog information for a given backup version is captured at the time of backup.

See [Figure 120 on page 1352](#) for an example of the output.

Listing summary information from the MCDS

This example shows you how to list summary information from the MCDS and write the results to an output data set.

```
LIST DSN SUMMARY ODS(LIST)
```

See [Figure 123 on page 1354](#) for an example of the output.

Listing specified volume information

This example shows you how to list only the volume information for the specific volume specified by the *volser* and how to write the results of the request to the terminal.

```
LIST TT0C(A00800) NODATASETINFORMATION TERM
```

See [Figure 152 on page 1384](#) for an example of the output.

Listing specified volume and data-set-related information

This example shows you how to list the volume information for the specified volume *volser* and the data-set-related information (the default of DATASETINFORMATION will be used) and how to write the results of the request to an output data set.

```
LIST TT0C(BATP01) OUTPUTDATASET(LIST)
```

See [Figure 153 on page 1385](#) for an example of the output.

Listing volume information for failed RECYCLE ML2

This example shows you how to list the volume information for the migration level 2 volumes that have previously failed RECYCLE and how to write the results of the request to an output data set.

```
LIST TT0C SELECT(ML2 FAILEDRECYCLE) ODS(LIST)
```

See [Figure 157 on page 1386](#) for an example of the output.

Listing tape volumes with incomplete data set information

This example shows you how to list all the tape volumes that have incomplete data set information saved in the OCDS TT0C record.

```
LIST TT0C SELECT(FAILEDCREATE)
```

See [Figure 158 on page 1386](#) for an example of the output.

Listing volume information for data sets spanning four or more volumes

This example shows how to list the volume information for the ML2 and backup volumes that contain data sets that span four or more volumes and how to write the results of the request to an output data set.

```
LIST TT0C SELECT(BOTH EXCESSIVEVOLUMES) ODS(LIST)
```

See [Figure 159 on page 1386](#) for an example of the output.

Listing information for connected volumes

This example shows all volumes that are connected to this volume and whether or not these volumes are in the library.

```
LIST TT0C SELECT(CONNECTED(A00800)) ODS(LIST)
```

See [Figure 151 on page 1384](#) for an example of the output.

Listing volume information about disaster alternate volumes

This example shows how to list the volume information about disaster alternate volumes.

```
LIST TT0C SELECT (LIBRARY DISASTERALTERNATEVOLUMES) ODS(LIST)
```

See [Figure 156 on page 1385](#) for an example of the output.

Listing volume information about alternate tape volumes

This example shows you how to list the volume information for the migration level 2 and backup volumes that do *not* have an ALTERNATE tape volume and are in a tape library. The result is printed to an output data set.

```
LIST TT0C SELECT (LIBRARY NOALTERNATEVOLUME) ODS(LIST)
```

See [Figure 155 on page 1385](#) for an example of the output.

Listing information about available tape volumes

This example shows you how to list tape volumes that are available for selection (not marked full) and thus identify the empty and partially full backup and migration tape volumes. The results go to the SYSOUT class.

```
LIST TT0C SELECT(NOTFULL) SYSOUT(H)
```

Listing information about partially filled ML2 tape volumes not associated for output by any migration or recycle task

This example shows you how to list all partially filled ML2 tapes that are not currently associated with an ML2 output task in any host. The results of the request are written to an output data set.

```
LIST TT0C SELECT(NOTASSOCIATED) ODS('JCA.ASSOCNOT.D041798')
```

See [Figure 160 on page 1386](#) for an example of the output.

Listing information about contents of the dump volume

This example shows you how to list all data sets that have been dumped to a specified dump volume.

```
LIST DUMPVOLUME(A00359) DUMPCONTENTS(PRIM02) ODS(List)
```

See [Figure 137 on page 1370](#) for an example of the output.

Listing information about a dump volume

This example shows how to list all data sets that have been dumped to a volume with a specified *volser*. The output includes the dump copy data set name.

```
LIST DUMPVOLUME(A00359) ODS(LIST)
```

See [Figure 134 on page 1366](#) for an example of the output.

Listing information about a specific dump class profile

This example shows how to list all data sets that have been dumped to a specific DUMPCLASS.

```
LIST DUMPCLASS(WEEKLY) ODS(LIST)
```

See [Figure 131 on page 1363](#) for an example of the output.

Listing information about aggregate data sets

This example shows how to list the aggregate version record (ABR record) Version 2 to the terminal.

```
LIST AGGREGATE(PAY1) VERSION(0002) TERM
```

See [Figure 110 on page 1344](#) for an example of the output.

Listing information about aggregate data sets and saving the output to the ODS

This example shows how to list the aggregate version record (ABR record) Version 1 to the ODS.

```
LIST AGGREGATE(PAY1) VERSION(0001) ODS(LIST)
```

See [Figure 111 on page 1344](#) for an example of the output.

Listing ML2 volumes taken away by recall or ABACKUP

This example shows how to list the ML2 volumes that were taken away from an output function because RECALL or ABACKUP functions need a data set on the volume.

```
LIST TT0C SELECT(RECALLTAKEAWAY)
```

Listing tape volumes that can use available tape capacity

This example shows how to list all tape volumes that are written by an IBM 3590 that is emulating an IBM 3490 in CAPACITYMODE(EXTENDED).

```
LIST TT0C SELECT(CAPACITYMODE(EXTENDED))
```

Listing tape volumes capable of being resumed after AUDIT MEDIACONTROLS was interrupted

This example shows how to list all tape volumes that were interrupted during AUDIT MEDIACONTROLS and are capable of being resumed.

```
LIST TT0C SELECT(RESUMEAUDIT)
```

Chapter 54. LOG command: Entering data into the DFSMSHsm log

The LOG command enters information into the DFSMSHsm log. This information could be a message or an explanation that the storage administrator or system programmer wants to write into the DFSMSHsm log. The information could also be automatically generated DFSMSHsm log data.

Syntax of the LOG command

► LOG — *data* ◄

Required parameters of the LOG command

This topic describes the required parameter of the LOG command.

data: Specifying the data for the log

Explanation

data is a required positional parameter specifying the information to enter into the DFSMSHsm log. For *data*, substitute any character string consisting of alphanumeric characters, special characters, and \$, #, or @.

Defaults

None.

Example of how to code the LOG command

The following example shows how to code the LOG command to enter data into the DFSMSHsm log.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Sending a message to the log

In this example, a message concerning the DFSMSHsm functions is sent to the DFSMSHsm log.

```
LOG ALL MIGRATION FUNCTIONS HELD AT 3:15 AM
```

Chapter 55. MIGRATE command: Requesting a space management function

The MIGRATE command requests the type of space management you want DFSMSHsm to do: migration, data set deletion, or data set retirement. You can issue the MIGRATE command to cause space management for:

- All eligible data sets from a specific level 0 volume. A level 0 volume is an SMS volume in a storage group, a DFSMSHsm primary volume, or a nonmanaged user volume.
- All eligible data sets from all primary volumes (PRIMARY).
- Storage groups.

You can issue the MIGRATE command to cause migration for:

- A specific data set from a level 0 volume to a migration level 1 volume or a migration level 2 volume (DATASETNAME)
- A specific data set from a DASD migration level 2 volume to a tape migration level 2 volume (DATASETNAME and MIGRATIONLEVEL2)
- A specific data set from a migration level 1 volume to a migration level 2 volume (DATASETNAME and MIGRATIONLEVEL2)
- All eligible data sets from all migration level 1 volumes to migration level 2 volumes (MIGRATIONLEVEL1).

On SMS-managed volumes only, you can also issue the MIGRATE command to cause class transitions for:

- All data sets on a specific volume. The management class is used to determine whether a data set is eligible to be migrated, transitioned, or both.
- All data sets in a specific storage group. The management class is used to determine whether a data set is eligible to be migrated, transitioned, or both.
- A specific data set.

On SMS-managed volumes only, you can also issue the MIGRATE command with the MOVE parameter to:

- Move specific data sets from one volume to another
- Move all data sets off a volume
- Move all data sets out of a storage group.

Note:

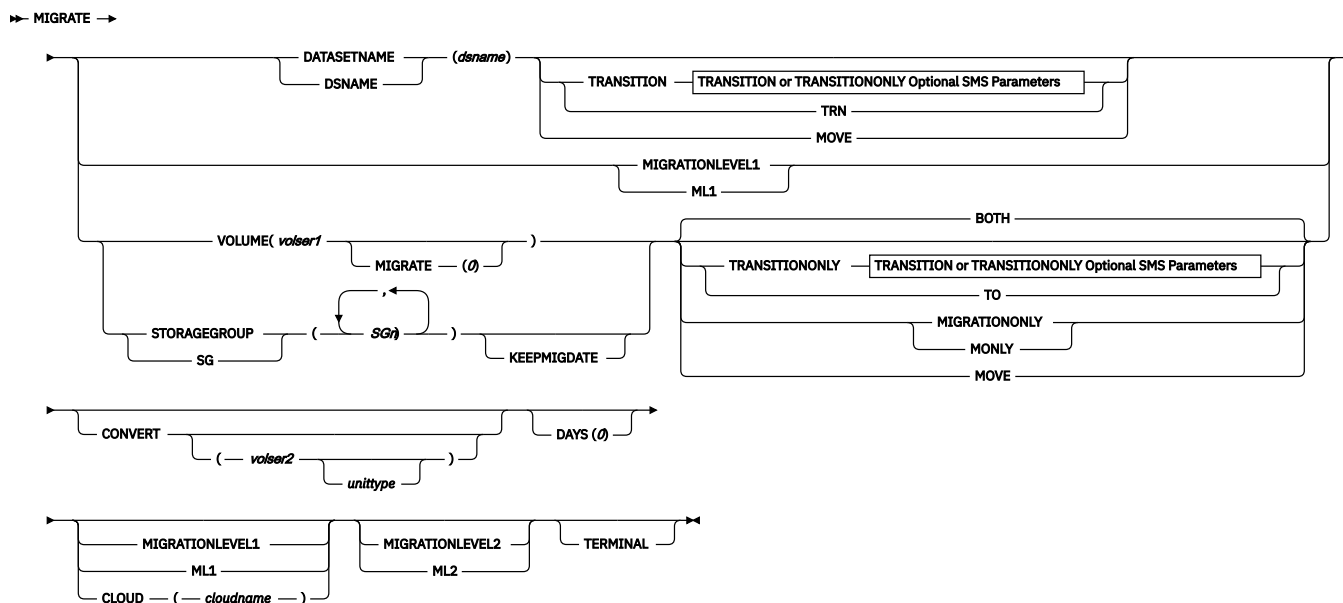

1. If you want to move data sets from one tape migration level 2 volume to another tape migration level 2 volume, you must recycle the tape migration level 2 volume. [Chapter 61, “RECYCLE command: Consolidating valid data to one tape from other tapes,” on page 1015](#) contains information about recycling tape volumes.
2. If you want to move all eligible data sets from a specific migration level 1 volume or a specific migration level 2 DASD volume to other migration level 2 volumes, you must use the FREEVOL command. See [Chapter 48, “FREEVOL command: Freeing DFSMSHsm-owned volumes,” on page 877](#).
3. Fast subsequent migration can take place under both data set and volume MIGRATE commands. For more information on setting up fast subsequent migration, see [“Reconnecting data sets using fast subsequent migration” on page 94](#).
4. For either volumes or storage groups, use the MIGRATIONONLY, TRANSITIONONLY, and BOTH options to indicate that only migrations should be processed, only transitions should be processed, or that both should be processed. The default is to process BOTH.
5. When processing the MIGRATE command, DFSMSHsm checks data sets for migration eligibility before attempting either migration or transition or both.

Requesting a space management function for SMS-managed data sets

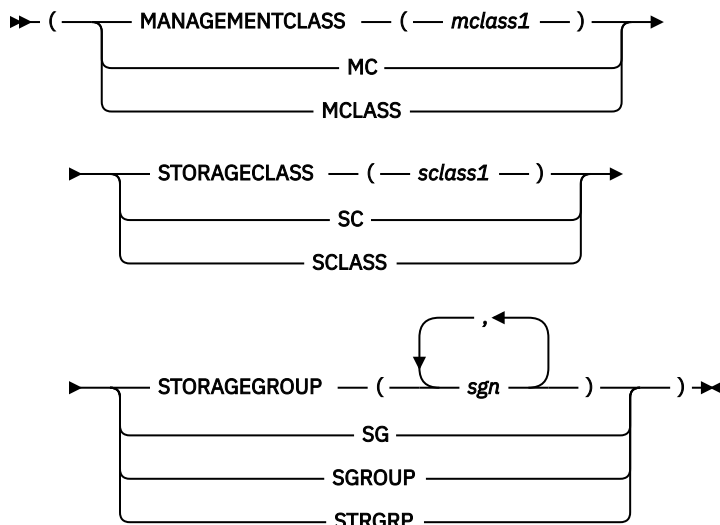

The functions performed for SMS data sets are determined by each data set's management class attributes. COMMAND migration must be allowed by the management class to which the data set belongs.

Note: If a management class cannot be obtained for an SMS-managed data set, the data set will not be migrated, and an error message is issued.

Syntax of the MIGRATE command for SMS-managed data sets

TRANSITION or TRANSITIONONLY Optional SMS Parameters

Note: You must specify either DATASETNAME, MIGRATIONLEVEL1, VOLUME, or STORAGEGROUP with each MIGRATE command.

Summary of parameters

The following table is a summary of the combination of parameters you can specify with the MIGRATE command. Specifying other combinations of parameters results in either an error message or one or more of the parameters being ignored.

Parameter	Related Parameters
CLOUD	VOLUME (MIGRATE) STORAGEGROUP DATASETNAME
CONVERT	VOLUME (MIGRATE)
DATASETNAME	CONVERT MIGRATIONLEVEL1 MIGRATIONLEVEL2 TRANSITION MOVE CLOUD
DAYS	MIGRATIONLEVEL1 VOLUME (MIGRATE) STORAGEGROUP
MIGRATIONLEVEL1	DAYS TERMINAL
MIGRATIONLEVEL2	DATASETNAME
MOVE	VOLUME (MIGRATE) STORAGEGROUP DATASETNAME
STORAGEGROUP	DAYS TRANSITIONONLY MIGRATIONONLY BOTH MOVE KEEPMIGDATE CLOUD
TRANSITION	DATASETNAME
TRANSITIONONLY MIGRATIONONLY BOTH	VOLUME (MIGRATE) STORAGEGROUP
VOLUME	CONVERT TERMINAL TRANSITIONONLY MIGRATIONONLY BOTH MOVE CLOUD

Required parameters of the MIGRATE command for SMS-managed data sets

This topic describes the required parameters of the MIGRATE command.

DATASETNAME: Specifying migration and/or class transition for a specific data set

Explanation: **DATASETNAME(*dsname*)** is the required parameter to migrate and/or perform class transition for a specific data set. For *dsname*, substitute the fully qualified name of the data set you want to migrate. You cannot specify an alias for *dsname*. If you do, DFSMSHsm does not migrate or perform a class transition for the data set.

The MIGRATE command overrides the data set's PRIMARY-DAYS-NON-USAGE and class transition management class attribute. The data set, however, is not migrated if the data set's management class specifically prevents migration.

If you choose class transition, any migration-related parameters are disallowed.

Defaults: None.

Note:

1. The volume where the data set resides must be mounted before you issue the MIGRATE command.
2. A data set that is eligible for migration with the target device of TAPE, that is also eligible for back up, is not migrated, and an error message issued.
3. If a management class cannot be obtained for a data set, the data set is not migrated, and an error message is issued.
4. DFSMSHsm does not handle partitioned data set members individually. If you specify a member name of a partitioned data set, DFSMSHsm processes the entire partitioned data set.
5. If *dsname* is a VSAM data set name, specify the base cluster name. The entire VSAM sphere is migrated. If the sphere has more than one AIX®, more than one path, or more than one path on the AIX, the data set can only be recalled by the base cluster name.

MIGRATIONLEVEL1: Specifying migration of data sets from level 1 to level 2 volumes

Note: Required vs. Optional: The following explanation refers to the MIGRATIONLEVEL1 required parameter. For the explanation of the MIGRATIONLEVEL1 optional parameter, see [“MIGRATIONLEVEL1: Specifying migration of a data set”](#) on page 962.

Explanation: **MIGRATIONLEVEL1** is the required parameter to migrate eligible data sets from all migration level 1 volumes to migration level 2 volumes.

Each migrated SMS data set is processed according to its management class attribute value for LEVEL-1-DAYS-NON-USAGE.

Defaults: None.

Note:

1. If you specify this parameter in a direct-to-tape environment, the command fails.
2. If you specify this parameter when level 1 to level 2 migration of automatic secondary space management is running, the command fails.

VOLUME: Specifying the space management attribute for the eligible data sets on a volume

Explanation: **VOLUME(*volser1*)** is the required parameter to specify migration and/or class transition for eligible data sets on one volume. Information for any migration is printed in the migration activity log.

For *volser1*, substitute the serial number of the level 0 volume from which you want to migrate or delete eligible data sets. Eligibility for processing is determined by each data set's management class attributes.

If the MIGRATE command is specified with only the VOLUME parameter, eligibility for migration and/or class transition is determined by the data set's management class attributes. Data sets will be processed until the low threshold has been met, regardless of whether there are more data sets eligible.

When the MIGRATE command is issued for an SMS-managed volume, that volume is considered DFSMSHsm-managed. DFSMSHsm maintains control records for the volume until a DELVOL command is issued against it.

Defaults: None.

Notes:

- The management class attribute COMMAND-OR-AUTO-MIGRATE=BOTH must be specified for an SMS-managed data set to be eligible for migration by a VOLUME command.
- The COMMAND-OR-AUTO-MIGRATE attribute does not effect Class Transition processing.

STORAGEGROUP: Specifying the space management attribute for the eligible data sets in a storage group

Explanation: **STORAGEGROUP(SGn)** is a required parameter specifying that DFSMSHsm migrate the eligible data sets on the volumes in one or more storage groups. For *SGn*, substitute the name or names of the storage groups that DFSMSHsm will be processing.

- If STORAGEGROUP is specified without *SGn*, the command fails.
- If STORAGEGROUP is specified with more than 30 storage groups, only the first 30 are processed.

When the MIGRATE STORAGEGROUP command is issued, DFSMSHsm will read the SMS storage group definition and determine the list of volumes defined by this storage group. The data sets residing on these volumes will then be processed in a similar way to Primary Space Management (PSM) processing:

- Phase 1:
 1. Issue a message for unmatched data sets.
 2. Delete temporary data sets.
 3. Delete expired data sets.
 4. Determine data sets that are eligible for migration.
 5. Exclude from migration to tape those data sets that are eligible to be backed up.
 6. Determine data sets that are eligible for extent reduction.
 7. Release unused space for eligible data sets
 8. Perform fast subsequent migration for eligible data sets.
 9. Determine data sets that are eligible for class transitions.
 10. Perform class transitions with management class changes only.
- Phase 2:
 1. Transition data sets that are candidates both for a class transition and extent reduction.
 2. Migrate data sets that are candidates both for migration and for extent reduction.
 3. Migrate data sets that are candidates only for extent reduction. Schedule a recall for each data set.
 4. Transition data sets that are candidates for a class transition in FIFO until the low threshold of occupancy is reached (DAYS(0) parameter is not specified).
 5. Migrate data sets in priority order until the low threshold of occupancy is reached (DAYS(0) parameter is not specified).

Notes:

1. If TRANSITIONONLY is specified, only Steps 9 and 10 of Phase 1 and Step 4 of Phase 2 are performed.
2. The max migration tasks SETSYS command (MAXMIGRATIONTASKS) determines the tasking level used for this function.

Defaults: None.

Optional parameters of the MIGRATE command for SMS-managed data sets

This topic describes the optional parameters of the MIGRATE command.

BOTH: Specifying that transition or migration of data sets should be processed

Explanation: **BOTH** is an optional parameter that you use to migrate SMS-managed data sets from a level 0 volume to a migration level 1 or migration level 2 volume, or transition to another level 0 volume. Data sets eligible for migration will be migrated, while data sets eligible for transition only will be transitioned. If a data set is eligible for both migration and transition, it will be migrated.

This parameter can be specified only with MIGRATE VOLUME or MIGRATE STORAGEGROUP command.

Defaults: None.

CONVERT: Specifying movement of data sets from one volume to another

Explanation: **CONVERT** is an optional parameter that you use to migrate all data sets, or a specific data set, from a level 0 volume to a migration level 1 volume and then immediately recall those data sets to another level 0 volume. You can use this parameter when you want to remove a volume from the system. The automatic class selection routines select the volume to which the data sets should be recalled.

The management class attribute PRIMARY-DAYS-NON-USAGE is not used for a MIGRATE CONVERT request. All eligible SMS-managed data sets are migrated to a migration level 1 volume. Before an SMS-managed data set is migrated, DFSMSHsm determines whether or not the data is eligible to be expired.

Defaults: Automatic class-selection routines choose the volume and type of unit to which SMS data sets are recalled.

Note:

1. The management class attribute, LEVEL-1-DAYS-NON-USAGE, are not used when processing a MIGRATE CONVERT request. All eligible data sets are migrated to a migration level 1 volume.
2. If you specify the DAYS(*days*) parameter with the CONVERT parameter, the *days* value must be zero. The default is zero, and the only value allowed is zero.

CLOUD: Specifying migration of a data set directly to cloud

Explanation: **CLOUD**(*cloud_network_connection_name*) is an optional parameter that is used to specify that a data set migrates from an SMS-managed volume to the specified cloud storage. The *cloud_network_connection_name* is the name of the SMS network connection construct or the CDA provider file (when OA66197 enabled). When *cloud_network_connection_name* is specified, the data set is migrated to the requested cloud storage, regardless of the data set's management class attributes, with the exception of migration not being allowed.

The CLOUD parameter cannot be specified with the following parameters: MIGRATIONLEVEL1, MIGRATIONLEVEL2, and CONVERT.

Note:

The following DFSMSHsm SETSYS settings do not apply to CLOUD(*cloud_network_connection_name*):

COMPACT, COMPACTPERCENT – COMPACT(ALL)

Migrating a data set to cloud storage ignores any current COMPACT setting. If the data set is being migrated to a cloud object storage that supports transparent cloud tiering compression, then the data

set can be compressed by TCT compression if it is not already compressed, encrypted, or compressed and encrypted.

CONVERSION(REBLOCKTOANY)

Because data movement is not performed by the host, reblocking of a data set cannot be performed.

CONCURRENT

Migrating a data set to Cloud storage will ignore any current setting relating to CONCURRENT.

Defaults: None.

DAYS: Specifying migration eligibility of data sets

Explanation: **DAYS(0)** is an optional parameter supplied for an SMS volume that allows the movement of all data sets for which automatic space management is supported, or transition of all of the data sets eligible for transition processing. The data set's management class attribute value for PRIMARY-DAYS-NON-USAGE need not have been met. The data set's management class attributes values for Time Since Creation, Time Since Last Use and Periodic are used to determine the data set eligibility for class transition processing. For SMS-managed volumes, the value specified for the DAYS subparameter must be zero. If a value other than zero is specified or if no value is specified, the command fails, and a message indicating the error is issued.

Defaults: None.

Notes:

- The management class attribute COMMAND-OR-AUTO-MIGRATE=BOTH must be specified for an SMS-managed data set to be eligible for migration by a VOLUME command.
- The COMMAND-OR-AUTO-MIGRATE attribute does not effect Class Transition processing.
- The DAYS(0) parameter behaves differently based on the keywords specified. Transition processing behaves differently than migration processing:
 - For migration processing, all data sets that are eligible to migrate will be migrated off of the volume, regardless of whether or not they met their Age criteria. Conversely, transition processing still requires the transition criteria to be met. During transition processing, the Low Threshold does not stop processing of data sets on the volume. All data sets on the volume are processed for migration and transition eligibility, even after the low threshold has been met.
 - If MIGRATIONONLY is specified, processing remains unchanged.
 - If BOTH is specified, since all data sets eligible for migration will be migrated and migration takes precedence over transitions, essentially all data sets eligible for migration are migrated. Only data sets that can not migrate but are eligible to be transitioned are transitioned. These data sets must still meet the transition eligibility criteria.
 - If TRANSITIONONLY is specified, all data sets eligible to be transitioned are processed, regardless of the Low Threshold on the volume.

KEEPMIGDATE: Specifying migration of a data set should keep its original migration date, if one exists.

Explanation: **KEEPMIGDATE** is an optional parameter that is used only when STORAGEGROUP(SGn) is specified. This optional parameter is used to specify that DFSMSHsm should use the original migration date (for example, if the data set was migrated, but since recalled), if one exists, upon migration of the data set.

Defaults: None.

Note: KEEPMIGDATE only applies when STORAGEGROUP(SGn) is specified, and as such, only applies to SMS managed data sets.

MIGRATIONLEVEL1: Specifying migration of a data set

Note: Required vs. Optional: The following explanation refers to the MIGRATIONLEVEL1 optional parameter. For the explanation of the MIGRATIONLEVEL1 required parameter, see [“MIGRATIONLEVEL1: Specifying migration of data sets from level 1 to level 2 volumes”](#) on page 958.

Explanation: **MIGRATIONLEVEL1** is an optional parameter when specifying the DATASETNAME(dsname) parameter. When you specify ML1 with dsname, the data set is migrated to the appropriate hierarchical level, as determined by the data set's management class.

Defaults: None.

MIGRATIONLEVEL2: Specifying migration of a data set directly to a level 2 volume

Explanation: **MIGRATIONLEVEL2** is an optional parameter specifying that a specific data set migrate from an SMS volume directly to a migration level 2 volume. You must specify the data set name with the DATASETNAME parameter to cause DFSMSHsm to migrate a specific data set directly to a migration level 2 volume.

An SMS-managed data set residing on an SMS volume or a migrated SMS-managed data set residing on a migration volume is migrated to a migration level 2 volume, regardless of the data set's management class attributes.

Defaults: None.

Note:

1. You must specify the MIGRATIONLEVEL2 parameter when you request that DFSMSHsm migrate a data set on a migration level 1 volume. DFSMSHsm migrates the data set to the type of migration level 2 volume that is consistent with your environment. For example, if you are in a tape migration environment, DFSMSHsm migrates the data set to a tape migration level 2 volume rather than a DASD migration level 2 volume. You specify the type of migration environment with the TAPEMIGRATION parameter of the SETSYS command.
2. The MIGRATIONLEVEL2 parameter is not necessary in a direct-to-tape environment.
3. The MIGRATIONLEVEL2 parameter can be used to override the management class attribute LEVEL-1-DAYS-NON-USAGE.

MIGRATIONONLY: Specifying that only migration of data sets should be processed

Explanation: **MIGRATIONONLY** is an optional parameter that you use to migrate all data sets, or a specific data set, from a level 0 volume to a migration level 1 or migration level 2. Data sets eligible for transition only will not be processed.

This parameter can be specified only with MIGRATE VOLUME or MIGRATE STORAGEGROUP command.

Defaults: None.

MOVE: Specifying that only moving of data sets should be processed

Explanation: **MOVE** is an optional parameter that you use to move all SMS-managed data sets from a level 0 volume to another level 0 volume. This parameter can be specified only with the MIGRATE VOLUME, MIGRATE STORAGEGROUP or MIGRATE DATASETNAME command.

The MOVE parameter invokes the ACS routines to determine the new volume to which a data set should be moved.

Defaults: None.

Note: When moving Db2 objects, DFSMSHsm must be authorized to the Db2 STOP and START commands.

TERMINAL: Requesting that volume space management messages appear at the terminal

Explanation: **TERMINAL** is an optional parameter specifying that all space management messages associated with the space management of a volume be sent to the system console and to the migration activity log.

Defaults: If you do not specify **TERMINAL** when you specify **MIGRATIONLEVEL1** or **VOLUME**, volume space management messages go only to the migration activity log.

Note: **TERMINAL** does not apply when you specify the **DATASETNAME** parameter. If you specify **TERMINAL** when it does not apply, DFSMSHsm ignores it.

TRANSITION: Specifying that only transitions of data set should be processed

Explanation: **TRANSITION** is an optional parameter that you use to transition eligible SMS-managed data sets from a level 0 volume to another level 0 volume.

The optional SMS subparameters of the **TRANSITION** parameter are:

MANAGEMENTCLASS

Specifies the target management class used for class transition processing. Alias: MC

STORAGECLASS

Specifies the target storage class used for class transition processing. Alias: SC

STORAGEGROUP

Specifies the target storage group list used for class transition processing. Up to 15 storage groups can be specified by this parameter. If **STORAGEGROUP** is specified with more than 15 storage groups, only the first 15 are processed. Alias: SG

Notes:

1. If the **TRANSITION** parameter is specified for a non-SMS managed data set, the command will be failed with the RC20 return code and the REAS38 reason code.
2. If the **TRANSITION** keyword for a data set that *cannot* be transitioned, the command will be failed with the RC20 return code and the REAS36 reason code.
3. If at least one SMS parameter is specified, then the specified value or values will be used and the ACS routines will not be called during class transition processing. The omitted values of management class, storage class or storage group will be taken from the data set's SMS construct.

Defaults: None.

TRANSITIONONLY: Specifying that only transition of data sets should be processed

Explanation:

TRANSITIONONLY

is an optional parameter that you use to transition all eligible SMS-managed data sets from a level 0 volume to another level 0 volume. Data sets eligible only for migration are not processed.

This parameter can be specified only with **MIGRATE VOLUME** or **MIGRATE STORAGEGROUP** command.

The optional SMS subparameters of the **TRANSITIONONLY** parameter are:

MANAGEMENTCLASS

Specifies the target management class used for class transition processing. Alias: MC

STORAGECLASS

Specifies the target storage class used for class transition processing. Alias: SC

STORAGEGROUP

Specifies the target storage group list used for class transition processing. Up to 15 storage groups can be specified by this parameter. If STORAGEGROUP is specified with more than 15 storage groups, only the first 15 are processed. Alias: SG

Defaults: None.

Note: If at least one SMS parameter is specified, then the specified value or values are used and the ACS routines are not called during class transition processing. The omitted values of management class, storage class, or storage group are taken from the data set's SMS construct.

Examples of how to code the MIGRATE command for SMS-managed data sets

The following examples present different ways to code the MIGRATE command.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Migration of eligible data sets from a specified volume

In this example, migration is requested for all eligible data sets on the specified volume. Eligibility is determined by each data set's management class.

```
MIGRATE VOLUME(SMS003)
```

Removing all data sets eligible to migrate from an SMS-managed level 0 volume

The following command migrates all eligible data sets from the specified volume. Those data sets meeting their management class expiration attribute values are expired.

```
MIGRATE VOLUME(SMS003) CONVERT
```

Performing class transitions for all eligible data sets in a storage group

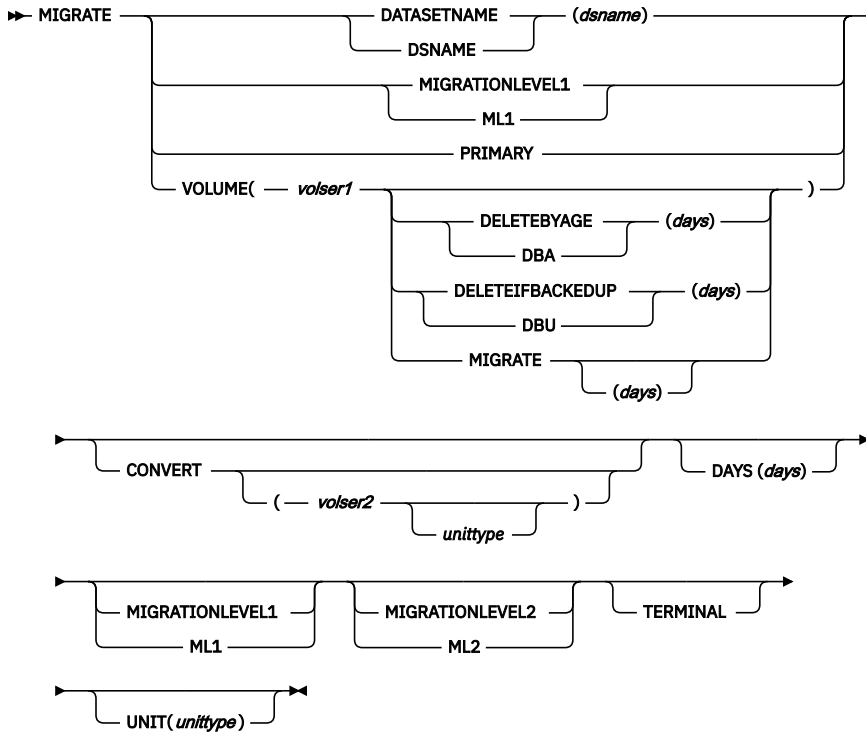

The following command performs class transitions for all eligible data sets in the specified storage group. The TRANSITIONONLY keyword specifies that only class transitions are performed, and no migrations.

```
MIGRATE STORAGEGROUP(STG004) TRANSITIONONLY
```

Requesting a space management function for non-SMS-managed data sets

Use the MIGRATE command to request that DFSMSHsm migrate eligible non-SMS data sets from ML1 volumes, primary volumes, or a specific volume. You can also use this command to migrate a specific data set.

Syntax of the MIGRATE command for non-SMS-managed data sets

Note: You must specify either DATASETNAME, PRIMARY, MIGRATIONLEVEL1, or VOLUME with each MIGRATE command.

Summary of parameters

The following table is a summary of the combination of parameters you can specify with the MIGRATE command. Specifying other combinations of parameters results in either an error message or one or more of the parameters being ignored.

Parameter	Related Parameters
CONVERT	UNIT VOLUME (MIGRATE)
DATASETNAME	CONVERT MIGRATIONLEVEL2
DAYS	MIGRATIONLEVEL1 VOLUME MIGRATE
MIGRATIONLEVEL1	DAYS TERMINAL
MIGRATIONLEVEL2	DATASETNAME
PRIMARY	TERMINAL
VOLUME	CONVERT TERMINAL UNIT

Required parameters of the MIGRATE command for non-SMS-managed data sets

This topic describes the required parameters of the MIGRATE command.

DATASETNAME: Specifying migration of a specific data set

Explanation: **DATASETNAME(*dsname*)** is the required parameter to migrate a specific cataloged data set. When you specify this parameter, DFSMSHsm migrates the cataloged data set without checking whether the data set has met the requirements for migration (such as minimum migration age). For *dsname*, substitute the fully qualified name of the data set you want to migrate. You cannot specify an alias for *dsname*. If you do, DFSMSHsm does not migrate the data set.

Defaults: None.

Note:

1. DFSMSHsm does not handle partitioned data set members individually. If you specify a member name of a partitioned data set, DFSMSHsm processes the entire partitioned data set.
2. The volume where the data set resides must be mounted before you issue the MIGRATE command.

MIGRATIONLEVEL1: Specifying migration of data sets from level 1 to level 2 volumes

Note: Required vs. Optional: The following explanation refers to the MIGRATIONLEVEL1 required parameter. For the explanation of the MIGRATIONLEVEL1 optional parameter see [“MIGRATIONLEVEL1: Specifying migration of a data set directly to appropriate level of hierarchy” on page 970.](#)

Explanation: **MIGRATIONLEVEL1** is the required parameter to migrate eligible data sets from all migration level 1 volumes to migration level 2 volumes.

When you specify MIGRATIONLEVEL1 for non-SMS-managed data sets, two conditions apply:

- If you also specify DAYS(*days*), DFSMSHsm migrates non-SMS-managed data sets based on the *days* value.
- If you do not specify DAYS(*days*), DFSMSHsm migrates non-SMS-managed data sets based on the current DFSMSHsm value for the MIGRATIONLEVEL1DAYS parameter of the SETSYS command.

Defaults: None.

Note:

1. If you specify this parameter in a direct-to-tape environment, the command fails.
2. If you specify this parameter when level 1 to level 2 migration of automatic secondary space management is run, the command fails.

PRIMARY: Specifying space management of eligible data sets on all primary volumes

Explanation: **PRIMARY** is the required parameter to migrate or delete eligible data sets on all primary volumes, depending on the space management technique for each volume. You specify the space management technique with the ADDVOL command. When you specify this parameter, DFSMSHsm processes all primary volumes, not just primary volumes with the primary volume attribute of automatic space management. You specify the primary volume attributes with the ADDVOL command.

Defaults: None.

VOLUME: Specifying the space management attribute for the eligible data sets on a volume

Explanation: **VOLUME(*volser1*)** is the required parameter to specify migration, data set deletion, or data set retirement for eligible data sets on one volume. Eligible data sets on a volume not managed by DFSMSHsm or SMS can migrate or be scratched if you specify the UNIT parameter. Information for any volume migration or data set deletion is printed in the migration activity log. Eligible data sets on a volume can be scratched after they have been inactive for the number of days you specified.

For *volser1*, substitute the serial number of the level 0 volume from which you want to migrate or delete eligible data sets.

The MIGRATE command fails if the command is specified with a single migration level 1 or migration level 2 volume and the MIGRATE optional parameter is either specified on the command or is the default. This function is allowed only by using the FREEVOL command.

Subparameter	Explanation
DELETEBYAGE (<i>days</i>)	The data sets on the volume are scratched if they have been inactive for the number of days you specified. If you specify DELETEBYAGE, the eligible data sets are scratched even if they do not have backup versions; however, if the expiration date of the data set has not been reached, DFSMSHsm does not delete the data set. For <i>days</i> , substitute a decimal number from 0 to 999. For example, if you substitute 10 for <i>days</i> , DFSMSHsm scratches those data sets that have not been referred to for 10 days.
DELETEIFBACKEDUP (<i>days</i>)	<p>The data sets on the volume are scratched if they have been inactive for the number of days you specified. The data set, however, must have a current backup version before DFSMSHsm can scratch it from the volume. A backup version is current if it was created on a date after the data set was last referenced. For <i>days</i>, substitute a decimal number from 1 to 999. For example, if you substitute 25 for <i>days</i>, DFSMSHsm scratches those data sets that have not been referred to for at least 25 days and that have current backup versions.</p> <p>DFSMSHsm can do data set deletion or data set retirement on any primary or migration volume. The migration level 2 volume can be tape or DASD.</p>

Subparameter	Explanation
MIGRATE	<p>All eligible data sets migrate from the specified level 0 volume to a migration level 1 volume or tape migration level 2 volume. The migration level used is determined by the SETSYS TAPEMIGRATION command. For <i>days</i>, substitute a decimal number from 0 to 999. For example, if you substitute a 5, DFSMSHsm migrates those data sets that have not been referred to for 5 days. This value is called the minimum migration age.</p> <p>When you request migration from a primary volume, the following conditions apply:</p> <ul style="list-style-type: none"> • If you specify the MIGRATE(<i>days</i>) subparameter, DFSMSHsm migrates the data sets based on the minimum migration age you specify with <i>days</i>. DFSMSHsm ignores any thresholds of occupancy for the volume. • If you do not specify the MIGRATE(<i>days</i>) subparameter, two conditions apply: <ul style="list-style-type: none"> – If you defined thresholds of occupancy with the ADDVOL command, DFSMSHsm migrates the data sets (starting with the oldest) until the low threshold of occupancy is reached or until DFSMSHsm finds a data set whose inactive age is less than the minimum migration age. You specified this minimum migration age with the ADDVOL or SETSYS command. – If you did not define thresholds of occupancy, DFSMSHsm migrates the data sets based on the minimum migration age specified with the MIGRATE(<i>days</i>) parameter of the ADDVOL command. If you did not specify the minimum migration age with the ADDVOL command, DFSMSHsm uses the current minimum migration age from the DAYS parameter of the SETSYS command.

Defaults: If you do not specify one of the MIGRATE, DELETEIFBACKEDUP, or DELETEBYAGE subparameters, DFSMSHsm uses the space management technique you specified in the ADDVOL command.

Note:

1. If you specify a volume that you have not added to DFSMSHsm with the ADDVOL command, you must also specify the UNIT parameter.
2. If you specify a tape migration level 2 volume and the MIGRATE subparameter, the command fails. To move data sets from a tape migration level 2 volume to another tape migration level 2 volume, use the RECYCLE command.
3. If the MIGRATE subparameter of the VOLUME parameter is specified on the MIGRATE command for a DASD migration level 1 volume, the command will fail, and an error message is issued. The migrate space management function for a DFSMSHsm migration level 1 DASD volume is supported only by using the FREEVOL command.

Optional parameters of the MIGRATE command for non-SMS-managed data sets

This topic describes the optional parameters of the MIGRATE command.

CONVERT: Specifying movement of data sets from one volume to another

Explanation: **CONVERT** is an optional parameter that you use to migrate all data sets, only aged data sets, or a specific data set from a level 0 volume to a migration level 1 volume and then immediately recall

those data sets to another level 0 volume. You can use this parameter when you want to remove a volume from the system. For example, you can use this parameter to move data sets from a 3380 volume to a 3390 volume.

For *volser2*, specify the volume where DFSMSHsm is to recall the data set. For *unittype2*, specify the type of unit where DFSMSHsm is to mount the target volume. If you do not specify *volser2*, DFSMSHsm selects the target volume the same way it normally selects target volumes during recall. If you use the *volser2* subparameter to specify a volume not managed by DFSMSHsm, you must also specify the *unittype2* subparameter.

In addition, when you specify MIGRATE(0), DFSMSHsm can process types of data sets that it does not normally process during migration. These are:

- Cataloged list and utility data sets that cannot be scratched because they have been referred to too recently.
- Data sets that have temporarily been marked as not able to be migrated because a job in a JES3 system planned to use them.

Note: In a JES3 system, two jobs could use the same data set at the same time if you submit one job before the conversion is done and you submit the second job after the conversion. Therefore, ensure that no jobs are waiting to run if those jobs use the data sets on the volume being converted.

Defaults: For cataloged data sets, you do not have to specify *volser2* or *unittype2*. If you do not specify these values, DFSMSHsm chooses the volume and type of unit.

Note:

1. The space management technique must be migration. You can specify the MIGRATE subparameter of the VOLUME parameter, the MIGRATE parameter of the ADDVOL command, or use the default of migration on the ADDVOL command.
2. To prevent the source volume from being selected as the target volume for recall, specify the NOAUTORECALL parameter of the ADDVOL command for the source volume until the migration finishes.
3. If you want DFSMSHsm to convert all data sets on a level 0 volume, you must also specify the MIGRATE(0) subparameter of the MIGRATE command. If, however, you used the SETMIG command to specify the DATASETNAME, LEVEL, or VOLUME parameter with the NOMIGRATION parameter, DFSMSHsm will not migrate the specified entry when you specify the CONVERT parameter even if you also specified the MIGRATE(0) parameter. For example, if you specified SETMIG LEVEL(USER) NOMIGRATION, those data sets with the first qualifier of USER do not migrate from the primary volume.
4. If you specify the CONVERT parameter in a direct-to-tape environment, the command fails.
5. You can use the CONVERT parameter with the UNIT parameter if you want to convert non-SMS-managed volumes not managed by DFSMSHsm to volumes managed by DFSMSHsm.
6. VSAM data sets created on the same day that the MIGRATE VOLUME (MIGRATE(0)) CONVERT command was issued are not migrated because of a data integrity exposure.

DAYS: Specifying migration eligibility of data sets

Explanation: **DAYS(days)** is an optional parameter specifying how many consecutive days that data sets on migration level 1 volumes are to remain inactive before they are eligible for migration. For *days*, substitute a decimal number from 0 to 999.

Defaults: If you do not specify DAYS(days), DFSMSHsm migrates the data sets from the volume based on the current DFSMSHsm value for the MIGRATIONLEVEL1DAYS parameter of the SETSYS command.

Note: The DAYS(days) parameter can be used for non-SMS level 0 volumes and has the same meaning as if it was specified using the VOLUME(volser MIGRATE(days)) method. See the VOLUME parameter for a description of the parameter. If both DAYS(days) and VOLUME(volser MIGRATE(days)) are specified, the VOLUME(volser MIGRATE(days)) value is used.

MIGRATIONLEVEL1: Specifying migration of a data set directly to appropriate level of hierarchy

Note: Required vs. Optional: The following explanation refers to the MIGRATIONLEVEL1 optional parameter. For the explanation of the MIGRATIONLEVEL1 required parameter, see [“MIGRATIONLEVEL1: Specifying migration of data sets from level 1 to level 2 volumes”](#) on page 966.

Explanation: **MIGRATIONLEVEL1** is an optional parameter that can be used with the DATASETNAME(dsname) parameter. When you specify ML1 with dsname, the data set will be migrated to the appropriate hierarchical level, as determined by the SETSYS TAPEMIGRATION parameter.

Defaults: None.

MIGRATIONLEVEL2: Specifying migration of a data set directly to a level 2 volume

Explanation: **MIGRATIONLEVEL2** is an optional parameter specifying that a specific data set migrate from a primary volume directly to a migration level 2 volume. You must specify the data set name with the DATASETNAME parameter to cause DFSMSHsm to migrate a specific data set.

Defaults: None.

Note:

1. You must specify the MIGRATIONLEVEL2 parameter when you request that DFSMSHsm migrate a data set on a migration level 1 volume. DFSMSHsm migrates the data set to the type of migration level 2 volume that is consistent with your environment. For example, if you are in a tape migration environment, DFSMSHsm migrates the data set to a tape migration level 2 volume rather than to a DASD migration level 2 volume. You specify the type of migration environment with the TAPEMIGRATION parameter of the SETSYS command.
2. The MIGRATIONLEVEL2 parameter is not necessary in a direct-to-tape environment.

TERMINAL: Requesting that volume space management messages appear at the terminal

Explanation: **TERMINAL** is an optional parameter specifying that all space management messages associated with the space management of a volume be sent to the system console and to the migration activity log.

Defaults: If you do not specify TERMINAL when you specify MIGRATIONLEVEL1, PRIMARY, or VOLUME, volume space management messages go only to the migration activity log.

Note: TERMINAL does not apply when you specify the DATASETNAME parameter. If you specify TERMINAL when it does not apply, DFSMSHsm ignores it.

UNIT: Specifying the type of device

Explanation: **UNIT(unittype)** is an optional parameter specifying the type of unit where DFSMSHsm can allocate the nonmanaged source volume.

For *unittype*, substitute the type of unit where DFSMSHsm can allocate the volume.

The following are valid types of DASD units:

- 3380
- 3390
- 9345

Defaults: None.

Note:

1. You must specify the UNIT parameter if the volume you specify is not managed by DFSMSHsm.
2. DFSMSHsm ignores the UNIT parameter if you specify the MIGRATIONLEVEL1 or DATASETNAME parameters.

Examples of how to code the MIGRATE command for non-SMS-managed data sets

The following examples show different ways to code the MIGRATE command.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Migration of all the data sets from a volume

In this example, migration is requested for all the data sets on the primary volume.

```
MIGRATE VOLUME( PRIM03 MIGRATE(0) )
```

The following command also migrates all data sets from a primary volume:

```
MIGRATE VOLUME( PRIM01 ) DAYS(0)
```

Migration of data sets based on the number of elapsed days since the data set was last referred to

In this example, migration is requested for data sets that reside on the primary volume and have not been referred to for at least five days.

```
MIGRATE VOLUME( PRIM01 MIGRATE(5) )
```

Direct migration of a data set to a level 2 volume

In this example, the specified data set migrates directly to a migration level 2 volume.

```
MIGRATE DATASETNAME( FET7603.JOB33.LOAD ) MIGRATIONLEVEL2
```

Migration of data sets from a volume not managed by DFSMSHsm

In this example, migration is attempted for all the data sets that meet the DAYS criterion of the SETSYS command and reside on a volume not managed by DFSMSHsm.

```
MIGRATE VOLUME( MSS004 ) UNIT(3390)
```

Data set deletion of eligible data sets on a volume

In this example, all eligible data sets on the primary volume that have not been referred to for at least 20 days and whose expiration dates have been reached are scratched.

```
MIGRATE VOLUME( VOL005 DELETEBYAGE(20) )
```

Moving all data sets from a volume not managed by DFSMSHsm to primary volumes

In this example, all DFSMSHsm-supported data sets on a volume not managed by DFSMSHsm move to primary volumes that allow automatic recall.

```
MIGRATE VOLUME(VOL081 MIG(0)) UNIT(3390) CONVERT
```

Moving all data sets from a primary volume

In this example, you want to remove all data sets from a primary volume.

```
MIGRATE VOLUME(ONVOL MIG(0)) CONVERT
```

Moving data sets from a primary volume to another primary volume

In this example, the volume was added to control of DFSMSHsm with the space management technique of MIGRATE. The target volume is a volume managed by DFSMSHsm. All supported data sets that have not been referred to in the last five days are moved from the 3380 volume (USER80) to the target 3390 volume (NEW90).

```
MIGRATE VOLUME(USER80 MIGRATE(5)) CONVERT(NEW90)
```

Moving one data set from one primary volume to another primary volume

In this example, one data set is moved from a volume to another primary volume without setting up an IEHMOVE utility job.

```
MIGRATE DATASETNAME(MYDS) CONVERT
```

You could issue this command to cause extent reduction or to move this data set from a full volume to another volume whose free space is in less demand.

Migration of data sets from all migration level 1 volumes

In this example, migration is requested for the data sets on all migration level 1 volumes that have not been referred to for at least two days.

```
MIGRATE MIGRATIONLEVEL1 DAYS(2)
```

Data set deletion of a tape migration level 2 volume

In this example, data set deletion is requested for the data sets on a tape migration level 2 volume that have not been referred to for 30 days and whose expiration dates have been reached.

```
MIGRATE VOLUME(M2TP04 DELETEBYAGE(30))
```

Data set retirement of a migration level 1 volume

In this example, data set retirement is requested for the data sets on a migration level 1 volume that have not been referred to for 45 days and that have a current backup version.

```
MIGRATE VOLUME(ML1003 DELETEIFBACKEDUP(45))
```

Chapter 56. ONLYIF command: Running commands in ARCCMDxx conditionally

The ONLYIF command allows a single command or group of commands contained within a BEGIN ... END block, immediately following the ONLYIF command, to be run conditionally depending on the host specified. An ONLYIF command cannot follow another ONLYIF command and it cannot be nested within a BEGIN ... END block.

The following examples apply to all supported keywords on the ONLYIF statement. This includes HSMHOST, SYSNAME and HMSYM.

Text on the line immediately following an ONLYIF command is run as the conditional command. That is, if the line is blank or commentary, it is considered the command to be run. For example, the comment after the ONLYIF command is considered for processing, not the command (*command1*). The command applies to all hosts.

```
ONLYIF HSMHOST(hostID1)
/* The following command is issued on all hosts. */
command1
```

To avoid this error, use a continuation character to join the comment to the command. For example:

```
ONLYIF HSMHOST(hostID1)
/* The following command is issued on hostID1 only. */ +
command1
```

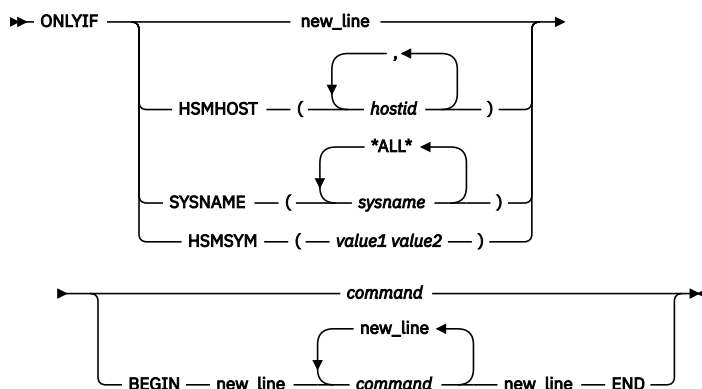

Or, surround multiple lines with BEGIN and END. For example:

```
ONLYIF HSMHOST(hostID1,hostID2)
BEGIN
/* The following commands are issued for hostID1 and hostID2 only. */
command1
command2
END
```

Related reading

For more information about the commands you can specify in the DFSMSHsm SYS1.PARMLIB member ARCCMDxx, see [z/OS DFSMSHsm Implementation and Customization Guide](#).

Syntax of the ONLYIF command

Required parameters of the ONLYIF command

This topic describes the required parameter of the ONLYIF command.

Topic

[“HSMHOST: Specifying the host ID of a specific host or hosts” on page 974](#)

[“SYSNAME: Specifying the system name where the next line should be processed” on page 974](#)

[“HMSYM: Specifying the HSM system symbol and its value where the next line should be processed” on page 974](#)

HSMHOST: Specifying the host ID of a specific host or hosts

Explanation

HSMHOST(*hostid*, *hostid*, ...) is a required parameter used to specify the host ID for the DFSMSHsm host on which the command or BEGIN ... END block should be run. The parameter variable is explained:

hostid

Single character host ID of the DFSMSHsm host. The host ID is specified by the HOST keyword in the PROC statement used to start DFSMSHsm. Multiple host IDs are separated by a comma.

Defaults

None.

SYSNAME: Specifying the system name where the next line should be processed

Explanation

SYSNAME is a required parameter used to specify the system name on which the command on the next line, or a BEGIN ... END block, should be run, if the system HSM is initialized on matches this system name. Valid values are 1-8 character names or the reserved string *ALL*. The system name is defined by the SYSNAME parameter in the IEASYMxx or IEASYSxx PARMLIB members.

Defaults

If the keyword is not specified or *ALL* is specified, the next line is processed on all systems.

HMSYM: Specifying the HSM system symbol and its value where the next line should be processed

Explanation

HMSYM is a required parameter used to perform a comparison of a user defined system symbol, *value1*, and its current value to the literal *value2* specification.

value1, *value2*

These values specify the system symbol and the literal value that is checked to match the current value set in the system for this symbol. The command on the next line, or a BEGIN...END block, should be run if the literal value for this keyword matches the system setting for it. The system symbol must be between 1-44 characters long. The values must adhere to standard system symbolic syntax rules for defining static system symbols. The system symbol and its current value is defined by the SYSDEF SYMDEF command of the IEASYMxx parmlib member.

Defaults

None.

Optional parameters of the ONLYIF command

This topic describes the optional parameters of the ONLYIF command.

BEGIN: Begin a group of commands

Explanation

BEGIN is an optional parameter (or operator) that is specified on a new line immediately following the ONLYIF command. All commands following the BEGIN parameter to the next END parameter are conditionally issued as a group.

Defaults

None.

END: End a group of commands

Explanation

END is an optional parameter (or operator) which marks the end of a group of commands started by the BEGIN parameter. The END parameter must be specified on a new line immediately following the last conditional command.

Defaults

None.

Examples of how to code the ONLYIF command

The following examples present how to code the ONLYIF command.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

The following examples apply to all supported keywords on the ONLYIF statement. This includes HSMHOST, SYSNAME and HSMSYM.

Specifying a different HSMPLEXNAME in an HSM configuration for a production system and a disaster recovery exercise system that both share the same SYSNAME and the same DFSMSHsm parmlib member

In this example, an HSM system symbol HSMSYS is set to PROD on the production system and DR for the disaster recovery system. These system symbols are defined by statements in the IEASYMxx parmlib. When DFSMSHsm is started on the production system, the HSMSYS symbol resolves to PROD which matches its second literal value of PROD on the first ONLYIF HSMSYM command. In this case, the ONLYIF evaluates to be true and the subsequent statement is executed. Additional statements between the BEGIN/END keywords can be added to conditionally be run. The second ONLYIF HSMSYM evaluates not to be true since it is looking for a value of DR and the subsequent statement, and only that statement, is skipped.

```

ONLYIF HSMSYM(&HSMSYS PROD)
BEGIN
  SETSYS HSMPLEXNAME(PROD)
END
ONLYIF HSMSYM(&HSMSYS DR)
  SETSYS HSMPLEXNAME(DR)

```

Specifying different start and stop times for automatic primary space management for 2 hosts

In this example, DFSMSHsm host HSM1 is configured with a planned start time for automatic primary space management at 4:00 a.m. and the quiesce time is 7:30 a.m. DFSMSHsm host HSM2 is configured with a planned start time for automatic primary space management at 9:00 a.m. and the quiesce time is 11:00 a.m.

```

ONLYIF HSMHOST(HSM1)
  SETSYS PRIMARYSPMGMTSTART(400 730)
ONLYIF HSMHOST(HSM2)
  SETSYS PRIMARYSPMGMTSTART(900 1100)

```

Specifying different maximum number of tasks DFSMSHsm can concurrently process for several hosts

In this example, DFSMSHsm host HSM1 can have a maximum of 7 automatic volume space management tasks that can run concurrently and a maximum of 5 volume backup tasks that can run concurrently. All other hosts can have a maximum of 3 automatic volume space management tasks that can run concurrently and a maximum of 9 volume backup tasks that can run concurrently.

```

SETSYS MAXMIGRATIONTASKS(3) MAXBACKUPTASKS(9)
ONLYIF HSMHOST(HSM1)
  SETSYS MAXMIGRATIONTASKS(7) MAXBACKUPTASKS(5)

```

Specifying continuation characters for commands with several parameters

In this example, all DFSMSHsm hosts (host HSM1) will have the following attributes:

- a maximum of 1 automatic volume space management task.
- when small data sets migrate, they are not packed into predefined VSAM key-sequenced small-data-set-packing data sets on a migration level 1 volume.
- interval migration is not performed.
- a maximum of 2 recall tasks can run concurrently.
- a maximum of 1 tape recall task that can request tape mounts.

Host HSM1 will have these attributes:

- a maximum of 3 automatic volume space management tasks can run concurrently.
- when small data sets migrate, they are eligible to be packed into predefined VSAM key-sequenced small-data-set-packing data sets on a migration level 1 volume.
- interval migration is performed.
- a maximum of 8 recall tasks can run concurrently.
- a maximum of 4 tape recall tasks that can concurrently request tape mounts.

```

SETSYS MAXMIGRATIONTASKS(1) NOSMALLDATASETPACKING NOINTERVALMIG +
  MAXRECALLTASKS(2) TAPEMAXRECALL(1)
ONLYIF HSMHOST(HSM1)
  SETSYS MAXMIGRATIONTASKS(3) SMALLDATASETPACKING INTERVALMIG +
    MAXRECALLTASKS(8) TAPEMAXRECALL(4)

```

Specifying various commands within ARCCMDxx using ONLYIF

In this example, DFSMSHsm host HSM1 runs automatic backup on weekdays (Monday through Friday) and the cycle is started or reset on January 3, 1994 (Monday). Host HSM2 runs automatic backup on Saturday only and the cycle is started or reset on January 3, 1994 (Monday). Host HSM3 prevents all DFSMSHsm functions from running.

```
ONLYIF HSMHOST(HSM1)
  DEFINE BACKUP( YYYYYNN -      /* run backup on weekdays only */
    CYCLESTARTDATE(1994/01/03) /* cycle defined on a Monday */
ONLYIF HSMHOST(HSM2)
  DEFINE BACKUP( NNNNNYN -      /* run backup only on Saturdays */
    CYCLESTARTDATE(1994/01/03) /* cycle defined on a Monday */
ONLYIF HSMHOST(HSM3)
  HOLD ALL                      /* functions held on test system */
```

Specifying that automatic dump only run on three hosts

In this example, the SETSYS and DEFINE commands to set up automatic dump are ran on DFSMSHsm hosts HSM1, HSM2, and HSM3 only.

Note: The indentation of lines between the BEGIN and END parameters is for ease of reading only, and is not required.

```
ONLYIF HSMHOST(HSM1,HSM2,HSM3)
BEGIN
  SETSYS AUTODUMPSTART(0300 0400 0500)
  SETSYS BACKUP(TAPE)
  SETSYS MAXDUMPTASKS(3)
  DEFINE BACKUP(Y)
  DEFINE DUMPCYCLE(Y)
  DEFINE DCLASS(DCLASS1 DATASETRESTORE FREQ0)
END
```

Chapter 57. PATCH command: Modifying storage within DFSMSHsm

The PATCH command is to be used only for maintenance purposes and is explained in the [*z/OS DFSMSHsm Diagnosis*](#).

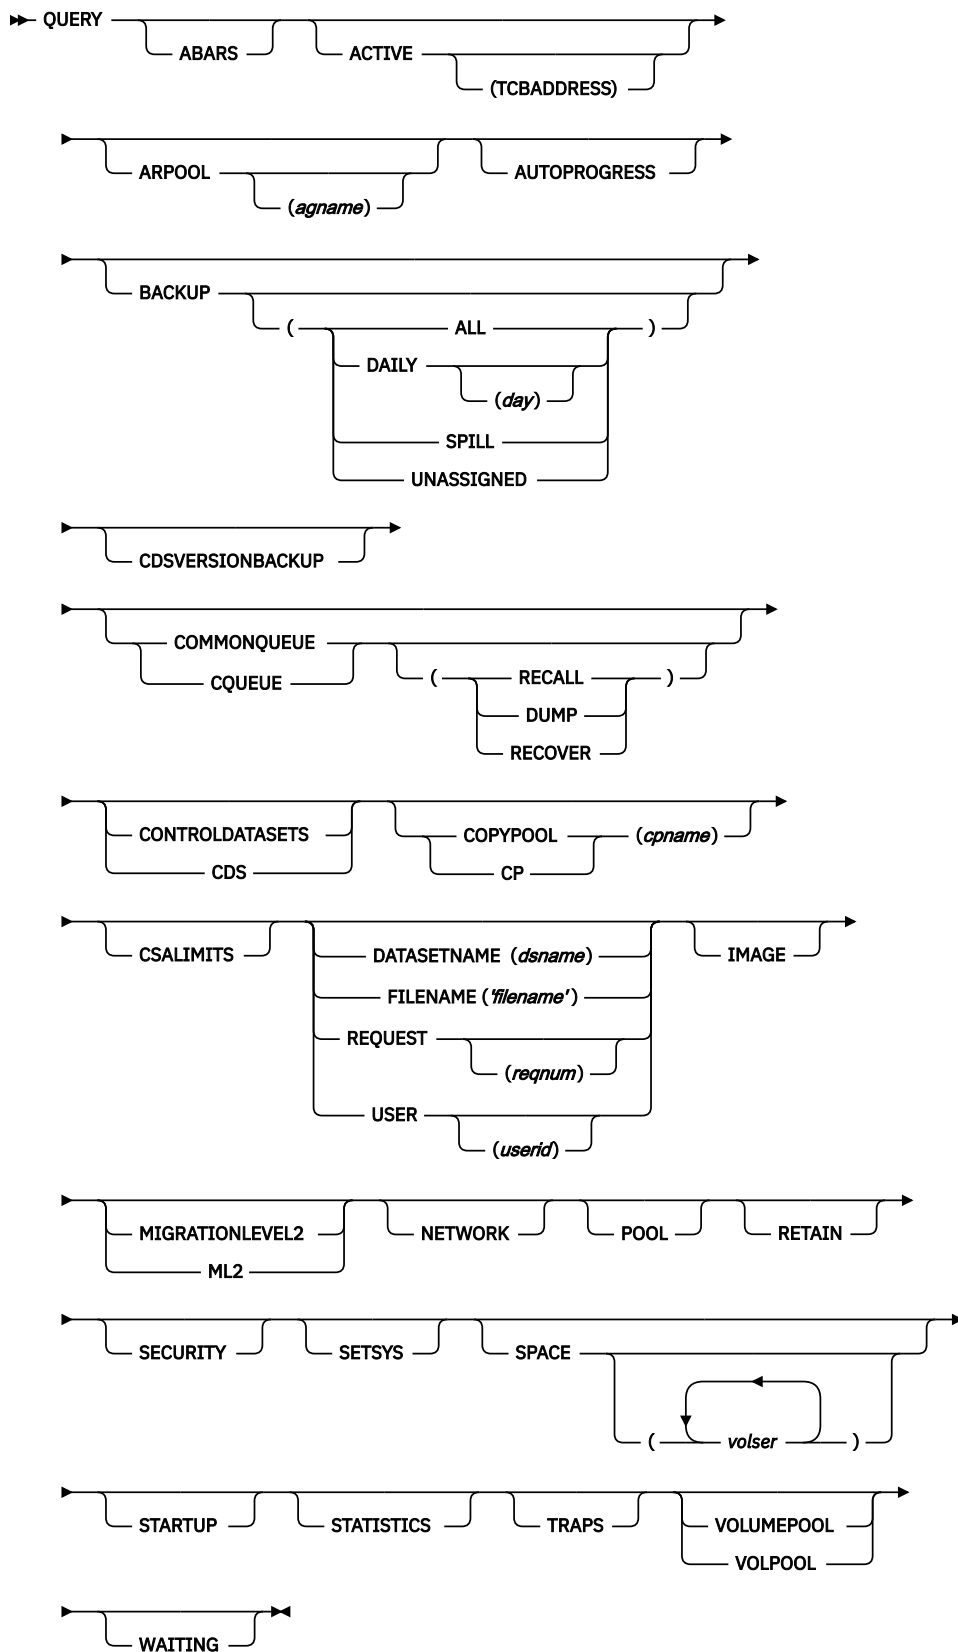

Chapter 58. QUERY command: Displaying the status of parameters, statistics, and requests

The QUERY command can do the following tasks:

- Determine the DFSMSHsm control parameters (SETSYS).
- Determine the DFSMSHsm control parameters that apply to aggregate backup and recovery (ABARS).
- Request a list of DFSMSHsm statistics (STATISTICS).
- Determine the status of pending DFSMSHsm requests (WAITING).
- Request volume space-use information (SPACE).
- Request control data set space-use information (CONTROLDATASETS).
- Determine whether multiple backup data set support is enabled (CDSVERSIONBACKUP).
- Request the common service area storage limits (CSALIMITS).
- Request the status of each DFSMSHsm volume and data set subtask, each long-running command, and what each active one is doing (ACTIVE).
- Request a list of recall pools (POOL).
- Request a list of volumes defined to be used during aggregate recovery processing (ARPOOL).
- Request a list of the backup parameters and backup volumes (BACKUP).
- Request a list of the source volume serial numbers for any volumes in a specified copy pool that have an outstanding FlashCopy relationship (COPYPOOL).
- Request a list of selected DFSMSHsm requests (DATASETNAME|REQUEST|USER).
- Request a list of the DFSMSHsm address spaces that are active on the z/OS image (IMAGE).
- Request a list of key ranges and associated DASD ML2 volumes, and tape ML2 volumes (MIGRATIONLEVEL2).
- Request a list of the first qualifiers of data sets excluded from space management (RETAIN).
- Determine whether access to DFSMSHsm commands is controlled using the RACF FACILITY class or the AUTH command (SECURITY).
- Determine the parameters specified when DFSMSHsm was started (STARTUP).
- Request a list of trap requests specified with the TRAP command (TRAPS).
- Request a list of current volume pools (VOLUMEPOOL).
- Request a list that indicates the number of volumes that have not been processed and the total volumes eligible to be processed. This list can be used to indicate how much work remains to be done for an automatic function currently in progress (AUTOPROGRESS).
- Request percent full information for the common queue (COMMONQUEUE).
- Request percent full, outstanding recall requests, and recall requests that are currently being processed in the common recall queue (COMMONQUEUE(RECALL)).
- Request outstanding and active dump or recover requests that are being processed in a common dump queue or common recover queue.
- Request information concerning cloud endpoints DFSMSHsm knows about (NETWORK).

For more information about the messages associated with the QUERY command, see [Chapter 77, “Using the QUERY command,”](#) on page 1389.

Syntax of the QUERY command

Note:

1. You must specify at least one of the optional parameters to have anything displayed.

2. Any QUERY command issued within the startup procedure may not always produce correct data because DFSMSHsm is not yet completely initialized.
3. The SPACE parameter is not supported for SMS-managed volumes.
4. The QUERY command does not support sending the results of the query to an output data set; however, it does support extended consoles. Using TSO/E extended consoles, you can submit programs that can issue a console command, such as a QUERY, and get the results back for interpretation. DFSMSHsm provides a sample REXX program called QUERYSET in SYS1.SAMPLIB(ARCTOOLS). For more details, refer to [z/OS TSO/E REXX Reference](#).

Optional parameters of the QUERY command

This topic describes the optional parameters of the QUERY command.

ABARS: Displaying aggregate backup and recovery control parameters

Explanation: **ABARS** is an optional parameter requesting a list of the DFSMSHsm control parameters that apply to aggregate backup and recovery. These control parameters are:

- ABARSACTLOGMSGLVL
- ABARSACTLOGTYPE
- ABARSBUFFERS
- ABARSDELETEACTIVITY
- ABARSOPTIMIZE
- ABARSTAPES
- ABARSPROCNAME
- ABARSUNITNAME
- ABARSVOLCOUNT
- ARECOVERML2UNIT
- ARECOVERPERCENTUTILIZED
- ARECOVERTGTGDS
- ARECOVERUNITNAME
- MAXABARSADDRESSSPACE

Defaults: None.

ACTIVE: Displaying all active requests

Explanation: **ACTIVE** is an optional parameter requesting the status of each DFSMSHsm volume, data set subtask, and long-running command, and what each active one is doing.

TCBADDRESS is an optional subparameter of **ACTIVE** requesting only messages directly related to data movement activities be listed, along with extra information allowing cancellation of the active task.

To aid in virtual storage constraint relief (VSCR), the active parameter will display the amount of virtual storage (above and below the 16M line) that is unallocated and available to DFSMSHsm. The two largest free areas are shown to indicate the level of fragmentation.

Defaults: None.

Note: In a common recall, dump, or recover queue environment, only recall requests from the host that is issuing the QUERY ACTIVE command are returned.

ARPOOL: Displaying aggregate recovery pools

Explanation: **ARPOOL** is an optional parameter requesting a list of the aggregate recovery pools as specified with the DEFINE ARPOOL command.

If *agname* is specified, the pool for that *agname* and the associated volume serial numbers are listed. If *agname* is not specified, all pools and the volume serial numbers for each pool are listed. If the DEFINE ARPOOL was not previously issued or was issued with the ALL, LOVOLS(*), or ML1VOLS(*) parameters, then a message is issued indicating this. A list of the currently ADDVOLed ML1 and primary volumes is also displayed.

Defaults: None.

AUTOPROGRESS: Displaying an indication of volumes to be processed

Explanation: **AUTOPROGRESS** is an optional parameter you can specify to request information about the number of volumes to be processed. You can get an indication of the number of volumes that have not been processed by an automatic function and the total number of volumes that are eligible for processing by an automatic function. For each automatic function that is processing DFSMSHsm-managed volumes on the host where the QUERY AUTOPROGRESS command is issued, the following is reported:

- The number of eligible SMS-managed volumes restricted to this DFSMSHsm host that have not been processed. *Restricted to this DFSMSHsm host* means that the storage group with which a volume is associated specifies processing for this function only by the host in which the QUERY AUTOPROGRESS command was issued.
- The total number of eligible SMS-managed volumes restricted to this DFSMSHsm host. *Restricted to this host* means that the storage group with which a volume is associated specifies processing for this function only by the DFSMSHsm host in which the QUERY AUTOPROGRESS command was issued.
- The number of eligible SMS-managed volumes that are not restricted to processing by any DFSMSHsm host and have not been processed by this function.
- The total number of eligible SMS-managed volumes that are not restricted to processing by any DFSMSHsm host.
- The number of eligible non-SMS-managed volumes that have not been processed by this function.
- The total number of non-SMS-managed volumes that are eligible for processing by this function in this DFSMSHsm host.
- The number of copy pools and copy pool volumes that remain to be processed by auto dump.

When QUERY AUTOPROGRESS is used, DFSMSHsm displays the information for each automatic function currently processing DFSMSHsm-managed volumes. If no automatic functions are processing, DFSMSHsm indicates this with message ARC0246I.

Note:

1. The count of volumes that remain to be processed may not reflect another processing unit's activity. A volume that is eligible for processing by multiple-DFSMSHsm-hosts may have been processed in a DFSMSHsm host other than the one where the QUERY AUTOPROGRESS command was issued. If the DFSMSHsm host running the QUERY AUTOPROGRESS command has not detected that another DFSMSHsm host has processed a volume, that volume is included in the count of volumes that have not been processed.
2. A volume is considered *eligible* if it is defined (via the Storage Group for SMS-managed volumes or the ADDVOL command for non-SMS-managed volumes) as being eligible to be processed by this DFSMSHsm host for the active function. For Interval Migration, eligible volumes are only the ones that are above their associated threshold level.
3. A volume is considered *not processed* when both the following conditions are true:
 - The volume is not currently being processed by the active function.
 - The minimum time has elapsed since the last time the associated automatic function processed the volume.

Defaults: None.

BACKUP: Displaying backup parameters and backup volumes

Explanation: **BACKUP** is an optional parameter for requesting a list of the backup and dump parameters and backup volumes.

Subparameter	Explanation
ALL	A list of all nonfull tape backup volumes and all DASD backup volumes is generated.
DAILY	A list of all nonfull daily tape backup volumes and all daily DASD backup volumes is generated. For <i>day</i> , substitute a decimal number from 1 to 31 to list the daily backup volumes associated with the specified day in the backup cycle.
SPILL	A list of all nonfull tape spill backup volumes and all DASD spill backup volumes is generated.
UNASSIGNED	<p>A list of all nonfull unassigned tape backup volumes and all unassigned DASD backup volumes is generated. There are two types of unassigned volumes:</p> <ul style="list-style-type: none"> Unassigned backup volumes are those that you specified with the ADDVOL command without using the DAILY or SPILL subparameter (ADDVOL <i>volser</i> BACKUP). Unassigned daily backup volumes are those that you specified as daily backup volumes with the ADDVOL command, but that you did not associate with any day in the backup cycle (ADDVOL <i>volser</i> BACKUP(DAILY)).

Defaults: If you specify DAILY without *day*, DFSMSHsm lists all daily nonfull tape backup volumes and all daily DASD backup volumes.

Note: Full backup tapes may appear in the list if you have not issued a FIXCDS REFRESH command.

CDSVERSIONBACKUP: Displaying the control data set multiple backup support parameters

Explanation: **CDSVERSIONBACKUP** is an optional parameter requesting a list of the parameters related to the multiple backup copies of the control data sets and journal data set. When you specify this parameter, DFSMSHsm lists the values you specified with the CDSVERSIONBACKUP parameter of the SETSYS command.

Defaults: None.

COMMONQUEUE: Displaying common queue information

Explanation: **COMMONQUEUE** is an optional parameter that you can specify without any subparameters to display percent full information for the common RECALL queue. The common DUMP and RECOVER queue information will not be displayed if no subparameter is specified.

COMMONQUEUE(RECALL) is a subparameter that you can specify to display percent full, outstanding recall requests, the HOST ID from which the recall request was originated, and recall requests that are currently being processed in the common recall queue. When you specify this parameter, DFSMSHsm provides a snapshot of all recall activity across the CRQplex.

COMMONQUEUE(DUMP) is a subparameter that you can specify to display the status of dump requests that are being processed and queued in the common dump queue of which the host issuing the query command is a member. When connected to a DFSMSHsm dump group, this query provides a snapshot of all dump activity across all dump group members.

COMMONQUEUE(RECOVER) is a subparameter that you can specify to display the status of recover requests that are being processed and queued in the recover group queue of which the host issuing the query command is a member. When connected to a DFSMSHsm recover group, this query provides a snapshot of all recover activity across all dump group members.

Defaults: None.

CONTROLDATASETS: Displaying control data set space-use information

Explanation: **CONTROLDATASETS** is an optional parameter requesting a list of the space-use information for the MCDS, BCDS, OCDS, and journal data set. The list consists of the following information:

- The serialization technique being used.
- The total space in each data set.
- The percentage of the total occupied space in each data set to the extent that DFSMSHsm can determine it.
- The threshold percentage value currently assigned for each data set. When this threshold is exceeded, DFSMSHsm sends warning messages to the operator.
- The key boundaries of multicluseter data sets.

Defaults: None.

Note: Information for the JOURNAL data set is based on the last journal update on the host that the QUERY command is entered on. The actual value can be affected by updates made on other hosts.

COPYPOOL: Displaying copy pool information

Explanation: **COPYPOOL**(*cpname*) is an optional parameter that you specify to list which source volumes in the specified copy pool have an outstanding FlashCopy relationship.

You can use this command to determine if another backup version can be created or if a recover can be performed.

Defaults: None.

CSALIMITS: Displaying the common service area storage limits

Explanation: **CSALIMITS** is an optional parameter requesting a list of the common service area (CSA) storage limits. You specify the CSA storage limits with the SETSYS command.

Defaults: None.

DATASETNAME, FILENAME, REQUEST, and USER: Displaying selected requests

Explanation: **DATASETNAME**(*dsname*), **FILENAME**(*filename*), **REQUEST**, and **USER** are mutually exclusive, optional parameters that request a list of selected DFSMSHsm requests.

DATASETNAME(*dsname*) specifies a list of the requests that are associated with the specified data set name. For *dsname*, substitute the fully qualified name of the data set for which you want the list of requests.

FILENAME(*filename*) specifies a list of requests that are associated with the specified UNIX file name enclosed in single quotation marks. For *filename*, substitute the absolute path and UNIX file name for the file for which you want the list of requests. *filename* must be enclosed in single quotation marks.

REQUEST(*reqnum*) specifies a list of the specified request number for all requests. For *reqnum*, substitute the DFSMSHsm request number.

USER(*userid*) specifies a list of the requests that are associated with a specified user. For *userid*, substitute a 1-8 alphanumeric character string for the identification of the particular user.

Defaults: If you specify USER without *userid*, DFSMSHsm lists requests for all users. If you specify REQUEST without *reqnum*, DFSMSHsm lists information for all requests.

Note:

1. DFSMSHsm does not handle partitioned data set members individually. If you specify a partitioned data set with a member name, DFSMSHsm displays the entire partitioned data set.
2. In a common recall, dump, or recover queue environment, recall requests from only the host that is issuing the QUERY DATASETNAME|REQUEST|USER command are returned.

IMAGE: Displaying information for the DFSMSHsm address spaces active within a single z/OS image

Explanation: **IMAGE** is an optional parameter requesting information on the DFSMSHsm address spaces that are active within a single z/OS image. Information displayed includes the host identifier, procedure name used to start the address space, the job identifier, the address space identifier, and the host mode (MAIN or AUX). The information is displayed in message ARC0250I.

Defaults: None.

MIGRATIONLEVEL2: Displaying key ranges and migration level 2 volumes

Explanation: **MIGRATIONLEVEL2** is an optional parameter requesting a list of key ranges and the DASD migration level 2 volume associated with each key range as specified with the DEFINE command. This parameter also displays the tape migration level 2 volumes currently selected for use by the migration functions that output to tape if migration tapes are used in the requesting DFSMSHsm host.

Defaults: None.

NETWORK: Displaying cloud endpoint statistics known to DFSMSHsm

Explanation: **NETWORK** is an optional parameter requesting DFSMSHsm to output informational statistical data about known cloud endpoints.

Defaults: None.

Note: DFSMSHsm does not display endpoints information for S3 cloud providers.

POOL: Displaying recall pools

Explanation: **POOL** is an optional parameter requesting a list of the recall pools as specified with the DEFINE command.

Defaults: None.

Note: An SMS-managed volume may be displayed on the output listing if the volume was converted from non-SMS-managed to SMS-managed since the last time the pool was defined.

RETAIN: Displaying data set levels prevented from space management

Explanation: **RETAIN** is an optional parameter requesting a list of the first qualifiers of data sets prevented from space management with the SETMIG command. Data set names and volumes prevented from migrating with the DATASETNAME or VOLUME parameters of the SETMIG command are not listed.

Defaults: None.

SECURITY: Displaying the type of command authorization in effect

Explanation: **SECURITY** is an optional parameter that you specify to request information about the type of command authorization in effect. When you specify this command, DFSMSHsm issues a message that indicates whether RACF profiles or the DFSMSHsm AUTH command protects DFSMSHsm commands.

Defaults: None.

SETSYS: Displaying control parameters

Explanation: **SETSYS** is an optional parameter requesting a list of the DFSMSHsm control parameters. You can change most of these parameters with the SETSYS command; some can only be changed at the startup of DFSMSHsm.

Defaults: None.

SPACE: Displaying volume space-use information

Explanation: **SPACE** is an optional parameter requesting a list of information about space used on the specified non-SMS-managed primary volumes and migration level 1 volumes. For *volser* ..., substitute the serial numbers of the volumes whose space-use information you want listed.

Defaults: If you specify SPACE without *volser*, DFSMSHsm lists space-use information for all primary non-SMS-managed volumes and migration level 1 volumes.

STARTUP: Displaying the startup information

Explanation: **STARTUP** is an optional parameter requesting a list of the parameters that were specified when DFSMSHsm was started. These parameters were specified on the PROC statement in the DFSMSHsm startup procedure.

Defaults: None.

STATISTICS: Displaying daily statistics

Explanation: **STATISTICS** is an optional parameter requesting a list of selected DFSMSHsm daily statistics that have accumulated for the current day.

Defaults: None.

TRAPS: Displaying trap requests

Explanation: **TRAPS** is an optional parameter requesting a list of trap requests that were specified with the TRAP command.

Defaults: None.

VOLUMEPOOL: Displaying current volume pools

Explanation: **VOLUMEPOOL** is an optional parameter requesting a list of the current volume pools that you have specified with the DEFINE command. The current volume pool names and the volumes that make up the volume pools are listed.

Defaults: None.

WAITING: Displaying the number of requests waiting to be processed

Explanation: **WAITING** is an optional parameter requesting a list of the number of requests on each functional queue waiting for DFSMSHsm to process them.

Defaults: None.

Note: In a common recall, dump, or recover queue environment, only recall requests from the host that is issuing the QUERY WAITING command are returned.

Examples of how to code the QUERY command

For a list of the messages generated by the QUERY command, see [Chapter 77, “Using the QUERY command,” on page 1389](#).

Chapter 59. RECALL command: Recalling a specific migrated data set

The RECALL command recalls a migrated data set. If you want, you can specify the volume and type of unit where DFSMSHsm is to recall the data set.

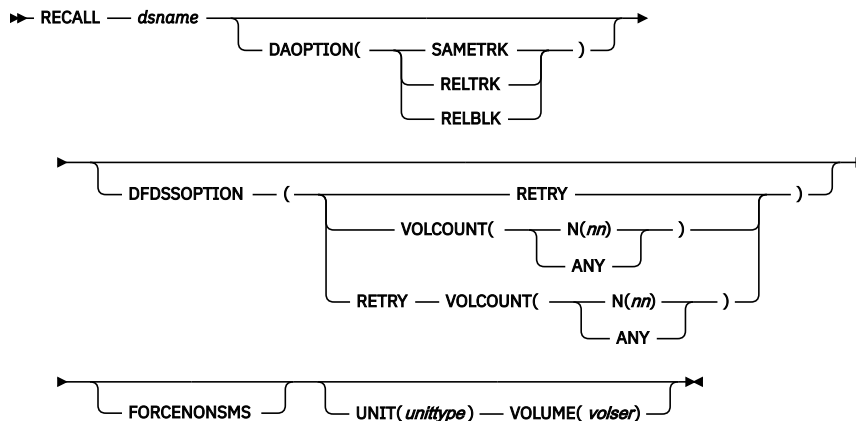

If you specify the volume and type of unit when recalling an SMS-managed data set, the volume and unit type will be passed to the automatic class selection (ACS) Routines. ACS ultimately determines to which volume the data set is recalled.

The FORCENONSMS parameter allows the ability to force recall of an SMS-managed data set to a non-SMS-managed volume. It is not possible to convert a data set that is *not* extended format to a data set that is extended format during a recall. However, you can convert an extended format data set to a data set that is *not* extended format during a recall, if you specify the FORCENONSMS optional parameter.

If you do not specify the target volume for a recalled non-SMS-managed data set, and the data set migrated from a primary volume whose primary volume attribute was automatic backup or automatic migration, DFSMSHsm automatically tries to recall it to a primary volume having the same set of attributes as the volume it migrated from. If no volume is found and the UNLIKE subparameter was specified with the SETSYS RECALL command, then DFSMSHsm can recall to a volume that has unlike attributes.

If a host is connected to a common recall queue (CRQ), recall requests are sent to the CRQ. For information about the common recall queue functions, see [z/OS DFSMSHsm Implementation and Customization Guide](#).

Syntax of the RECALL command

Note: You can specify RETRY, VOLCOUNT, or both with the DFDSSOPTION, but you must specify at least one parameter.

Required parameters of the RECALL command

This topic describes the required parameter of the RECALL command.

dsname: Specifying the name of the data set to be recalled

Explanation: *dsname* is a required positional parameter specifying the data set that you want to recall. For *dsname*, substitute the fully qualified name of the data set.

Defaults: None.

Note:

1. Because *dsname* is a required positional parameter, you must specify it immediately after the command name.
2. You cannot specify an alias for *dsname*. If you do, DFSMSHsm does not recall the data set.
3. DFSMSHsm does not handle partitioned data set members individually. If you specify a member name of a partitioned data set, DFSMSHsm processes the entire partitioned data set. If *dsname* is a VSAM data set name, specify the base cluster name, any component name, or any path name. If the sphere has more than one AIX, more than one path, or more than one path to the AIX, only the base cluster name can be specified for RECALL. The entire VSAM sphere is recalled.

Optional parameters of the RECALL command

This topic describes the optional parameters of the RECALL command.

DAOPTION: Selecting target volume track length

Explanation: **DAOPTION(SAMETRK | RELTRK | RELBLK)** are mutually exclusive, optional parameters specifying the type of data set accessing required (relative track or relative block) upon recall of a direct access data set. This, in turn, implies the allowable target volume device types.

Subparameter	Explanation
SAMETRK	If DFSMSHsm is not directed to a volume by the VOLUME parameter, it selects a target volume having the same track length as the last L0 volume from which the data set was migrated. If DFSMSHsm is directed to a specific volume by the VOLUME parameter, this volume must have the same track length as the last L0 volume from which the data set was migrated. Data will be moved as a track-to-track image, accessible for both relative track and relative block processing.
RELTRK	If DFSMSHsm is not directed to a volume by the VOLUME parameter, it attempts to select a target volume having the same track length as the last L0 volume from which the data set was migrated. If no volume of equal track length is available, the target volume selected may have a larger track length than the last L0 volume. If DFSMSHsm is directed to a specific volume by the VOLUME parameter, this volume must have the same or greater track length than the last L0 volume from which the data set was migrated. Data is moved as a track-to-track image, accessible by relative track addressing.
RELBLK	If DFSMSHsm is not directed to a volume by the VOLUME parameter, it attempts to select a target volume having the same track length as the last L0 volume from which the data set was migrated. If no volume of equal track length is available, the target volume selected may have a larger or smaller track length than the last L0 volume. If DFSMSHsm is directed to a specific volume by the VOLUME parameter, this volume can have any track length. Data will be moved to fill out the track, accessible by relative block addressing.

Defaults: If DAOPTION is not specified, the target volume selection is unchanged and data is moved as a track image, allowing for relative track addressing.

Note: Only basic direct access method (BDAM) data sets are supported by this option. Using DAOPTION to recall a data set as SMS-managed is not supported. If a data set would be SMS-managed after the recall, the FORCENONSMS parameter of RECALL must be used to force it to be non-SMS-managed.

DFDSSOPTION: Pass optional parameters to DFSMSdss

Explanation: **DFDSSOPTION(RETRY | VOLCOUNT)** is an optional parameter that causes DFSMSHsm to pass optional parameters to DFSMSdss when recalling certain types of data sets or to specify the number of volumes a data set can extend to.

RETRY is applicable to the recalling of the following types of data sets and is ignored by DFSMSHsm if specified for other types of data sets:

- Partitioned data set: When the initial recall of the data set fails and a DFSMSdss message requests the use of the NOPACKING option. RETRY specifies for DFSMSHsm to pass this NOPACKING option to DFSMSdss.
- Keyed VSAM data set: When the initial recall of the data set fails and a DFSMSdss message requests the use of the FREESPACE(0 0) option, to retry the restore to a like device, or both. If the data set is not SMS-managed, also specify VOLUME(volser) UNIT(unittype) parameter on the recall command. RETRY specifies for DFSMSHsm to pass this FREESPACE option to DFSMSdss.

Note: If the RETRY parameter is specified, then the ACS routine that indicates a RECALL environment will always be invoked, even if one or more class transitions were missed while the data set was migrated or if the data set was transitioned before migration.

VOLCOUNT(ANY | N(nn)) allows an SMS data set to extend to additional volumes within the same storage group, when space is available. The VOLCOUNT parameter is limited to SMS data set types supported as multivolume data sets. Refer to *z/OS DFSMSdss Storage Administration* for more information regarding restrictions and limitations of the VOLCOUNT parameter.

VOLCOUNT(ANY) results in the allocation of the target data set on as many volumes as required, to a maximum of 59.

VOLCOUNT(N(nn)) allows users to specify the number of volumes to be used for SMS data set allocation. nn can be any value from 0 to 59. When you specify the number of volumes the data set is allocated to, the allocation of the data set will be limited to that number of volumes or will be extended to that number of volumes.

The VOLCOUNT(N(nn)) parameter is ignored if specified with the DFSMSHsm VOLUME parameter. If a volume count VOLCOUNT(N(nn)) is specified and the VOLUME parameter is also specified, the resulting volume count for the data set will be one (1). If inadequate space exists on the specified volume, the allocation fails.

Defaults: None.

Note: If you specify the RECALL command with the VOLCOUNT parameter, it overrides any option used on the SETSYS VOLCOUNT command.

FORCENONSMS: Recalling an SMS-managed data set to a non-SMS-managed volume

Explanation: **FORCENONSMS** is an optional parameter that forces a data set to be recalled to a non-SMS-managed volume. Use this parameter if SMS is not active or if SMS is active and you need to return a data set to non-SMS-managed status.

Defaults: None.

Note: If SMS is not active, a recall request for an SMS-managed data set will fail unless the FORCENONSMS parameter is specified on the RECALL command.

UNIT: Specifying the type of device

Explanation: **UNIT(unittype)** is an optional parameter specifying the type of unit to which DFSMSHsm can allocate the target volume. A target volume is the volume that receives the recalled data set. For *unittype*, substitute the type of unit to which DFSMSHsm can allocate the target volume.

The following are valid types of DASD units:

- 3380
- 3390
- 9345

Defaults: None.

Note:

1. If you specify UNIT, you must also specify the VOLUME parameter.
2. If the block size of the data set is greater than the track capacity of the target volume, track overflow must be supported in both software and hardware. This applies to devices whose track size is less than 32K.
3. When you specify the UNIT parameter, DFSMSHsm passes that unit name to the automatic class selection (ACS) routines to determine whether the data set should be recalled to an SMS-managed volume. See [Chapter 2, “Space management of SMS-managed storage,” on page 23](#) for more information about automatic class selection.

VOLUME: Specifying the volume to receive the recalled data set

Explanation: **VOLUME(*volser*)** is an optional parameter specifying the volume that is to receive the recalled data set. This volume is called the target volume. The volume does not have to be managed by DFSMSHsm. For *volser*, substitute the serial number of the target volume.

Defaults: If you do not specify the VOLUME parameter, DFSMSHsm recalls the non-SMS-managed data set to the eligible primary volume with the most space available, unless the recalled data set is associated with a recall pool.

Note:

1. If you specify VOLUME, you must also specify the UNIT parameter.
2. In a JES3 environment, do not specify the *volser* of a volume because JES3 preselects a set of volumes. If you specify a volume that is not in that preselected list, DFSMSHsm fails the recall.
3. When you specify the VOLUME parameter, the target volume must have enough space available for the data set. Otherwise, DFSMSHsm fails the recall.
4. When you specify the VOLUME parameter, DFSMSHsm passes that volume serial number to the automatic class selection (ACS) routines to determine whether the volume is managed by SMS before recalling the data set. See [Chapter 2, “Space management of SMS-managed storage,” on page 23](#) for more information about automatic class selection.
5. If both VOLUME and the VOLCOUNT(N(*nn*)) parameters are specified, the resulting volume count for the data set will be one (1). If space does not exist on the specified volume, the allocation fails.

Examples of how to code the RECALL command

The following examples present different ways to code the RECALL command.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Recalling an SMS-managed data set to a non-SMS-managed volume

In this example, a data set that was SMS-managed at the time it was migrated is recalled as a non-SMS-managed data set.

```
RECALL JMG4916.PLACE.TEXT FORCENONSMS VOLUME(VOL255) UNIT(3390)
```

Recalling an SMS-managed data set to a volume selected by ACS services

In this example an SMS-managed data set is recalled to a volume selected by automatic class selection routines.

```
RECALL JMG2384.PLACE2.TEXT
```

Recalling a non-SMS-managed data set to a specific volume

In this example, the data set is recalled to a specific volume.

```
RECALL XXX5634.PARTS.ASM VOLUME(VOL123) UNIT(3390)
```

Recalling a non-SMS-managed data set to a volume selected by DFSMSHsm

In this example, the data set is recalled to a primary volume selected by DFSMSHsm.

```
RECALL LHE1256.REVISION.TEXT
```

Recalling a DA data set for relative block accessing

In this example, a data set is directed to a specific volume and the data is moved so that it can be accessed by relative block addressing.

```
RECALL ND5718.PARTS DAOPTION(RELBLK) +  
VOLUME(VOL195) UNIT(3390)
```

Recalling a data set that failed because of inadequate space

In this example, a data set was not recalled by DFSMSdss because an inadequate space condition occurred. The RECALL command can be issued again with the VOLCOUNT parameter allowing the data set to be recalled to as many volumes as needed (maximum of 59) for successful allocation. DFSMSHsm passes the VOLCOUNT parameter to DFSMSdss.

```
RECALL C253800.ID.PARTS DFDSSOPTION(VOLCOUNT(ANY))
```

Chapter 60. RECOVER command: Recovering a backup version or dump copy of a data set, or UNIX file, or a volume

The RECOVER command causes DFSMSHsm to invoke DFSMSdss to do a physical restore of the requested data set or volume when you specify the FROMDUMP parameter with the command. If you also specify the APPLYINCREMENTAL parameter with the RECOVER command (following the restore), DFSMSHsm recovers data sets incrementally backed up by DFSMSHsm if backup occurred after the dump. You can tell DFSMSHsm to use a particular dump copy as the source of the restore by specifying one of the following parameters with the RECOVER command:

- DATE
- DUMPCCLASS
- DUMPGENERATION
- DUMPVOLUME

When the RECOVER command is issued without the FROMDUMP parameter, DFSMSHsm recovers a level 0 volume, or an incremental backup version of a data set or UNIX file, or a dump copy of a data set, depending on which copy is more current. If there are no records of the data set or UNIX file in the BCDS, and there is no catalog entry for the data set on the volume from which the dump copy was made, the recovery fails. If a dump copy of the data set exists, a RECOVER command issued with the FROMDUMP parameter could successfully recover the data set.

When FROMDUMP DUMPVOLUME is not specified, the restore of a multiple striped data set will be from an incremental backup version. If no incremental backup version exists, the restore will fail. To restore an extended format data set from a dump volume, the FROMDUMP DUMPVOLUME parameter must be used for each extended format data set.

You can use the recovered version of the data set or UNIX file to replace an existing data set or UNIX file accordingly. You can also rename the recovered version to have two versions of the same data set. If you want to recover backup versions of a migrated data set, use one of the following procedures:

Recall the migrated data set and recover a backup version of that data set. Delete the migrated data set and recover a backup version of the deleted data set. Specify the NEWNAME parameter and recover a backup version of that data set. The NEWNAME parameter cannot be the name of a migrated data set. If none of the previous three procedures works, use the FIXCDS command to delete the MCDS data set (MCD) record for the migrated data set and uncatalog the data set. Then, recover the backup version of the data set.

You normally run volume recovery when an entire DASD pack has been lost or damaged or when a significant amount of the data is no longer accessible.

If a data set being recovered spans to a second or more volumes, and the data set resides on disaster alternate volumes that are in a tape library, DFSMSHsm will verify and correct the tape library volume record for the first volume and the original volumes in the volume list only. The message ARC0184I RC=4 is issued for all other volumes that are disaster alternate volumes. The message ARC0184I RC=4 is issued for an MCT record that cannot be found for the disaster alternate volume.

Disaster alternate volumes do not have MCT records. The MCT is for an original volume only. The message ARC0184I RC=4 is not an indication of an error condition for a disaster alternate volume. The disaster alternate volume will be allocated and the recovery process will continue.

This following example shows a volume list for a data set spanning four volumes.

```
TAPEA - DISASTER ALTERNATE VOLUME - TAPE LIBRARY RECORD VERIFIED.
TAPEB - DISASTER ALTERNATE VOLUME - MESSAGE ARC0184I RC=4.
TAPEC - ORIGINAL TAPE VOLUME - TAPE LIBRARY RECORD VERIFIED.
TAPED - DISASTER ALTERNATE VOLUME - MESSAGE ARC184I RC=4.
```

When replacing an existing SMS-managed data set, DFSMSHsm normally recovers or restores the data set to the volume on which the data set is currently cataloged; however, for SMS-managed VSAM data sets, VTOC/Data Set Services selects the target volume. In addition, the SMS class names that currently exist in the catalog for the data set are maintained, regardless of what the class names were at the time of backup or dump.

When recreating a deleted data set, DFSMSHsm determines a new class name by invoking the ACS routines. The result of invoking ACS determines if the data set is to be SMS-managed, VTOC/Data Set Services chooses the target volume, and the newly determined class name is associated with the data set.

The exception to the previous rules for replacing and re-creating SMS-managed data sets is when the FORCENONSMS parameter is issued with the RECOVER command. The FORCENONSMS parameter can force recovery of an SMS-managed data set to a non-SMS-managed volume. It is not possible to convert a data set that is not extended format to a data set that is extended format during recovery. However, you can convert an extended format data set to a data set that is not extended format during a recovery, if you specify the FORCENONSMS optional parameter.

If the dump data was encrypted with a password and DFSMSHsm will be used to recover the dump, then DFSMSHsm will automatically send the encryption password to DFSMSdss to decrypt the data during recovery. If the dump data will be recovered with DFSMSdss directly, then use the LIST DUMPVOLUME command to determine which password should be specified on the DFSMSdss RESTORE command. If the dump data was encrypted with an RSA key label, the data will automatically be decrypted upon recovery if the recovery is performed within the same encryption environment as the dump was created. If the encryption environment has changed or the recovery is being performed in a different environment, the appropriate RSA key label must be specified on the DFSMSHsm RECOVER or DFSMSdss RESTORE command.

The REPLACE subparameter is required when replacing an existing data set.

- For more information about recovering non-SMS-managed data sets, see [“Data set restore from a DFSMSHsm dump copy”](#) on page 314.

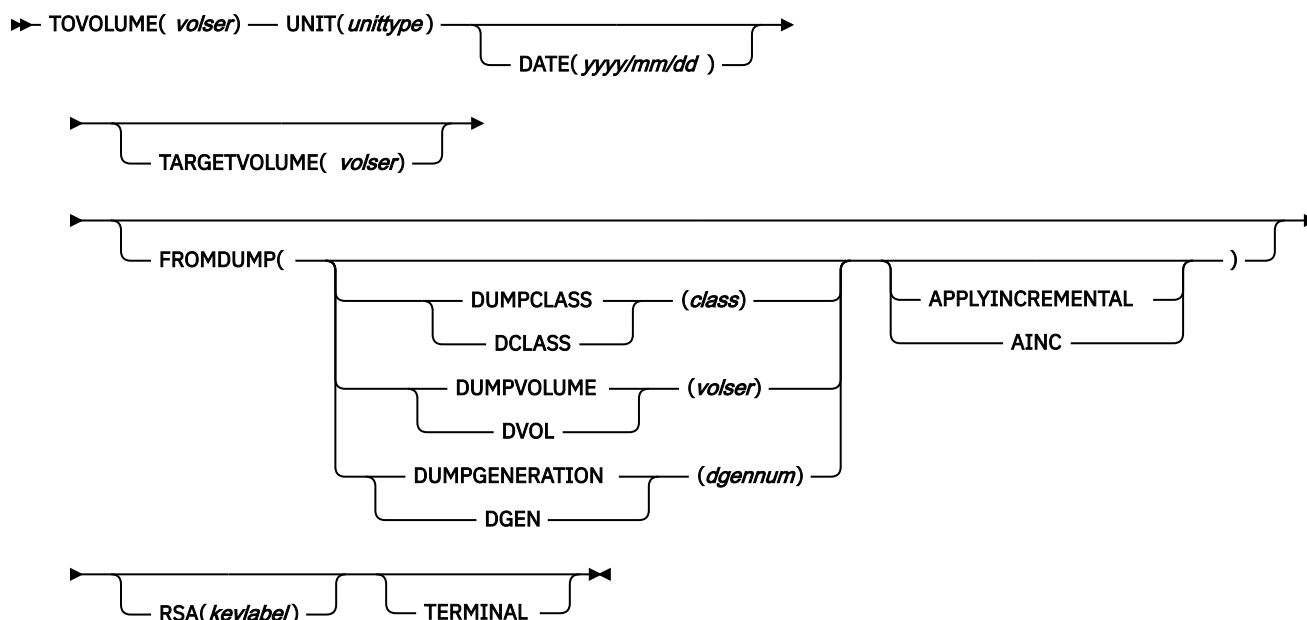

Syntax of the RECOVER command

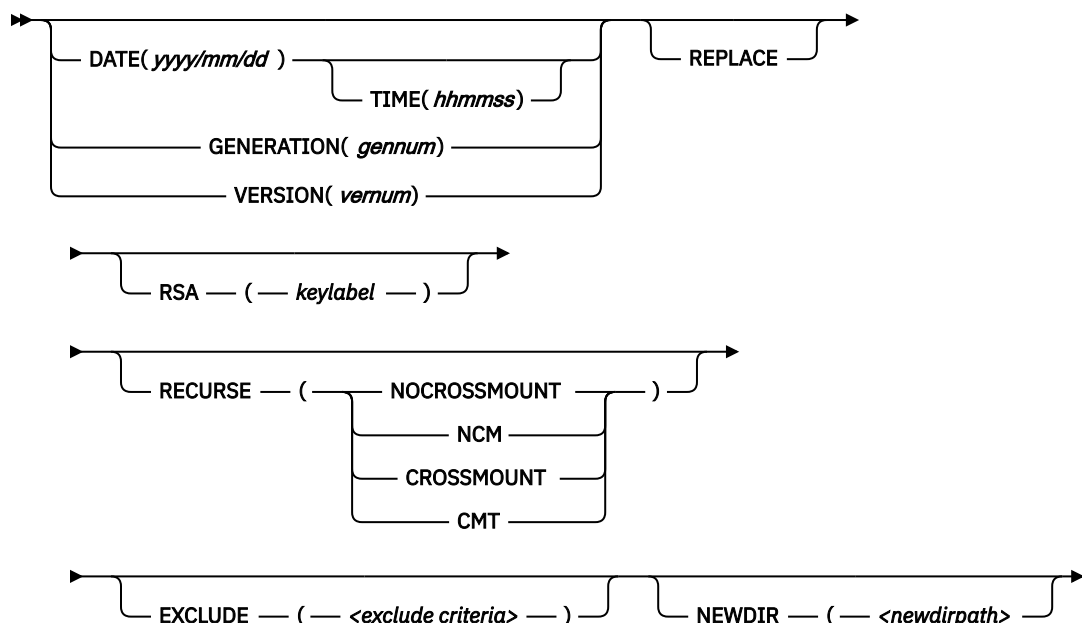

A: RECOVER optional parameters

B: RECOVER optional parameters

C: RECOVER optional parameters

Required parameters of the RECOVER command

This topic describes the required parameters of the RECOVER command.

dsname: Specifying the name of the data set to be recovered

Explanation: *dsname* is a required positional parameter specifying the fully qualified name of the data set you want to recover. For *dsname*, substitute the fully qualified name of the data set you want to recover. You can specify an asterisk (*) as the *dsname* to request that the volume you identify with the TOVOLUME parameter is recovered. Unless FROMDUMP is specified, the volume must be a level 0 volume. If FROMDUMP is specified, the volume can be a DFSMSHsm-owned DASD volume.

During volume recovery, if DFSMSHsm created backup versions of both cataloged and uncataloged data sets that have the same data set name and DFSMSHsm created them from the volume being

recovered, DFSMSHsm recovers the backup version that has the latest creation date and the same data set organization.

Defaults: None.

Note:

1. Because *dsname* is a required positional parameter, you must specify it immediately after the command name. You cannot specify an alias for *dsname*. If you do, DFSMSHsm does not recover the data set.
2. DFSMSHsm does not handle partitioned data set members individually. If you specify a partitioned data set with a member name, DFSMSHsm recovers the entire partitioned data set.
3. A DUMP VTOC copy data set must exist in order to restore a data set from a DUMP copy, except when the DUMPVOLUME subparameter is specified. By using the DUMPVOLUME subparameter, you are deliberately bypassing this requirement; therefore, no data set verification is performed on the dump tape. If the data set you are trying to restore is not on the dump tape, DFSMSHsm still ends with a successful message even though the data set was not restored.
4. DFSMSHsm cannot recover an integrated catalog facility catalog data set from a dump copy. An integrated catalog facility catalog that was dumped by DFSMSHsm can be recovered from a dump copy without DFSMSHsm.

***pathname*: Specifying the name of the UNIX file to be recovered**

Explanation: *pathname* specifies that DFSMSHsm will recover one or more files from their respective backup versions. *pathname*, must be enclosed in single quotation marks and is considered to be made up of two parts: an absolute directory path starting and ending in a forward slash, followed by a *pattern*(/*directory/path/pattern*):

- The *pattern* can contain any valid UNIX file name characters, and may contain wildcard characters ? and *. If the UNIX file name contains the question mark (?), asterisk (*), or backslash (\) characters, the backslash character (\) must be used to escape that character. (for example, \?, *, or \\).
- If *pattern* doesn't contain any wildcard characters, this is treated as an absolute path to a specific UNIX file. This indicates that DFSMSHsm will recover that UNIX file from its backup inventory, if it exists.
- If *pattern* doesn't contain any characters at all, or is only a single asterisk, this is treated as an absolute path to a directory - (/u/dir1/). This indicates that DFSMSHsm will recover all the files and empty directories contained therein. If the RECURSE keyword is specified, DFSMSHsm will examine subdirectories for files to recover.
- Wildcard in *pattern* An asterisk (*) can be used to match any number of characters within a file name. The asterisk may be used at any position in the pattern. A second asterisk may also be used at the end of the pattern to indicate any number of characters following specific text. A question mark (?) can be used to represent any single character in the file name. Multiple ? characters are allowed in the pattern. If the RECURSE keyword is specified, DFSMSHsm will examine subdirectories for files matching the pattern.

Optional parameters of the RECOVER command

This topic describes the optional parameters of the RECOVER command.

DAOPTION: Selecting target volume track length

Explanation: **DAOPTION(SAMETRK | RELTRK | RELBLK)** are mutually exclusive, optional parameters specifying the type of data set accessing required (relative track or relative block) upon recovery of a direct access data set. This, in turn, implies the allowable target volume device types.

Subparameter	Explanation
SAMETRK	Data is moved as a track-to-track image and the target volume track size must be the same as the L0 volume from which the data set was backed up. If DFSMSHsm is directed to a specific volume by the TOVOLUME parameter, this volume must have the same track length as the L0 volume from which the data set was backed up. Data can be accessed for both relative track and relative block processing.
RELTRK	Data is moved as a track-to-track image and the target volume track size must be the same or greater than the L0 volume from which the data set was backed up. If DFSMSHsm is directed to a specific volume by the TOVOLUME parameter, this volume must have the same or greater track length as the L0 volume from which the data set was backed up. Data can be accessed for relative track processing.
RELBLK	Data is moved to fill out the track and the target volume track size can be the same, greater, or smaller than the L0 volume from which the data set was backed up. Data can be accessed for relative block processing.

Defaults: If DAOPTION is not specified, the data is moved as a track image, allowing for relative track accessing.

Note: Only basic direct access method (BDAM) data sets are supported by this option. Using DAOPTION to recover a data set as SMS-managed is not supported. If a data set would be SMS-managed after the recover, the FORCENONSMS parameter of RECOVER must be used to force it to be non-SMS-managed.

DATE, GENERATION, and VERSION: Specifying the particular backup version or dump copy to recover

Explanation: **DATE**(*yyyy/mm/dd*), **GENERATION**(*gennum*), and **VERSION**(*vernum*) are mutually exclusive, optional parameters specifying the particular backup version or dump copy of one or more data set or UNIX file you want to recover.

DATE(*yyyy/mm/dd*) can be used to specify the particular dump copy to be used for a restore. DATE applies when recovering a backup version or dump copy of a specific data set or UNIX file or an entire volume. For *yyyy/mm/dd*, substitute the date for the backup version or dump copy of the data set or UNIX file or volume that you want to recover in the following form. A leading zero is not required for a one-digit month or day. If DFSMSHsm is recovering a data set or UNIX file, it recovers the latest backup version that was created on or before the date you specified. If DFSMSHsm is recovering a volume, DFSMSHsm recovers the latest backup version of each data set that was backed up on or after the date you specified. If DFSMSHsm is recovering a volume from a dump copy, the most recent dump copy made on or before the date is selected. If DFSMSHsm is recovering a data set from a dump copy and the data set is cataloged, the most recent dump copy made on or before the date is selected. If the data set is not cataloged, there must be an incremental backup version created on or prior to the date for the data set to be recovered from the dump copy.

TIME(*hhmmss*)

is an optional sub-parameter of DATE that specifies the exact time in hours, minutes, and seconds (*hhmmss*) when the backup version is created. The valid range for hours is 00–23, and for minutes and seconds is 00–59. If you specify TIME, you must also specify DATE, otherwise the RECOVER command fails. You must specify a fully qualified data set name. You cannot specify TIME on a volume recovery request. If a version with specified date and time cannot be found, the command fails.

GENERATION(*gennum*) specifies that you want to recover a particular incremental backup version of a specific data set or UNIX file. For *gennum*, substitute the relative generation number of the backup version of the data set or UNIX file to be recovered. A 0 specifies the latest version, 1 specifies the next to the latest version, and so on, to the maximum number of versions existing for the data set or UNIX file. The *gennum* can be up to 3 digits long.

VERSION(*vernum*) specifies that you want to recover a particular version of a backed up data set or UNIX file. For *vernum*, substitute a decimal number from 1 to 999 for the particular backup version you want to recover. If DFSMSHsm is unable to find the specified backup version, the recover fails and message ARC1128I is issued.

Defaults: If you do not specify DATE, GENERATION, or VERSION, DFSMSHsm recovers the latest backup version of the data set or UNIX file.

Note:

1. The GENERATION and VERSION parameters do not apply to volume recovery. If you specify GENERATION or VERSION when it does not apply, DFSMSHsm ignores it.
2. The GENERATION or VERSION parameters should not be specified if FROMDUMP is specified.
3. DATE should not be specified if DUMPVOLUME or DUMPGENERATION is specified.
4. If either the GENERATION or the VERSION parameter is specified, DFSMSHsm selects only from incremental backups and will not recover from physical dump copies, even if the physical dump is more recent.
5. To recover a retained backup version specify the date, and if necessary, the time that the retained backup copy was created. You cannot recover a retained copy with the GENERATION and VERSION keywords.

DFDSSOPTION: Pass optional parameters to DFSMSdss

Explanation: **DFDSSOPTION(RETRY | VOLCOUNT)** is an optional parameter that causes DFSMSHsm to pass optional parameters to DFSMSdss when recovering certain types of data sets or to specify the number of volumes a data set can extend to.

RETRY is applicable to the recovery of the following types of data sets and is ignored by DFSMSHsm if specified for other types of data sets:

- Partitioned data set: When the initial recovery of the data set fails and a DFSMSdss message requests the use of the NOPACKING option. RETRY specifies for DFSMSHsm to pass this NOPACKING option to DFSMSdss.
- Keyed VSAM data set: When the initial recovery of the data set fails and a DFSMSdss message requests to use the FREESPACE(0 0) option, to retry the restore to a like device, or both. If the data set is not SMS-managed, also specify the TOVOLUME(volser) UNIT(unitttype) parameters on the recover command. RETRY specifies for DFSMSHsm to pass this FREESPACE option to DFSMSdss.

VOLCOUNT(ANY | N(*nn*)) allows an SMS data set to extend to additional volumes within the same storage group, when space is available. The VOLCOUNT parameter is limited to SMS data set types supported as multivolume data sets. Refer to [z/OS DFSMSdss Storage Administration](#) for more information regarding restrictions and limitations of the VOLCOUNT parameter.

VOLCOUNT(ANY) results in the allocation of the target data set on as many volumes as required, to a maximum of 59.

VOLCOUNT(N(*nn*)) allows users to specify the number of volumes to be used for SMS data set allocation. *nn* can be any value from 0 to 59. When you specify the number of volumes the data set is allocated to, the allocation of the data set will be limited to that number of volumes or will be extended to that number of volumes.

The VOLCOUNT(N(*nn*)) parameter is ignored if specified with the DFSMSHsm TOVOLUME parameter. If a volume count VOLCOUNT(N(*nn*)) is specified and the TOVOLUME parameter is also specified, the resulting volume count for the data set will be one (1). If inadequate space exists on the specified volume, the allocation fails.

Defaults: None.

Note: If you specify the RECOVER command with the VOLCOUNT parameter, it overrides any option used on the SETSYS VOLCOUNT command.

EXCLUDE and EXCLUDEF: Specifying files or directories to be excluded from processing

EXCLUDE | EXCLUDEF are mutually exclusive, optional parameters that are used to specify files and directories that are to be excluded during Unix File backup processing.

EXCLUDE(<exclude_criteria>) - specifies a comma-separated list of exclude criteria directly on the command. This criteria is to be applied to the UNIX files examined during the UNIX File backup processing.

The exclude criteria list specified on the command with EXCLUDE keyword has the following restrictions and rules unique to the keyword:

- The *exclude_criteria* list must be specified in single quotes
- The *exclude_criteria* list cannot exceed 1023 characters

EXCLUDEF(' <filepath>') - specifies the UNIX path to a file that contains the exclude criteria to be applied to the UNIX files examined during the UNIX File backup processing. The file path must be specified in single-quotes and must be an absolute path. Any imbedded single quotes in the filename must be specified with a second single quote, e.g. the filename exclude'criteria.txt would be specified as: 'exclude'criteria.txt'. (optional)

The exclude criteria file specified using the EXCLUDEF keyword has the following restrictions and rules unique to the keyword:

- Line starting with a blank character is a comment.
- Each line can only contain one criterion.
- A single line cannot be longer than 1023 characters.
- Total length of all exclude criteria with added commas to separate them cannot exceed 32767 characters. For 'n' number of criteria, 'n-1' number of COMMA should also be accounted for to calculate the total size.

Exclude criteria, whether specified on the command in a comma separated list using the EXCLUDE keyword or specified within a file using the EXCLUDEF keyword, must conform to the following rules:

- Absolute directory path, beginning and ending with a forward-slash character.
- Partial directory path, ending with a forward-slash character. If the directory name begins with a forward slash character, then it is considered an absolute path. If the directory name does not begin with a forward slash character, it is considered a relative path that begins at the directory requested on the command. A directory name that is a relative path is considered relative to the directory requested on the command only, even when the command requests recursion.
- Filename pattern (does not contain forward slashes). Can contain * or ? wildcard. An asterisk (*) can match with 0 or more characters in a filename. A question mark (?) can match with a single character. Wildcard characters may be escaped with the backslash character if desired.
- A filename pattern can begin with an absolute or relative path, however wildcard characters can only be used in the filename pattern. A directory path containing an asterisk (*) or question mark (?) is considered an invalid pattern.
- If a filename contains special characters that are not to be treated as wildcard or escape characters i.e. an asterisk (*), a question mark (?), or backslash (\), these characters must be escaped using a backslash (\). If these characters are not escaped, they will be treated as wildcard or escape characters.
- A directory wildcard may be specified in the directory portion of a criterion by specifying /.../ (<forward slash><period><period><period><forward slash>). A directory wildcard can match with 0 or more directories.
- If a criterion begins with a directory wildcard (/.../) then it is treated as relative path.
- A comma cannot be used with the exclude criterion.
- A single criterion cannot exceed 1023 characters.
- A single forward slash or a single asterisk are treated as invalid patterns.

- A directory path cannot contain consecutive forward slashes.

The example below shows sample criteria in a file specified by the EXCLUDEDEF keyword. The same criteria could be specified on the command using the EXCLUDE keyword where each criterion is separated by a comma.

```
Useful comment (maybe with commas) <= blank in 1st position - ignored
                                     <= empty line - ignored
/a/b/c/                             <= absolute directory
/a/b/c/x1.txt                       <= absolute directory with filename
/a/.../d/.../g/syslog1.txt         <= absolute directory with wildcards
/a/.../d/.../g/*log?.txt           <= absolute directory and filename with wildcards
e/f/g                               <= relative directory
e/f/g/mvs.log                      <= relative directory with filename
d/e/f/g/*log?.txt                  <= relative directory with filename wildcard
d/.../g/sys*. *                    <= relative directory and filename with wildcards
/.../d/.../g/sys*. *               <= relative difrectory and filename with wildcards
*.log                              <= filename with wildcards
*.log2                             <= blank in 1st position makes a comment, ignored
\*abc                              <= escaping wildcards - files with exact name *abc
\\abc                              <= escaping wildcards - files with exact name \abc
```

Defaults: No files are excluded from processing.

FORCENONSMS: Recovering an SMS-managed data set to a non-SMS-managed volume

Explanation: **FORCENONSMS** is an optional parameter that forces a data set to be recovered to a non-SMS-managed volume. Use this parameter if SMS is not active or if SMS is active and you need to return a data set to non-SMS-managed status.

Defaults: None.

Note:

1. If SMS is not active, a recover request for an SMS-managed data set fails unless the FORCENONSMS parameter is specified on the RECOVER command.
2. A non-SMS target volume must be known to DFSMSHsm to complete the request. This can be obtained through:
 - The TOVOLUME and UNIT parameters if the data was backed up as SMS.
 - The volume from which the data set was backed up if backed up as non-SMS.
 - The volume from which the data set migrated if migrated as non-SMS.

FROMDUMP: Specifying which dump copy is used for restoring data sets

Explanation: **FROMDUMP** is an optional parameter specifying which dump copy should be used for the restore.

FROMDUMP specifies the recovery should use a dump copy from dump volumes.

DUMPClass(*class*) | DUMPVOLUME(*volser*) | DUMPGENERATION(*dgennum*) are mutually exclusive, optional subparameters of FROMDUMP specifying a particular class, volume, or generation from which the restore should be made. Neither DUMPGENERATION nor DUMPVOLUME should be specified if the DATE parameter is specified.

Subparameter	Explanation
DUMPClass(<i>class</i>)	The dump copy to be used to restore a data set or volume should come from a particular class. This subparameter is needed only if the source volume was dumped to more than one dump class. For <i>class</i> , substitute from 1 to 8 alphanumeric characters for the class of the volume from which the data set or volume is to be restored.

Subparameter	Explanation
DUMPVOLUME(<i>volser</i>)	A particular dump volume is used for restoring a data set or a volume. For <i>volser</i> , substitute the volume serial number of one of the dump volumes that contains part of the wanted dump copy of the source volume to be restored. DUMPVOLUME is not valid when GENERATION, VERSION, DATE, DUMPCLASS, or DUMPGENERATION are specified.
SOURCEVOLUME(<i>volser</i>)	The identified dump copy is used when the data set to be recovered from a dump is not cataloged or is migrated, and has no backup copy, and more than one valid dump copy is stacked on the volume specified with DUMPVOLUME.

If a multivolume, cataloged data set is to be recovered, the RECOVER command must be issued with the FROMDUMP parameter and the DUMPVOLUME subparameter to ensure that DFSMSHsm directs each part of the data set to the correct volume. In this case, the TOVOLUME parameter is optional but, if used, must be the name of the volume as identified in the catalog entry.

There must be similar device types between the original DASD and the target DASD, with the exception that you may recover data dumped from a 3380 DASD to a 3390 DASD that is in 3380 emulation mode. The following is a scenario example:

- The volume serial number PRIM01 is a 3380 DASD dumped to tape cartridge DUMP05.
- All 3380 DASD devices have been replaced by 3390 DASD.
- The 3390 DASD runs in a 3380 emulation mode and initializes with the volume serial number PRIM01.
- The command to recover PRIM01 is as follows:

```
RECOVER * TOVOLUME (PRIM01) UNIT (3380) FROMDUMP (DUMPVOL (DUMP05))
```

DUMPGENERATION(*dgennum*) specifies that a particular dump generation should be used as a source for restoring a volume. The *dgennum*, can be up to three digits long, but its value must be between zero and 99. Zero is the most-recent generation. Use the LIST command to determine what generation numbers exist. DUMPGENERATION should not be specified if you are restoring a single data set.

APPLYINCREMENTAL specifies that an incremental volume recovery process is to follow immediately after the volume restore and is to be a part of the single request to recover a specific volume. APPLYINCREMENTAL has meaning only when a volume is being restored. The volume does not have to have been processed by the DFSMSHsm volume backup function. If the volume was not backed up with the DFSMSHsm function, DFSMSHsm still tries to find more recent backup versions created from individual data set backup requests after the dump copy was created. It is not applicable if a data set request is entered.

Note:

1. The APPLYINCREMENTAL parameter is not honored if DFSMSHsm determines that the target volume is owned by a ICF catalog that resides on the target volume. This is to avoid conflicts in the way DFSMSHsm supports ICF catalogs and the data sets cataloged in them.
2. If Data Facility Product Version 2 Release 3.0 or higher is not installed, you cannot use the APPLYINCREMENTAL parameter during backup and recovery when the target volume has an Integrated Catalog Facility catalog.
3. The APPLYINCREMENTAL parameter is not allowed when the target volume is a DFSMSHsm-owned volume.
4. The SOURCEVOLUME subparameter is only used to identify which dump copy on a dump volume should be used to restore a data set. It does not have all the implications of the FROMVOLUME parameter.
5. If you use DUMPVOLUME to specify a dump tape, and that dump volume has more than one valid dump copy stacked on it, each dump copy is for a different source volume. For DFSMSHsm to restore the data set, it must be told which source volume (which dump copy) is needed. It uses information in

the following order: FROMVOLUME (if specified); SOURCEVOLUME (if specified); the volser where the data set is cataloged; if not cataloged, the volume from which the data set was last backed up. If none of these is specified or available, the RECOVER command fails.

6. The VTOC and the volume serial on the target volume may have changed as a result of this operation. Before the volume can be accessed on any remote system, the UCB must be refreshed. The refresh occurs automatically if the volume is online and the device manager REFUCB function is enabled. You enable the REFUCB function through PARMLIB member DEVSUPxx or the MODIFY DEVMAN command. For more information, refer to the description of the REFUCB keyword in [z/OS MVS Initialization and Tuning Reference](#) or [z/OS MVS System Commands](#).

Defaults: None.

FROMVOLUME: Specifying the volume from which the backup version of a data set has been created

Explanation: **FROMVOLUME(volser)** is an optional parameter specifying that the data set was uncataloged and that it resided on the volume specified by *volser* when DFSMSHsm created the backup version or dump copy. For *volser*, substitute the serial number of the volume where the data set resided when DFSMSHsm created the backup version or dump copy. If FROMVOLUME is used to direct DFSMSHsm to restore a data set from a dump copy, the dump copy made from FROMVOLUME specified is used regardless of the catalog status of the data set when the dump copy was first made. The data set is restored to the FROMVOLUME specified and left uncataloged.

Defaults: None.

Note:

1. The FROMVOLUME parameter applies only to data set recovery; it does not apply to volume recovery. If you specify FROMVOLUME when it does not apply, DFSMSHsm ignores it.
2. You must specify the FROMVOLUME parameter if the data set you want to recover was uncataloged when it was backed up.
3. DFSMSHsm recovers only cataloged data sets unless you specify FROMVOLUME.
4. DFSMSHsm does not catalog the recovered backup version or dump copy when you specify the FROMVOLUME parameter.
5. The FROMVOLUME parameter does not apply to VSAM data sets.
6. If the data set does not exist on the target volume for the recovery, automatic class selection routines are invoked to determine if the data set should be recovered as SMS, if FROMVOLUME is not specified.
7. If FROMVOLUME is specified, DFSMSHsm recovers the data set as a non-SMS.

NEWDIR : Recover files to a different directory

During a file recovery request, this optional parameter specifies a target directory that the recovered files should be placed into. The specified *newdirpath* must be an absolute path ending in a forward slash, for an existing directory. The requesting user must have search and write permission for the directory.

Restriction: This parameter only applies when a file path is specified on the request. The total length of the recovered file names plus the length of the new directory cannot exceed 1023 characters.

Defaults: Recovered files are placed in the original location where they existed at the time of backup.

NEWNAME: Specifying a new data set name for the recovered data set

Explanation: **NEWNAME(newdsname)** is an optional parameter specifying a new, fully qualified data set name for the recovered backup version or dump copy. For *newdsname*, substitute a new, fully qualified data set name for the recovered data set.

If a cataloged data set exists with the same name as the new name you are specifying, you must specify the REPLACE parameter to replace the existing cataloged data set. If an uncataloged data set with the

same name as the new name you are specifying exists on the volume, you must specify the REPLACE parameter to replace the existing uncataloged data set.

Defaults: None.

Note:

1. The NEWNAME parameter applies only to data set recovery. If you specify NEWNAME when it does not apply, DFSMSHsm ignores it.
2. You must specify NEWNAME when a data set exists with the same data set name as the data set that you are recovering and you want to keep both versions of the data set.
3. If a VSAM data set is being recovered and you specify NEWNAME, the new data set name can be cataloged in the same or different catalog as the original data set under the following restrictions:
 - a. If the new data set will be cataloged in a different catalog than the original, only the base cluster will be recovered, even when there were alternate indexes at the time of backup. You may use the access method services (AMS) BLDINDEX facility to rebuild the alternate indexes (AIX).
 - b. If the old data set does not exist, the new data set can be recovered provided the original data set's data and index components follow these standard naming conventions:
 - The old data component was the base cluster name followed by the .DATA qualifier.
 - The old index component was the base cluster name followed by the .INDEX qualifier.

For VSAM data sets not cataloged in the Integrated Catalog Facility catalog, if you specify TOVOLUME with NEWNAME, the volume must be owned by the catalog where the data set being recovered will be cataloged.

4. The following only applies if DFHSM 2.6.0 (or earlier release) was used to move the data during backup. When you specify NEWNAME for VSAM data sets, DFSMSHsm will fail the recovery if the original data set exists and has two or more paths defined to the base cluster. In some cases the path defined to the base cluster will not be recovered; use the (AMS) DEFINE PATH command.

Additionally, the data and index object names of the data set being recovered must be the same as the data and index object names that were exported. The object names of the data set being recovered will be passed to AMS IMPORT for renaming the NEWNAME data set. The access method services facility (AMS) then verifies that the data and index object names of the data set being recovered are the same as the ones that were exported.

5. DFSMSHsm does not handle partitioned data set members individually. If you specify a partitioned data set with a member name for either the data set name or the new data set name, DFSMSHsm fails the command.
6. You can recover a backup version of a migrated data set if you specify the NEWNAME parameter. For VSAM data sets, the following is required for recovery to a new name:
 - There is zero or one path defined to the base cluster, and
 - There is zero or one alternate index, and
 - There is zero or one path defined to the alternate index.

The newname parameter cannot be the name of the migrated data set.

RECURSE: Examine subdirectories of the specified UNIX file path

Explanation: **RECURSE(CROSSMOUNTS|CMT|NOCROSSMOUNTS|NCM)** Requests DFSMSHsm to examine subdirectories of the specified path, looking for files that match pattern to recover from the DFSMSHsm backup inventory.

NOCROSSMOUNTS is the default, and directs DFSMSHsm to not recover files that came from a different file system than the initial specified path.

CROSSMOUNTS tells DFSMSHsm to examine directories that are in a different filesystem from the file system containing the starting location when choosing files to recover.

Defaults: None. Only the requested directory is examined for files to recover.

REPLACE: Specifying that the recovered backup version or dump copy is to replace any existing data set of the same name

Explanation: **REPLACE** is an optional parameter specifying the recovered backup version or a dump copy of the uncataloged data set replaces any existing uncataloged data set with the same data set name on the target volume. If the data set is cataloged, DFSMSHsm scratches it and recatalogs the data set with the same data set name. If you specify the NEWNAME parameter and the new name is the same as the name of an existing data set, you must specify the REPLACE parameter. If you do not, DFSMSHsm fails the RECOVER command..

Defaults: When DFSMSHsm recovers a volume, it always replaces data sets with the same name on the target volume.

Note:

1. If you do not specify the REPLACE or NEWNAME parameter for an existing data set, DFSMSHsm does not recover the data set. For cataloged data sets, the old copy remains cataloged. For uncataloged data sets, the data set by the same name remains on the target volume.
2. The data set to be replaced must have the same organization as the data set from which the backup version was created. If the backup version is being recovered and both the backup version and the target data set are cataloged, DFSMSHsm fails the RECOVER request when the data set organizations do not match.

RSA: Specifying that the RSA parameter is to override the RSA key label

Explanation: **RSA** Specifies the RSA parameter to override the RSA key label that DFSMSdss would otherwise use to restore the encrypted dump. The key label can consist of up to 64 characters, of which the first character must be alphabetic or national.

TARGETVOLUME: Specifying the volume to receive the restored data sets

Explanation: **TARGETVOLUME**(*volser*) is an optional parameter specifying that volume restore should use the volume specified by *volser* and change this *volser* to the *volser* of the TOVOLUME parameter during the restore operation.

Defaults: None

Note:

1. TARGETVOLUME is only valid when the TOVOLUME and FROMDUMP parameters are specified. If you specify TARGETVOLUME when it does not apply, an error message will be issued.
2. If you do not specify TARGETVOLUME, a volume with the *volser* specified in the TOVOLUME parameter must exist and be online.
3. If an SMS-managed volume is being restored and APPLYINCREMENTAL is specified, either the TARGETVOLUME or another SMS-managed volume must be available to be selected as directed by your ACS routines in order for the APPLYINCREMENTAL portion to recover later backup versions. Note that even if the TARGETVOLUME is SMS and selectable, APPLYINCREMENTAL processing may select a different SMS volume if available.
4. If APPLYINCREMENTAL and TARGETVOLUME are specified, the TOVOLUME must be varied OFFLINE before issuing the RECOVER command. If the TOVOLUME is ONLINE, the command will fail and new message ARC0256I will be issued. This new message is documented below.
5. After the RECOVER command completes, additional steps may be required to complete the volume change and to establish access to the restored volume. Check all DFSMSHsm, DFSMSdss, and system messages issued during the Volume Restore. Since the TARGETVOLUME must be online, if the TOVOLUME is also ONLINE, check for DFSMSdss message ADR344I indicating that a duplicate volume will be varied offline. ADR344I includes the unit to be varied offline. Following this, check for messages like IEF281I 0E19 NOW OFFLINE indicating the volume is offline. If this is the unit for TARGETVOLUME, after the command completes, you will need to vary the TOVOLUME unit OFFLINE

and then vary the TARGETVOLUME unit ONLINE. You should display the units before issuing the command, and note the units and associated volsers for both the TOVOLUME and TARGETVOLUME.

TERMINAL: Requesting that volume recovery messages appear at the terminal

Explanation: **TERMINAL** is an optional parameter requesting that volume recovery messages be sent to the system console and to the backup activity log when DFSMSHsm recovers a volume.

Defaults: If you do not specify **TERMINAL** when you want to recover a volume, DFSMSHsm sends the output only to the backup activity log.

Note: **TERMINAL** applies only to volume recovery. In addition, you must issue the **TERMINAL** parameter of the **RECOVER** command from the system console. If you specify **TERMINAL** when it does not apply, DFSMSHsm ignores it.

TOVOLUME: Specifying the volume to receive the recovered data set

Explanation: If you are recovering a data set, **TOVOLUME(volser)** is an optional parameter specifying which volume should receive the recovered data set. For *volser*, substitute the serial number of the volume that is to receive one or more recovered data sets.

If you are recovering a volume, **TOVOLUME(volser)** is a required parameter specifying which volume you want to recover. For *volser*, substitute the serial number of the volume that is to be recovered. The *volser* that is to be recovered must be the same as the source *volser* of the volume that was backed up or dumped.

If you specify **TOVOLUME** when recovering an SMS-managed data set, the *volser* will be passed to the automatic class selection (ACS) routines; ACS, however, ultimately determines to which volume the data set is recovered. The **TOVOLUME** parameter is ignored if an existing SMS data set is recovered as SMS.

Defaults: If you are recovering from a backup version of a cataloged data set and do not specify **TOVOLUME**, DFSMSHsm recovers the backup version to the volume where the catalog entry shows the data set currently exists. If no catalog entry exists, DFSMSHsm recovers the backup version to the volume where the data set resided when it was backed up unless the backup version was created from a data set on a migration volume. If the data set was backed up while residing on a migration volume and you do not specify the **TOVOLUME** parameter, DFSMSHsm recovers the backup version to the volume from which the data set last migrated.

If you are recovering from a backup version of an uncataloged data set and do not specify **TOVOLUME**, DFSMSHsm recovers the backup version to the volume where the data set resided when it was backed up, unless it is recovered as SMS.

Note:

1. If you specify **TOVOLUME**, you must also specify the **UNIT** parameter.
2. If DFSMSHsm is recovering a VSAM data set not cataloged in an integrated catalog facility catalog, **TOVOLUME** can only specify a volume owned by the catalog where the data set being recovered is cataloged or will be cataloged.
3. The **TOVOLUME** parameter is passed to the ACS routines when processing a data set that will be recovered to an SMS-managed volume.
4. If a data set that was SMS-managed when backed up has been deleted, and if ACS determines that data set is now non-SMS, **TOVOLUME** is required to recover that data set to a non-SMS-managed volume. If **TOVOLUME** is not specified, the recovery will fail with message ARC1170I and reason code 13.
5. If both **TOVOLUME** and the **VOLCOUNT(N(nn))** parameters are specified, the resulting volume count for the data set will be one (1). If space does not exist on the specified volume, the allocation fails.

Attention

If you specify TOVOLUME for a data set that was backed up with DFSMSdss and you direct it to a volume that has an uncataloged data set with the same name, DFSMSdss tries to restore the cataloged data set on top of the uncataloged data set; as a result, your attempt fails. DFSMSHsm scratches the uncataloged data set because DFSMSdss fails to restore the cataloged data set.

UNIT: Specifying the type of device

Explanation: **UNIT(*unittype*)** is an optional parameter specifying the type of unit where DFSMSHsm can mount the target volume. You use this parameter with the TOVOLUME parameter.

DFSMSHsm incremental volume recovery and volume restore with APPLYINCREMENTAL do not support a device change on the volume that is recovered. If the device type is changed after the volume is backed up and the device type in the catalog for all data sets residing on the volume is not changed, all VSAM data sets will not be recovered. All non-VSAM data sets may appear to be recovered successfully, but the first allocation after the recovery will fail due to the inconsistent unit name and device type that was created by the recovery.

If you specify the type of unit when recovering an SMS-managed data set, that unit type will be passed to the automatic class selection (ACS) routines; ACS, however, ultimately determines to which unit type the data set is recovered. For *unittype*, substitute the type of unit where DFSMSHsm is to mount the target volume.

The following are valid types of DASD units:

- 3380
- 3390
- 9345

Defaults: None.

Note:

1. If you specify UNIT, you must also specify the TOVOLUME parameter.
2. If the block size of the data set is greater than the track capacity of the target volume, track overflow must be supported in both the software and the hardware. This applies to devices whose track size is less than 32 KB.

Examples of how to code the RECOVER command

The following examples present different ways to code the RECOVER command.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Recovering a cataloged data set to a specific volume

In this example, a backup version or dump copy of a cataloged data set is recovered to the TOVOLUME specified.

```
RECOVER PAC3105.PROJECT.LOAD TOVOLUME(VOL005) UNIT(3390)
```

Recovering an uncataloged data set to a specific volume

In this example, a data set that was uncataloged when it was backed up or dumped is recovered to the TOVOLUME specified.

```
RECOVER JAB1234.ANALYSIS.TEXT TOVOLUME(VOL001) UNIT(3390) +
FROMVOLUME(JAB456)
```

Recovering a next-to-latest backup generation of a cataloged data set

In this example, a next-to-latest backup generation of a cataloged data set is recovered.

```
RECOVER MIL9876.SETUP.ASM GENERATION(1)
```

Recovering the oldest backup version of a cataloged data set

In this example, the oldest backup version of a cataloged data set is recovered.

```
RECOVER C253800.PUBS.ASM VERSION(1)
```

Recovering a data set to replace an existing data set with the same name

In this example, a data set is recovered to the volume the data set is currently cataloged on, and it replaces a data set having the same name. DFSMSHsm scratches the original data set.

```
RECOVER PAC5432.REPORT.CNTL REPLACE
```

Recovering and renaming a data set

In this example, the recovered data set is given a different name. The original data set remains unchanged.

```
RECOVER MIL3210.INPUT.LIST NEWNAME(MIL3210.FINAL.LIST)
```

Recovering an entire volume

In this example, an entire volume is recovered. It is assumed that the volume is current as of the date specified. For example, the volume has been restored with a DFSMSdss dump tape made on that date. Data sets are recovered to the volume only if a backup version was created on or after the specified date.

```
RECOVER * TOVOLUME(SAR005) UNIT(3390) DATE(1991/01/01)
```

Recovering the most recently dumped version of a data set of a specific dump class and renaming the data set

In this example, the most recently dumped version of a specific data set that was dumped to a specific dump class (EXTRA) is recovered and given a different name.

```
RECOVER B110066.POF.N.F230EP06.DSET3 +  
NEWNAME(B110066.POFNEW.NRECOV.F230EP06.DSET3) +  
FROMDUMP(DUMPCCLASS(EXTRA))
```

Recovering the second-most recently dumped version of a volume

In this example, the second-most recently dumped version is used to do a full-volume restore of volume P1. Immediately following the restore, the data sets that were incrementally backed up since the dump occurred are recovered.

```
RECOVER * TOVOLUME(PTU001) +  
FROMDUMP(DUMPGENERATION(1) APPLYINCREMENTAL) +  
UNIT(3390)
```

Recovering a data set and forcing it to a non-SMS-managed volume

In this example, a data set that was SMS-managed when it was backed up or dumped is being forced to a non-SMS-managed volume during recovery.

```
RECOVER SMS.REPT.CNTL FORCENONSMS +
TOVOLUME(VOL006) UNIT(3390)
```

Recovering a data set for relative block accessing

In this example, a data set is to be recovered so that it can be accessed for relative block addressing. Even though the data set would have been SMS-managed after the recovery, it is directed to a non-SMS volume.

```
RECOVER TK1789.PARTS.DA3 DAOPTION(RELBLK) +
TOVOLUME(NONSMS) UNIT(3390) FORCENONSMS
```

Recovering a migrated data set to level 0

In this example, a non-VSAM, migrated data set is recovered. The NEWNAME parameter identifies a data set that is not migrated.

```
RECOVER TEST.DSET.N01 NEWNAME(TEST.DSET.N02)
```

Recovering a lost volume to a DASD volume with a different volser

In this example, a lost volume is to be recovered to a DASD volume with a different volser. The TARGETVOLUME parameter saves you the step of "clipping" a volume to the lost volser.

```
RECOVER * TOVOLUME(VOL008) UNIT(3390) TARGETVOLUME(SAR10) +
FROMDUMP(DUMPVOLUME(DUMP05) APPLYINCREMENTAL)
```

Recovering a data set that failed because of inadequate space

In this example, a data set was not recovered by DFSMSdss because an inadequate space condition occurred. The RECOVER command can be issued again with the VOLCOUNT parameter allowing the data set to be recovered to as many volumes as needed (maximum of 59) for successful allocation. DFSMSHsm passes the VOLCOUNT parameter to DFSMSdss.

```
RECOVER C253800.ID.PARTS DFDSOPTION(VOLCOUNT(ANY))
```

Chapter 61. RECYCLE command: Consolidating valid data to one tape from other tapes

The RECYCLE command consolidates data from any migration or backup tape volume (except an unassigned backup volume) that contains a small percentage of valid data. This lets you reuse your nearly empty tape volumes. Tape volumes that may have data checks or invalid file block identifiers can also be recycled.

When you issue the generic RECYCLE command, DFSMSHsm moves valid backup versions or valid migration copies from several tapes to one tape volume. The specific RECYCLE command moves valid backup versions or valid migration copies from one tape, or a connected set of tapes, to one tape volume. For example, if you specify RECYCLE SPILL, DFSMSHsm moves the valid data from all eligible tape spill backup volumes to one tape spill backup volume until that spill backup volume becomes full. DFSMSHsm then selects another available tape spill backup volume to receive the valid data sets. If you had specified SETSYS TAPEDELETION(SCRATCHTAPE), the recycled tapes become scratch tapes. If you had specified SETSYS TAPEDELETION(HSMTAPE), the recycled tapes become unassigned tapes.

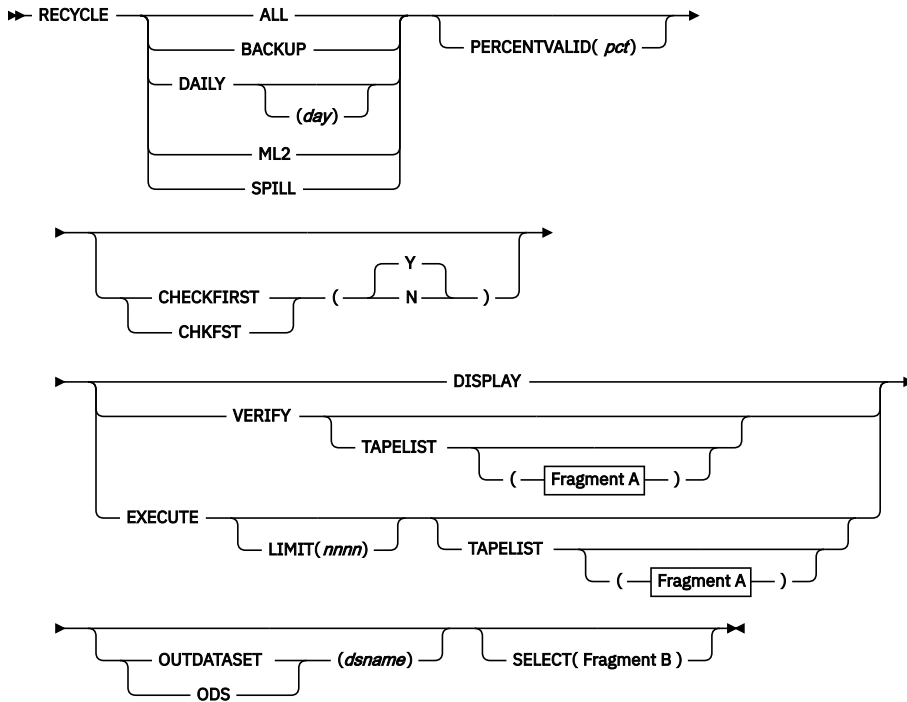

When you recycle a tape backup volume (daily or spill), DFSMSHsm copies the valid data on the tape volume to an available tape spill backup volume. When you recycle a tape migration level 2 volume, DFSMSHsm copies the valid data on the tape volume to an available tape migration level 2 volume.

Although an MVS image can process only one RECYCLE request at a time, RECYCLE initiates up to 15 tape processing tasks when you issue a generic RECYCLE command. Each task that moves data requires two tape drives, one for input and one for output. The SETSYS MAXRECYCLETASKS parameter allows you to specify the number of tape processing tasks that can run at a time.

RECYCLE for the same volume type (ML2, DAILY, SPILL) cannot be issued concurrently from two separate hosts. For example, a request to RECYCLE ML2 tapes from a second MVS image fails if the first image is already recycling ML2 tapes.

RECYCLE will only process connected sets that span 254 or fewer volumes.

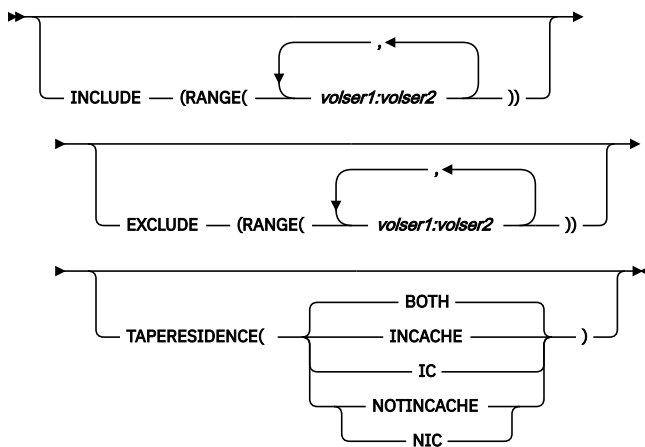

Syntax of the generic RECYCLE command

A: TAPELIST optional parameters

B: SELECT optional parameters

Syntax of the specific RECYCLE command

Required parameters of the RECYCLE command

This topic describes the required parameters of the RECYCLE command.

ALL, BACKUP, DAILY, ML2, SPILL and VOLUME: Specifying the tape volumes to be recycled

Explanation: **ALL**, **BACKUP**, **DAILY**, **ML2**, **SPILL**, and **VOLUME(volser)** are mutually exclusive, required parameters specifying the types of tape volumes to be recycled.

ALL specifies that DFSMSHsm should recycle all eligible daily, ML2, and spill tape volumes.

BACKUP specifies that both daily and spill backup tapes are to be used as input in the RECYCLE processing.

DAILY specifies that DFSMSHsm should recycle all eligible tape daily backup volumes.

Subparameter	Explanation
day	DAILY(day) specifies that DFSMSHsm should recycle all eligible tape volumes assigned to that day in the backup cycle. For <i>day</i> , substitute a decimal number to represent the day in the backup cycle assigned to the tape daily backup volume. You use the DEFINE BACKUP command to define the backup cycle.

ML2 specifies that DFSMSHsm should recycle all eligible tape migration level 2 volumes. If the SETSYS ML2PARTIALSNOTASSOCIATEDGOAL(*nnn*) parameter has been specified with a value other than NOLIMIT and the number of ML2 partial tapes not currently associated as output for any migration or recycle task and meeting the recycle criteria is greater than *nnn* then DFSMSHsm recycles the excess over *nnn*, that is, those tapes with the least percent of valid data. A partial is a tape that is not full and not empty.

SPILL specifies that DFSMSHsm should recycle all eligible tape spill backup volumes.

VOLUME(volser) specifies the volume to be recycled. For *volser*, substitute the serial number of the volume to be recycled. When you specify a volume serial number, DFSMSHsm does not check whether the specific tape volume is eligible for recycling. This allows you to recycle tapes that are not full or that were otherwise not selected by generic recycle.

Defaults: None.

Note:

1. If you specify a generic request, a connected set is eligible for recycling only if the following conditions are met for all volumes in the set:
 - The tape volume is a migration level 2 tape or a backup tape, but not an unassigned backup tape.
 - The tape volume is either marked full, or a partial ML2 tape that is not connected to any other tape and not currently associated with any migration or recycle output task.
 - The tape volume is marked full.
 - The percentage of valid data is equal to or less than the applicable value. This percentage is specified with the PERCENTVALID parameter, the SETSYS ML2RECYCLEPERCENT parameter, or the SETSYS RECYCLEPERCENT parameter. When these parameters are not specified, the DFSMSHsm default is 20%.
 - The volume has not previously failed recycle processing, or if it has failed, now contains no valid data.
 - The TTOC for the volume is complete.
 - The volume does not have a disaster alternate volume.
2. Dump volumes are not recycled.

- For performance reasons, DFSMSHsm does not update the OCDS TTOC every time a data set is migrated or backed up to a tape volume. If DFSMSHsm abends, an I/O error occurs, or a system fails, the OCDS TTOC may not be updated. If you specify the RECYCLE command to recycle a tape volume that has missing TTOC entries, message ARC0378I is issued, indicating that the tape media and the OCDS TTOC have a mismatch. Use the AUDIT MEDIACONTROLS FIX command to resolve the problem. For more information, see [“MEDIACONTROLS VOLUMES, MEDIACONTROLS\(SDSP\) VOLUMES and MEDIACONTROLS\(CLOUD\): Requesting an audit of control information”](#) on page 748.

EXECUTE, VERIFY, and DISPLAY: Specifying whether to list or to recycle tape volumes

Explanation: **EXECUTE**, **VERIFY**, and **DISPLAY** are mutually exclusive, required parameters that specify whether to recycle, print tape lists, or list volumes that meet eligibility criteria (percent valid) for recycling.

EXECUTE specifies that DFSMSHsm should recycle a specific tape volume, a category of backup volumes, tape migration level 2 volumes, or a combination of all volumes. Volumes that meet the eligibility criteria are recycled. To recycle volumes that do not meet the eligibility criteria, you must prepare the volumes for recycle by following the specified actions.

VERIFY specifies that DFSMSHsm produces one set of tape volume serial numbers that are listed twice: in two different formats and in one output data set. Customers can use the first list as a **pull list** and the second list as a **mount list**.

- **Pull list:** One or more tape groups of the requested category (ML2, SPILL, and so forth) to be pulled from tape storage. Each group is ordered by volume serial. The groups are in the order in which RECYCLE will most likely request that tapes be mounted when the RECYCLE EXECUTE command is issued. Volumes in a connected set are not split between groups. Empty tapes are included and identified as such, but are not mounted during RECYCLE processing. Pull lists are used by operators to fetch and transport the required tapes during RECYCLE processing.
- **Mount list:** A list of all tapes to be recycled for a given category, ordered by the reuse capacity. This is the order in which recycle most likely requests the tapes be mounted. However, this projected mount order may differ from the actual mount order due to other factors affecting recycle processing including, but not limited to, running more than 1 recycle task, unrecoverable errors, a mixture of device types within the mount list, or connected sets containing more than 5 volumes. The volumes in a connected set are identified and listed together. Empty tapes are included and identified as such, but are not mounted during RECYCLE processing. Mount lists aid tape operators with the mounting order of tapes that are being recycled.

Both of these lists are dynamically allocated to either a SYSOUT data set or to the data set having the prefix that you specified with the TAPELIST PREFIX(*tapelist_prefix*) parameter or to the fully qualified data set name that you specified with the TAPELIST FULLDSNAME(*tapelist_dsn*) parameter. The data set is deallocated when the command completes.

DISPLAY gives you a formatted list in volume serial sequence of the tape volumes eligible for recycling that meet the percent valid criteria. The list is dynamically allocated to either a SYSOUT data set or the data set specified by the OUTDATASET parameter. If you request DISPLAY for a specific tape volume, you will get a list of the connected set containing that volume. DFSMSHsm sends a message containing the information to your terminal or optionally directs this information to a data set specified by the OUTDATASET parameter.

When you specify the VERIFY or DISPLAY parameters, the total output includes one or more of the following volumes:

- Eligible tape daily backup volumes assigned to a particular day (or to all days) in the backup cycle
- Eligible tape spill backup volumes
- Eligible tape migration level 2 volumes

When you specify the VERIFY or DISPLAY parameters, DFSMSHsm does not ask for any tapes to be mounted.

Defaults: None.

Note:

1. If you are a customer without an ATL but with a relatively *small* number of tapes that you must pull manually from shelf storage, use the DISPLAY parameter.
However, if you are a customer without an ATL but with a *large* number of tapes that you must pull manually, the VERIFY parameter (or EXECUTE TAPELIST) is a better choice.
2. With the VERIFY parameter, the number of volumes in a pull group (and the total number of volumes to be pulled) can be specified with the optional TAPELIST parameter.
3. If you specify the VERIFY parameter with a single volume, DFSMSHsm treats the command as if you had specified DISPLAY.

Optional parameters of the RECYCLE command

This topic describes the optional parameters of the RECYCLE command.

CHECKFIRST: Allowing connected set to be recycled sooner

Explanation: **CHECKFIRST** is an optional parameter that allows connected sets to be recycled sooner. In determining whether to recycle a connected set, DFSMSHsm requires the first tape within the connected set to meet the PERCENTVALID specification before continuing on with the calculation for the entire connected set's. You can bypass this first volume check by using the CHECKFIRST(N) parameter of the RECYCLE command. If CHECKFIRST(N) is specified, the entire connected set's percentage of valid data is calculated regardless of the percent of valid data on the first volume.

Notes:

1. If you enter the RECYCLE command with the VOLSER parameter, the system ignores the CHECKFIRST parameter.
2. Be aware that CHECKFIRST(N) causes recycle processing to always determine the percent valid for the entire connected set, which can slow recycle performance if you have many connected sets.

Defaults: If CHECKFIRST is not specified on the RECYCLE command, then recycle performs as if CHECKFIRST(Y) had been specified.

FORCE: Forcing DFSMSHsm to permit a tape recycle

Explanation: **FORCE** is a parameter specifying whether to permit the specified 3480 single-file tape or equivalent to be recycled even though the tape contains data checks or invalid file block identifiers. The FORCE optional parameter is valid only when used with the specific RECYCLE command for a single volume request. The only connected volume set that will be processed, is a connected set containing the specified volume.

When the FORCE parameter is in effect, RECYCLE works the same as when FORCE is not specified, except when a data check or an invalid file block identifier is encountered. DFSMSHsm invalidates the data set being processed before continuing with the next data set on the tape. Migrated data sets are deleted, including the catalog entry. In this case, it is the storage administrator's task to recover the data set from another source. For backup copies, the version with the error is invalidated. Because the records necessary to access the data will be lost when using the FORCE parameter, it should be specified only when no alternate volume previously generated by the TAPECOPY command is available.

When processing tape volumes with known errors, use the following steps:

1. If an alternate tape volume exists, use the tape replace function (see Chapter 69, [“TAPERPL command: Replacing cartridge-type tape volumes with their alternate volumes,”](#) on page 1235) instead of recycling the volume.
2. If you do not have an alternate volume, the following steps are recommended to reduce the exposure of deleting accessible data when an error occurs—such as a hardware malfunction:
 - a. Use the RECYCLE command without the FORCE parameter to move all data without errors to another tape volume.

- b. Now use the RECYCLE command with the FORCE parameter to effectively remove all references to any data that is still inaccessible. After this process, the tape volume is deleted.

For a full discussion of recovery situations, refer to [Chapter 8, “Aggregate backup and recovery support \(ABARS\),”](#) on page 319.

Defaults: None.

Note: If you specify RECYCLE VOLUME FORCE and the TTOC for the volume is incomplete, RECYCLE will not process this volume. You will need to use the AUDIT MEDIACONTROLS function to prepare the volume for RECYCLE. For more information on the recovery procedures that have to be performed to be able to recycle these data sets, refer to [“How to handle inconsistencies between tape media contents and OCDS TTOC records”](#) on page 550.

LIMIT: Quiescing recycle processing when the desired number of tapes have been returned to scratch

Explanation: **LIMIT(*nnnn*)** is an optional parameter specifying when recycle quiesces. RECYCLE quiesces after the net specified number of tapes have been returned to scratch status. Each task completes the connected set currently being processed and no additional ones are started. You can specify the number of scratch tapes needed (*nnnn*) from 1 to 9999. The LIMIT parameter is subject to the number of tapes allowed by the PERCENTVALID parameter; the LIMIT parameter provides a way to stop processing before all the candidates meeting the PERCENTVALID value are processed.

Net is determined by tapes read in for input minus tapes written to for output. For RECYCLE ALL, the LIMIT is applied to ML2 tapes and BACKUP tapes separately. That is, RECYCLE ALL LIMIT(100) results in 100 net ML2 tapes and 100 net BACKUP tapes, unless you do not have enough tapes that meet the eligibility criteria, for example, when the values indicated by the SETSYS RECYCLEPERCENT or the SETSYS ML2RECYCLEPERCENT parameter have been met.

Defaults: If LIMIT(*nnnn*) is not specified on the RECYCLE command, DFSMSHsm processes all tapes eligible for RECYCLE processing.

Note: The LIMIT parameter specifies an upper bound on the net number of volumes to be returned to scratch status in a given category. If the TAPELIST(TOTAL) parameter is also specified, the TOTAL parameter specifies an upper bound on the number of volumes to be recycled in a given category. In each case, DFSMSHsm treats the upper bounds as approximate, since a connected set is recycled completely or not at all. If the value specified with the TOTAL parameter is too small, the value specified with the LIMIT parameter may not be reached.

OUTDATASET: Directing recycle messages

Explanation: **OUTDATASET(*dsn*)** is an optional parameter specifying where to send the messages generated during RECYCLE processing. For (*dsn*), substitute the fully qualified name of the data set to receive the RECYCLE messages. The recycle command log records all data movement activity that results from processing the RECYCLE command. Any error messages that the RECYCLE command processor issues are also written in this log.

If the data set does not exist, DFSMSHsm dynamically allocates and catalogs an output data set with the following characteristics:

- Data set name specified (*dsname*)
- Record format of fixed-blocked with ANSI control characters (FBA)
- Logical record length of 121
- Data set is system reblockable
- Primary allocation of 20 tracks (see note)
- Secondary allocation of 50 tracks (see note)
- Unit of SYSALLDA. (see note)

If the data set already exists, DFSMSHsm will use the data set. The data set must have the following characteristics.

- The data set must be cataloged and on DASD.
- The data set record format must be FBA, and the logical record length must be 121.
- The data set is system reblockable
- The user can choose the primary space allocation.
- If the data set does not contain data, DFSMSHsm starts writing output data at the beginning of the data set.
- If the data set contains data, DFSMSHsm writes the output data after the existing data.

Defaults: If OUTDATASET(*dsn*) is not specified on the RECYCLE command, DFSMSHsm sends all messages generated during RECYCLE processing to the SYSOUT specified by the SETSYS parameter.

Note: If you select the OUTDATASET option, you can use the PATCH command to change the unit name, primary allocation, and secondary allocation. If you select the SYSOUT option, you can use the PATCH command to change whether, and how, DFSMSHsm limits the lines of SYSOUT output. Refer to the [z/OS DFSMSHsm Implementation and Customization Guide](#) for a list of the available PATCH commands.

PERCENTVALID: Specifying the percent valid criteria for recycle eligibility

Explanation: PERCENTVALID(*pct*) is an optional parameter specifying the maximum percentage of valid data that a volume can have and still be eligible for recycling. DFSMSHsm ignores this parameter if you specified the volume to be recycled. For *pct*, substitute a decimal number from 0 to 100. For example, if you specify *pct* as 30, a connected set (including a single volume) whose first volume in the set contains 30% or less valid data AND whose entire set contains 30% or less valid data is eligible for recycling.

Note: If 0 (zero) is specified, no tape drives are required. Only tapes that contain no valid data are returned to scratch.

By default, DFSMSHsm requires the first volume in the connected set to meet the percent valid criterion before determining the connected set's percentage of valid data. To allow connected sets to be recycled earlier and potentially free up more volumes to scratch or tape pools, you can use the CHECKFIRST(N) parameter to specify that the first volume of a connected set need not meet the PERCENTVALID requirement as long as the entire connected set meets the PERCENTVALID requirement. For example:

```
RECYCLE PERCENTVALID(pct) CHECKFIRST(N)
```

Defaults: If PERCENTVALID(*pct*) is not specified on the RECYCLE command, DFSMSHsm selects an appropriate value based on the volume type parameter specified. Also, recycle processing always performs the first volume check when evaluating the connected set's recycle eligibility.

RECYCLE ALL is treated functionally as a RECYCLE ML2 followed by a RECYCLE BACKUP.

When processing ML2 volumes, DFSMSHsm uses the ML2RECYCLEPERCENT value that has been specified on the SETSYS command. If ML2RECYCLEPERCENT has not been specified, DFSMSHsm uses the SETSYS RECYCLEPERCENT value. If RECYCLEPERCENT has not been specified, the DFSMSHsm default is 20%.

For all backup volume type parameter specifications (Backup, Daily, or Spill), DFSMSHsm uses the RECYCLEPERCENT value.

You can override this default by specifying the RECYCLE PERCENTVALID parameter.

Note:

1. During RECYCLE execution, a DELVOL operation is performed for any volume having 0% valid data.
2. For a discussion of how DFSMSHsm calculates percentages based on valid blocks and connected sets, refer to [Chapter 13, "Managing DFSMSHsm media,"](#) on page 527.

SELECT: Specifying tape eligibility for generic recycle

Explanation: **SELECT** is an optional parameter that is used to specify a selection filter for the eligibility test performed by the RECYCLE function. The SELECT parameter provides increased granularity to filter out tapes that are considered eligible by the percent valid criteria but do not meet the range that is specified with the SELECT parameter.

When the SELECT parameter is specified, you must specify **one** or **both** of the following SELECT sub-parameters:

Subparameter	Explanation
INCLUDE	INCLUDE(RANGE (volser1:volser2 ...)) specifies that this range of tape volumes is included in the RECYCLE eligibility tests. INCLUDE(RANGE(volser1:volser2 ...)) is a required sub-parameter of the SELECT parameter.
EXCLUDE	EXCLUDE(RANGE (volser1:volser2,...)) specifies that this range of tape volumes is not included in the RECYCLE eligibility tests. EXCLUDE(RANGE(volser1:volser2,...)) is a required sub-parameter of the SELECT parameter.
RANGE	RANGE (volser1:volser2,...) specifies a single volser range, a list of volser ranges, a single volume, or a list of volumes. When you specify a volser range, <i>volser1</i> is the beginning of the range, and <i>volser2</i> is the end of the range. When you specify a single volume, use that volume serial number for both <i>volser1</i> and <i>volser2</i> . The only limit on the number of volumes or ranges used for RANGE is the RECYCLE command's limit of 1023 characters for a single command. All tape volumes within a specified range are included. If you are including a connected set of tapes, all tape volumes in the connected set must be within the specified range of volumes to be considered as eligible. If any tape volume within a connected set is specified in the excluded range, then that whole connected set is excluded. Message ARC0849I is issued when an ending volume serial is specified before a starting volume serial.
TAPERESIDENCE	TAPERESIDENCE(BOTH INCACHE NOTINCACHE) only applies to IBM virtual tape server volumes. The TAPERESIDENCE parameters are ignored when recycling non-VTS tape volumes. IBM VTS tape volumes that are eligible for recycle and reside either in cache, not in cache, or both in cache and not in cache as specified via the select parameter will be included in recycle processing.

Note: The SELECT parameter applies only to generic RECYCLE processing. The SELECT parameter is not valid if specified with the RECYCLE VOLUME command.

Defaults:

- If SELECT is not specified on the RECYCLE command, DFSMSHsm uses the percentage specified with the PERCENTVALID parameter to determine RECYCLE eligibility.
- When recycling tape residing in an IBM VTS and the SELECT(TAPERESIDENCE(BOTH | INCACHE | NOTINCACHE)) parameters are not specified on the RECYCLE command, DFSMSHsm will use the SETSYS RECYCLETAPERESIDENCE setting as the default.

TAPELIST: Listing volumes for pulling and mounting tapes

Explanation: **TAPELIST** is an optional parameter that can be used with the VERIFY or EXECUTE parameters (it is ignored if used with the DISPLAY parameter). When TAPELIST is used with the VERIFY parameter, it allows you to review the output while other RECYCLE commands can continue processing. When TAPELIST is used with the EXECUTE parameter, DFSMSHsm produces the same lists as those

produced by the VERIFY parameter, plus, you are given the option to continue the RECYCLE processing after the lists are produced.

The lists are dynamically allocated to either a SYSOUT data set or to the data set generated or specified by the TAPELIST PREFIX parameter or the TAPELIST FULLDSNAME parameter.

Subparameter	Explanation
PULLSIZE	PULLSIZE(<i>nnn</i>) allows you to select the number of tape volumes that is feasible to physically transport at one time from shelf storage to your tape drives (for example, on a cart) or the number of tape volumes that can be managed by an operator after they are brought to the vicinity of the tape drives. Specify a value between 1 and 999.
TOTAL	TOTAL(<i>nnnn</i>) allows you to select the total number of volumes (including empty volumes) to be listed in all pull groups for a given category of DFSMSHsm tapes. If the EXECUTE parameter is specified, this restricts the total number of volumes that can be recycled for that category. Specify a value between 1 and 9999.
PREFIX	<p>PREFIX(<i>tapelist_prefix</i>) is mutually exclusive with the FULLDSNAME parameter. This optional parameter is used to specify the name of the TAPELIST output.</p> <p>You can select the data set prefix to be used for that data set name. DFSMSHsm generates a fully qualified data set name by appending the following qualifiers to <i>tapelist_prefix</i>:</p> <ul style="list-style-type: none"> • .BACKUP, .DAILY, .ML2, or .SPILL, depending on the category of tape volumes specified on the command • date stamp .Dyyyyddd, where <i>yyyy</i> represents the year and <i>ddd</i> the day of the year • time stamp .Thhmmss, where <i>hh</i>, <i>mm</i>, and <i>ss</i> represent the hour, minute, and second <p>Because the maximum length of a data set name is 44 characters, the allowable length of <i>tapelist_prefix</i> is 20 characters, so that the generated data set name will be valid regardless of the volume category specified.</p> <p>When the PREFIX parameter is specified, DFSMSHsm dynamically allocates and catalogs an output data set with the following characteristics:</p> <ul style="list-style-type: none"> • Data set name generated from <i>tapelist_prefix</i> • Record format of FBA • Logical record length of 121 • Data set is system reblockable • Primary allocation of 20 tracks • Secondary allocation of 50 tracks • Unit of SYSALLDA

Subparameter	Explanation
FULLDSNAME	<p>FULLDSNAME(<i>tapelist_dsn</i>) is mutually exclusive with the PREFIX parameter. This optional parameter is used to specify the name of the TAPELIST output.</p> <p>You can select the fully qualified name to be used for the TAPELIST output. If <i>tapelist_dsn</i> data set does not exist, DFSMSHsm dynamically allocates and catalogs an output data set with the following characteristics:</p> <ul style="list-style-type: none"> • Data set name of <i>tapelist_dsn</i> • Record format of FBA • Logical record length of 121 • Data set is system reblockable • Primary allocation of 20 tracks • Secondary allocation of 50 tracks • Unit of SYSALLDA <p>However, if <i>tapelist_dsn</i> does exist, this output data set must be available so that DFSMSHsm can use it for output. This output data set must have the following characteristics:</p> <ul style="list-style-type: none"> • Cataloged and reside on DASD • Record format of FBA • Logical record length of 121 • Data set is system reblockable • Primary allocation of the user's choice • If the data set does not contain data, DFSMSHsm starts writing output data at the beginning of the data set. • If the data set contains data, DFSMSHsm writes the output data after the existing data.

When DFSMSHsm completes writing to the data set, DFSMSHsm deallocates the data set allowing you to browse or print it. If you have specified the EXECUTE parameter, then before DFSMSHsm allocates any tape drives, it issues a WTOR message to the tape operator:

```
ARC0825D RECYCLE TAPE LIST CREATED, DSN=dsname. DO YOU WISH
TO CONTINUE? REPLY 'N' TO STOP RECYCLE OR 'Y' WHEN READY TO
MOUNT TAPES.
```

Replying Y causes recycle processing to select and allocate the first input tapes for as many recycle tasks as are defined. Replying 'N' ends recycle processing for that category of volumes.

Defaults

- If the PULLSIZE parameter is not specified, DFSMSHsm uses the value of 40.
- When the TOTAL parameter is not specified, DFSMSHsm lists pull groups for all the eligible volumes in the category being recycled and if the EXECUTE parameter is specified, recycles all of them.
- When the PREFIX parameter and the FULLDSNAME parameter are not specified, DFSMSHsm writes the TAPELIST output to the SYSOUT class specified by the SETSYS parameter.

Note:

1. If you specify the RECYCLE ALL command and do not specify the FULLDSNAME parameter, DFSMSHsm creates two data sets: one for ML2 volumes and one for backup (daily and spill) volumes. If you also specify the EXECUTE parameter, DFSMSHsm writes the ARC0825D message twice, following the deallocation of each of the two data sets. Your response need not be the same to each

message. If the operator's response is to not continue with ML2 volumes, DFSMSHsm later writes the ARC0825D message with the second data set name, allowing you to recycle backup volumes.

2. Because the volumes in a connected set are not split across pull groups, some pull groups may have fewer volumes than the PULLSIZE value.
3. Empty tapes are not mixed with nonempty tapes within a pull group.
4. If a connected set contains more volumes than the PULLSIZE value, that connected set is listed in a pull group by itself.
5. The TOTAL parameter specifies an upper bound on the number of volumes to be in the list and therefore recycled in a given category. The LIMIT parameter specifies an upper bound on the net number of volumes that can be returned to scratch status in a given category. In each case, the upper bounds are approximate, since a connected set is recycled completely or not at all. If the TOTAL value is too small, the LIMIT value may not be reached.
6. If you specify the RECYCLE ALL command, the total number of volumes pulled can be as much as twice the TOTAL value, one set of migration level 2 volumes and one set of backup volumes.
7. If you specify the RECYCLE ALL command with the TAPELIST(FULLDSNAME) parameter, DFSMSHsm uses this specified data set for the TAPELIST of migration level 2 volumes followed by the lists of backup volumes. You should realize that the backup pass may fail if you have this data set in use after the L2 TAPELIST output is written and do not release it before the backup pass starts. Therefore, you should not use ALL and FULLDSNAME together unless you can be sure that the data set will be freed by the time RECYCLE processing requires it.
8. If you specify the TAPELIST parameter with the DISPLAY parameter or when specifying a single volume, DFSMSHsm ignores the TAPELIST parameter.
9. If all of your tape volumes are in automated tape libraries, the output from the TAPELIST or VERIFY parameters will benefit you as a reporting tool.
10. You can use the PATCH command to change the unit name, primary allocation, and secondary allocation. Refer to the *z/OS DFSMSHsm Implementation and Customization Guide* for a list of the available PATCH commands.

Examples of how to code the RECYCLE command

The following examples present different ways to code the RECYCLE command.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Recycling all volumes, do not check the first volume in a connected set for percent valid criteria

In this example, this command recycles all eligible backup and migration volumes. It also requests that DFSMSHsm not check that the first volume in a connected set meet the percent valid criteria as long as the average percent valid for all volumes in the connected set meets the percent valid criteria.

```
RECYCLE ALL EXECUTE CHECKFIRST(N) PERCENTVALID(25)
RECYCLE PERCENTVALID(25) CHECKFIRST(N)
```

Displaying a list of all eligible tape daily backup volumes

In this example, a formatted list is printed of all tape daily backup volumes that contain 5% or less valid data and are eligible for recycling. Volumes that have 0% valid data are not listed because they do not need to be pulled for a subsequent recycle.

```
RECYCLE DISPLAY DAILY PERCENTVALID(5)
```

Recycling tape spill volumes

In this example, DFSMSHsm recycles all tape spill backup volumes that contain 25% or less valid data and are eligible for recycling.

```
RECYCLE EXECUTE SPILL PERCENTVALID(25)
```

Recycling tape migration level 2 volumes

In this example, DFSMSHsm recycles all tape migration level 2 volumes that are eligible for recycling. DFSMSHsm uses the value specified with the SETSYS ML2RECYCLEPERCENT command to determine the percent valid criteria. If the SETSYS ML2RECYCLEPERCENT is not specified, DFSMSHsm uses the value specified with the SETSYS RECYCLEPERCENT command.

```
RECYCLE EXECUTE ML2
```

Recycling a specific tape volume

In this example, a specific tape volume is recycled. DFSMSHsm does not check the percentage of valid data on the volume or whether the volume is full before it recycles the volume.

```
RECYCLE EXECUTE VOLUME(BATP01)
```

Recycling a tape volume with known errors

In this example, a specific tape volume with known errors is recycled.

```
RECYCLE VOLUME(TAP230) FORCE EXECUTE
```

Displaying a list of both daily and spill backup tapes

In this example, a list of both daily and spill backup tapes that are already empty but have not yet been returned to scratch is displayed.

```
RECYCLE BACKUP DISPLAY PERCENTVALID(0)
```

Recycling a limited number of backup tapes

In this example, DFSMSHsm recycles both daily and spill backup tapes and it quiesces the RECYCLE process when 150 tapes have been returned to scratch. The messages generated during the RECYCLE processing are written to the requested output data set.

```
RECYCLE BACKUP EXECUTE LIMIT(150) OUTDATASET(C253800.RECYCLE.OUTPUT)
```

Producing a list of tape volume serials before recycling those volumes

In this example, DFSMSHsm produces a list of tape volume serials in a pull list format and a mount list format. An operator can transport 100 tapes on each cart and a total of 500 tapes is requested. The list of tape volume serials is written to the output data set prefixed by the requested data set name. After the tapes have been collected, the tape operator can reply "Y" to the ARC0825D message. Then RECYCLE begins to process those tape volumes.

```
RECYCLE BACKUP EXECUTE TAPELIST(PULLSIZE(100) TOTAL(500) PREFIX(REMOTE))
```

Another example of producing a list of tape volume serials before recycling those volumes

In this example, DFSMSHsm produces a list of tape volume serials in both pull list format and mount list format. The PULLSIZE default of 40 is used. All connected sets whose percent valid is not greater than 75% are listed. The list is written to the output data set with a prefix of 'A'.

Note: This example is used to illustrate outputs. We would not expect you to use this command with a PERCENTVALID percentage of 75%.

```
RECYCLE ALL EXECUTE TAPELIST(PREFIX(A)) PERCENTVALID(75)
```

The following is a sample listing of the output data set. For this example, the pull list and the mount list for only ML2 volumes are shown.

```
OUTPUT LIST DATASET: A.ML2.D1996109.T093226
LEGEND:
'*' INDICATES EMPTY TAPE, '-' INDICATES CONTINUATION FROM OR TO
DFSMSHSM RECYCLE PULL LIST FROM 0.0% TO 0.0%
*555060 *555075 *555100 *555222 *555990 *555995

DFSMSHSM RECYCLE PULL LIST FROM 0.8% TO 49.9%
555001 555003 555004 555005 555006 555007 555008 555009
555011 555012 555013 555014 555015 555016 555017 555018
555019 555022 555026 555027 555028 555029 555031 555032
555034 555035 555036 555037 555038 555040 555041 555042
555043 555044 555045 555046 555047 555048 555049 555050

DFSMSHSM RECYCLE PULL LIST FROM 51.4% TO 57.3%
555021 555023 555024 555039 555115 555116 555117 555118
555119 555120
END OF DFSMSHSM RECYCLE PULL LIST
```

Note:

1. The volumes listed in the 0.0% to 0.0% section are empty and will not be mounted
2. The volumes listed in the 0.8% to 49.9% section represent the pull default size of 40 volumes. The volumes are listed in collating sequence to simplify locating them in tape storage.

```
DFSMSHSM RECYCLE MOUNT LIST FROM 0.0% TO 57.3%
*555060 *555075 *555100 *555222 *555990 *555995 555011 555007
555004 555032 555012 555035 555048 555015 555001 555044
555042 555045 555008 555034- -555029 555009 555028 555038
555040 555018 555006 555049 555005 555041 555046 555037
555026 555036 555047 555016 555022 555017 555013 555050
555031 555019 555003 555027 555014 555043 555024 555039
555119- -555120- -555118- -555117- -555116- -555115 555023 555021
END OF DFSMSHSM RECYCLE MOUNT LIST
```

Note:

1. The volume 555015 needs a different device type than the other volumes. It will not be requested after volume 555048, instead volume 555015 will be requested at a later time, when a new drive allocation is performed.
2. When attempting to recycle connected set 555034–555029, an open error occurred on 555034 causing the connected set to fail recycle processing. A mount for 555029 will not be attempted.
3. The connected set 555119–555120–555118–555117–555116–555115 consisted of more than 5 volumes. This connected set will not be mounted on an already mounted drive, independent of the SETSYS RECYCLEINPUTDEALLOCFREQUENCY setting, but will be skipped until a new drive allocation is performed.

Converting current media tapes to a newer tape media

In this example, the SELECT parameter is used to specify a selection filter for RECYCLE processing. For this example, assume the current media to be 3490 tapes and the newer media to be 3590 tapes. Also

assume that the 3490 tapes all have volsers in the range of A00000 through A39999 and 3590 tapes all have volsers in the range of B00000 through B39999.

You can use the INCLUDE parameter to specify a range of tapes to RECYCLE that are 3490 tape media by entering the following command:

```
RECYCLE ALL EXECUTE SELECT(INCLUDE(RANGE(A00000:A39999))) PERCENTVALID(100)
```

Or, you can use the EXCLUDE parameter to specify a range of tapes to exclude from RECYCLE processing that are 3590 tape media by entering the following command:

```
RECYCLE ALL EXECUTE SELECT(EXCLUDE(RANGE(B00000:B39999))) PERCENTVALID(100)
```

Selecting connected tapes for RECYCLE using the SELECT parameter

In this example, three ways to use the SELECT parameter when selecting connected sets for RECYCLE processing are shown. For this example, assume that there are only three connected sets:

- Set A consists of TAPE01 and TAPE09
- Set B consists of TAPE02 and TAPE04
- Set C consists of TAPE03, TAPE05, and TAPE10

In this example, you want to recycle only sets A and C. To recycle connected sets A and C using the SELECT INCLUDE parameters, enter the following command:

```
RECYCLE ALL EXECUTE SELECT(INCLUDE(RANGE(TAPE01:TAPE03,TAPE05:TAPE10)))
```

Although TAPE02 from set B is included in the range, TAPE04 is not included in the range and this makes set B ineligible for RECYCLE processing.

To recycle connected sets A and C using the SELECT EXCLUDE parameters, enter the following command:

```
RECYCLE ALL EXECUTE SELECT(EXCLUDE(RANGE(TAPE02:TAPE02)))
```

Because TAPE02 is specified as the range to exclude and because TAPE02 is part of the connected set B, set B is excluded from RECYCLE processing.

To recycle connected sets A and C using both the SELECT INCLUDE and EXCLUDE parameters, enter the following command:

```
RECYCLE ALL EXECUTE SELECT(INCLUDE(RANGE(TAPE01:TAPE10)) +  
EXCLUDE(RANGE(TAPE04:TAPE04)))
```

Connected set B is not eligible for RECYCLE processing because TAPE04 is specifically excluded.

Selecting single tapes for RECYCLE using the SELECT parameter

In this example, the SELECT parameter is used to select a list of single volumes for RECYCLE processing. To recycle volumes A, J, and Q, enter the following command:

```
RECYCLE ALL EXECUTE SELECT(INCLUDE(RANGE(A:A,J:J,Q:Q)))
```

Chapter 62. RELEASE command: Releasing all or some DFSMSHsm functions for processing

The RELEASE command releases for processing all or part of the DFSMSHsm functions that have been held. You cannot release the processing of a subfunction while the processing of its main function is being held. For example, you cannot release the subfunction BACKUP(AUTO) if the main function BACKUP is held. When you release a main function, the held main function processing and its associated subfunctions processing are released. Commands that failed after you issued the HOLD command are not restarted.

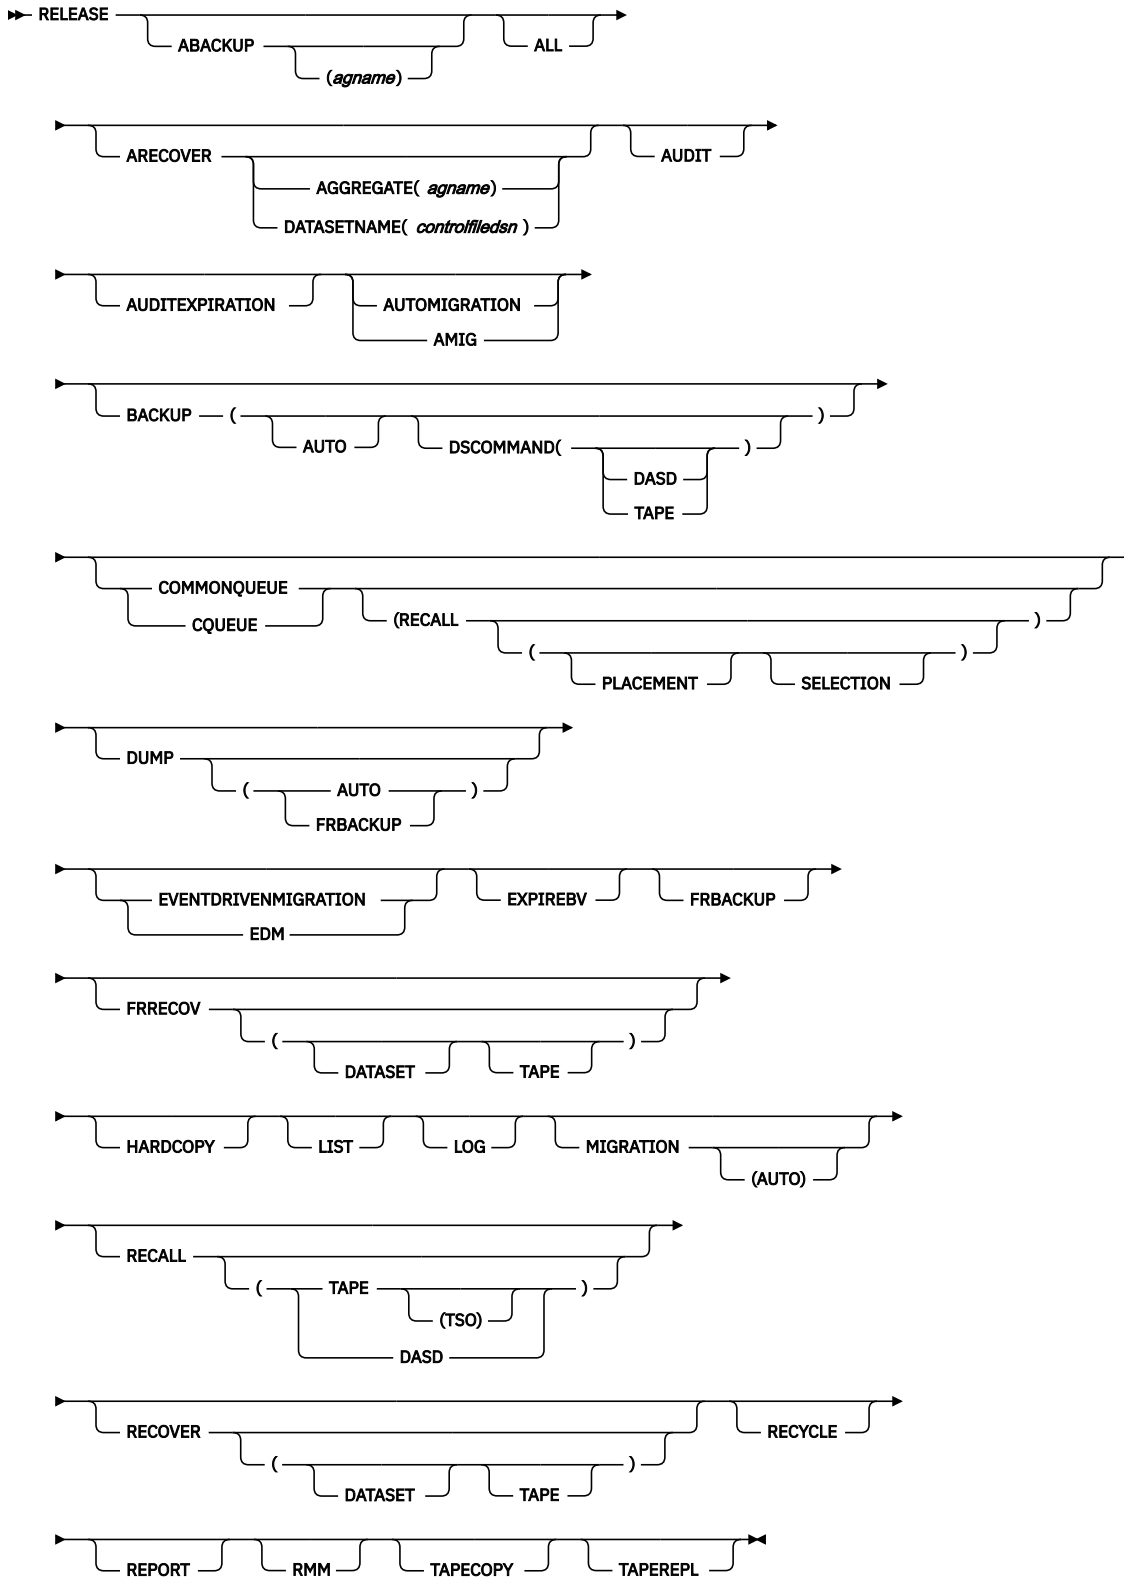

If a journal becomes full, processing is held for all migration, backup, and dump functions. To resume journaling and other DFSMSHsm functions, enter the BACKVOL CDS command to null the journal. If multiple systems share the journal, enter the BACKVOL CDS command on one of the systems, and then enter the RELEASE ALL command on all of the systems that share the journal.

If DFSMSHsm functions are held because of a full journal, the RELEASE command will not appear to be effective until the control data sets are backed up. For more information, see [Chapter 20, “Data recovery scenarios,”](#) on page 629.

The RELEASE command allows migration target levels (ML1 or ML2 tape) that have become unavailable as targets because of some error condition to become available for retry. For more information, see [Chapter 13, “Managing DFSMSHsm media,”](#) on page 527.

In addition, you can also decide to print the activity logs or you can enable the EDGTVEXT interface again after it was disabled because of an ABEND in DFSMSrmm.

Syntax of the RELEASE command

Note:

1. Although the RELEASE command has no required parameters, you must specify at least one parameter to release a DFSMSHsm function for processing.

2. In a multiple address space for DFSMSHsm environment, ABARS commands, like RELEASE ABACKUP or RELEASE ARECOVER, can only be issued by the host identified as the main host. DFSMSHsm ignores the ABARS commands if directed to a host identified as HOSTMODE=AUX.

Optional parameters of the RELEASE command

This topic describes the optional parameters of the RELEASE command.

ABACKUP: Releasing aggregate backup

Explanation

ABACKUP(*agname*) is an optional parameter specifying that DFSMSHsm release for processing any ABACKUP commands currently held in queues and allow new ABACKUP commands to be received. The variable is explained:

agname

Releases any ABACKUP commands held for a particular aggregate group.

Defaults

None.

ALL: Releasing all DFSMSHsm functions

Explanation

ALL is an optional parameter specifying that DFSMSHsm release all functions controlled by this command, except writing in the DFSMSHsm log and printing the activity logs.

Defaults

None.

Usage notes:

1. If you want DFSMSHsm to begin recording in the DFSMSHsm log, you must specify the LOG parameter. If you want DFSMSHsm to print the activity logs, you must specify the HARDCOPY parameter.
2. RELEASE ALL does not release holds on the common recall queue (CRQ). To release a hold on the CRQ, specify RELEASE COMMONQUEUE. To release a hold on only specific CRQ functions, specify the appropriate optional sub-parameters.
3. RELEASE ALL will release AUTOEXPIRATION.

ARECOVER: Releasing aggregate recovery

Explanation

ARECOVER is an optional parameter specifying that DFSMSHsm release for processing any ARECOVER commands currently held in queues and allow new ARECOVER commands to be received. The parameters of the ARECOVER parameter are explained:

AGGREGATE (*agname*)

Releases any ARECOVER commands held for a particular aggregate group.

DATASETNAME (*controlfiledsn*)

Releases any ARECOVER commands held for a particular control file.

Defaults

None.

AUDIT: Releasing the audit function

Explanation

AUDIT is an optional parameter specifying that the audit function is released. DFSMSHsm starts processing any queued AUDIT commands. Any AUDIT command that was interrupted by a HOLD command does not restart.

Defaults

None.

AUTOEXPIRATION: Releasing automatic expiration

Explanation

AUTOEXPIRATION is an optional parameter specifying that DFSMSHsm release a hold on automatic expiration of data sets. Automatic expiration will take place during the next run of a DFSMSHsm space management function.

Defaults

None.

Note: Short hand for the command is 'AEXP'.

AUTOMIGRATION: Releasing only automatic volume and automatic secondary space management

Explanation

AUTOMIGRATION is an optional parameter specifying that DFSMSHsm release automatic volume and automatic secondary space management.

If tape migration has ended while DASD migration continues, or if DASD migration has ended while tape migration continues, this parameter allows both DASD and tape to resume their acceptability as migration targets.

Defaults

None.

Usage notes:

1. You cannot release the AUTOMIGRATION if MIGRATION is held.
2. You can not release the sub-function AUTOEXPIRATION through the RELEASE AUTOMIGRATION command. You must use RELEASE AUTOEXPIRATION (RELEASE AEXP).

BACKUP: Releasing backup

Explanation

BACKUP is an optional parameter specifying whether DFSMSHsm should release all backup processing or release only:

- All data set backup requests
- All data set backup requests to either DASD or tape
- Data set backups to DASD
- Data set backups to tape
- All automatic backups.

BACKUP by itself specifies that DFSMSHsm releases all backup processing. The parameters of the BACKUP parameter are explained:

AUTO

Releases automatic backup processing only.

DSCOMMAND

Releases data set backups for both tape and ML1 DASD requests.

DASD

Releases data set backups directed to ML1 DASD

TAPE

Releases data set backups directed to tape.

Defaults

None.

Usage notes:

1. You cannot release a subfunction if the initial HOLD was done at a higher level. For example, you cannot release the subfunction BACKUP(AUTO) if the main function BACKUP is held.

For another example: If you issue HOLD BACKUP(DSCOMMAND(TAPE)), DFSMSHsm holds only the data set backup by command to tape subfunction. Then, if you issue RELEASE BACKUP(DSCOMMAND), DFSMSHsm releases data set backup by command to tape because TAPE is a subfunction of DSCOMMAND. However, if you issue HOLD BACKUP, DFSMSHsm holds all backup processing. Then, if you issue RELEASE BACKUP(DSCOMMAND(TAPE)), DFSMSHsm *still* holds data set backup by command to tape because all backup to tape was held at the BACKUP level.
2. Releasing a particular function releases the hold on that function's subfunctions, as well.
3. If the time is still within the backup start window, automatic backup starts processing any functions that have not already been processed. Any volumes that were not already fully processed are candidates for processing if less than 24 hours has passed since automatic backup was last started from the beginning and if the time is still within the backup window.
4. If automatic backup is not scheduled to run on a particular day, you can use the BACKUP parameter of the RELEASE command to move backup versions (and backup migrated data sets). Automatic backup is scheduled not to run if you specified SETSYS AUTOBACKUPSTART(0) or specified *N* for this day in the backup cycle.

COMMONQUEUE: Releasing holds on the common queue

Explanation

COMMONQUEUE is an optional parameter that specifies that DFSMSHsm release all holds at the COMMONQUEUE, RECALL, PLACEMENT, and SELECTION levels. All unselected recall requests in the local queue move to the common recall queue (CRQ). The parameters of the COMMONQUEUE parameter are explained:

RECALL

Specifies that if there is no hold at the COMMONQUEUE level, then release a hold at the RECALL, PLACEMENT, and SELECTION levels. All unselected recall requests in the local queue move to the common recall queue (CRQ).

PLACEMENT

Specifies that if there is no hold at the COMMONQUEUE level or RECALL level, then release a hold at the PLACEMENT level. All unselected recall requests in the local queue move to the common recall queue (CRQ).

SELECTION

Specifies that if there is no hold at the COMMONQUEUE level or RECALL level, then release a hold at the SELECTION level.

Defaults

None.

Usage notes:

1. For an overview of how the CRQ operates after a HOLD or RELEASE command is issued, see [Chapter 4, “Other space management considerations,” on page 127.](#)

DUMP: Releasing dump**Explanation**

DUMP is an optional parameter specifying whether DFSMSHsm should release both automatic dump and command dump or only automatic dump.

The parameters of the DUMP parameter are explained:

AUTO

Releases automatic dump processing only.

FRBACKUP

Releases the dump processing of FRBACKUP target volumes.

This command will have the same effect if the system issuing the command is connected to a dump group in the HSMplex. Dump tasks from this system will now be able to be used by the group master scheduler system for dump processing.

The RELEASE DUMP command allows dump processing.

If any variant of RELEASE for dump is issued on a host running a CDQ, that host is eligible to be selected for CDQ volume dump processing if the following conditions are met:

- No other HOLD for DUMP is in place for the host.
- SETSYS MAXDUMPTASKS(x) is specified with a value greater than 0.
- If the host is the CDQ MS, it is eligible to perform MS assignment responsibilities for the dump function.

Defaults

None.

Usage notes:

1. You cannot release the subfunction DUMP(AUTO) if the main function DUMP is held.
2. If the time is still within the dump window, automatic dump starts to process any functions that had not been completed when the dump function was held.

EVENTDRIVENMIGRATION: Releasing Interval and On-demand Migration

Explanation: **EVENTDRIVENMIGRATION** is an optional parameter specifying that DFSMSHsm should release both interval Migration and On-demand Migration.

Defaults: None.

Note: When you issue the RELEASE command, Interval or On-demand migration will not be started automatically. They will start at the next time interval or volume threshold event.

Note: RELEASE EVENDRIVENMIGRATION will only cause Interval and/or On-demand migration functions to be released. Other automatic migration functions may still be held.

EXPIREBV: Releasing the expire backup versions function

Explanation

EXPIREBV is an optional parameter specifying that DFSMSHsm release the expire backup versions function. DFSMSHsm starts processing any queued EXPIREBV commands.

Entering a RELEASE EXPIREBV command does not restart an EXPIREBV command that was in process at the time a HOLD EXPIREBV command was issued. To continue processing, you must reenter the EXPIREBV command. If the function is held when the command is reentered, the command will be saved by DFSMSHsm and processed once the function is released.

Defaults

None.

FRBACKUP: Releasing the fast replication backup or dump function

Explanation

FRBACKUP is an optional parameter that you specify to release the fast replication backup or dump functions. When you issue this command, DFSMSHsm starts processing any queued FRBACKUP, FRBACKUP DUMP, or FRBACKUP DUMPONLY commands.

This command will have the same effect if the system issuing the command is connected to a dump group in the HSMplex. Dump tasks from this system will now be able to be used by the group master scheduler system for FRBACKUP processing.

Defaults

None.

FRRECOV: Releasing the fast replication recover function

Explanation

FRRECOV is an optional parameter that you specify to release the fast replication recovery function. When you issue this command, DFSMSHsm starts processing any queued FRRECOV commands.

The parameters of the FRRECOV parameter are explained:

TAPE

Releases the recovery processing of FRBACKUP generated dump volumes.

DATASET

Is an optional parameter for HOLD FRRECOV. Data set recoveries are held when HOLD ALL, HOLD FRRECOV or HOLD FRRECOV(DATASET) is specified. The existing TAPE keyword will hold data set recoveries from tape.

The RELEASE FRRECOV command has the same effect when the system that issues the command is connected to a CVQ. However, this host volume recover tasks in the CVQ are used by only the master scheduler host when the following conditions are met:

- No other HOLD RECOVER is in place for the host.

- SETSYS MAXDUMPRECOVERTASKS(x) is specified with a value greater than 0.

If the host is the CVQ master scheduler, it is also eligible to perform MS assignment responsibilities for fast replication recovery requests.

Defaults

None.

HARDCOPY: Releasing the activity logs

Explanation

HARDCOPY is an optional parameter specifying that DFSMSHsm print four activity logs that have data. Printing occurs when ACTLOGTYPE is specified as SYSOUT on the SETSYS command.

If the activity logs are allocated to DASD, printing does not occur, but the current logs are closed and new copies of the logs are allocated for use. Allocating the activity logs to DASD allows you to view or browse the currently allocated activity logs for messages that may have passed too quickly from your screens.

The following activity logs can be printed with the RELEASE HARDCOPY command:

- Backup
- Dump
- Migration
- Command

After printing (or closing) these logs, DFSMSHsm allocates new activity logs.

Defaults

None.

Usage notes:

1. The activity log for Aggregate Backup and Recovery cannot be printed with the RELEASE HARDCOPY command. This activity log is written to either a SYSOUT or DASD data set as determined by the ABARSACTLOGTYPE parameter of the SETSYS command.

LIST: Releasing the list function

Explanation

LIST is an optional parameter specifying that DFSMSHsm release the list function. DFSMSHsm starts processing any queued LIST commands. Any list operation that was in process when list was held is not restarted.

Defaults

None.

LOG: Releasing logging

Explanation

LOG is an optional parameter specifying that DFSMSHsm begin recording in the DFSMSHsm log.

Defaults

None.

MIGRATION: Releasing space management

Explanation

MIGRATION is an optional parameter specifying whether DFSMSHsm should release automatic volume and automatic secondary space management plus command space management or only automatic volume and automatic secondary space management.

The MIGRATION parameter, without any subparameters, specifies that DFSMSHsm release command space management plus automatic volume and automatic secondary space management.

MIGRATION(AUTO) is a subparameter specifying that DFSMSHsm release only automatic volume and automatic secondary space management.

If tape migration has ended while DASD migration continues or if DASD migration has ended while tape migration continues, this parameter allows both DASD and tape to resume their acceptability as migration targets (for both MIGRATION alone and with AUTO).

Defaults

None.

Usage notes:

1. You cannot release the sub-function MIGRATION(AUTO) if the main function MIGRATION is held.
2. You can not release the sub-function AUTOEXPIRATION through the RELEASE MIGRATION(AUTO) command. You must use RELEASE AUTOEXPIRATION (RELEASE AEXP).
3. If the time is still within the automatic primary space management or automatic secondary space management processing window, any automatic primary space management or automatic secondary space management functions that were not completed when migration was held begin processing.

RECALL: Releasing recall and deletion

Explanation

RECALL is an optional parameter specifying whether DFSMSHsm should release automatic recall, recall by command, and deletion of a migrated data set from all volumes, from all tape volumes, or recalls that need tapes and were submitted by a TSO user.

The parameters of the RECALL parameter are explained:

TAPE

Releases held recalls from tape volumes.

TSO

Releases held recalls that required tapes that were submitted by a TSO user.

DASD

Releases held recalls from DASD volumes only, while maintaining the hold on recalls from tape volumes.

Defaults

If you specify the RECALL parameter with any other parameters, then the default is to release all recall and data set deletion tasks from all volumes.

Usage notes:

1. You cannot release the subfunction RECALL(TAPE(TSO)) if either the subfunction RECALL(TAPE) or the main function RECALL is held.
2. You cannot release the subfunction RECALL(TAPE) if the main function RECALL is held.
3. The RECALL(DASD) parameter does not follow the function-to-subfunction release relationship restriction described in the introduction topic [Chapter 62, “RELEASE command: Releasing all or some DFSMSHsm functions for processing,” on page 1029](#). The HOLD RECALL status is converted to a HOLD RECALL(TAPE) -- allowing recall from DASD to continue. There is no corresponding HOLD RECALL(DASD) command.

RECOVER: Releasing recovery and restore

Explanation

RECOVER is an optional parameter specifying whether DFSMSHsm should release all recovery processing or only tape data set recovery and restore processing.

The parameter of the RECOVER parameter is explained:

TAPEDATASET

Releases only tape data set recover and restore processing tasks.

The RELEASE FRRECOV command has the same effect when the system that issues the command is connected to a CVQ. However, this host volume recover tasks in the CVQ are used by only the master scheduler host when the following conditions are met:

If the host is the CVQ master scheduler, it is also eligible to perform MS assignment responsibilities for fast replication recovery requests.

- No other HOLD RECOVER is in place for the host.
- SETSYS MAXDUMPRECOVERTASKS(x) is specified with a value greater than 0.

Defaults

If you specify the RECOVER parameter with any other parameters, then the default is to release all recover and restore processing tasks.

Usage notes:

1. You cannot release the subfunction RECOVER(TAPEDATASET) if the main function RECOVER is held.

RECYCLE: Releasing the recycle function

Explanation

RECYCLE is an optional parameter specifying that DFSMSHsm release the recycle function. DFSMSHsm starts processing any queued recycle request. Any volumes that were being recycled when recycle was held are not restarted.

Defaults

None.

REPORT: Releasing the report function

Explanation

REPORT is an optional parameter specifying that DFSMSHsm release the report function. DFSMSHsm starts processing any queued report request. Any report that was in process when reporting was held is not restarted.

Defaults

None.

RMM: Releasing the DFSMSrmm function

Explanation

RMM is an optional parameter that enables the EDGTVEXT interface again after it was disabled because of an ABEND in DFSMSrmm.

Defaults

None.

TAPECOPY: Releasing the tape copy function

Explanation

TAPECOPY is an optional parameter specifying that the tape copy function is released. DFSMSHsm starts processing any queued TAPECOPY commands.

If the HOLD command has been issued while the TAPECOPY command is processing more than one volume, either from a volume list from the command or an input data set, processing stops after the current volume. TAPECOPY *does not* resume volume processing when the RELEASE command is issued. Therefore, you must reissue the TAPECOPY command to complete the processing of the remaining volumes in the list.

Defaults

None.

TAPEREPL: Releasing the tape replace function

Explanation

TAPEREPL is an optional parameter specifying that the tape replace function is released. DFSMSHsm starts processing any queued TAPEREPL commands.

If the HOLD command has been issued while the TAPEREPL command is processing more than one volume, either from a volume list from the command or an input data set, processing stops after the current volume. TAPEREPL *does not* resume volume processing when the RELEASE command is issued. Therefore, you must reissue the TAPEREPL command to complete the processing of the remaining volumes in the list.

Defaults

None.

Examples of how to code the RELEASE command

The following examples present different ways to code the RELEASE command.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Printing the activity logs

In this example, DFSMSHsm prints activity logs that have data and allocates new activity logs.

```
RELEASE HARDCOPY
```

Releasing the aggregate backup function

In this example, DFSMSHsm releases the backup of aggregated data sets for processing.

```
RELEASE ABACKUP
```

Releasing the aggregate recovery function

In this example, DFSMSHsm releases the recovery of aggregated data sets for processing.

```
RELEASE ARECOVER
```

Releasing common queue functions

In this example, DFSMSHsm releases the common queue functions for processing.

```
RELEASE COMMONQUEUE
```

Releasing placement of recall requests in the CRQ

In this example, DFSMSHsm releases the CRQ placement function for processing.

```
RELEASE COMMONQUEUE(RECALL(PLACEMENT))
```

Releasing selection of recall requests in the CRQ

In this example, DFSMSHsm releases the CRQ selection function for processing.

```
RELEASE COMMONQUEUE(RECALL(SELECTION))
```

Releasing automatic volume and automatic secondary space management functions

In this example, DFSMSHsm releases the recall and deletion of a migrated data set and automatic volume and automatic secondary space management functions for processing. The MIGRATION parameter of the HOLD command was not specified previously.

```
RELEASE RECALL AUTOMIGRATION
```

Releasing the backup functions

In this example, DFSMSHsm releases the backup functions for processing.

```
RELEASE BACKUP
```

Releasing the expiration of backup versions

In this example, DFSMSHsm releases the expiration of backup versions for processing.

```
RELEASE EXPIREBV
```

Releasing the fast replication backup function

In this example, DFSMSHsm releases the fast replication backup for processing.

```
RELEASE FRBACKUP
```

Releasing the fast replication recover function

In this example, DFSMSHsm releases the fast replication recovery function for processing.

```
RELEASE FRRECOV
```

Releasing the list function

In this example, DFSMSHsm releases the list function for processing.

```
RELEASE LIST
```

Releasing all requests for tape recalls in the queue

In this example, DFSMSHsm releases all requests for tape recalls in the queue for processing.

```
RELEASE RECALL(TAPE)
```

Releasing all requests for tape recalls submitted by an interactive TSO user

In this example, DFSMSHsm releases all requests for tape recalls submitted by an interactive TSO user for processing.

```
RELEASE RECALL(TAPE(TSO))
```

Releasing the tape copy function

In this example, DFSMSHsm releases the tape copy function for processing.

```
RELEASE TAPECOPY
```

Releasing the tape replace function

In this example, DFSMSHsm releases the tape replace function for processing.

```
RELEASE TAPEREPL
```

Releasing automatic backup and command data set backups to tape

In this example, DFSMSHsm releases automatic backups and command data set backups directed to tape for processing.

```
RELEASE BACKUP(AUTO DSCOMMAND(TAPE))
```

Chapter 63. REPORT Command: Requesting reports based on DFSMSHsm statistics records

The REPORT command generates reports based on DFSMSHsm statistics records in the MCDS. You can get daily statistics reports and volume statistics reports for one function or for all DFSMSHsm functions, for one volume or for all volumes that have statistics records in the MCDS, and for statistics that have been created on a specific date or between two specific dates.

You can restrict the report to the functions DFSMSHsm performs, such as migration and backup, and you can restrict the report to specific dates.

You can request the following kinds of reports by using the REPORT command:

- Daily statistics report (DAILY)
- Volume statistics report (VOLUMES)

You can restrict the scope and format of the statistics reported as follows:

- Backup statistics report (FUNCTION BACKUP)
- Delete statistics report (FUNCTION DELETE)
- Migration statistics report (FUNCTION MIGRATION)
- Recall statistics report (FUNCTION RECALL)
- Recovery statistics report (FUNCTION RECOVER)
- Recycle statistics report (FUNCTION RECYCLE)
- Spill statistics report (FUNCTION SPILL)
- Transition statistics report (FUNCTION TRANSITION)
- Statistics other than function statistics (NOFUNCTION)

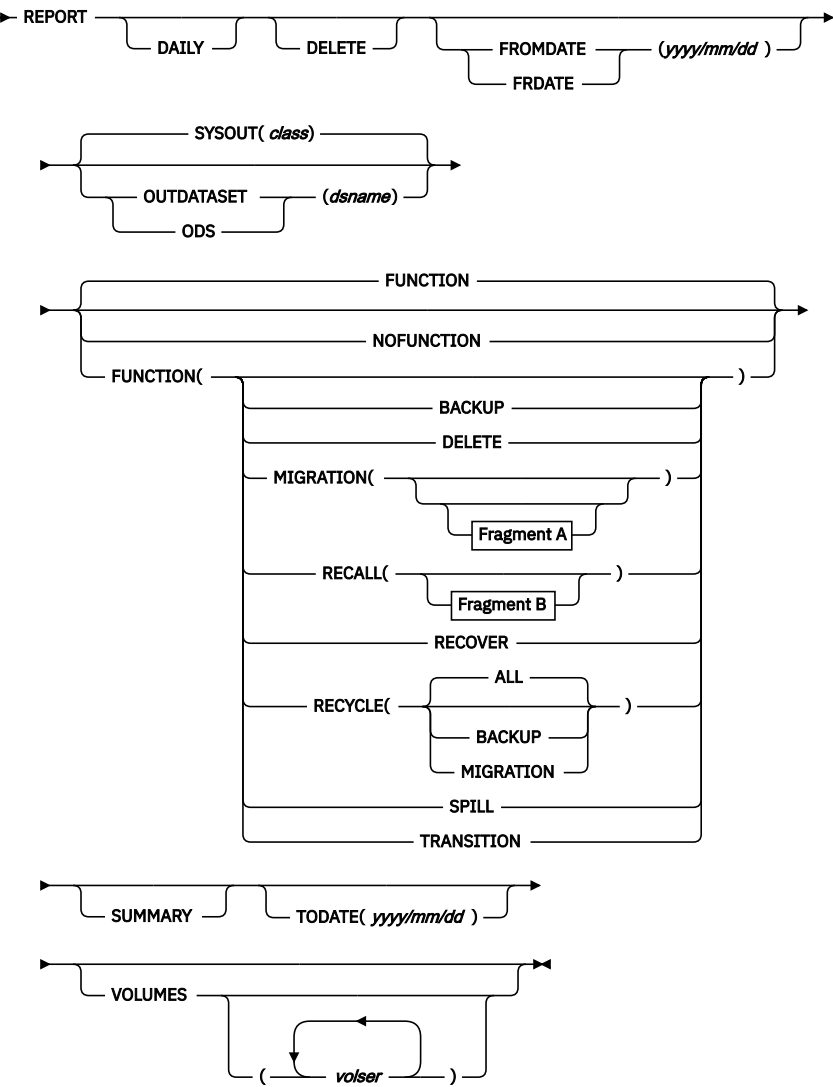

You can further restrict the scope of the statistics reports as follows:

- Statistics for dates on or after a specified date (FROMDATE)
- Statistics between two specified dates (FROMDATE and TODATE)
- Summary totals for the statistics reports (SUMMARY)

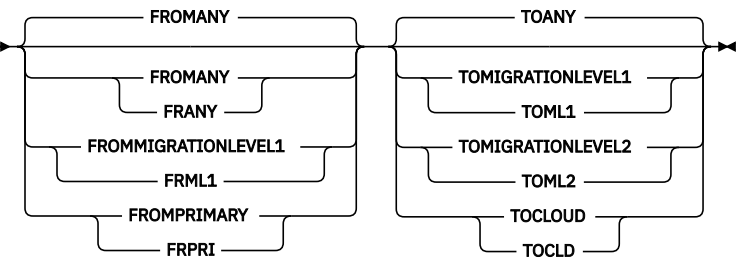

DFSMSHsm allows only one REPORT command to run at a time. [Chapter 78, “Using the REPORT command,”](#) on page 1401 contains sample reports of daily statistics and volume statistics.

For an alternative method of creating customized reports about HSM activities from SMF (FSR and WWFSR) records see [Chapter 14, “Obtaining information from DFSMSHsm,”](#) on page 559 and [z/OS DFSMSrmm Reporting](#).

Syntax of the REPORT command

A: MIGRATION optional parameters

B: RECALL optional parameters

Summary of parameters

The following table is a summary of the combination of parameters you can specify with the REPORT command:

Parameter	Related Parameters
DAILY	All parameters except VOLUMES
DELETE	DAILY or VOLUMES
FROMDATE	DAILY, SUMMARY, TODATE, or VOLUMES
FUNCTION (and all subparameters of FUNCTION)	DAILY or VOLUMES
NOFUNCTION	DAILY or VOLUMES
OUTDATASET	DAILY or VOLUMES
SUMMARY	DAILY, FROMDATE, FUNCTION, TODATE, or VOLUMES
SYSOUT	DAILY or VOLUMES
TODATE	DAILY, FROMDATE, or VOLUMES
VOLUMES	All parameters except DAILY

Optional parameters of the REPORT command

This topic describes the optional parameters of the REPORT command.

DAILY: Requesting daily statistics

Explanation: DAILY is an optional parameter requesting a daily statistics report for all functions. See [Figure 162 on page 1405](#) for an example of the REPORT DAILY output.

Defaults: If you do not specify DAILY or VOLUMES, DFSMSHsm prints a daily statistics report.

Note:

1. If you want a report of daily statistics for all DFSMSHsm functions, specify REPORT DAILY FUNCTION. DFSMSHsm then reports statistics for the current date unless you also specify the FROMDATE and TODATE parameters.
2. For a daily report, the numbers printed on the report indicate the number of attempted DFSMSHsm functional processing requests. Functional processing is not attempted for the following invalid requests:
 - HMIGRATE requests for uncataloged data sets. The command function verifies that the data sets are cataloged before sending an MWE to DFSMSHsm.
 - HRECALL requests for uncataloged data sets. The command function verifies that the data sets are cataloged before sending an MWE to DFSMSHsm.

- Any request that attempts to migrate a volume that is not added to DFSMSHsm without specifying the UNIT parameter.

REPORT DAILY causes DFSMSHsm to update the daily statistics record (DSR) in the MCDS with information from the copy in storage where the command was processed. The report for today does not include any information about functions that were attempted in the last hour from any other DFSMSHsm host in the environment.

3. You can specify either DAILY or VOLUMES. If you specify both parameters, DFSMSHsm prints a volume statistics report.
4. MIGRATION and RECALL statistics do not include amounts for extent reductions.

DELETE: Deleting statistics records used as input to the report

Explanation: DELETE is an optional parameter specifying that DFSMSHsm delete the statistics records used as input to the report after DFSMSHsm finishes processing the REPORT command.

Defaults: If you do not specify DELETE with REPORT, DFSMSHsm does not delete the statistics records used as input to the report.

Note: This parameter is not related to the DELETE subparameter of the FUNCTION parameter.

FROMDATE: Requesting statistics of activity on or after the specified date

Explanation: FROMDATE(*yyyy/mm/dd*) is an optional parameter limiting the statistics report to activity that occurred on or after the date you specify. For *yyyy/mm/dd*, substitute the first date you want DFSMSHsm to report statistics. For example, if you specify FROMDATE(2001/02/01), DFSMSHsm reports statistics for Feb. 1, 2001 through the current date.

A leading zero is not required for a one-digit month or day.

Defaults: If you do not specify FROMDATE, the starting date defaults to the current date.

If you specify a FROMDATE that is later than TODATE, DFSMSHsm sets FROMDATE to the same date as TODATE.

Note:

1. You must specify *yyyy/mm/dd* if you specify FROMDATE.
2. If you specify that DFSMSHsm report the statistics for the current day, DFSMSHsm does not give you the latest statistics. The statistics records are kept in storage and accumulated with a control data set copy of the record only once an hour. Also, each DFSMSHsm host uses the same control data set record. New records are created each day for the DFSMSHsm activities that have occurred today. Therefore, use today's statistics report as an indication of trends of DFSMSHsm activity.
3. If FROMDATE is specified, it must not be after TODATE (specified or defaulted).
4. For REPORT VOLUMES, DFSMSHsm does not allow requesting a range of dates spanning the century. In other words, both FROMDATE and TODATE (whether specified or defaulted) must be before 1 January 2000, or both FROMDATE and TODATE (whether specified or defaulted) must be after 31 December 1999.

FUNCTION and NOFUNCTION: Requesting statistics by function

Explanation: FUNCTION and NOFUNCTION are mutually exclusive optional parameters specifying whether to report the statistics by function.

FUNCTION

specifies that statistics for each specified function are reported.

NOFUNCTION

specifies that function statistics are not reported.

Defaults: The default is FUNCTION. If you specify FUNCTION without any subparameters, DFSMSHsm reports the statistics for all functions.

Note: Because of the number of subparameters of the FUNCTION parameter, each subparameter is described separately.

FUNCTION(BACKUP): Requesting statistics of the backup function

Explanation: BACKUP is an optional subparameter of the FUNCTION parameter to request a statistics report of data sets that have been backed up to daily backup volumes. You can also use it to request a statistics report of EXPIREBV requests.

Defaults: None.

FUNCTION(DELETE): Requesting statistics of the delete function

Explanation: DELETE is an optional subparameter of the FUNCTION parameter to request a statistics report of the migrated data sets that have been deleted or data sets that have been scratched during data set deletion or data set retirement. Deletion of primary data sets includes only those deleted by the DELETEBYAGE (DBA) or DELETEIFBACKEDUP (DBU) functions. The DBA and DBU functions apply only to non-SMS-managed data sets.

Defaults: None.

FUNCTION(MIGRATION): Requesting statistics of the migration function

Explanation: MIGRATION is an optional subparameter of the FUNCTION parameter to request a statistics report about migration.

Use the subparameters of the MIGRATION parameter to select statistics reports about data sets migrated between specified levels of DFSMSHsm storage. For example, when you specify MIGRATION and the FROMPRIMARY and TOMIGRATIONLEVEL1 subparameters, you get a statistics report about only those data sets that DFSMSHsm migrated from primary volumes to migration level 1 volumes.

The following table shows the type of statistics report you get for migration:

Source Volume Subparameter	Target Volume Subparameter	Type of Migration on Statistics Report
FROMANY	TOANY	Primary to Level 1 Primary to Level 2 Primary to Cloud SUBSEQUENT MIGS
FROMANY	TOMIGRATIONLEVEL1	Primary to Level 1
FROMANY	TOMIGRATIONLEVEL2	Primary to Level 2 SUBSEQUENT MIGS
FROMANY	TOCLOUD	Primary to Cloud
FROMMIGRATIONLEVEL1	TOANY	SUBSEQUENT MIGS
FROMMIGRATIONLEVEL1	TOMIGRATIONLEVEL1	
FROMMIGRATIONLEVEL1	TOMIGRATIONLEVEL2	SUBSEQUENT MIGS
FROMPRIMARY	TOANY	Primary to Level 1 Primary to Level 2
FROMPRIMARY	TOMIGRATIONLEVEL1	Primary to Level 1
FROMPRIMARY	TOMIGRATIONLEVEL2	Primary to Level 2
FROMPRIMARY	TOCLOUD	Primary to Cloud

Defaults: When you specify MIGRATION without specifying subparameters, the defaults are FROMANY and TOANY.

Note:

1. When you specify FROMANY and TOMIGRATIONLEVEL2, DFSMSHsm includes data sets that migrate from migration level 2 volumes to different migration level 2 volumes in the statistics of data sets that migrate from migration level 1 volumes to migration level 2 volumes.
2. If you want information about movement from one tape migration level 2 volume to another tape migration level 2 volume, use the RECYCLE parameter.
3. SUBSEQUENT MIGS reflects all movements of data sets from migration level 1 to migration level 1, migration level 1 to migration level 2, and migration level 2 to migration level 2. This includes FREEVOL moves but does not include RECYCLE moves.

FUNCTION(RECALL): Requesting statistics of the recall function

Explanation: RECALL is an optional subparameter of the FUNCTION parameter to request a statistics report for the recall function. The parameters of the RECALL parameter are explained:

FROMANY

specifies that DFSMSHsm should create a statistics report of the data sets recalled from migration level 1 and migration level 2 volumes.

FROMCLOUD

specifies that DFSMSHsm should create a statistics report of the data sets recalled from cloud storage.

FROMMIGRATIONLEVEL1

specifies that DFSMSHsm should create a statistics report of the data sets recalled from migration level 1 volumes.

FROMMIGRATIONLEVEL2

specifies that DFSMSHsm should create a statistics report of the data sets recalled from migration level 2 volumes.

Defaults: When you specify RECALL without specifying subparameters, the default is FROMANY.

FUNCTION(RECYCLE): Requesting statistics of the recycle function

Explanation: RECYCLE is an optional subparameter of the FUNCTION parameter to request a statistics report of the data sets that have been recycled. The parameters of the RECYCLE parameter are explained:

BACKUP

specifies that DFSMSHsm should create a statistics report about the data sets that DFSMSHsm moved from tape backup volumes to tape spill backup volumes during recycle processing.

MIGRATION

specifies that DFSMSHsm should create a statistics report about the data sets that DFSMSHsm moved from the tape migration level 2 volumes to other tape migration level 2 volumes during recycle processing.

ALL

specifies that DFSMSHsm should create a statistics report about tape migration level 2 volumes and tape backup volumes.

Defaults: If you specify RECYCLE and do not specify a subparameter, the default is ALL.

FUNCTION(RECOVER): Requesting statistics of the recovery function

Explanation: RECOVER is an optional subparameter of the FUNCTION parameter to request a statistics report of the data sets that have been recovered from backup volumes.

Defaults: None.

FUNCTION(SPILL): Requesting statistics of the spill function

Explanation: SPILL is an optional subparameter of the FUNCTION parameter to request a statistics report of subsequent movement of backup versions.

Note: These statistics include data sets spilled from daily BACKUP volumes, data sets moved as a result of the FREEVOL BACKUPVOLUME command, and data sets moved from ML1 volumes to BACKUP volumes.

Defaults: None.

FUNCTION(TRANSITION): Requesting statistics of the transition function

Explanation: TRANSITION is an optional subparameter of the FUNCTION parameter to request a statistics report of class transition-related information.

Defaults: None.

OUTDATASET and SYSOUT: Specifying the output location

Explanation: OUTDATASET(*dsname*) and SYSOUT(*class*) are mutually exclusive, optional parameters specifying the output location for the statistics report.

OUTDATASET(*dsname*)

specifies the name of the data set where DFSMSHsm is to write the output data. For *dsname*, substitute the fully qualified name of the data set to receive the statistics report.

If the data set does not exist, DFSMSHsm dynamically allocates and catalogs an output data set with the following characteristics:

- Data set name specified (*dsname*)
- Record format of fixed-blocked with ANSI control characters (FBA)
- Logical record length of 121
- Data set is system reblockable
- Primary allocation of 20 tracks (see second note)
- Secondary allocation of 50 tracks (see second note)
- Unit of SYSALLDA (see second note)

If the data set already exists, DFSMSHsm will use the data set. The data set must have the following characteristics:

- The data set must be cataloged and on DASD.
- The data set record format must be FBA, and the logical record length must be 121.
- The data set is system reblockable.
- The user can choose the primary space allocation.
- If DFSMSHsm needs additional extents after the primary space allocation, DFSMSHsm uses a secondary space allocation of 50 tracks. (see second note)
- If the data set does not contain data, DFSMSHsm starts writing output data at the beginning of the data set.
- If the data set contains data, DFSMSHsm writes the output data after the existing data.

SYSOUT(*class*)

specifies that the statistics report is to be sent to the specified system output class. For *class*, substitute the alphanumeric character for the system output class.

Defaults: The default is SYSOUT, and *class* defaults to the current DFSMSHsm value for the SYSOUT parameter. You specify the current DFSMSHsm value with the SETSYS command. If you do not specify SYSOUT with the SETSYS command, the default is class A.

Note:

1. DFSMSHsm does not handle partitioned data set members individually. If you specify a partitioned data set with a member name as the output data set, the statistics report could be written over existing data. If you do not allocate an output data set with the required characteristics, I/O errors could occur on the output data set.
2. If you select the OUTDATASET option, you can use the PATCH command to change the unit name, primary allocation, and secondary allocation. If you select the SYSOUT option, you can use the PATCH command to change whether, and how, DFSMSHsm limits the lines of SYSOUT output. Refer to the [*z/OS DFSMSHsm Implementation and Customization Guide*](#) for the PATCH command.

SUMMARY: Requesting only the totals of the statistics

Explanation: SUMMARY is an optional parameter requesting that DFSMSHsm print a summary of statistics for the days you specified with the FROMDATE and TODATE parameters.

Defaults: None.

Note:

1. You specify REPORT DAILY FUNCTION SUMMARY to get the summary totals for the daily statistics for all functions. You specify REPORT VOLUME FUNCTION SUMMARY to get the summary totals for the volume statistics for all volumes and for all functions. You specify the VOLUMES parameter with a volume serial number to get summary statistics for only one volume. If you request a summary of specified functions, the summary contains the statistics totals for only the specified functions.
2. When you specify SUMMARY, you get only the summary report. If you do not specify SUMMARY, you get the statistics report you requested, and a summary at the end of the report if DFSMSHsm reported the statistics for more than one day.

TODATE: Requesting statistics of activity on or before the specified date

Explanation: TODATE(*yyyy/mm/dd*) is an optional parameter you use with FROMDATE to limit statistics reports to activity that occurred during that range of time. For *yyyy/mm/dd*, substitute the last date you want statistics reported.

A leading zero is not required for a one-digit month or day.

Defaults: If you do not specify TODATE, the ending date defaults to the current date.

Note:

1. You must specify *yyyy/mm/dd* if you specify TODATE.
2. If you specify that DFSMSHsm report the statistics for the current day, DFSMSHsm does not give you the latest statistics. The statistics records are kept in storage and accumulated with a control data set copy of the record only once an hour. Also, each DFSMSHsm host uses the same control data set record. New records are created each day for the DFSMSHsm activities that occurred today. Therefore, use today's statistics report as an indication of trends of DFSMSHsm activity.
3. If TODATE is specified, it must not be before FROMDATE (specified or defaulted).
4. For REPORT VOLUMES, DFSMSHsm does not allow requesting a range of dates spanning the century. In other words, both FROMDATE and TODATE (whether specified or defaulted) must be before 1 January 2000, or both FROMDATE and TODATE (whether specified or defaulted) must be after 31 December 1999.

For REPORT VOLUMES, DFSMSHsm will not report volume statistics for the current date unless that date is within the range of dates requested.

VOLUMES: Requesting volume statistics

Explanation: VOLUMES(*volser* ...) is an optional parameter requesting a volume statistics report for specified volumes or for all volumes with statistics records in the MCDS. For *volser*, substitute the serial number of the volume or a list of serial numbers of the volumes whose statistics you want reported.

You specify REPORT VOLUMES FUNCTION to get a list of the volume statistics for all functions for all volumes managed by DFSMSHsm. You specify VOLUMES with a volume serial number to get a statistics report for a specific volume. If you do not specify the FROMDATE and TODATE parameters, you receive a statistics report only for the current date.

See [Figure 163 on page 1410](#) for an example of the REPORT VOLUMES output.

Defaults: If you specify VOLUMES without *volser*, DFSMSHsm reports statistics for all volumes that have statistics records.

Note: Any data sets that existed on a volume before you used the ADDVOL command to add the volume to DFSMSHsm control are not included in the report unless DFSMSHsm audited the volume just before the report and no other data sets have been allocated to the volume since the audit.

The volume report information is obtained from the volume statistics record (VSR) in the MCDS. These records are written to the MCDS each hour. Any activity that has occurred since the last update of the VSR will not be reported.

Examples of how to code the REPORT command

For examples of the REPORT command, see [Chapter 78, “Using the REPORT command,” on page 1401](#).

Chapter 64. SETMIG command: Changing the space management status of non-SMS-managed data sets or volumes

The SETMIG command changes the space management status of a specific data set or group of data sets on level 0 volumes. It can also change the space management status of a specific primary volume. You use this command to temporarily change the type of space management for specific cases.

You can change the space management status in three ways:

- Data set migration only by command
- Command and automatic space management
- No command or automatic space management

If you specify a value for DATASETNAME(*dsname*), you do not have to repeat the SETMIG command each time you start DFSMSHsm. But if you specify a value for LEVEL(*qualifier*) or VOLUME(*volser*), you must repeat the SETMIG command each time you start DFSMSHsm.

SETMIG is not supported for SMS-managed volumes or data sets except to remove or restore the SYS1 and HSM data set qualifier restriction when using the LEVEL parameter. If an SMS-managed volume is specified, an error message is issued and no function is performed. The SETMIG command is processed for an SMS-managed data set, but it has no effect on the processing of the data set, because the space management status is determined by a data set's management class attribute.

Syntax of the SETMIG command

A: DATASETNAME and VOLUME optional parameters

B: LEVEL optional parameters

Required parameters of the SETMIG command

This topic describes the required parameters of the SETMIG command.

DATASETNAME, LEVEL, and VOLUME: Changing the space management status

Explanation

DATASETNAME(*dsname*), LEVEL(*qualifier*), and VOLUME(*volser*) are mutually exclusive, required parameters to change the space management status of a data set, group of data sets, or volume.

DATASETNAME(*dsname*)

Changes the space management status of a data set on a level 0 volume.

dsname

Fully qualified name of the data set whose space management status is changing.

LEVEL(*qualifier*)

Changes the space management status of a group of data sets that have the same set of initial characters of the data set name. The data sets are on level 0 volumes.

qualifier

First qualifier of the data set name or any number of contiguous characters, beginning with the first character of the data set name for a group of data sets whose space management status is changing. In other words, any number of leading characters of a data set name can be specified, and the last set of characters can be a partial qualifier.

VOLUME(*volser*)

Changes the space management status of the primary volume.

volser

Serial number of the volume. If you specified the AUTOMIGRATION parameter of the ADDVOL command for this volume, you can use the VOLUME parameter of the SETMIG command to temporarily exclude the volume from automatic primary space management. Even if you temporarily exclude the volume from automatic primary space management, you can still issue commands to migrate a specific data set on the volume.

Defaults

None.

Usage notes:

1. DFSMSHsm does not handle partitioned data set members individually. If you specify a partitioned data set with a member name, DFSMSHsm changes the status of the entire partitioned data set.

Optional parameters of the SETMIG command

This topic describes the optional parameters of the SETMIG command.

COMMANDMIGRATION, MIGRATION, and NOMIGRATION: Specifying the way space management is controlled

Explanation

COMMANDMIGRATION, MIGRATION, and NOMIGRATION are mutually exclusive, optional parameters specifying how space management is controlled for a data set, a group of data sets, or all data sets on a volume.

COMMANDMIGRATION

valid only with the LEVEL parameter, specifies that DFSMSHsm allows space management by data set command for any of a group of data sets you identified with the LEVEL parameter. DFSMSHsm does not manage these data sets when it processes a volume.

MIGRATION

specifies that DFSMSHsm will do space management automatically or by command for a data set, a group of data sets, or all data sets on a volume. You specify the MIGRATION parameter only if you previously specified the COMMANDMIGRATION or NOMIGRATION parameter with the SETMIG command.

NOMIGRATION

specifies that DFSMSHsm will not do space management for the data set, group of data sets, or the volume; however, DFSMSHsm will do space management by data set command for data sets when this parameter is specified with the VOLUME parameter. If NOMIGRATION is specified with the data set name or LEVEL parameter, DFSMSHsm will not do space management by data set command.

Defaults

None.

Usage notes:

1. The COMMANDMIGRATION parameter applies only when you specify the LEVEL parameter. If you specify COMMANDMIGRATION when it does not apply, DFSMSHsm ignores it.
2. SETMIG with the MIGRATION option is only used to remove a previously entered SETMIG restriction.
3. If no SETMIG command is issued for a given data set, the data set is eligible for both command and automatic migration.
4. If a data set is specified in more than one LEVEL parameter, that data set is given the space management status that is the most restrictive. For example, given the following commands:

```
SETMIG LEVEL(A.B) MIGRATION
SETMIG LEVEL(A) COMMANDMIGRATION
```

any data sets that have the first two qualifiers of A.B are covered under LEVEL(A) COMMANDMIGRATION since it is more restrictive and the first SETMIG command is ignored. This is true regardless of the order in which the SETMIG commands are issued. The most restrictive SETMIG option is NOMIGRATION followed by COMMANDMIGRATION. The MIGRATION option basically indicates that there are no restrictions or that any previous restrictions are being removed.

Examples of how to code the SETMIG command

The following examples present different ways to code the SETMIG command.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Changing the space management status of a specific data set

In this example, the space management status of a particular data set is changed to prevent space management by volume processing or data set command.

```
SETMIG DATASETNAME(FST1234.COMPARE.REPORT) NOMIGRATION
```

Changing the space management status of a group of data sets

In this example, the space management status of a group of data sets with the same first qualifier of the data set name is changed to prevent space management by volume processing or by command.

```
SETMIG LEVEL(JJT2143) NOMIGRATION
```

Changing the space management status of a volume

In this example, the space management status of a DFSMSHsm-managed volume is changed to allow automatic and command space management, which was previously restricted, to occur from the volume.

```
SETMIG VOLUME(VOL123) MIGRATION
```

Changing the space management status of a group of data sets to allow space management only by command

In this example, the space management status of a group of data sets is changed to allow space management of a data set only when requested by a command.

```
SETMIG LEVEL(MIL3691.REV3) COMMANDMIGRATION
```

This command would apply to all the data sets listed here:

- MIL3691.REV3
- MIL3691.REV3VER2.LISTING
- MIL3691.REV3456.TEST
- MIL3691.REV3TST.EXAM.LIST

Chapter 65. SETSYS command: Establishing or changing the values of DFSMSHsm control parameters

When you start DFSMSHsm, a subset of DFSMSHsm control parameters is established by default. You can override DFSMSHsm defaults by specifying one or more SETSYS commands in the ARCCMDxx PARMLIB member used when you start DFSMSHsm. You can issue the SETSYS command with specific parameter values after DFSMSHsm is started to change the current defaults. The changed values remain in effect until you restart DFSMSHsm. For an example of how to set up the ARCCMDxx PARMLIB member, see the DFSMSHsm installation verification procedure in *z/OS Program Directory* in the *z/OS Internet library* (www.ibm.com/servers/resourcelink/svc00100.nsf/pages/zosInternetLibrary).

If you do not specify the SETSYS command, DFSMSHsm does not do any automatic space management, backup, or dump. Therefore, if you want to take advantage of the automatic functions of DFSMSHsm, use the SETSYS command.

Do not confuse DFSMSHsm defaults with the SETSYS command defaults. Except for certain values, there are no SETSYS command defaults. A SETSYS command does not have required parameters, so unless you indicate a specific parameter value for the SETSYS command, the DFSMSHsm control parameter is the default. An exception to this is the CDSVERSIONBACKUP parameter.

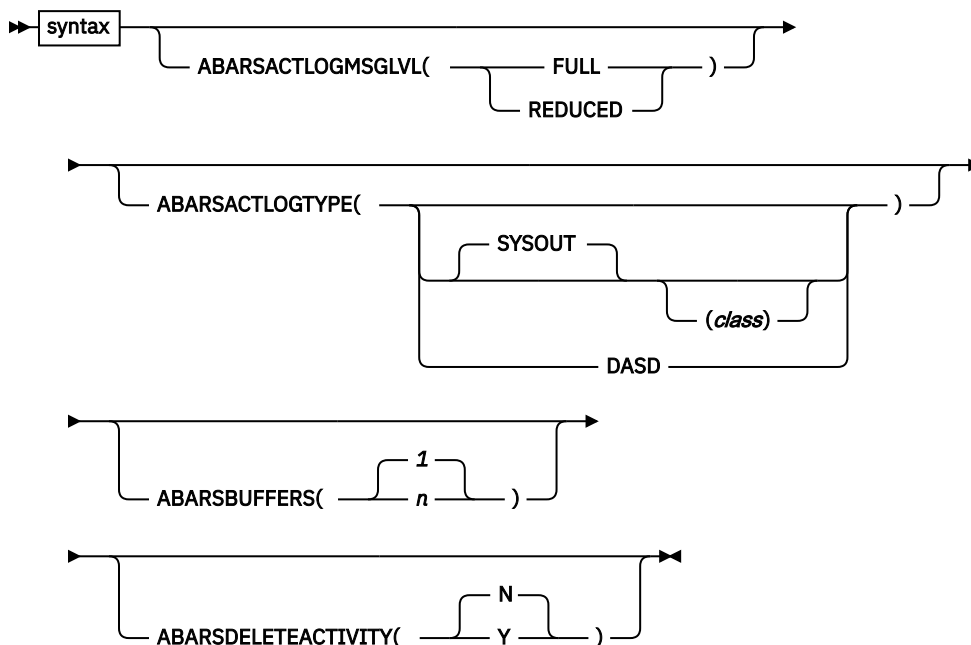

The following link provides a deep dive into the many knobs and dials available to configure DFSMSHsm uniquely to your environment.

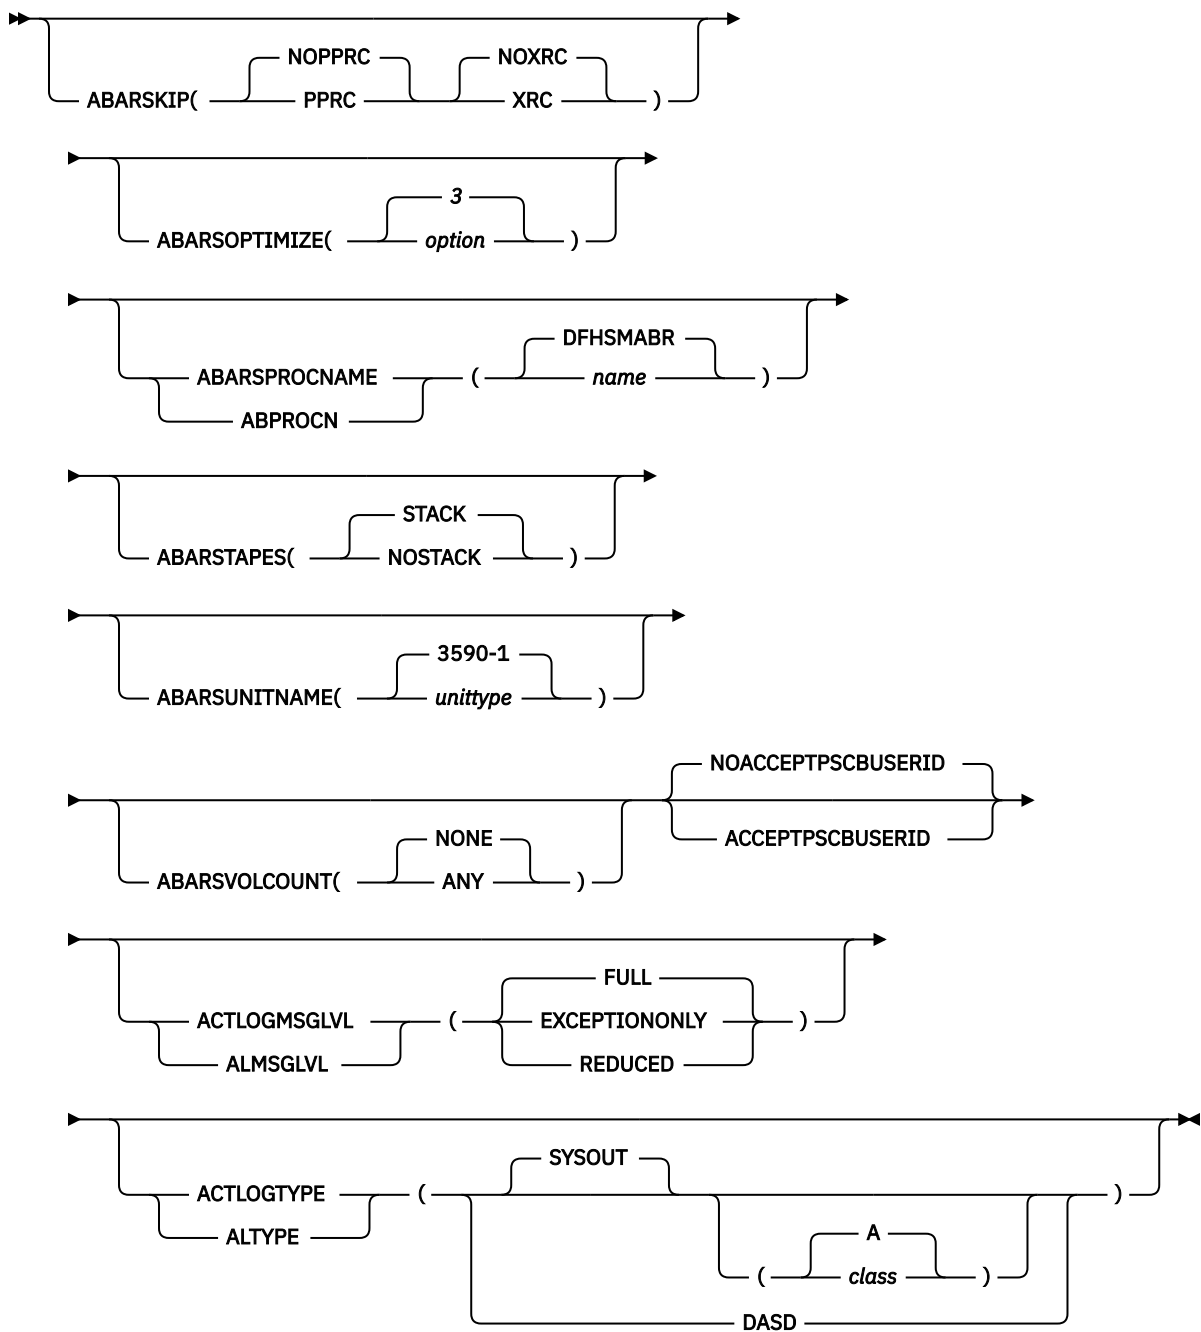

[DFSMSHsm Education Series-hsm SETSYS \(mediacenter.ibm.com/media/DFSMSHsm%20Education%20Series-hsm%20SETSYS/1_qh3d8942\)](http://mediacenter.ibm.com/media/DFSMSHsm%20Education%20Series-hsm%20SETSYS/1_qh3d8942)

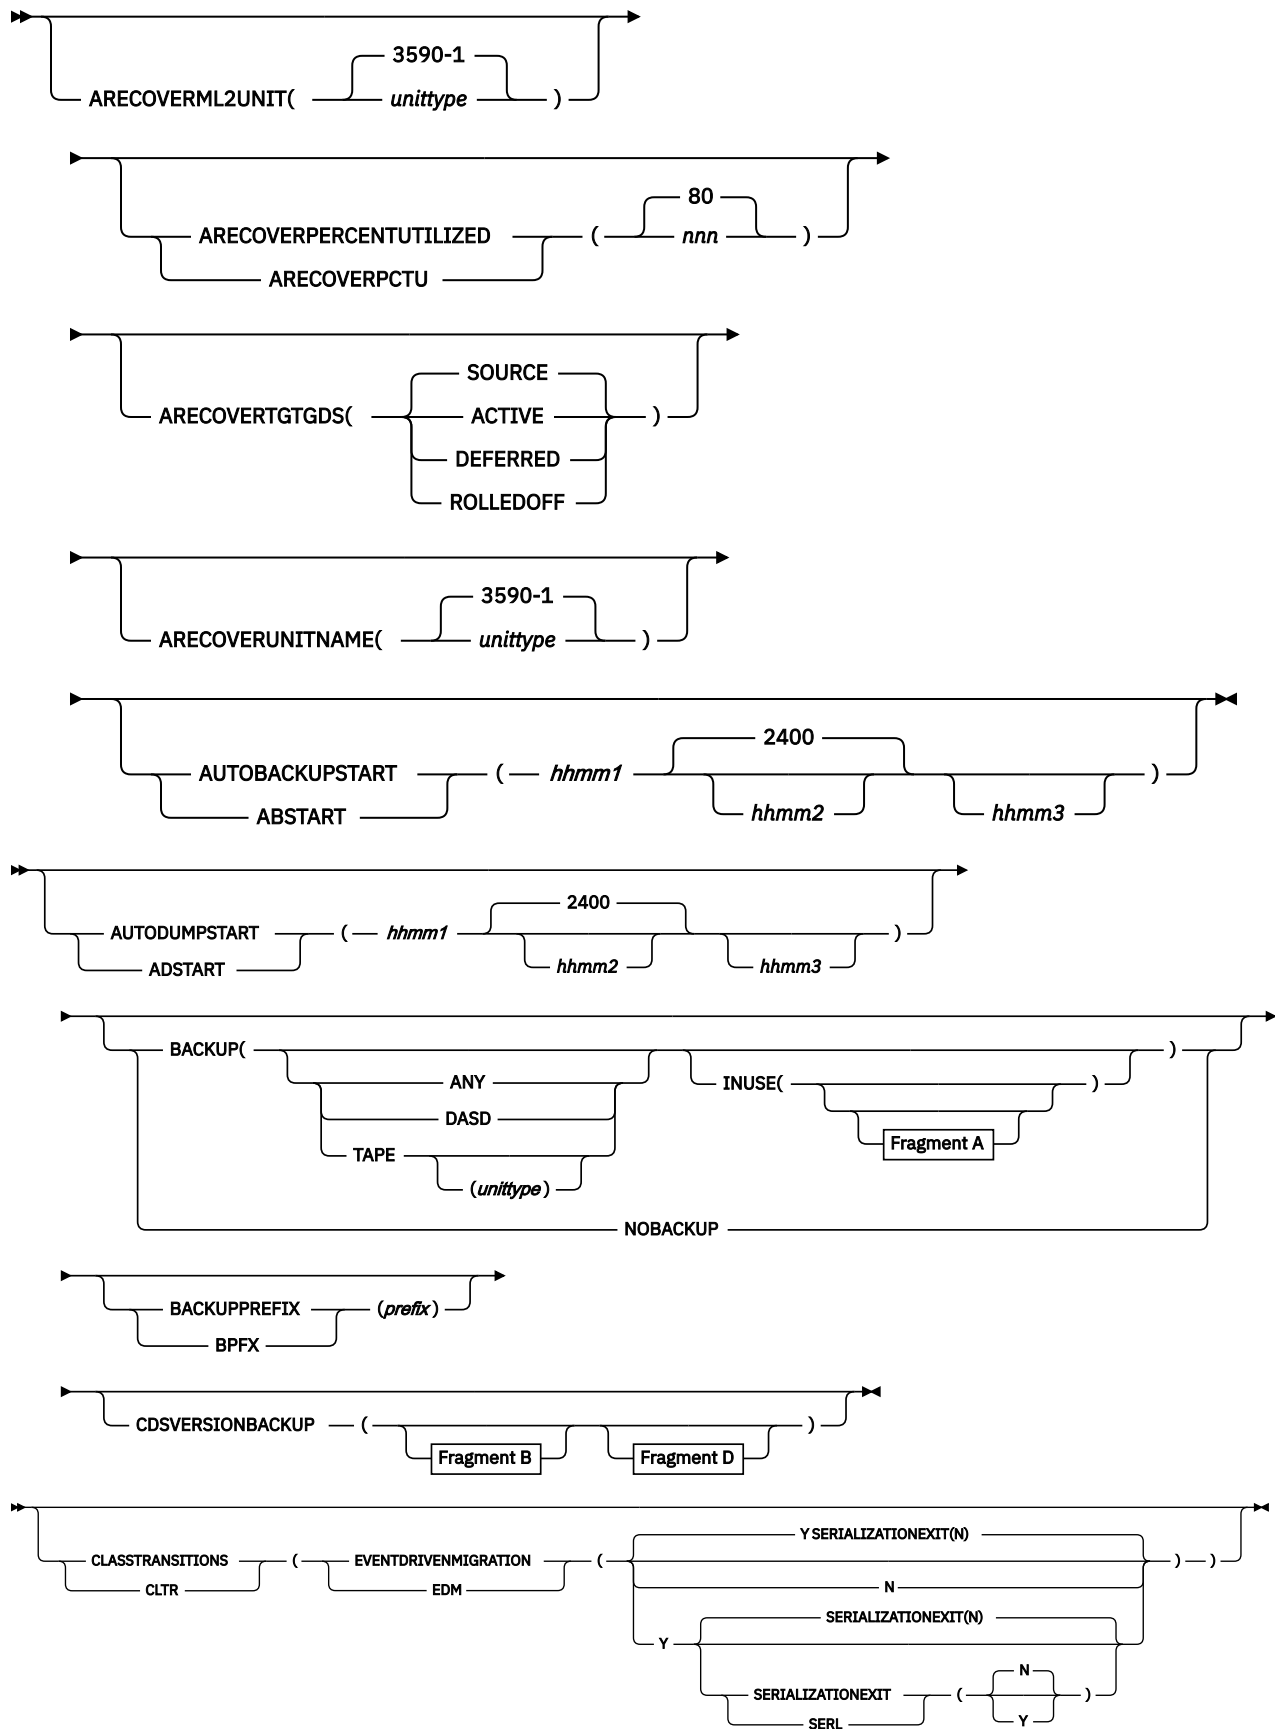

Note: Although the SETSYS command has no required parameters, you must specify at least one of the optional parameters to change any system parameters or default values.

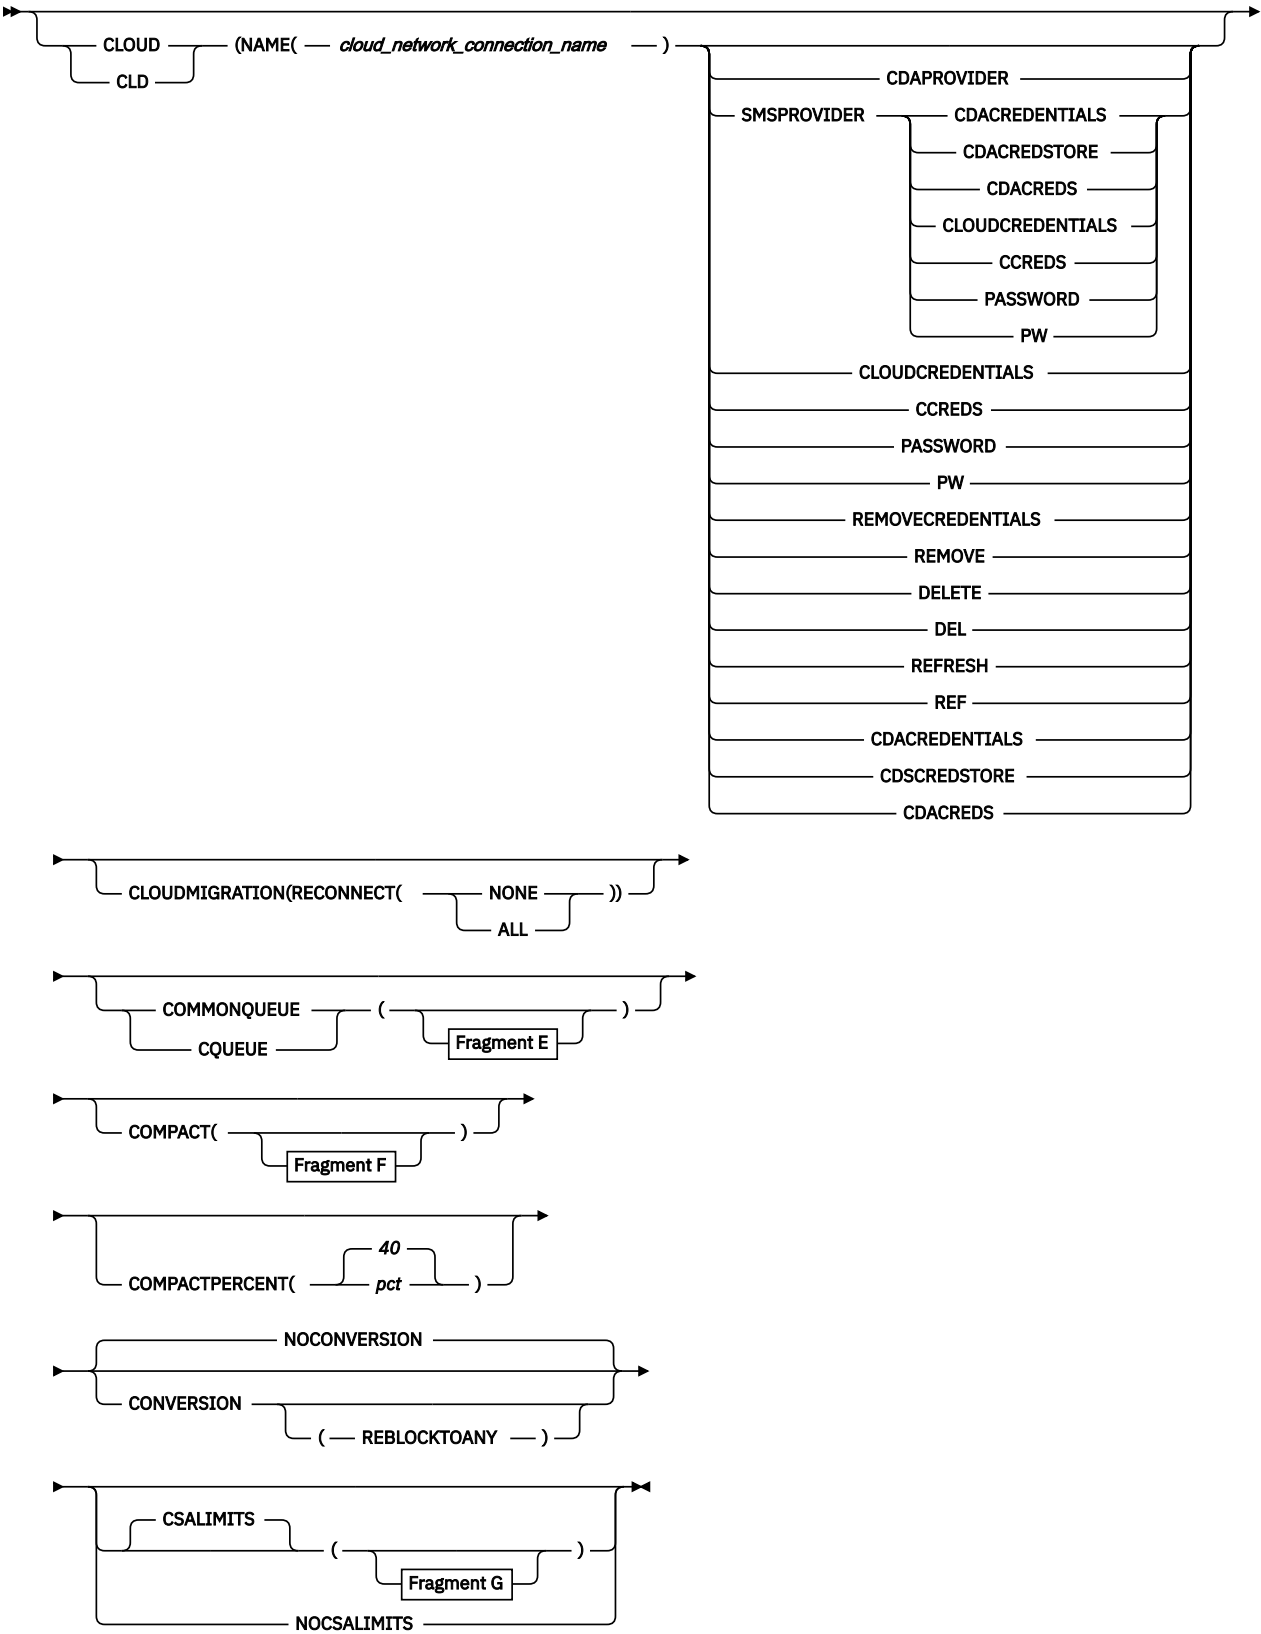

Syntax of the SETSYS command

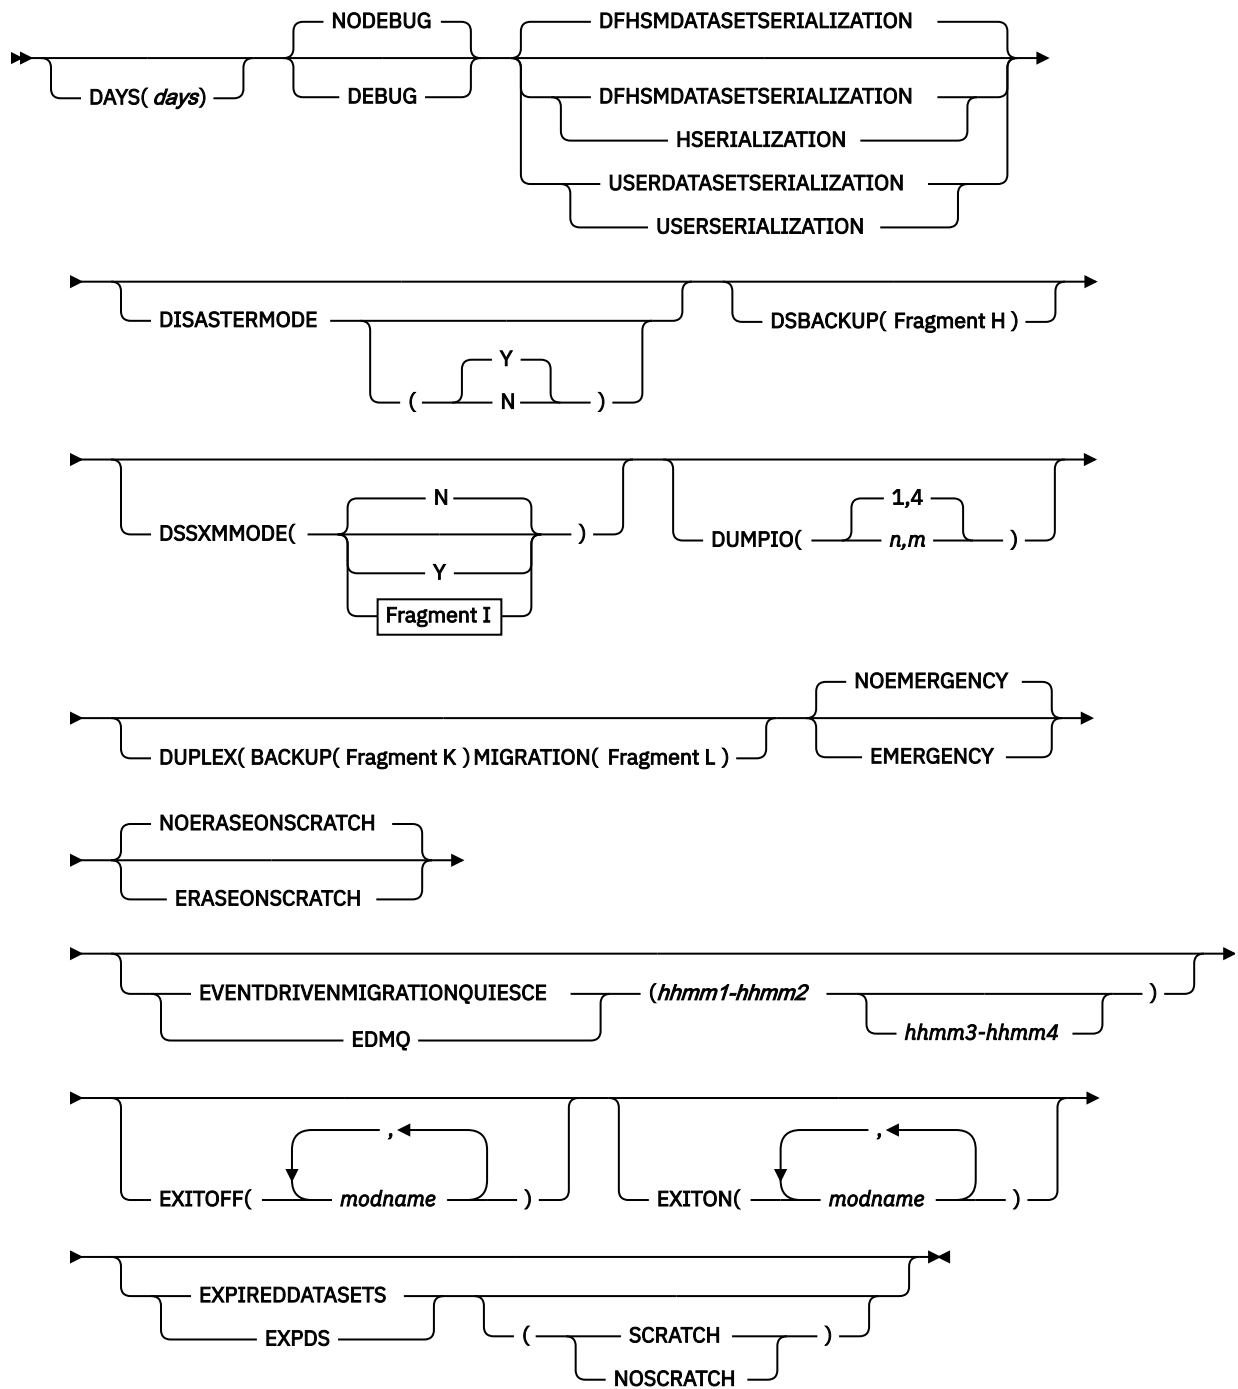

➤ SETSYS ➤

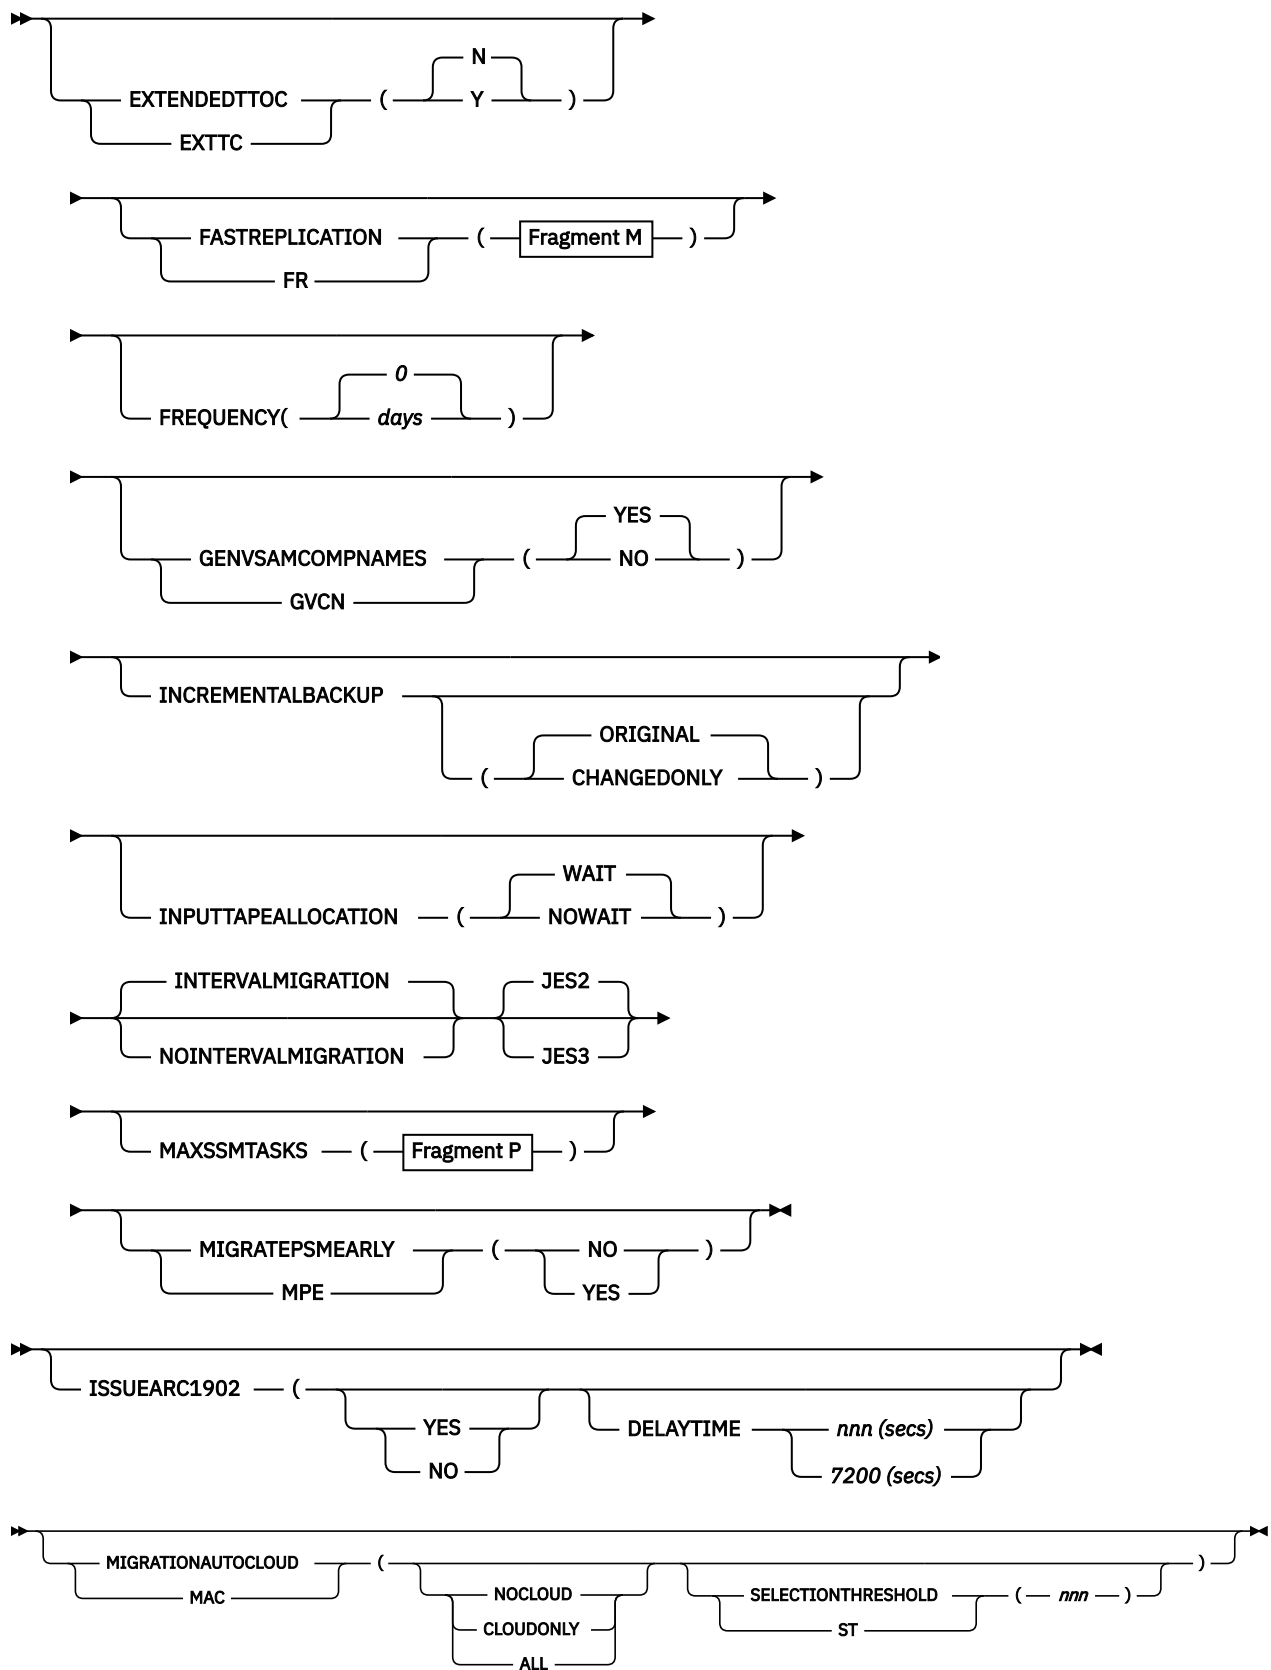

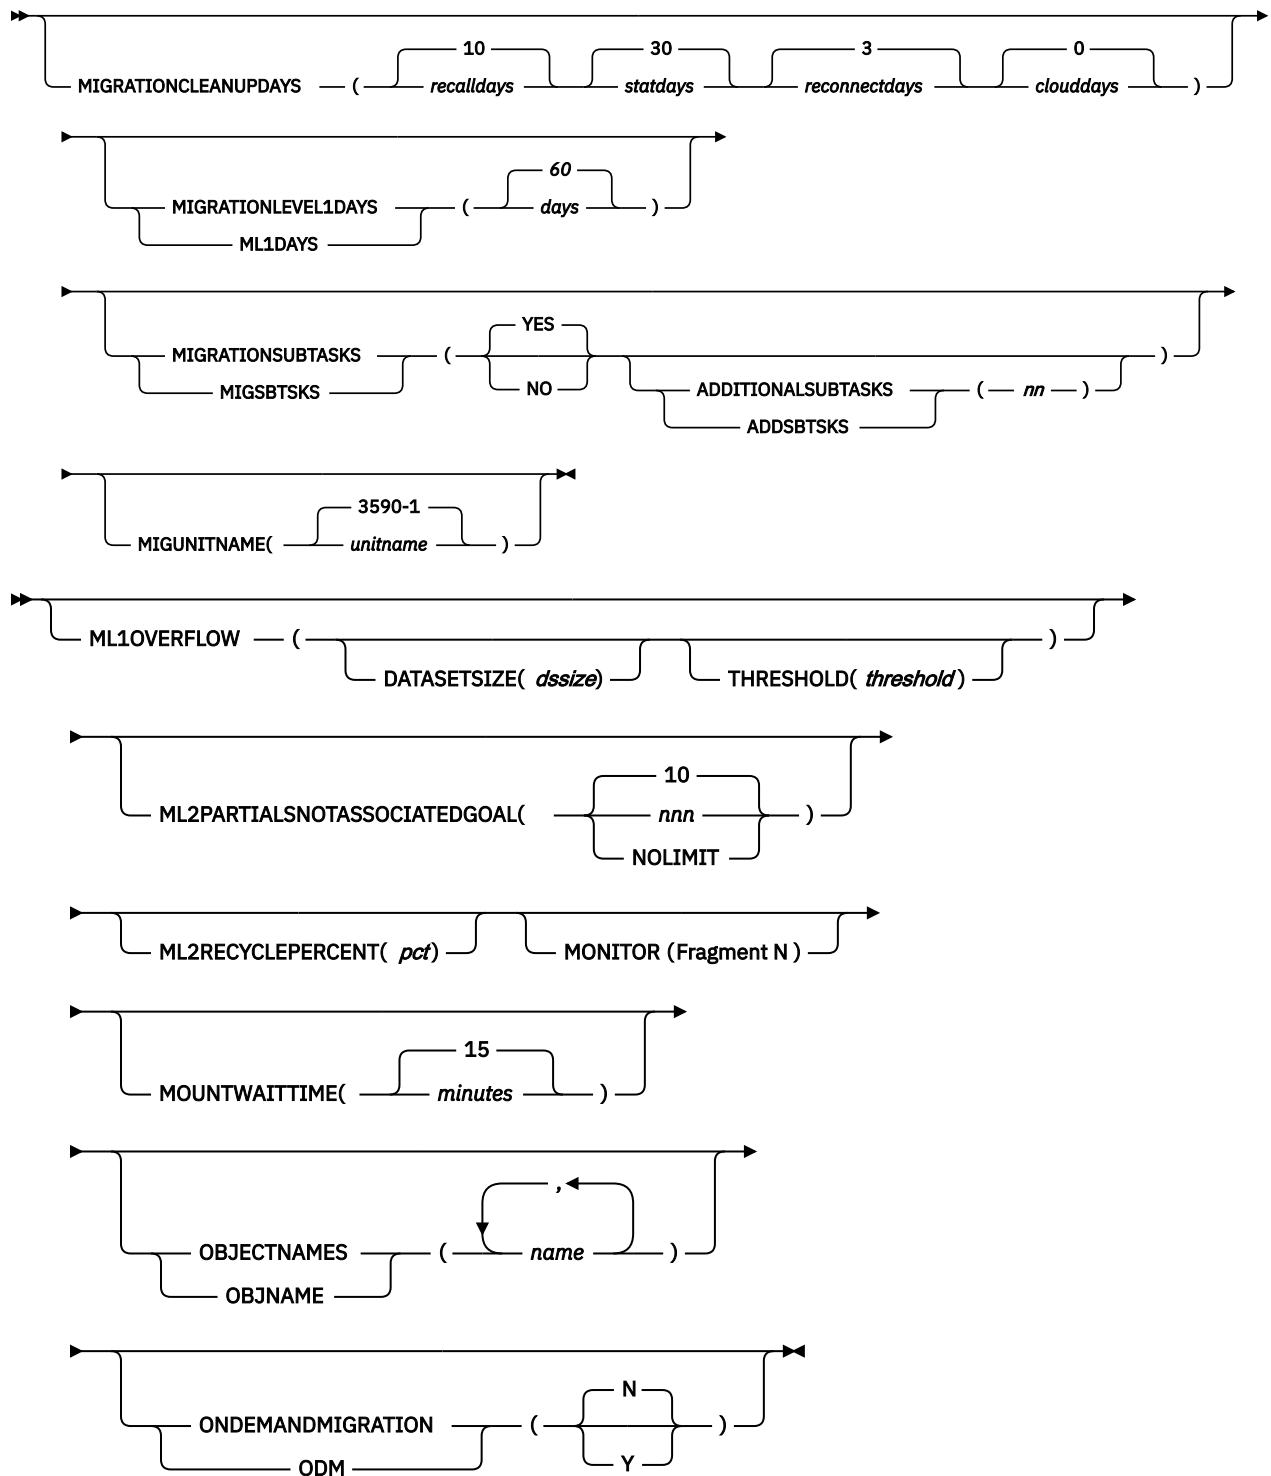

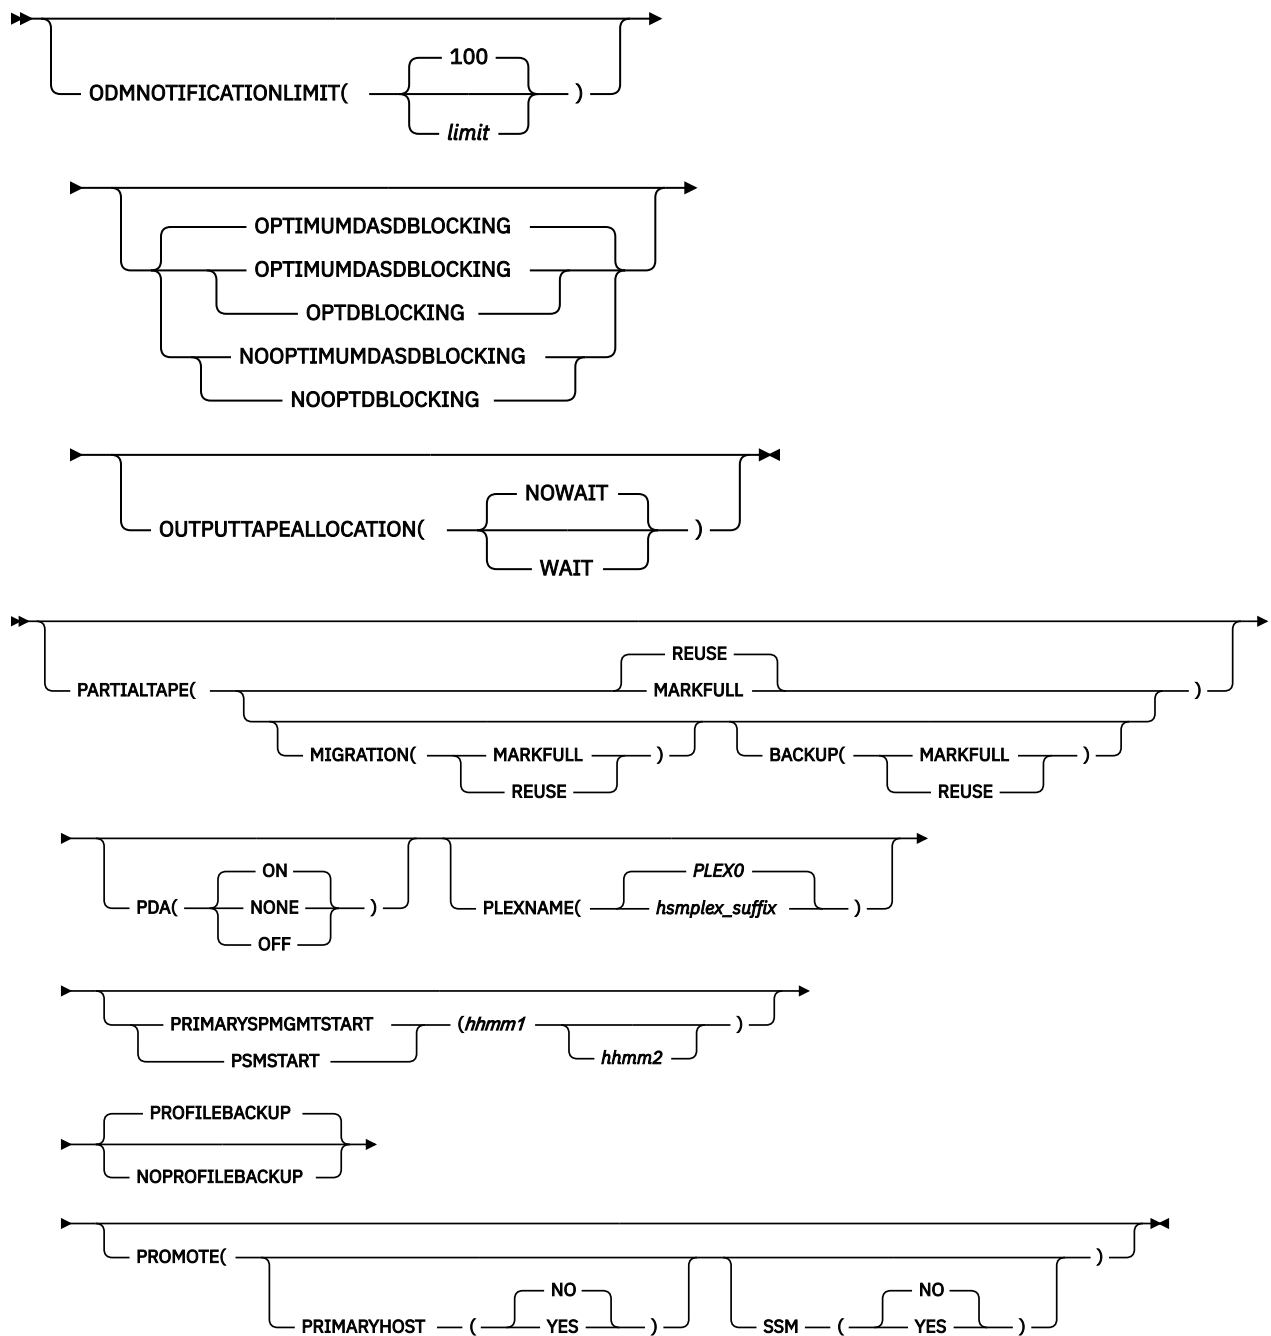

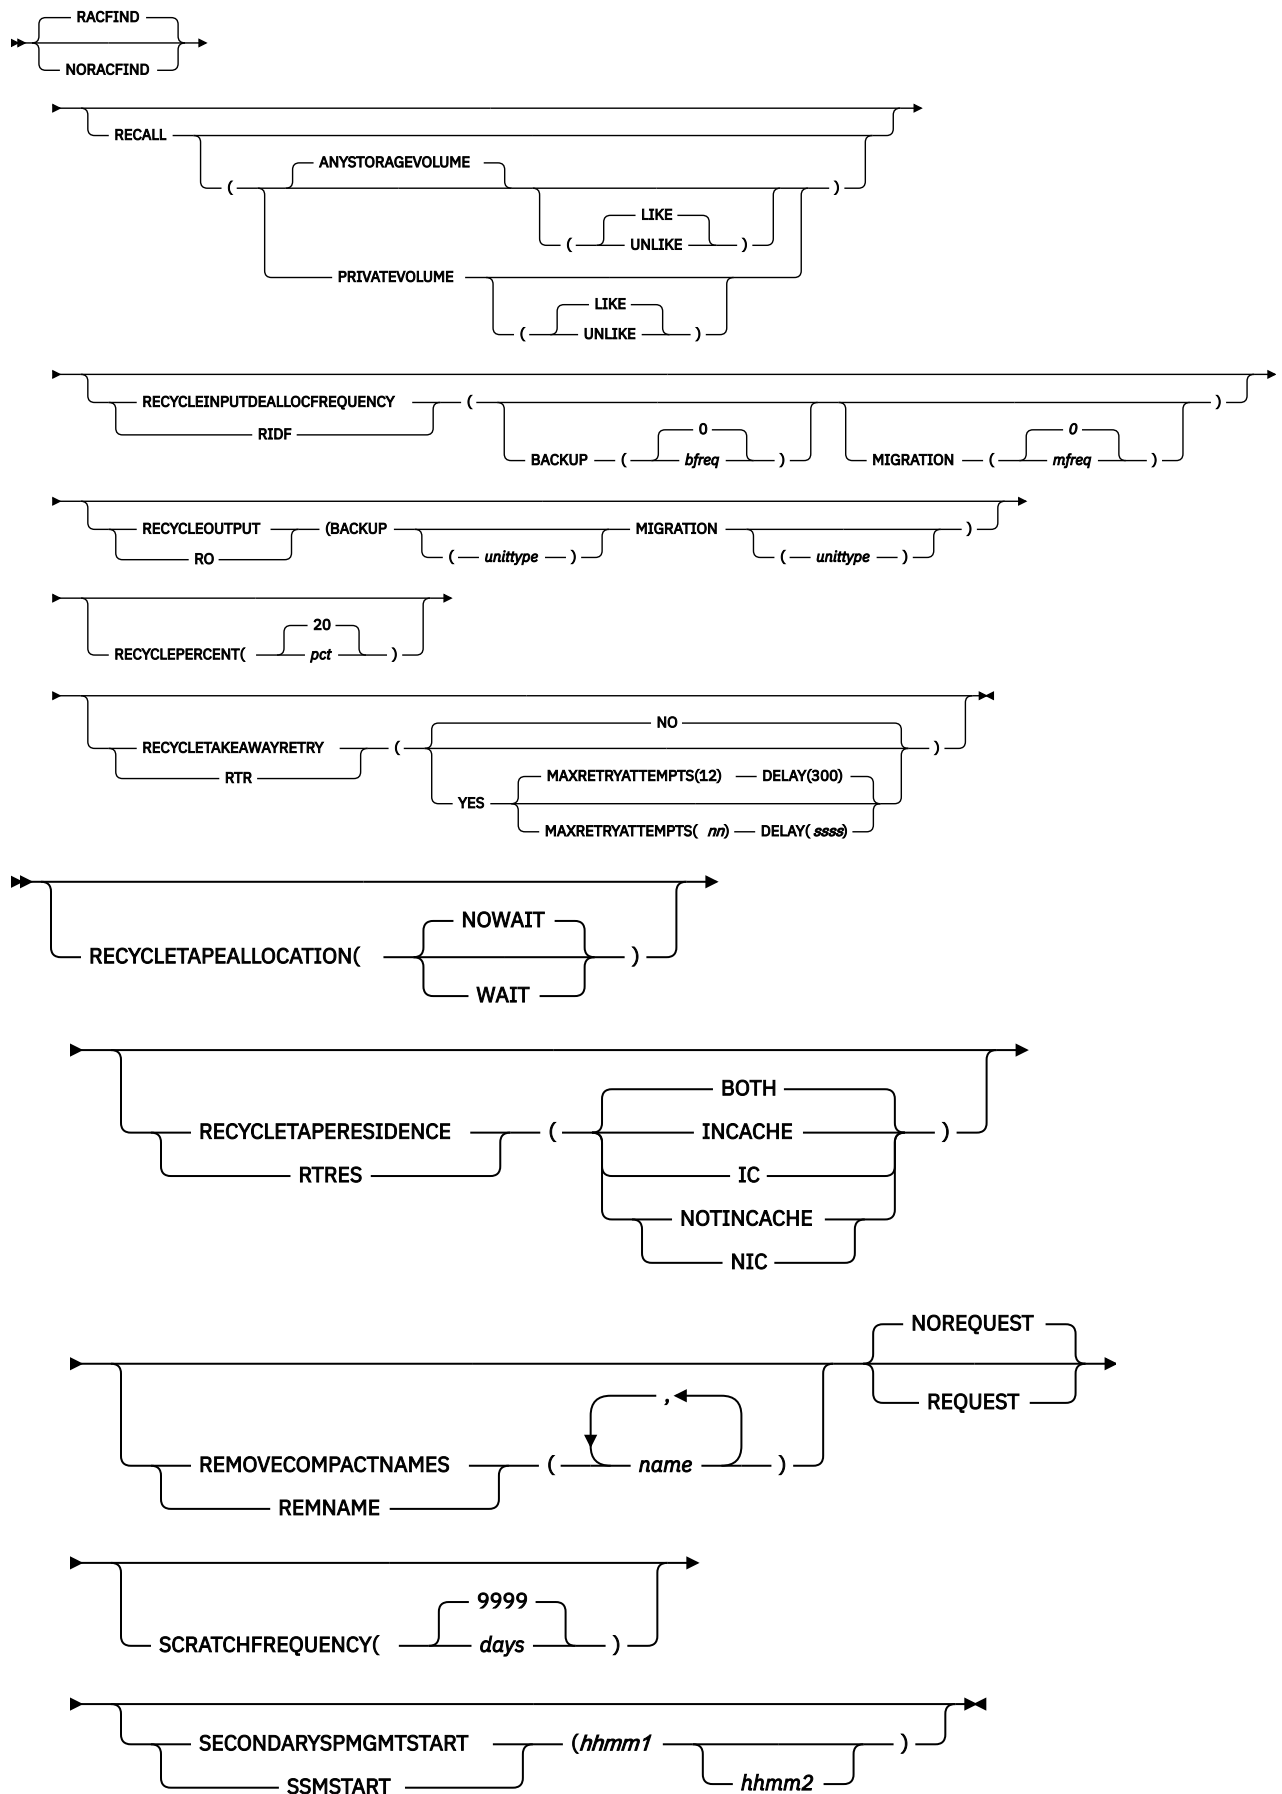

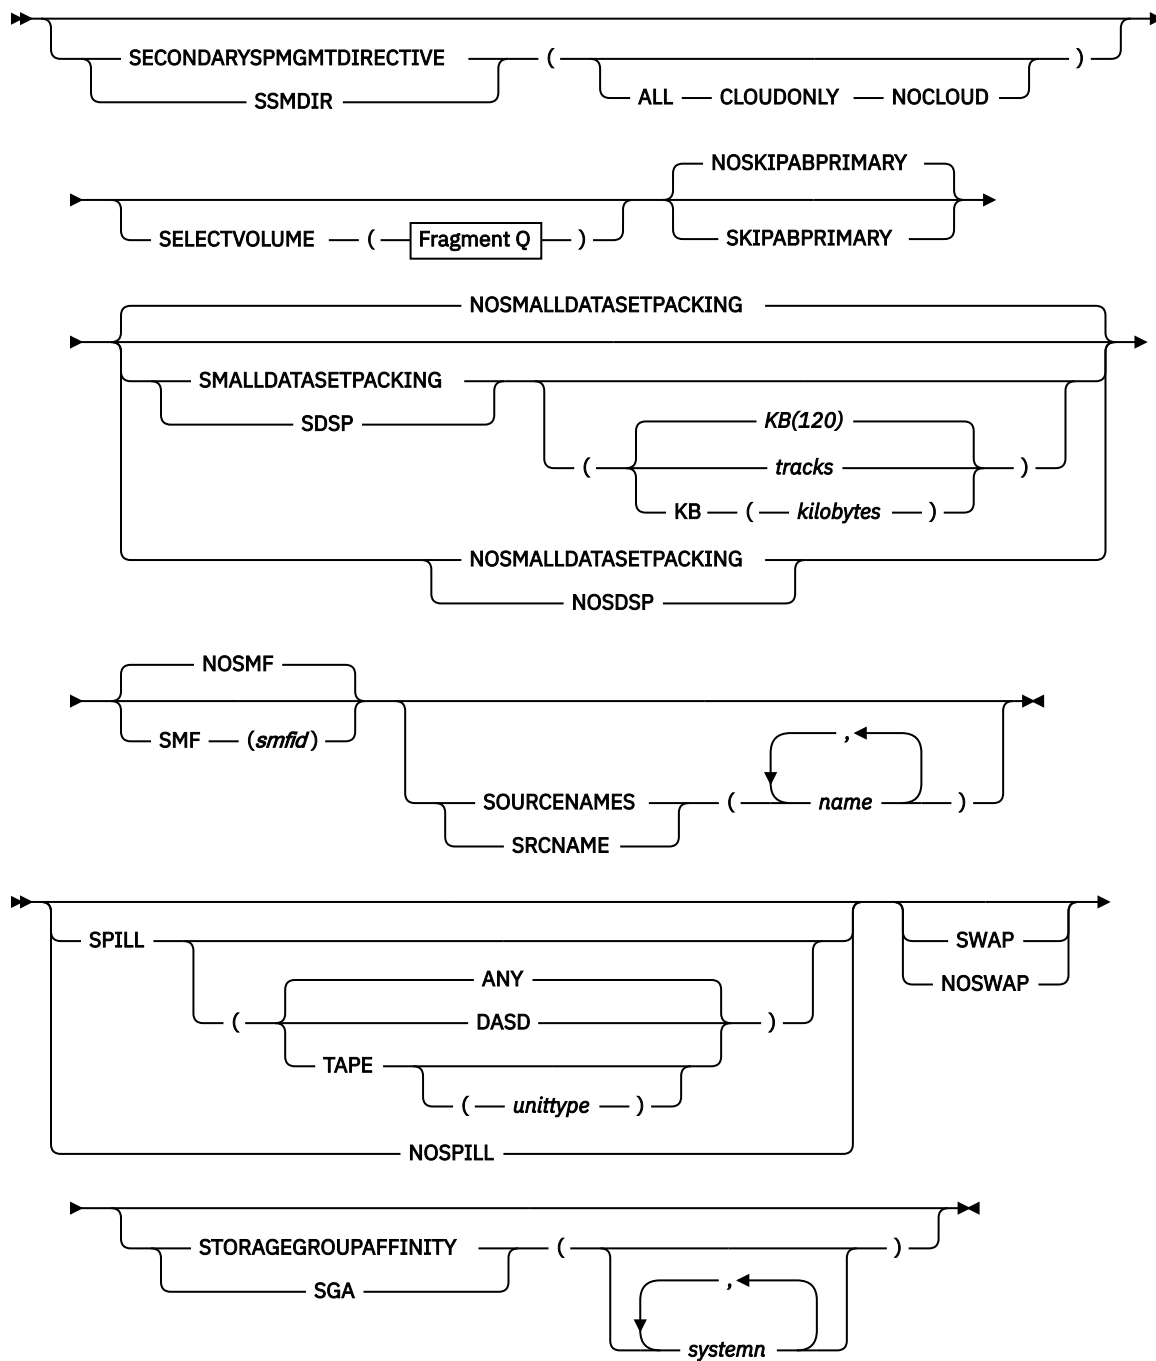

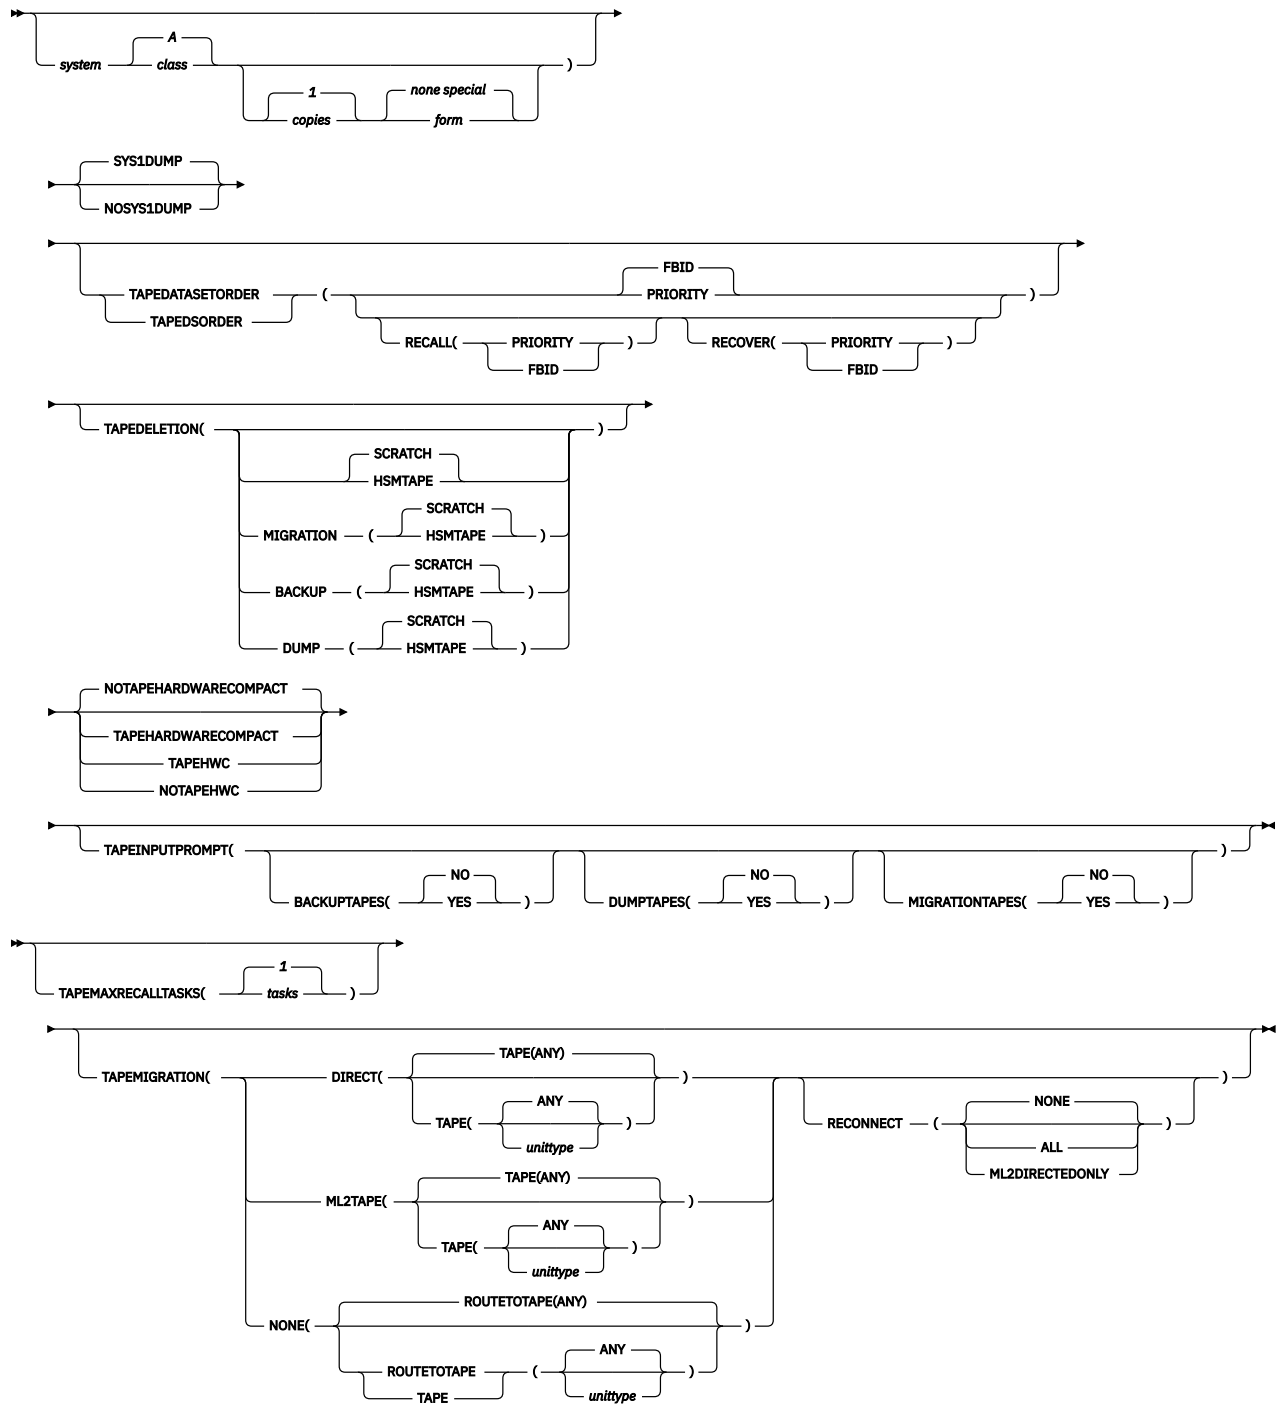

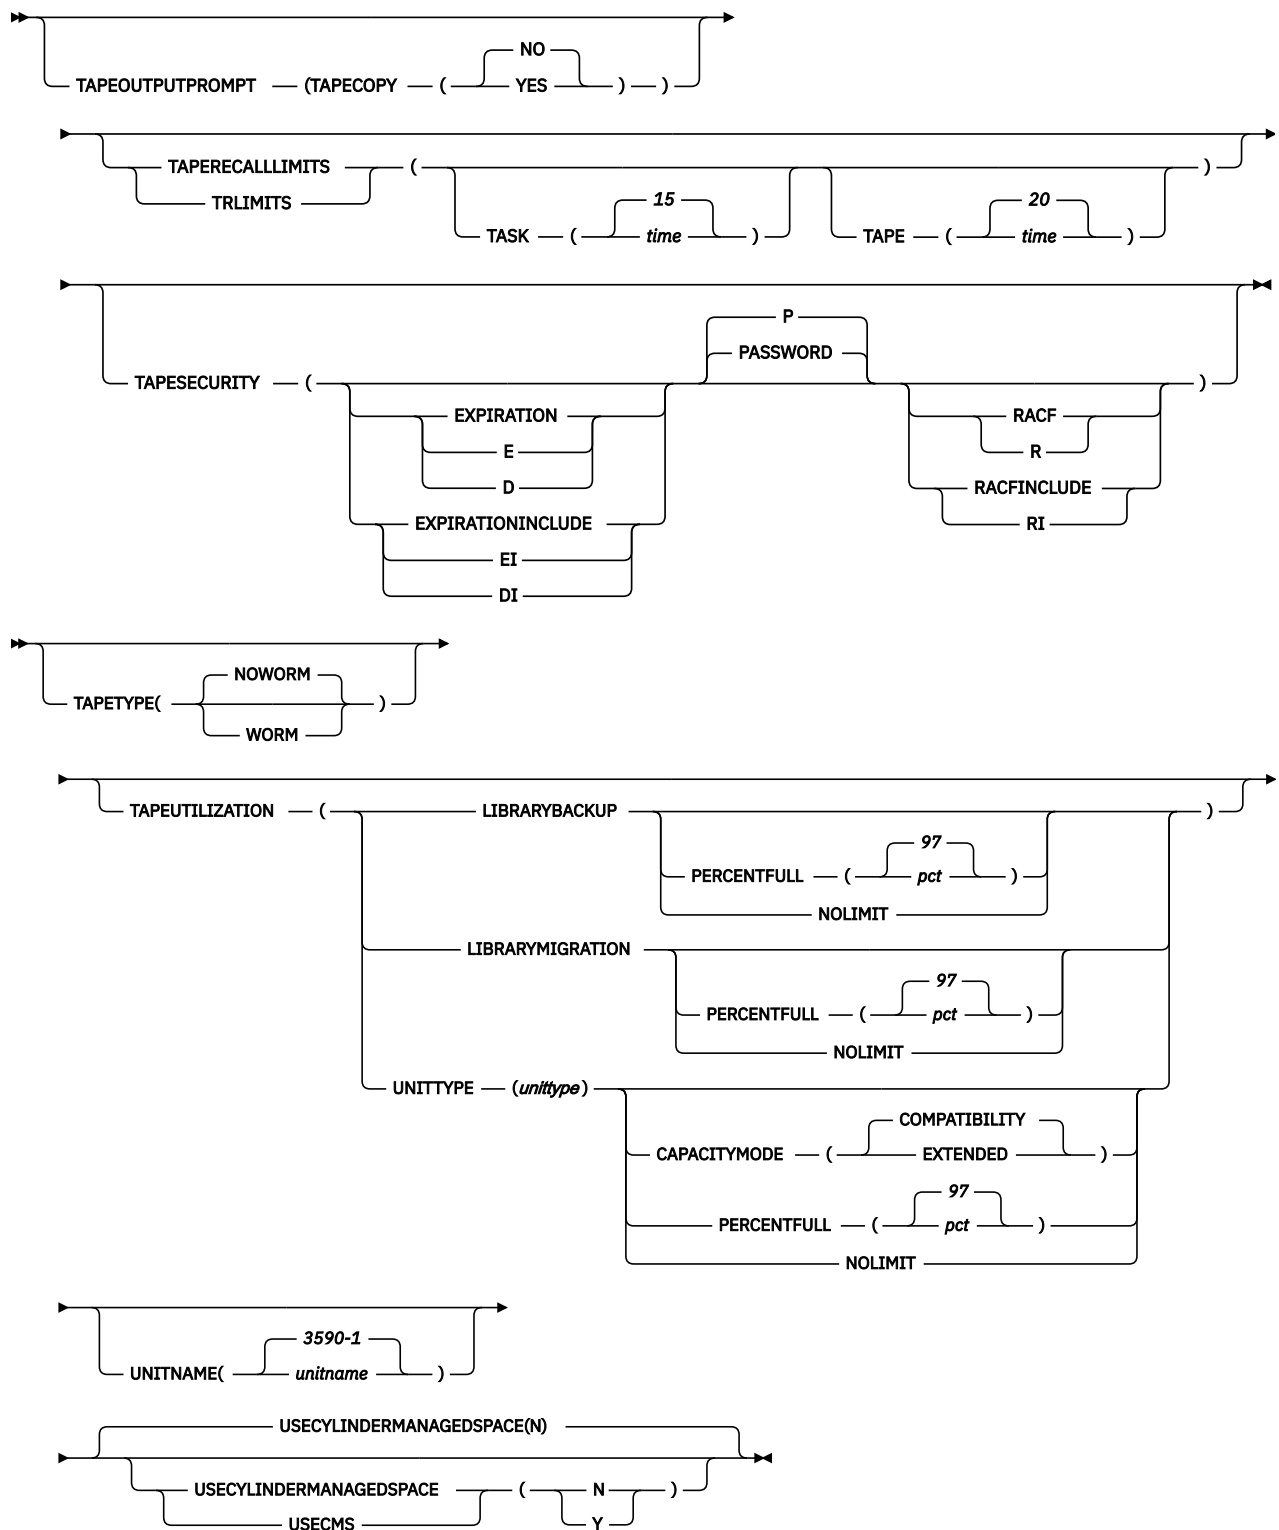

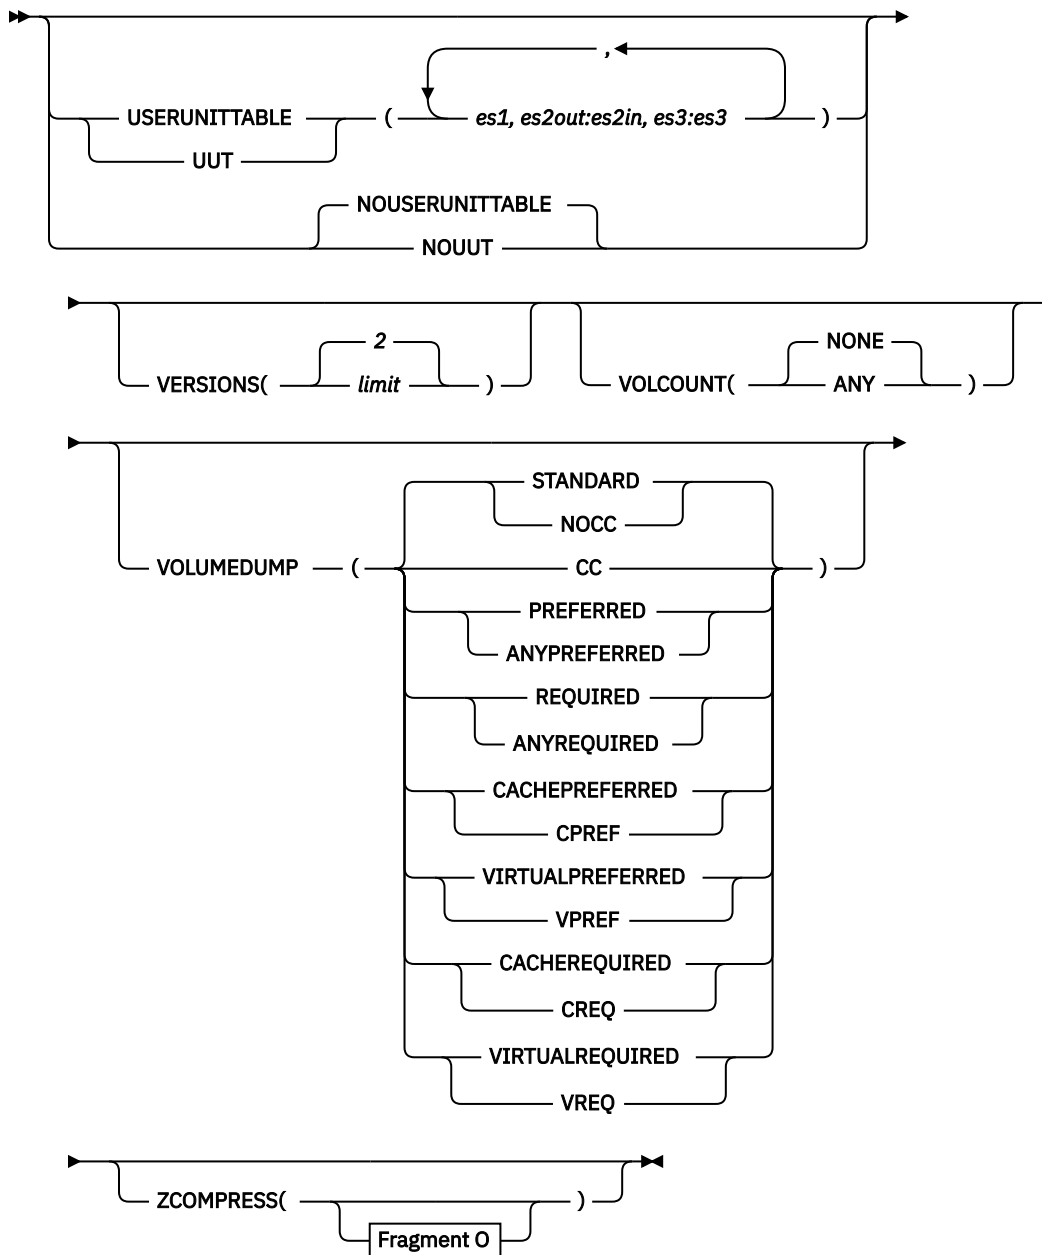

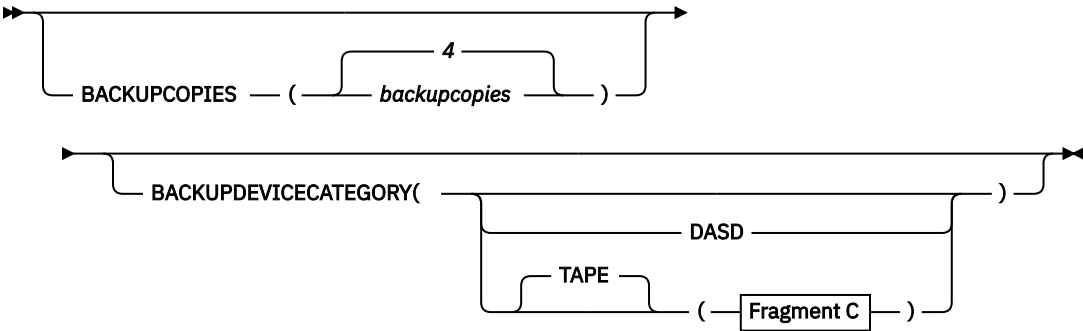

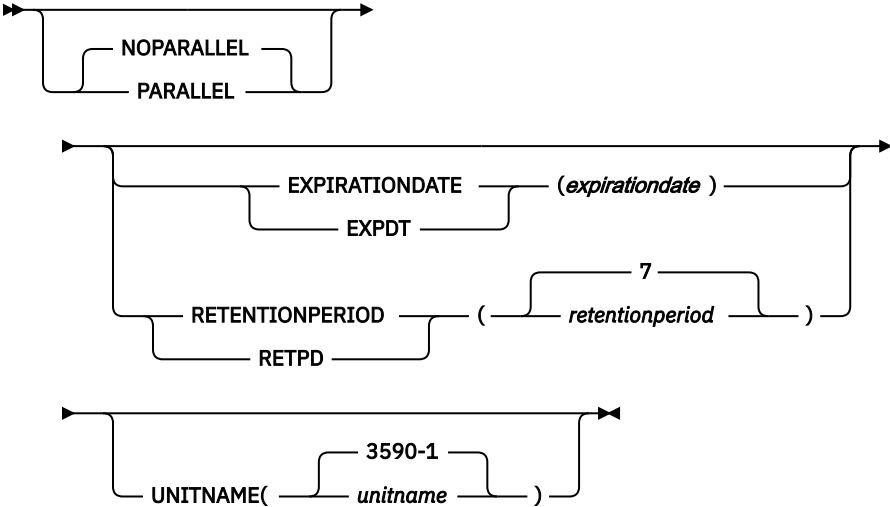

A: INUSE optional parameters

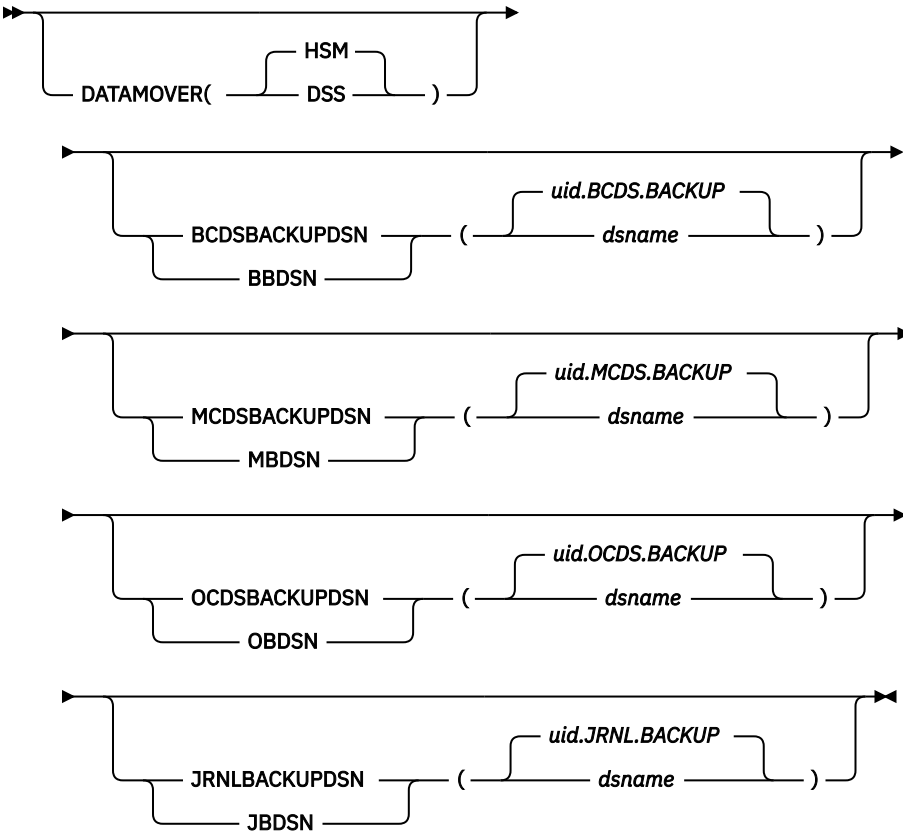

B: CDSVERSIONBACKUP optional parameters

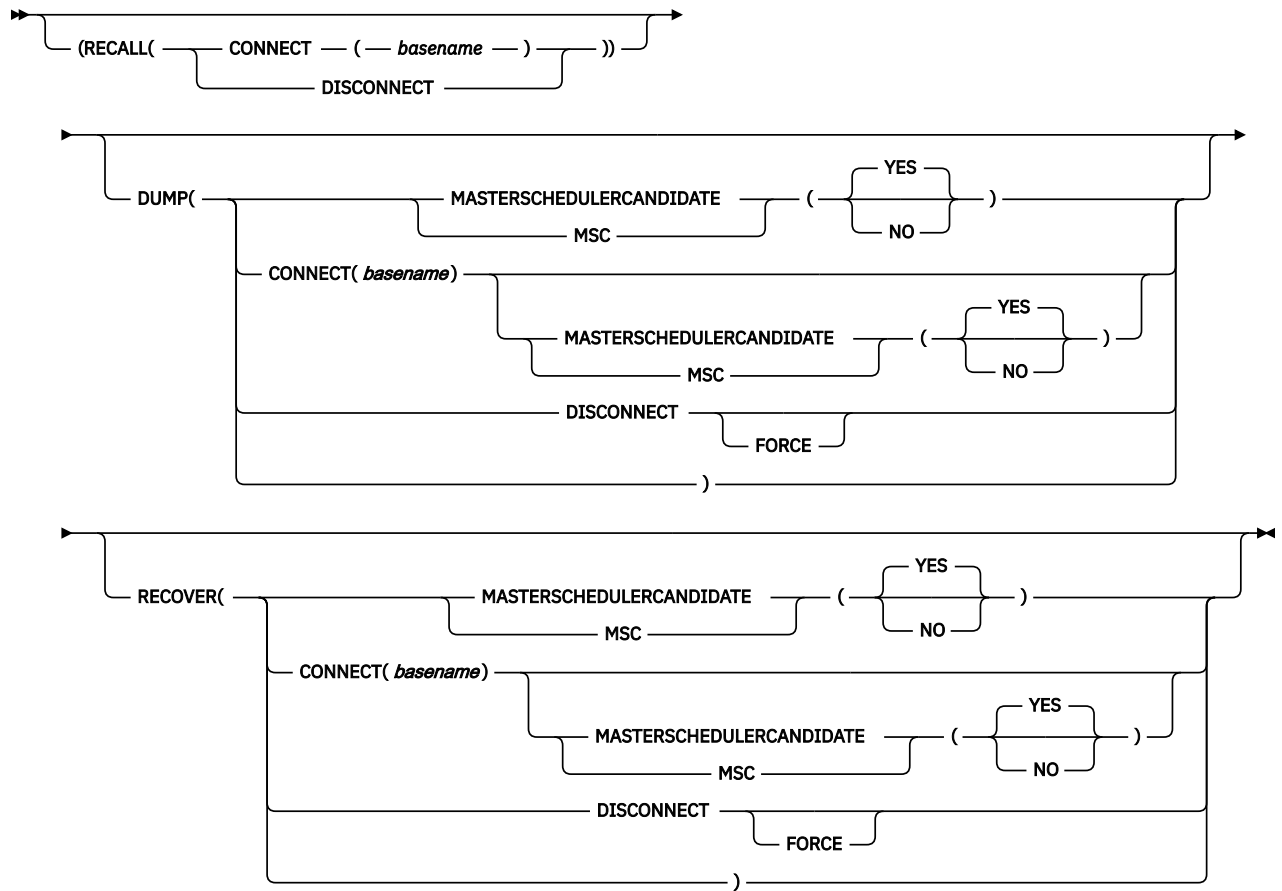

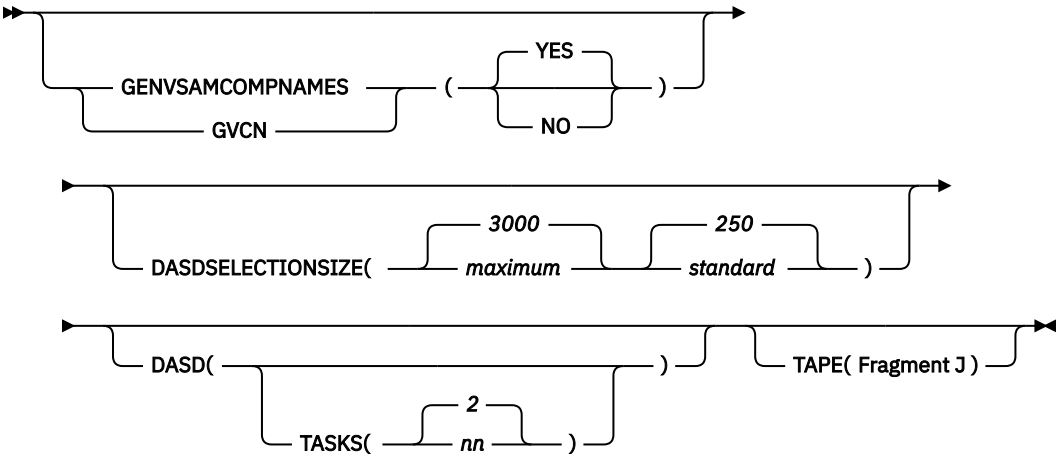

C: TAPE optional parameters

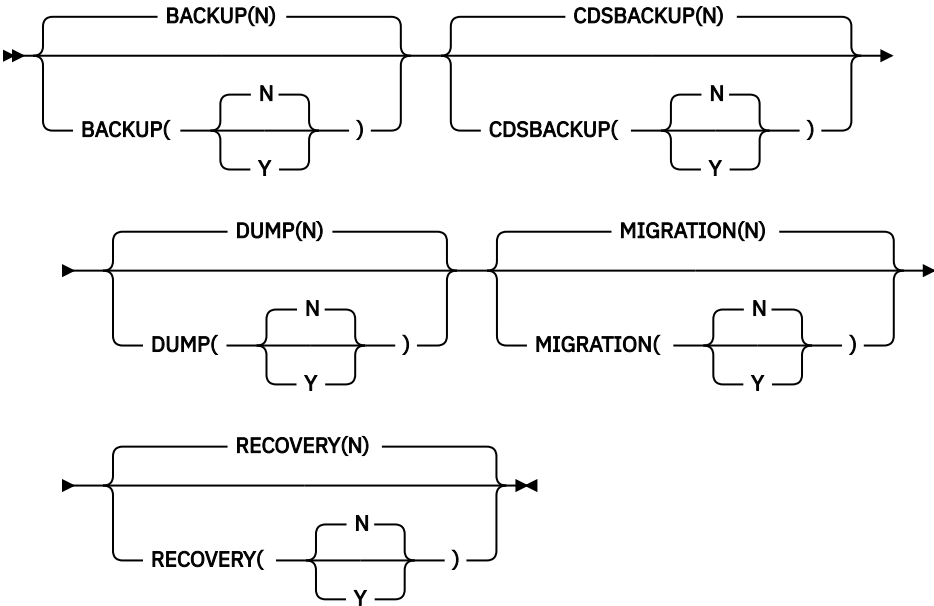

D: CDSVERSIONBACKUP optional parameters

E: COMMONQUEUE optional parameters**F: COMPACT optional parameters****G: CSALIMITS optional parameters****H: DSBACKUP optional parameters**

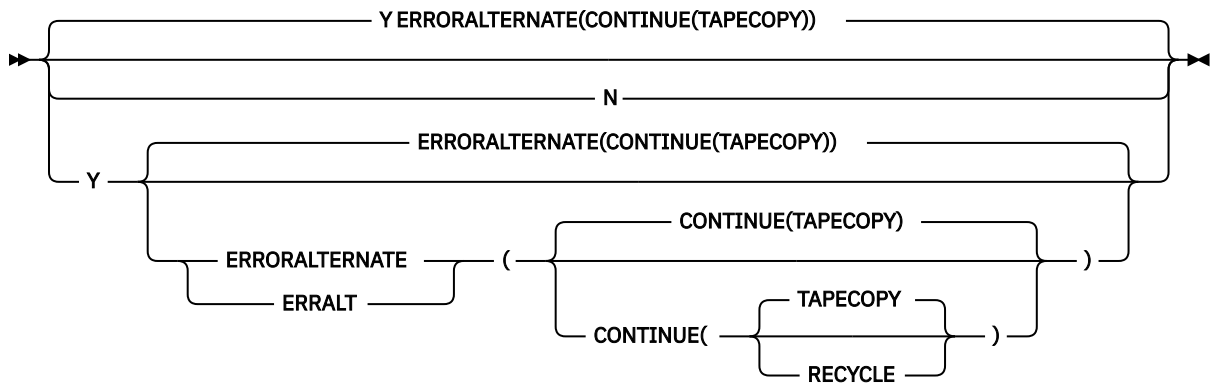

I: DSSXMMODE optional parameters

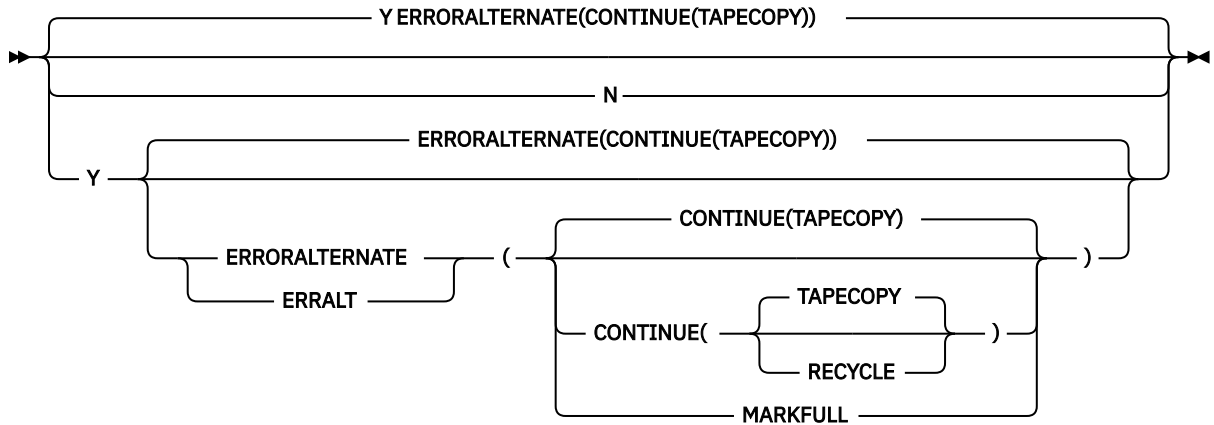

J: TAPE optional parameters

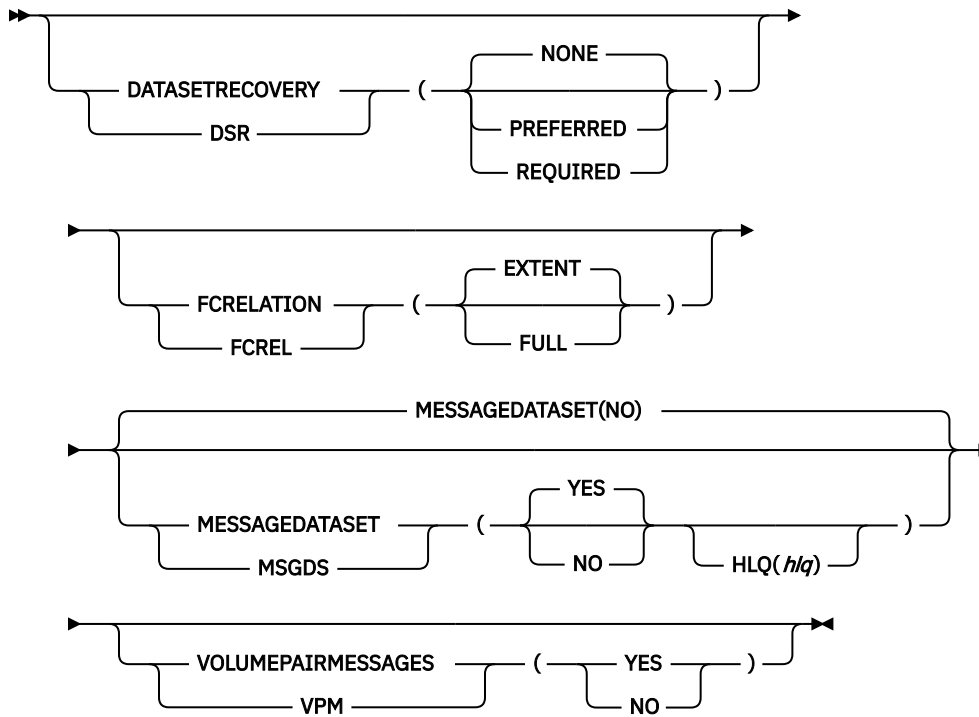

K: DUPLEX BACKUP optional parameters

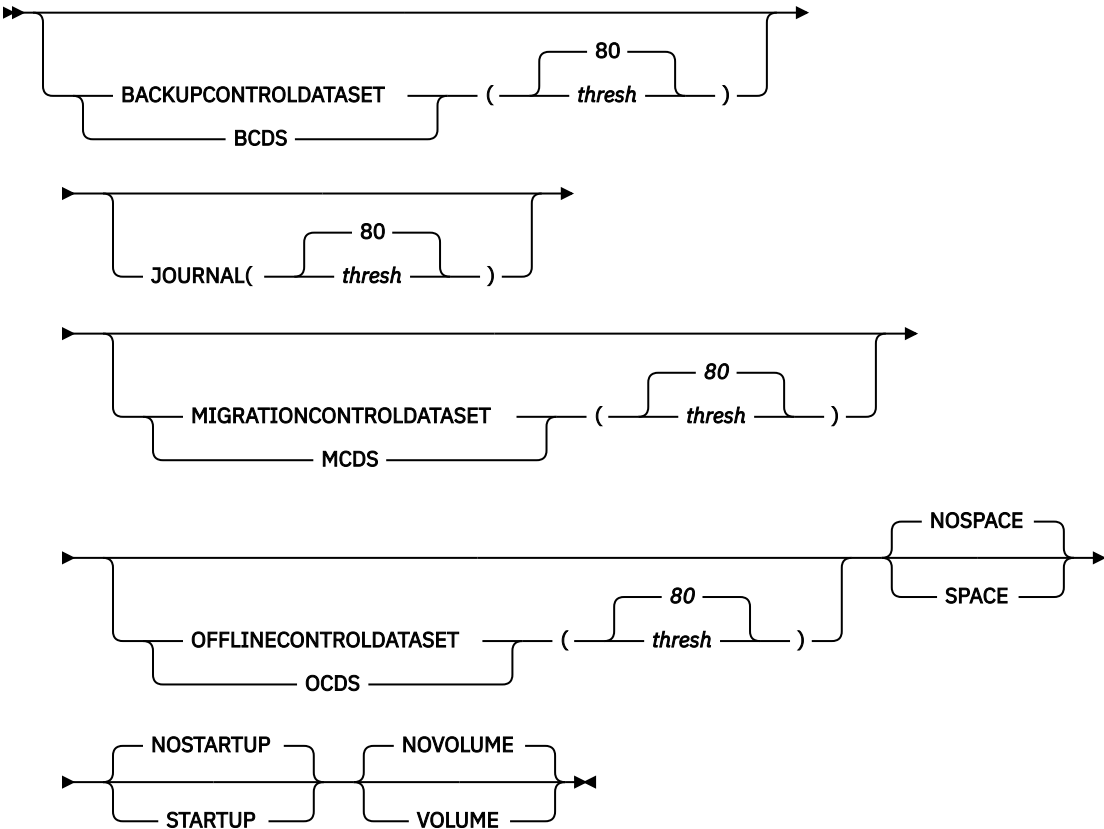

L: DUPLEX MIGRATION optional parameters

M: FASTREPLICATION optional parameters

N: MONITOR optional parameters

O: ZCOMPRESS optional parameters

P: MAXSSMTASKS optional parameters

Q: SELECTVOLUME optional parameters

R: TAPELIBRARYPRESELECT optional parameter

Note: In a multiple address space for DFSMSHsm environment, SETSYS commands with ABARS parameters, like ABARSxxx, ARECOVERxxx, or MAXABARSADDRESSSPACE, or the SETSYS CSALIMITS command can be directed only to the host identified as the main host. DFSMSHsm ignores these commands if directed to a host identified as HOSTMODE=AUX.

SETSYS fast-path for DFSMSHsm functions

DFSMSHsm performs two main functions: availability management and space management. Availability management is used to make data available by automatically copying new and changed data sets to backup volumes and DASD volumes to dump tapes. Space management is used to manage DASD space by enabling inactive data sets to be moved off fast-access storage devices thus creating free space for new allocations. DFSMSHsm also provides other supporting functions that are essential to your installation's DFSMSHsm environment.

The following table illustrates the functions performed by DFSMSHsm for availability management, space management and these supporting functions.

Main functions	Supporting functions
Availability management: ABARS Backup Dump Fast replication Recover Space management: Class transitions Expiration Extent reduction Interval migration Migration On-demand migration Recall Recycle Secondary space management	CDS (backup, journaling, and monitoring) Logging and diagnosis MVS environment Security Tape environment

The SETSYS command and its parameters are used to establish a DFSMSHsm environment. When DFSMSHsm is installed, a default set of SETSYS parameters is used. You can specify one or more SETSYS commands in the ARCCMDxx PARMLIB member that is used during the startup of DFSMSHsm or you can issue SETSYS commands with specific parameter values after DFSMSHsm is started.

Table 58 on page 1076, Table 59 on page 1078 and Table 60 on page 1080 lists both the main and supporting functions performed by DFSMSHsm and the SETSYS parameters that affect them. The left column lists the functions and the right column lists the SETSYS parameters that affect these functions. The tables emphasize SMS-managed user data and exclude parameters that relate to non-SMS user data and backup to DASD. Refer to the SETSYS examples at the end of this SETSYS topic for common user scenarios that you can use for your installation.

Relationship of SMS to SETSYS parameters

Table 62 on page 1083 lists the relationship of SETSYS parameters to SMS-managed DASD volumes and data sets. Parameters that apply equally to both SMS-managed and non-SMS-managed DASD volumes and data sets are not included.

All SETSYS parameters that affect tape data set names, tape volumes, and tape unit types are applicable to SMS-managed tape environments, and might have different meanings from non-SMS-managed tape environments, depending on the SMS implementation.

Table 61 on page 1082 list the abbreviations and their meaning are used in Table 62 on page 1083.

Table 61. SMS relationship abbreviations and their meaning		
Abbreviations	Meaning	Description
APP	Applicable	Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

Table 61. SMS relationship abbreviations and their meaning (continued)

Abbreviations	Meaning	Description
CAPP	Conditionally Applicable	Parameter applies in some instances to SMS-managed DASD volumes or data sets.
NAPP	Not Applicable	Parameter does not apply to SMS-managed DASD volumes or data sets.

Summary of DFSMSHsm default values

Table 63 on page 1084 is a summary of the defaults DFSMSHsm uses if you never specify a SETSYS command during or after startup.

Table 63. Summary of DFSMSHsm Default Values	
DFSMSHsm default value	Result
ABARSACTLOGMSGGLVL(FULL)	All DFSMSdss messages that are written to the ABARS activity log.
ABARSACTLOGTYPE SYSOUT(A)	ABARS activity logs are allocated to the SYSOUT class A.
ABARSDELETEACTIVITY(N)	The ABARS activity log is not automatically deleted.
ABARSKIP(NOPPRC NOXRC)	ABACKUP processing will not skip data sets on volumes that are protected by peer-to-peer remote copy or extended remote copy.
ABARSOPTIMIZE(3)	DFSMSHsm reads five tracks at a time.
ABARSPROCNAME(DFHSMABR)	DFSMSHsm uses DFHSMABR as the base procedure name on the internal START command to start the secondary address space.
ABARSTAPES(STACK)	The default is STACK and DFSMSHsm stacks output files onto a minimum number of tape volumes.
ABARSUNITNAME(3590-1)	ABARS selects 3590-1 units when invoking aggregate backup or aggregate recovery.
ABARSVOLCOUNT(NONE)	The default is NONE and DFSMSHsm does not pass the VOLCOUNT parameter to DFSMSdss.
ACTLOGMSGGLVL(FULL)	Messages are generated and logged for all activities.

Table 63. Summary of DFSMSHsm Default Values (continued)	
DFSMSHsm default value	Result
ACTLOGTYPE SYSOUT(A)	If you specified SYSOUT without a class, the output is class A, one copy, no special forms.
ARECOVERML2UNIT(3590-1)	ARECOVER selects 3590-1 units when recovering data sets to ML2 tape.
ARECOVERPERCENTUTILIZED(80)	When specifying this parameter, DFSMSHsm uses a default of 80% to fill non-SMS DASD recovery volumes. Otherwise, the valid values you can use range from 1 to 100.
ARECOVERTGTGDS(SOURCE)	The default is SOURCE.
ARECOVERUNITNAME(3590-1)	DFSMSHsm uses a unit of 3590-1 for aggregate recovery of data sets recovered to tape.
AUTOBACKUPSTART(0)	DFSMSHsm does not run automatic backup.
AUTODUMPSTART(0)	DFSMSHsm does not run automatic dump.
BACKUP(INUSE(RETRY(N) DELAY(15) SERIALIZATION(REQUIRED)))	DFSMSHsm does not retry a backup attempt that fails because the data set is in use. If RETRY(Y) is later specified, DFSMSHsm delays for 15 minutes before attempting a retry, and requires the data set to be serialized during the retry.
BACKUPCOPIES(4)	The default value is read from the multiple-host processor control record (MHCR). The record is updated with values that are specified on the SETSYS CDSVERSIONBACKUP command every time the command is issued. If the MHCR record does not exist, or the parameter (or subparameter) has never been specified, DFSMSHsm keeps four copies of the journal and control data sets.
BACKUPDEVICECATEGORY(TAPE)	The default value is read from the multiple-host processor control record (MHCR). The record is updated with values specified on the SETSYS CDSVERSIONBACKUP command every time the command is issued. If the MHCR record does not exist, or the parameter (or subparameter) has never been specified, DFSMSHsm backs up the control data sets to tape.
BACKUPPREFIX	DFSMSHsm uses the UID you specified in the DFSMSHsm startup procedure.
BCDSBACKUPDSN(uid.BCDS.BACKUP)	The default value is read from the multiple-host processor control record (MHCR). The record is updated with values specified on the SETSYS CDSVERSIONBACKUP command every time the command is issued. If the MHCR record does not exist, or the parameter (or subparameter) has never been specified, the backup data set name for the backup control data set is uid.BCDS.BACKUP.

Table 63. Summary of DFSMSHsm Default Values (continued)

DFSMSHsm default value	Result
CDSVERSIONBACKUP parameters listed separately: BACKUPCOPIES BACKUPDEVICECATEGORY BCDSBACKUPDSN DENSITY JRNBACKUPDSN MCDSBACKUPDSN NOPARALLEL OCDSBACKUPDSN RETENTION PERIOD UNITNAME	<p>The default value is read from the multiple-host processor control record (MHCR). The record is updated with values specified on the SETSYS CDSVERSIONBACKUP command every time the command is issued. If the MHCR record does not exist, or the parameter (or subparameter) has never been specified, DFSMSHsm makes multiple backup versions of the control data sets and the journal data set.</p>
CLASSTRANSITIONS(EVENTDRIVENMIGRATION(Y SERIALIZATIONEXIT(N)))	<p>Class transitions will be performed during event-driven migration, but user data set serialization error exits will <i>not</i> be used.</p>
COMPACT(NONE)	<p>DFSMSHsm does not compact any data sets.</p>
COMPACTPERCENT(40)	<p>If you specify that DFSMSHsm compact data sets, DFSMSHsm uses a default of 40% to determine whether a data set will be compacted in the future. Otherwise, DFSMSHsm ignores this parameter.</p>
CSALIMITS(MWE(4) MAXIMUM(100) ACTIVE(90) INACTIVE(30))	<p>DFSMSHsm limits the common service area storage for MWE allocation. The NOWAIT MWE limit is 4, the maximum limit is 100 KB, the active limit is 90 KB, and the inactive limit is 30 KB.</p>
DATAMOVER	<p>The default value is read from the multiple-host processor control record (MHCR). The record is updated with values specified on the SETSYS CDSVERSIONBACKUP command every time the command is issued. If the MHCR record does not exist, or the parameter (or subparameter) has never been specified, DFSMSHsm default for the type of data movement used when performing CDSVERSIONBACKUP, is DATAMOVER(HSM).</p>
DAYS(1) or DAYS(2)	<p>In a single-DFSMSHsm-host environment, the data sets must be at least one day old. In a multiple-DFSMSHsm-host environment, the data sets must be at least two days old.</p>
DFHSMDATASETSERIALIZATION	<p>Data set serialization of system resources is not provided by system facilities.</p>
DISASTERMODE(N)	<p>If you specify N, DFSMSHsm will request the original tape volume and makes no substitution.</p>

Table 63. Summary of DFSMSHsm Default Values (continued)	
DFSMSHsm default value	Result
DSBACKUP	For DASDSELECTIONSIZE, the default for <i>maximum</i> is 3000 KB and <i>standard</i> is 250 KB. For DASD(TASKS) or TAPE(TASKS), the default is 2. For DEMOUNTDELAY, the default for MAXIDLETASKS is 0 and MINUTES is 60. If GENVSAMCOMPNames(YES) GVCN(YES), and <i>dsname</i> is a VSAM base cluster and <i>newdsname</i> is either migrated or uncataloged, DFSMSHsm will process the request, and default names will be assigned to the VSAM data and index components. If GVCN(NO), and <i>dsname</i> is a base cluster and <i>newdsname</i> is migrated or uncataloged, the HBACKDS command will fail. If GVCN(YES NO) is specified, and <i>newdsname</i> is cataloged and not migrated, or if the data set to be backed up is non-VSAM, the HBACKDS command will fail.
DSSXMMODE(N)	DFSMSDss will not be loaded into its own address space for the DFSMSHsm function being invoked. Instead, DFSMSDss will be loaded in the DFSMSHsm address space.
DUMPIO(1,1)	DFSMSDss reads one track at a time.
DUPLEX	If you do not specify DUPLEX and either of its subparameters, duplexing does not occur.
EXITOFF	Installation exits remain in their current state.
EXITON	No installation exits are active.
EXPIREDDATASETS(NOSCRATCH)	DFSMSHsm ignores the expiration date of a data set and processes it as if the expiration date were not reached.
EXTENDEDITOC(N)	DFSMSHsm does not attempt to use extended TTOCs for migration tapes or backup tapes.
FASTREPLICATION(DATASETRECOVERY(NONE))	Traditional copy methods are used for data set level recovery. Fast replication is not used.
FASTREPLICATION(MESSAGE DATASET(NO))	DFSMSHsm does not log fast replication messages in message data sets
FASTREPLICATION(FCRELATION(EXTENT))	Extent-level FlashCopy relationships will be established during backup and recovery. Free space is not flashed.
FASTREPLICATION(VOLUMEPAIRMESSAGES(NO))	FlashCopy volume pairing debug message ARC1809I is disabled.
FREQUENCY(0)	DFSMSHsm backs up data sets every time volume backup runs.
INCREMENTALBACKUP(ORIGINAL)	DFSMSHsm creates an initial backup version (if one does not exist) for all non-VSAM and integrated catalog facility VSAM data sets regardless of the change bit in the format 1 DSCB.
INPUTTAPEALLOCATION(NOWAIT)	DFSMSHsm does not ask dynamic allocation to wait for an input tape unit to be allocated. Recall and recovery use input tape units.
INTERVALMIGRATION	DFSMSHsm does interval migration.

<i>Table 63. Summary of DFSMSHsm Default Values (continued)</i>	
DFSMSHsm default value	Result
ISSUEARC1902	Issue of ARC1902I is disabled and the delay time is set to default value of 7200 secs
JES2	DFSMSHsm uses job entry subsystem 2.
JOURNAL(SPEED)	DFSMSHsm puts the journal entries on a queue but does not wait for the record to be written before DFSMSHsm continues processing.
JRNLBKUPDSN(uid.JRNL.BACKUP)	The default value is read from the multiple-host processor control record (MHCR). The record is updated with values specified on the SETSYS CDSVERSIONBACKUP command every time the command is issued. If the MHCR record does not exist, or the parameter (or subparameter) has never been specified, the backup data set name for the journal control data set is uid.JRNL.BACKUP.
MAXABARSADDRESSSPACE(1)	DFSMSHsm runs aggregate backup or recovery in one secondary address space.
MAXBACKUPTASKS(2)	DFSMSHsm concurrently runs two volume backup tasks.
MAXCOPYPOOLTASKS(FRBACKUP(15) FRRECOV(15) DSS(24))	DFSMSHsm concurrently processes a limited number of DFSMSdss invocation tasks for FRBACKUP and FRRECOV. The FRBACKUP limit is 15 and the FRRECOV limit is 15. The DSS limit is the number of volumes that DFSMSHsm passes to DFSMSdss to process concurrently per DFSMSdss invocation.
MAXDSRECOVERTASKS(2)	DFSMSHsm concurrently runs two data set recovery tasks.
MAXDSTAPERECOVERTASKS	DFSMSHsm uses the value of MAXDSRECOVERTASKS.
MAXDUMPRECOVERTASKS(1)	One volume recovery from dump task is processed at a time.
MAXDUMPTASKS(2)	DFSMSHsm concurrently processes two volume dump tasks.
MAXEXTENTS(0)	DFSMSHsm does not do extent reduction for active non-VSAM data sets.
MAXINTERVALTASKS(2)	Defaults to the value of MAXMIGRATIONTASKS.
MAXMIGRATIONTASKS(2)	DFSMSHsm defaults to a maximum of 2 migration tasks that can run concurrently.
MAXRECALLTASKS(15)	DFSMSHsm concurrently processes 15 recall tasks.
MAXRECYCLETASKS(2)	DFSMSHsm concurrently processes two tasks, each with one input and one output unit during RECYCLE processing
MAXSSMTASKS(CLEANUP(2) TAPEMOVEMENT(1))	DFSMSHsm concurrently processes a limited number of secondary space management tasks. The statistics and migration cleanup tasks limit is 2 and the automatic tape migration task limit is 1.

Table 63. Summary of DFSMSHsm Default Values (continued)	
DFSMSHsm default value	Result
MCDSBACKUPDSN(uid.MCDS.BACKUP)	The default value is read from the multiple-host processor control record (MHCR). The record is updated with values specified on the SETSYS CDSVERSIONBACKUP command every time the command is issued. If the MHCR record does not exist, or the parameter (or subparameter) has never been specified, the backup data set name for the migration control data set is uid.MCDS.BACKUP.
MIGRATEPREFIX	DFSMSHsm uses the UID you specified in the DFSMSHsm startup procedure.
MIGRATIONAUTOCLOUD(NOCLOUD)	Eligible data sets are migrated to the non-cloud tier indicated by the management class.
MIGRATIONAUTOCLOUD (SELECTIONTHRESHOLD(40))	If the percentage of data sets that are migrated from a volume to the cloud is not greater than 40, this volume will be selected without checking for "free" threads. Otherwise, the volume will be selected if a "free CEC thread can be found to process the migration.
MIGRATIONCLEANUPDAYS(10 30 3 0)	DFSMSHsm keeps MCDS data set records for recalled data sets for 10 days. DFSMSHsm keeps daily and volume statistics records for 30 days. DFSMSHsm keeps MCDS data set records for reconnectable data sets for 3 days beyond their predicted remigration date. DFSMSHsm will not create "Retained" MCA records or keep track of old cloud migration copies by default.
MIGRATIONLEVEL1DAYS(60)	DFSMSHsm does not migrate the data set from a migration level 1 volume to a migration level 2 volume if someone has recalled the data set within the last 60 days.
MIGRATIONSUBTASKS(NO)	DFSMSHsm does not use migration subtasks.
MIGUNITNAME(3590-1)	DFSMSHsm uses a unit of 3590-1 to mount scratch tapes during migration.
ML1OVERFLOW(DATASSETSIZE(2000000))	If the calculated size of a data set being backed up or migrated is equal to or greater than 2000000 K bytes, DFSMSHsm prefers the OVERFLOW ML1 volume with the least amount of free space that still has enough remaining space for the data set. If the calculated size of the data set is less than 2000000 K bytes, DFSMSHsm prefers the NOOVERFLOW ML1 volume with the maximum amount of free space and least number of users.
ML2PARTIALSNOTASSOCIATEDGOAL	If the number of ML2 partial tapes not associated with any migration or recycle output task is more than 10 at the time of a RECYCLE ML2 command, DFSMSHsm recycles the least full of the excess, leaving the 10 with the highest percentages written.
ML2RECYCLEPERCENT	This parameter has no default, however, if it is not specified, the default functionally used is the value specified for RECYCLEPERCENT. If RECYCLEPERCENT is not specified, its default is 20%.

Table 63. Summary of DFSMSHsm Default Values (continued)

DFSMSHsm default value	Result
MONITOR(BACKUPCONTROLDATASET(80) JOURNAL(80) MIGRATIONCONTROLDATASET(80) OFFLINECONTROLDATASET(80) NOSPACE NOSTARTUP NOVOLUME)	DFSMSHsm prints space and volume information only in the DFSMSHsm log. DFSMSHsm sends warning messages to the operator when the journal data set or any control data set is 80% full.
MOUNTWAITTIME(15)	DFSMSHsm waits 15 minutes for an operator to mount the tape before it issues another message asking if the tapes can be mounted.
NOACCEPTPSCBUSERID	DFSMSHsm does not attempt to retrieve the user ID for TSO batch requests.
NOBACKUP	DFSMSHsm does not back up or recover any data sets.
NOCONVERSION	DFSMSHsm does not reblock data sets when it recalls or recovers them.
NODEBUG	DFSMSHsm processes all data sets and volumes.
NOEMERGENCY	DFSMSHsm processes all data sets normally.
NOERASEONSCRATCH	DFSMSHsm does not check for erase of DFSMSHsm-owned data sets. DFSMSHsm does not ask RACF for the erase status of the user's data set when backup versions and migration copies are scratched from DFSMSHsm-owned DASD volumes. The data set is deleted but the DASD residual data is not overwritten by data management.
NOOPTIMUMDASDBLOCKING	DFSMSHsm writes to DFSMSHsm-owned DASD in 2 KB blocks.
NOPARALLEL	The default value is read from the multiple-host processor control record (MHCR). The record is updated with values specified on the SETSYS CDSVERSIONBACKUP command every time the command is issued. If the MHCR record does not exist, or the parameter (or subparameter) has never been specified, DFSMSHsm will backup the control data sets and the journal serially.
NOREQUEST	DFSMSHsm does not ask operator permission when starting automatic volume space management, automatic secondary space management, automatic backup, and automatic dump at the requested time.
NOSKIPABPRIMARY	DFSMSHsm automatically backs up data sets on primary volumes.
NOSMALLDATASETPACKING	DFSMSHsm does not pack small data sets into SDSP data sets on migration level 1 volumes.
NOSMF	DFSMSHsm does not write SMF records.
NOTAPEHARDWARECOMPACT	Improved data recording capability (IDRC) is not used when 3480X is used as the output device.
NOUNLOAD	DFSMSHsm does not unload your virtual volumes.

Table 63. Summary of DFSMSHsm Default Values (continued)	
DFSMSHsm default value	Result
NOUSERUNITTABLE	DFSMSHsm does not use esoteric tape unit names.
OBJECTNAMES	DFSMSHsm uses the general compaction table.
OCDSBACKUPDSN(uid.OCDS.BACKUP)	The default value is read from the multiple-host processor control record (MHCR). The record is updated with values specified on the SETSYS CDSVERSIONBACKUP command every time the command is issued. If the MHCR record does not exist, or the parameter (or subparameter) has never been specified, the backup data set name for the offline control data set is uid.OCDS.BACKUP.
ODMNOTIFICATIONLIMIT(100)	Message ARC1901E is issued to the operator's console when the number of volumes concurrently queued for on-demand migration exceeds 100 volumes.
ONDEMANDMIGRATION(N)	On-demand migration is disabled.
OUTPUTTAPEALLOCATION(NOWAIT)	DFSMSHsm does not ask dynamic allocation to wait for an output tape unit to be allocated. Migration, backup, and dump use output tape units.
PARTIALTAPE(REUSE)	DFSMSHsm marks the tape volume full only when the volume reaches the percent full specified with the SETSYS TAPEUTILIZATION parameter.
PDA(ON)	DFSMSHsm defaults to ON if the subparameters NONE or OFF are not specified. Tracing begins at DFSMSHsm startup and continues until the OFF subparameter is specified or DFSMSHsm is stopped or ABENDs.
PLEXNAME(PLEX0)	DFSMSHsm uses a default HSMplex name of ARCPLEX0.
PRIMARYSPMGMTSTART(0)	DFSMSHsm does not run automatic primary space management.
PROFILEBACKUP	DFSMSHsm creates a backup RACF discrete profile for every cataloged RACF-indicated data set that it backs up.
PROMOTE	No host in an HSMplex is eligible to take over the Primary or Secondary Space Management functions of a failed host.
RACFIND	DFSMSHsm puts RACF-indication on migration copies and backup versions.
RECALL(ANYSTORAGEVOLUME)	DFSMSHsm recalls nonpooled data sets to an online primary volume with the storage use attribute and primary volume attribute of automatic recall.
RECYCLEINPUTDEALLOCFREQUENCY(BACKUP MIGRATION)	DFSMSHsm uses zero (0) for both the BACKUP and MIGRATION subparameters. This will keep an input unit allocated until the recycle processing has completed or as long as input can be read.
RECYCLEOUTPUT(BACKUP MIGRATION)	DFSMSHsm uses any available tape.
RECYCLEPERCENT(20)	The tape volume cannot contain more than 20% valid data when DFSMSHsm generically recycles a volume.

<i>Table 63. Summary of DFSMSHsm Default Values (continued)</i>	
DFSMSHsm default value	Result
RECYCLETAKEAWAYRETRY(NO)	DFSMSHsm does not automatically generate a new RECYCLE command for a tape when the original recycle must terminate due to the takeaway process, or when the tape is in use by the another DFSMSHsm task.
RECYCLETAPEALLOCATION(NOWAIT)	DFSMSHsm does not ask dynamic allocation to wait for a tape unit to be allocated during recycle processing.
RETENTIONPERIOD(7)	The default value is read from the multiple-host processor control record (MHCR). The record is updated with values specified on the SETSYS CDSVERSIONBACKUP command every time the command is issued. If the MHCR record does not exist, or the parameter (or subparameter) has never been specified, DFSMSHsm keeps the backup copies of the DFSMSHsm control data sets for 7 days.
SCRATCHFREQUENCY(9999)	DFSMSHsm keeps list data sets for 9,999 days before it scratches them.
SECONDARYSPMGMTSTART(0)	DFSMSHsm does not run automatic secondary space management.
SELECTVOLUME(SCRATCH)	DFSMSHsm chooses scratch tapes when an end-of-volume occurs on a tape volume while DFSMSHsm is using it.
SOURCENAMES	DFSMSHsm uses the general compaction table.
SPILL(ANY)	DFSMSHsm does spill processing on any type of spill backup volume that can be used for output.
SWAP NOSWAP	The system resource manager decides whether or not to make the DFSMSHsm address space able to be swapped.
SYSOUT(A 1)	DFSMSHsm prints to class A, makes one copy, and uses no special form.
SYS1DUMP	DFSMSHsm writes the output of a DFSMSHsm dump to a system dump data set.
TAPEDELETION(SCRATCHTAPE)	Tapes become scratch tapes after DFSMSHsm recycles them.
TAPEINPUTPROMPT(TAPES(YES))	DFSMSHsm issues action messages to the operator asking if needed input tapes are available.
TAPEMAXRECALLTASKS(1)	DFSMSHsm cannot process more than 1 tape recall task. The rest are DASD recall tasks. This parameter is a subset of the MAXRECALLTASKS parameter.
TAPEMIGRATION(NONE (ROUTETOTAPE(ANY)) RECONNECT(NONE))	DFSMSHsm selects the first available migration tape when a tape migration level 2 volume is required. If no tapes are available, DFSMSHsm selects a scratch tape with the unit name specified or defaulted from the MIGUNITNAME parameter of the SETSYS command. DFSMSHsm does not perform reconnection.

Table 63. Summary of DFSMSHsm Default Values (continued)	
DFSMSHsm default value	Result
TAPEOUTPUTPROMPT (TAPECOPY(NO))	If you specify N, DFSMSHsm issues no message to the operator during TAPECOPY processing indicating which type of target tape is to be mounted on a particular device.
TAPERECALLLIMITS(TASK(15) TAPE(20))	DFSMSHsm allows a task to continue processing from a single mount of a tape for at least 15 minutes and/or until a tape recall request of higher priority exists which can not be started until a task is freed up. Then the task is freed up for other recalls. DFSMSHsm allows a task to have a tape allocated and mounted for at least 20 minutes and/or until another host needs that mounted tape for a higher priority recall. Then the tape is freed up by this host which allows other hosts an opportunity to use that tape.
TAPESECURITY(PASSWORD)	DFSMSHsm uses password protection for its tape volumes.
TAPESPANSIZE(500)	DFSMSHsm can leave unused up to 500 megabytes (MB) of tape during attempts to eliminate spanning data sets.
TAPETYPE(NOWORM)	DFSMSHsm does not use WORM media for non-ABARS functions.
TAPEUTILIZATION PERCENTFULL(97)	DFSMSHsm forces an end-of-volume on a backup or migration tape volume when it is 97% full.
TAPEUTILIZATION CAPACITYMODE(COMPATIBILITY)	If you do not specify CAPACITYMODE(EXTENDED) for an esoteric capable of CAPACITYMODE switching, the drives operate in CAPACITYMODE(COMPATIBILITY) for output. The drives use CAPACITYMODE(COMPATIBILITY) or CAPACITYMODE(EXTENDED) as necessary for input.
UNITNAME(3590-1)	CDSVERSIONBACKUP: The default value is read from the multiple-host processor control record (MHCR). The record is updated with values specified on the SETSYS CDSVERSIONBACKUP command every time the command is issued. If the MHCR record does not exist, or the parameter (or subparameter) has never been specified, DFSMSHsm uses a unit of 3590-1 to allocate scratch tapes during backup. UNITNAME: DFSMSHsm uses a unit of 3590-1 to allocate scratch tapes during backup.
USECYLINDERMANAGEDSPACE(N)	Cylinder-managed space is not used for migration copies and backup versions. For allocation, DFSMSHsm does not specify an EATTR value.
VERSIONS(2)	DFSMSHsm keeps two backup versions of each data set.
VOLCOUNT(NONE)	The default is NONE and DFSMSHsm does not pass the VOLCOUNT parameter to DFSMSdss.
VOLUMEDUMP(NOCC)	Concurrent copy will not be used by DFSMSdss when dumping volumes.

Table 63. Summary of DFSMSHsm Default Values (continued)

DFSMSHsm default value	Result
ZCOMPRESS(NONE)	The default is NONE and the SETSYS COMPACT settings will be used.

Optional parameters of the SETSYS command

References to "all" data sets in the descriptions of the SETSYS parameters mean *both* SMS-managed and non-SMS-managed data sets for those parameters that are applicable to SMS.

ABARSACTLOGMSGLVL: Specifying which DFSMSdss messages are written to the log

ABARSACTLOGMSGLVL is used to specify which DFSMSdss messages are written to the respective ABARS activity log.

FULL

Specifies that all DFSMSdss messages are intercepted and written to the ABARS activity log.

REDUCED

Specifies that only DFSMSdss warning or error messages are displayed in the ABARS activity log. No informational messages will be written.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

ABARSACTLOGTYPE: Specifying the ABARS activity log output data set type

ABARSACTLOGTYPE is used to specify the ABARS activity log output data set type.

Subparameter	Explanation
SYSOUT(class)	Messages are written out to a spool data set. For <i>class</i> , substitute an alphanumeric character for the class ABARS is to use for output.
DASD	<p>DFSMSHsm dynamically allocates DASD data sets with a unit name of SYSALLDA and a size of 20 tracks for primary allocation and 50 tracks for secondary allocation. Activity logs have names in the following form:</p> <pre>mcvtactn.Hmcvthost.function.agname.Dyyddd.Thhmmss</pre> <p>where:</p> <ul style="list-style-type: none"> • mcvtactn = Activity log high-level qualifier. The default is HSMACT. • Hmcvthost = DFSMSHsm host ID from the PROC statement, preceded by H. • function = Either ABACKUP or ARECOVER. • agname = The name of the aggregate group being backed up. • Dyyddd = Year and day of allocation, preceded by D. • Thhmmss = Hour, minute, and second of allocation, preceded by T.

Note: SYSOUT has the advantage of not utilizing DASD space, whereas DASD has the advantage of being machine readable and readily available. Outputting to DASD will allow the ABACKUP activity log to be backed up as part of the aggregate backup output.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: SYSOUT is the initial default setting. If class is not specified, the default will be the SETSYS ACTLOGTYPE SYSOUT class. If ACTLOGTYPE has been set to DASD, the ABARSACTLOGTYPE class defaults to the SETSYS SYSOUT class, which in turn defaults to “A”.

If SETSYS ABARSACTLOGTYPE has not been issued, each time SETSYS ACTLOGTYPE is issued, it makes the corresponding change to the setting of ABARSACTLOGTYPE.

Note: Once SETSYS ABARSACTLOGTYPE is issued, any subsequent SETSYS ACTLOGTYPE command does not affect the ABARSACTLOGTYPE.

ABARSBUFFERS: Specifying the number of I/O buffers for ABARS

ABARSBUFFERS(*n*) is used to specify the number of I/O buffers to be used by ABARS when DFSMSHsm is used to read or write data sets during aggregate backup and recovery processing. This parameter does not affect the number of buffers used when DFSMSdss is invoked to DUMP or RESTORE data sets.

n specifies a number in the range of 1 to 9 indicating the number of buffers used for I/O processing. This number is internally multiplied by two (a buffer for input and a buffer for output).

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: If the number of buffers is not specified by the SETSYS ABARSBUFFERS(*n*) command, the default is one.

ABARSDELETEACTIVITY: Allowing DFSMSHsm to automatically delete the ABARS activity log

ABARSDELETEACTIVITY(Y | N) is used to select whether or not DFSMSHsm deletes the ABARS activity log during ABARS roll-off processing or EXPIREBV ABARSVERSIONS processing.

Y specifies that DFSMSHsm is to delete the ABARS activity log during ABARS processing. N specifies that no automatic deletion is performed by DFSMSHsm.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: The ABARS activity log is not automatically deleted during ABARS processing.

ABARSKIP: Specifying which types of data sets ABACKUP should skip

ABARSKIP is used to specify which types of data sets that ABACKUP processing should skip. If a data set in an aggregate group is on a volume or volumes that are protected by peer-to-peer remote copy, specifying ABARSKIP(PPRC) causes ABACKUP processing to skip the data set and not back it up. If a data set is on a volume or volumes protected by extended remote copy, specifying ABARSKIP(XRC) causes ABACKUP processing to skip the data set and not back it up.

Specifying ABARSKIP(NOPPRC) or ABARSKIP(NOXRC) causes ABACKUP processing to not skip the corresponding data set and it is backed up.

SMS relationship: Parameter has the same meaning when it is applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: The DFSMSHsm default is NOPPRC and NOXRC.

ABARSOPTIMIZE: Adjusting performance when backing up level 0 DASD specified in INCLUDE list

ABARSOPTIMIZE(*option*) is used to control the value that the ABACKUP function specifies in the OPTIMIZE parameter when invoking DFSMSdss to backup level 0 DASD data sets.

The valid specifications for the *option* value are:

- If value is 1, then DFSMSdss reads one track at a time
- If value is 2, then DFSMSdss reads two tracks at a time
- If value is 3, then DFSMSdss reads five tracks at a time
- If value is 4, then DFSMSdss reads one cylinder at a time

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: The default value for *option* is 3.

ABARSPROCNAME: Specifying the base procedure name to start the ABARS secondary address space

ABARSPROCNAME(*name*) is used to specify the JCL procedure name used on the START command issued by DFSMSHsm to start the ABARS secondary address space. For *name*, specify a procedure name that conforms to standard MVS JCL naming conventions.

DFSMSHsm appends *ABARSnnst* as an identifier to this procedure name when starting ABARS secondary address spaces. The value *nn* changes each time a new address space is started. The value will range from 1 to 64, so that each address space is started with a unique procedure name. The value *st* is derived from the current clock time when the procedure is started.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify a procedure name on any SETSYS command, the DFSMSHsm default is DFHSMABR.

ABARSTAPES: Allowing DFSMSHsm to stack the ABACKUP output files

ABARSTAPES(STACK | NOSTACK) is used to indicate to DFSMSHsm to stack the ABACKUP output files onto a minimum number of tape volumes during ABACKUP processing.

Subparameter	Explanation
STACK	DFSMSHsm stacks the ABACKUP output files onto a minimum number of tape volumes. STACK also indicates to the ARECOVER function that the ABACKUP output files are stacked and if ARECOVER determines that the ABACKUP output files are not stacked, ARECOVER attempts to recover the output files as if NOSTACK was specified.
NOSTACK	DFSMSHsm does not stack the ABACKUP output files. The ABACKUP function operates as it did in prior releases. NOSTACK also indicates to the ARECOVER function that the ABACKUP output files are not stacked and if ARECOVER determines that the ABACKUP output files are stacked, ARECOVER attempts to recover the output files as if STACK was specified.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: The default is STACK.

ABARSUNITNAME: Specifying a unit name for ABARS

ABARSUNITNAME(*unittype*) is used to specify the unit to be used when invoking aggregate backup or aggregate recovery.

Tape Library Relationship: A UNITNAME can be used for filtering in the ACS routines. If you specify the *unittype* for this command, it will be sent to the ACS routines in SMS for the ABARS function.

unittype specifies the tape unit to be allocated for the control file, instruction/activity log, and data file. The valid types of tape units are:

- 3400-3, 3400-4, 3400-5, 3400-6, 3400-9
- 3480
- 3480X
- 3490
- 3590-1

You can substitute an esoteric tape unit defined with the USERUNITTABLE parameter of the SETSYS command. If you specify an esoteric tape unit name that does not exist in the user unit table, the command fails. Specify 3400-9 when your 3480 Magnetic Tape Subsystem simulates your 3420 tape drives.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: If *unitname* is not specified by the SETSYS ABARSUNITNAME(*unitname*) or the UNIT parameter on the ABACKUP or ARECOVER command, it defaults to 3590-1.

ABARSVOLCOUNT: Specifying the method for determining volume count for SMS target data set allocations done by DFSMSdss

ABARSVOLCOUNT(ANY | NONE) is an optional parameter that affects how DFSMShsm will invoke DFSMSdss during the ARECOVER of data sets that were dumped by DFSMSdss. This parameter affects only the ARECOVER of data sets dumped from primary volumes (LO data sets). Refer to *z/OS DFSMSdss Storage Administration* for more specific information about the restrictions and limitations of the DFSMSdss VOLCOUNT parameter.

Subparameter	Explanation
ANY	DFSMShsm passes the VOLCOUNT(ANY) parameter to DFSMSdss during the ARECOVER of data dumped by DFSMSdss (LO data sets). This results in the allocation of the target data set on as many volumes as required, to a maximum of 59.
NONE	The VOLCOUNT parameter is not passed to DFSMSdss and DFSMShsm operates as it did prior to the VOLCOUNT support being added where the source volume count must be maintained (for example, no single volume data sets can be extended to multiple volumes). If, for example, ABARSVOLCOUNT(ANY) had been previously specified, issuing SETSYS ABARSVOLCOUNT(NONE) resets the associated DFSMShsm indicators.

The ABARSVOLCOUNT parameters of ANY or NONE are ignored if specified for data types to which they do not apply. Refer to the *z/OS DFSMShsm Implementation and Customization Guide* to determine data set types moved by DFSMSdss for DFSMShsm.

SMS relationship: Parameter applies in some instances to SMS-managed DASD volumes or data sets.

SETSYS default: There is no SETSYS default.

DFSMSHsm default: If you do not specify SETSYS ABARSVOLCOUNT, the default is NONE.

ACCEPTPSCBUSERID and NOACCEPTPSCBUSERID: Allowing non-RACF installations to issue authorized commands in a TMP environment

Explanation: **ACCEPTPSCBUSERID** | **NOACCEPTPSCBUSERID** are mutually exclusive, optional parameters you use to specify whether DFSMSHsm should have a way of issuing authorized DFSMSHsm commands in a TSO batch environment in installations not having RACF. When RACF is not installed, authorized DFSMSHsm commands issued in a pure batch environment fail because of a lack of authorization.

ACCEPTPSCBUSERID specifies that an installation not having RACF will have DFSMSHsm retrieve the user ID for TSO batch requests from the protected step control block (PSCB) and associate the user ID with the request. Thus, the current authorization checking for commands can be used to determine if the user ID is an authorized DFSMSHsm user ID. If no user ID is present in the PSCB, ****BATCH*** will be used. An installation must ensure that the user ID is placed in the PSCB if **ACCEPTPSCBUSERID** is specified. If an installation does not issue the SETSYS **ACCEPTPSCBUSERID** command and RACF is not installed, DFSMSHsm will not attempt to retrieve the user ID for TSO batch requests and all DFSMSHsm authorized-user commands will fail.

NOACCEPTPSCBUSERID specifies that DFSMSHsm will not attempt to retrieve the user ID for TSO batch requests when RACF is not installed.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is **NOACCEPTPSCBUSERID**.

Notes:

1. The SETSYS **ACCEPTPSCBUSERID** command applies only to TSO batch requests on systems where RACF is not installed.
2. When SETSYS **SYS1DUMP** is entered in the DFSMSHsm startup command member in a PARMLIB, there is a possibility of an ABEND occurring during DFSMSHsm initialization prior to this command being processed. If an ABEND occurs in this window and a dump listing is desired, include a **SYSUDUMP DD** card in the DFSMSHsm startup procedure.

ACTLOGMSGLVL: Specifying message level for recording data sets

Explanation: **ACTLOGMSGLVL(FULL | EXCEPTIONONLY | REDUCED)** is an optional parameter specifying the message log level for the activity log required for recording data sets processed by volume and level functions. Specifically, this parameter determines which ARC0734I data set movement messages will be written to the activity log. Only the issuance of the ARC0734I message is affected.

Subparameter	Explanation
FULL	Messages are generated and logged for all activities.
EXCEPTIONONLY	Messages are generated and logged for activities with a nonzero return code.
REDUCED	The original space management message or backup message is generated, but messages for subsequent movement and cleanup are suppressed.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify any of the subparameters with the ACTLOGMSGLVL parameter, the DFSMSHsm default is FULL.

Notes:

1. ACTLOGMSGLVL is not supported for secondary address spaces.
2. Any messages excluded from the activity logs by the use of ACTLOGMSGLVL will also be excluded from the HSMLOGX/Y.

ACTLOGTYPE: Specifying the type of output data set to receive messages

Explanation: **ACTLOGTYPE(SYSOUT(class) | DASD)** is an optional parameter specifying the activity logs as either a SYSOUT data set or a DASD data set. The content of the log is free-form and can be scanned to produce a desired output.

Subparameter	Explanation
SYSOUT(class)	Messages are written out to a spool data set. For <i>class</i> , substitute an alphanumeric character for the class DFSMSHsm is to use for output.
DASD	<p>DFSMSHsm dynamically allocates DASD data sets with a unit name of SYSALLDA and a size of 20 tracks for primary allocation and 50 tracks for secondary allocation. Activity logs have names in the following form:</p> <pre>mcvtactn.Hmcvthost.function.Dyyddd.Thhmmss or mcvtactn.HUmcvthost.function.Dyyddd.Thhmmss</pre> <p>where:</p> <ul style="list-style-type: none"> • <i>mcvtactn</i> = Activity log high-level qualifier, the default is HSMACT • <i>Hmcvthost</i> = DFSMSHsm host ID from the PROC statement, preceded by H • <i>HUmcvthost</i> = DFSMSHsm Filemode host ID from the PROC statement, preceded by HU • <i>function</i> = Either CMDLOG, BAKLOG, DMPLOG, or MIGLOG • <i>Dyyddd</i> = Year and day of allocation, preceded by D • <i>Thhmmss</i> = Hour, minute, and second of allocation, preceded by T

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: The SYSOUT class established by the SETSYS SYSOUT command.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is SYSOUT. If you do not specify *class* for SYSOUT, the DFSMSHsm default is A, one copy, and no special forms.

Notes:

1. If the SYSOUT class is modified with the SETSYS ACTLOGTYPE command, existing open SYSOUT activity logs are closed and new SYSOUT activity logs are opened using the output class specified with the command. For the DFSMSHsm secondary address space, the new output class is used for subsequent secondary address spaces as they are started.
2. ACTLOGTYPE is supported for secondary address spaces.
3. If you need to replace HSMACT as the activity log high-level qualifier, refer to [Tuning DFSMSHsm in z/OS DFSMSHsm Implementation and Customization Guide](#).

ARECOVERML2UNIT: Specifying the unit when recovering migrated data sets to nonspecific volumes

Explanation: **ARECOVERML2UNIT(*unittype*)** specifies the type of tape unit to use in a nonspecific volume request when recovering migrated data sets to ML2 tape volumes. For *unittype*, substitute a valid unit type or a valid esoteric unit name. The following are valid types of tape units: 3400-3, 3400-4, 3400-5, 3400-6, 3400-9, 3480, 3480X, 3490, and 3590-1. You specify 3400-9 when your 3480 Magnetic Tape Subsystem simulates your 3420 tape drives. You can substitute an esoteric tape unit defined with the SETSYS USERUNITTABLE command. If you specify an esoteric tape unit name that does not exist in the user unit table, the command fails.

When in a mixed tape drive environment you must use a customer defined esoteric *unittype* since the generic will contain a mix of machine types. For example, if your tape environment has both 3590 Model H drives and 3592 Model J drives defined as 3590, then the "3590-1" generic will contain both of these machine types. If you intend to recover ML2 tapes on the 3592 Model J drives, create an esoteric exclusively for them, define the esoteric to DFSMSHsm via the SETSYS USERUNITTABLE command, and define that esoteric as the ARECOVERML2UNIT.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

DFSMSHsm default: If you do not specify this parameter, the DFSMSHsm default is 3590-1.

ARECOVERPERCENTUTILIZED: Specifying the percentage of DASD space for non-SMS-managed volumes

Explanation: **ARECOVERPERCENTUTILIZED(*nnn*)** is an optional parameter that allows you to change the percentage to which DFSMSHsm allows DFSMSdss to fill non-SMS-managed DASD recovery volumes. For *nnn*, substitute an integer number between 1 and 100.

SMS relationship: Parameter does not apply to SMS-managed DASD volumes or data sets.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is 80% (080).

ARECOVERTGTGDS: Passing TGTGDS parameter to DFSMSdss during restore processing

Explanation: **ARECOVERTGTGDS(*option*)** is used to pass to DFSMSdss the TGTGDS parameter. This parameter provides greater flexibility managing SMS-managed generation data sets that are being restored to level 0 DASD.

The valid values for *option* are as follows:

- DEFERRED specifies that the target data set is to be assigned the DEFERRED status.
- ACTIVE specifies that the target data set is to be assigned the ACTIVE status, for example, rolled into the GDG base.
- ROLLEDOFF specifies that the target data set is to be assigned the ROLLEDOFF status.
- SOURCE specifies that the target data set is to be assigned the same status as that of the source data set.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: The default is SOURCE.

ARECOVERUNITNAME: Specifying tape unit type for aggregate recovery

Explanation: **ARECOVERUNITNAME(*unittype*)** is an optional parameter specifying the tape unit type for data sets being recovered to user tape volumes during an aggregate recovery.

For *unittype*, substitute the type of tape unit. The following are valid types of tape units:

- 3400-3, 3400-4, 3400-5, 3400-6, 3400-9
- 3480
- 3480X
- 3490
- 3590-1

You can substitute an esoteric tape unit defined with the SETSYS USERUNITTABLE command. If you specify an esoteric tape unit name that does not exist in the user unit table, the command fails. If you specify:

- 3400-9, your 3480 Magnetic Tape Subsystem simulates your 3420 tape drives.
- 3480 or 3480X, you use all the functions of the 3480 Magnetic Tape Subsystem.
- 3490, you use all the functions of the 3490 Magnetic Tape Subsystem.
- 3590-1, you use all the functions of the 3590 Magnetic Tape Subsystem.

You specify 3480 or 3480X when you use all the functions of the 3480 or 3480X Magnetic Tape Subsystem.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify *unittype* the default is 3590-1.

AUTOBACKUPSTART: Specifying when automatic backup is to start

Explanation: **AUTOBACKUPSTART((*hhmm1 hhmm2 hhmm3*)** is an optional parameter specifying the time when automatic backup can start. The first time you specify (*hhmm1*) is the time you plan for DFSMSHsm to start automatic backup. The second time you specify (*hhmm2*) is the latest time DFSMSHsm can start automatic backup. The third time you specify (*hhmm3*) is the time after which DFSMSHsm will not start automatic backup on additional volumes.

If DFSMSHsm does not start automatic backup between the planned start time and the latest start time, no automatic backup is run that day.

For *hhmm1*, substitute the planned time for DFSMSHsm to start automatic backup. If you specify *hhmm1* as zero, DFSMSHsm cannot start automatic backup.

Note: Time is based on the 24-hour clock and is expressed as a four-digit decimal number in the format *hhmm*. The hour is represented by *hh* and the minutes by *mm*. For example, 1:15 p.m. is 1315 and midnight is 2400. The maximum value you can specify for *hh* is 24, the maximum value you can specify for *mm* is 59, and the maximum value you can specify for *hhmm* is 2400.

For *hhmm2*, substitute the latest time DFSMSHsm can start automatic backup. If *hhmm2* is set to zero, this is the same as not including the *hhmm2* parameter and DFSMSHsm runs automatic backup processing until all volumes have been backed up. If you want automatic backup to begin after midnight, the value for the latest start time can be smaller than the planned start time. For example, you can specify 2330 for *hhmm1* and 0100 for *hhmm2*.

For *hhmm3*, substitute the time after which DFSMSHsm can no longer start automatic backup of additional volumes. If *hhmm3* is set to zero, this is the same as not including the *hhmm3* parameter. If you do not specify *hhmm3*, DFSMSHsm runs automatic backup processing until all volumes have been backed up.

If you want automatic backup to begin after midnight, *hhmm2*, the latest start time, can be smaller than *hhmm1*, the planned start time. As an example, you can specify 2330 for *hhmm1*, 0100 for *hhmm2*, and 0330 for *hhmm3*. DFSMSHsm assumes that *hhmm2* is a later time than *hhmm1* and *hhmm3* is a later time than *hhmm2*.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: If you do not specify a value for *hhmm2*, the SETSYS default is 2400.

DFSMShsm default: If you do not specify this parameter on any SETSYS command, the DFSMShsm default is no automatic backup.

Note:

1. If you do not specify a nonzero value for *hhmm1* during this start up of DFSMShsm, DFSMShsm does not do automatic backup.
2. The maximum value you can specify for *mm* is 59, and the maximum value you can specify for *hhmm1*, *hhmm2*, or *hhmm3* is 2400.
3. You use the BACKUP parameter of the DEFINE command to specify on which days DFSMShsm is to run automatic backup. The AUTOBACKUPSTART parameter specifies the time when automatic backup can start. If automatic backup does not start before the latest start time, DFSMShsm does not start automatic backup until the next day in the cycle that automatic backup is scheduled to run. If automatic backup did not start today, you can use AUTOBACKUPSTART to change the planned and latest start times.
4. DFSMShsm serializes access to your data sets and volumes for a short period of time while it runs automatic backup. Therefore, choose a time for automatic backup when the computing system is not very active and there is not much interactive user activity.
5. If you want the operator to decide whether DFSMShsm should start automatic backup, specify the REQUEST parameter and the AUTOBACKUPSTART parameter.
6. If you specify *hhmm3* as zero, automatic backup will process all eligible primary volumes.
7. The SETSYS command fails if *hhmm1* and *hhmm2* are equal or if *hhmm2* and *hhmm3* are equal.
8. DFSMShsm does not honor the value for *hhmm3* until the volume phase of the AUTOBACKUP function.

AUTODUMPSTART: Specifying when automatic dump is to start

Explanation: **AUTODUMPSTART(*hhmm1 hhmm2 hhmm3*)** is an optional parameter specifying the time when automatic dump can start. The first time you specify (*hhmm1*) is the time you plan for DFSMShsm to start automatic dump. The second time you specify (*hhmm2*) is the latest time DFSMShsm can start automatic dump. The third time you specify (*hhmm3*) is the time after which DFSMShsm will not start automatic dump on additional volumes.

If DFSMShsm does not start automatic dump on volumes by the *hhmm2* time, no automatic dumping is performed that day. Volumes being processed when the *hhmm3* time is reached are not affected.

For *hhmm1*, substitute the planned time for DFSMShsm to start automatic dump. If you specify *hhmm1* as zero, DFSMShsm does not start automatic dump.

Note: Time is based on the 24-hour clock and is expressed as a four-digit decimal number in the format *hhmm*. The hour is represented by *hh* and the minutes by *mm*. For example, 1:15 p.m. is 1315 and midnight is 2400. The maximum value you can specify for *hh* is 24, the maximum value you can specify for *mm* is 59, and the maximum value you can specify for *hhmm* is 2400.

For *hhmm2*, substitute the latest time DFSMShsm can start automatic dump. If *hhmm2* is set to zero, this is the same as not including the *hhmm2* parameter and DFSMShsm runs automatic dump processing until all volumes have been dumped. If you want automatic dump to begin after midnight, the value for the latest start time can be smaller than the planned start time. For example, you can specify 2330 for *hhmm1* and 0100 for *hhmm2*.

For *hhmm3*, substitute the time after which DFSMShsm can no longer start the automatic dumping of additional volumes. If *hhmm3* is set to zero, this is the same as not including the *hhmm3* parameter. If you do not specify *hhmm3*, DFSMShsm runs automatic dump processing until all volumes have been dumped.

If you want automatic dumping to begin after midnight, *hhmm2*, the latest start time, can be smaller than *hhmm1*, the planned start time. As an example, you can specify 2330 for *hhmm1*, 0100 for *hhmm2*, and

0330 for *hhmm3*. DFSMSShsm assumes that *hhmm2* is a later time than *hhmm1* and *hhmm3* is a later time than *hhmm2*.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: If you do not specify a value for *hhmm2*, the SETSYS default is 2400.

DFSMSShsm default: If you do not specify this parameter on any SETSYS command, the default is no automatic dump.

Note:

1. If you do not specify a nonzero value for *hhmm1* during this start up of DFSMSShsm, DFSMSShsm does not do automatic dumping.
2. The maximum value you can specify for *mm* is 59, and the maximum value you can specify for *hhmm1*, *hhmm2*, or *hhmm3* is 2400.
3. You use the DUMPCYCLE parameter of the DEFINE command to specify on which days DFSMSShsm is to run automatic dump. The AUTODUMPSTART parameter specifies the time when automatic dump can start. If automatic dump does not start before the latest start time, DFSMSShsm does not start automatic dump until the next day in the cycle that automatic dump is scheduled to run. If automatic dump did not start today, you can use AUTODUMPSTART to change the planned and latest start times.
4. AUTODUMPSTART has no meaning unless the BACKUP parameter is specified on a SETSYS command during this DFSMSShsm startup.
5. An explicit command must be issued to halt the automatic dump process before normal completion.
6. If you want the operator to decide whether DFSMSShsm should start automatic dump, specify the REQUEST parameter and the AUTODUMPSTART parameter.
7. As with automatic backup, DFSMSShsm serializes access to data sets and volumes for a short period of time. Therefore, select a time for automatic dump when the computing system is not very active and there is not much interactive user activity (usually at night).
8. Automatic dump usually starts at the planned start time. Assume, however, that DFSMSShsm is not running at the planned start time or the operating system is lost while automatic dump is running. When DFSMSShsm restarts, it checks whether the latest start time has passed. If it has not passed, DFSMSShsm restarts automatic dump. If the time has passed and you want automatic dump to run today, you can use this parameter to respecify the time when automatic dump can start.
9. If you specify *hhmm3* as zero, automatic dump processes all eligible primary volumes.
10. The SETSYS command will fail if *hhmm1* and *hhmm2* are equal.
11. DFSMSShsm can run automatic dump multiple times a day in a test environment. If automatic dump runs to completion and you want to start automatic dump again, use the following procedure:
 - a. Issue the SETSYS AUTODUMPSTART command to define a new start window.
 - b. Specify a start window that has a planned start time after the time that automatic dump last ended.
 - c. Do not confuse the time that automatic dump last ended with the specified latest start time.

Automatic dump starts immediately if the current time is in the new start window. If the current time is not in the new start window, automatic dump starts automatically when the planned start time occurs.

AUTOMIGRATIONSTART: Specifying the start time for automatic primary space management

The use of the SETSYS AUTOMIGRATIONSTART parameter is nonfunctional and its use has been replaced by other functions. The AUTOMIGRATIONSTART parameter is still supported but is no longer documented.

BACKUP and NOBACKUP: Specifying whether you intend to use DFSMSHsm backup, recovery, and dump

Explanation: **BACKUP** | **NOBACKUP** are mutually exclusive, optional parameters specifying whether you intend to use any of the following DFSMSHsm functions: backup, dump, recovery, and expiring backup versions. The **BACKUP** parameter allows you to specify restrictions as to what kind of volumes are allowed to be used for daily backup.

The target device type used for volume backups can come from multiple sources. There are the **BACKUPDEVICECATEGORY** options on the **BACKVOL** and **ADDVOL** commands and there are the **SETSYS BACKUP** options of **ANY** | **DASD** | **TAPE**. The target device type can apply to the backup from SMS DASD when specified on a **BACKVOL** command or with the **SETSYS BACKUP** command. For non-SMS DASD, the target device type can be specified by any **BACKVOL**, **ADDVOL**, or **SETSYS BACKUP** command.

Tape Library Relationship: A **UNITNAME** can be used for filtering in the ACS routines. If you specify the **unittype** for this command, it will be sent to the ACS routines in SMS for the **BACKUP** function.

BACKUP specifies that you intend to use some or all of the following DFSMSHsm functions: backup (automatic or command), dump (automatic or command), recovery, and expire backup versions.

To do the following functions	Use this DFSMSHsm command
Backup	HBACKDS, BACKDS, or BACKVOL
Automatic backup	SETSYS AUTOBACKUPSTART and DEFINE BACKUP
Dump	BACKVOL and DEFINE DUMPCLASS
Automatic dump	SETSYS AUTODUMPSTART, DEFINE DUMPCLASS, and DEFINE DUMPCYCLE
Recovery	HRECOVER or RECOVER
Expire backup versions	EXPIREBV

The **SETSYS BACKUP** options **ANY** | **DASD** | **TAPE**(*unittype*) are there to control the target of the backup output. The **SETSYS BACKUP** options apply only if the **BACKUPDEVICECATEGORY** option is not specified on the **BACKVOL** command (SMS or non-SMS) or on an **ADDVOL** command (non-SMS only).

Subparameter	Explanation
ANY	During volume backup processing, unless overridden by a BACKVOL command or by an ADDVOL of a non-SMS volume command, any type of daily backup volume (DASD or Tape) defined to DFSMSHsm by the ADDVOL can be used for output.
DASD	During volume backup processing, unless overridden by a BACKVOL command or by an ADDVOL of a non-SMS volume command, only DASD daily backup volumes defined by the DFSMSHsm ADDVOL command can be used for output.
TAPE	During volume backup processing, unless overridden by a BACKVOL command or by an ADDVOL of a non-SMS volume command, only tape daily backup volumes defined to DFSMSHsm via the ADDVOL command can be used for output.

Subparameter	Explanation
TAPE(<i>unittype</i>)	<p>For volume backup processing to non-SMS tape, only tape daily backup volumes that can be mounted and written on the specified type <i>unittype</i> can be used for output. For SMS tape, the specified type <i>unittype</i> will be passed to the ACS routines. A corresponding <i>unittype</i> restriction for dump output can be specified with the DEFINE DUMPCLASS command.</p> <p>For <i>unittype</i>, a generic or esoteric unit name can be specified. The following generic unit names are acceptable: 3480, 3480X, 3490 and 3590-1. If an esoteric unit name is specified, it must have been previously defined to DFSMSHsm using the USERUNITTABLE parameter of the SETSYS command. You specify 3480 or 3480X when you use all the functions of the 3480 or 3480X Magnetic Tape Subsystem.</p>

Related reading: For more information, see [“Selecting daily backup volumes”](#) on page 207.

INUSE, with its subparameters, specifies how DFSMSHsm should handle backing up a data set that is found to be in use (open for update) during volume backup processing. The following subparameters can be used with the INUSE parameter:

Subparameter	Explanation
RETRY(Y)	DFSMSHsm will retry once to back up a data set if the first attempt fails because (1) the data set is in use, or (2) a BWO candidate suffers a CA/CI split and the backup is discarded.
RETRY(N)	DFSMSHsm does not retry a backup if the first attempt fails because the data set is in use.
DELAY(<i>min</i>)	DFSMSHsm delays for <i>min</i> minutes before retrying a backup attempt which failed because a data set was in use. For <i>min</i> , specify a value from 0 to 999.
SERIALIZATION (PREFERRED)	If DFSMSHsm retries backing up a data set (after some delay) and finds the data set still (or again) in use, it should back up the data set anyway.
SERIALIZATION (REQUIRED)	If DFSMSHsm retries backing up a data set (after some delay) and finds the data set still (or again) in use, it should fail the backup.

NOBACKUP specifies that you do not intend to use DFSMSHsm backup, dump, recovery, or expire backup versions. When you specify this parameter, automatic backup and automatic dump are not run, and DFSMSHsm fails any backup, dump, recovery, or expire backup versions commands.

If you specify the NOBACKUP parameter while DFSMSHsm functions are running, the following will occur:

If . . .	Then . . .
Volume backup is running	The volume backup operation ends after the data set currently being processed has been backed up.
Volume dump is running	The volume dump operation ends after the volume currently being processed has been dumped.
Automatic backup is running	Automatic backup prematurely ends after all volume backup operations in process have ended.
Automatic dump is running	Automatic dump prematurely ends after all volume dump operations in process have ended.

If . . .	Then . . .
EXPIREBV is running	EXPIREBV prematurely ends after all expire backup versions operations in process have ended.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: The following table describes the SETSYS BACKUP and SETSYS NOBACKUP default.

If . . .	Then . . .
You specify BACKUP without any subparameters	Any previous backup output specification and specifications for handling data sets in use are retained.
You specify RETRY without a value	The SETSYS default is N.
You specify DELAY without a value	The SETSYS default is 15.
You specify SERIALIZATION without a value	The SETSYS default is REQUIRED.

DFSMSHsm default: The following table describes the SETSYS BACKUP and SETSYS NOBACKUP DFSMSHsm default.

If . . .	Then . . .
You do not specify either BACKUP or NOBACKUP on any SETSYS command	The DFSMSHsm default is NOBACKUP. If BACKUP has been specified but never (within this start-up of DFSMSHsm) with any of the ANY DASD TAPE options specified, then the default option of ANY is used. If an option of BACKUP (either ANY DASD TAPE) has been specified already but <i>not</i> on this issuance of the BACKUP command, then the command is treated as if the option ANY was specified. This means that the ANY option is the default option for BACKUP.
You do not specify INUSE on any SETSYS BACKUP command	DFSMSHsm does not retry any data set backup if the first attempt finds that the data set is currently in use (that is, the backup fails).
You do not specify the RETRY subparameter on any SETSYS BACKUP command	DFSMSHsm does not retry any data set backup if the first attempt finds that the data set is currently in use (that is, the backup fails).
You do not specify the DELAY subparameter but you specify RETRY(Y)	DFSMSHsm delays for 15 minutes before doing a retry.
You do not specify the SERIALIZATION subparameter on any SETSYS command	If DFSMSHsm attempts a retry of a backup and finds the data set still in use, it will fail the backup.

Note:

1. If DFSMSHsm has scheduled a retry of a backup, and you then change the value of the DELAY subparameter, DFSMSHsm will use the most recent DELAY value to determine the time for attempting the retry.

2. Installation exit ARCBDEXT, if enabled, can override the RETRY and SERIALIZATION options for a given data set.
3. BWO data sets with CA/CI split will not be retried if SERIALIZATION(PREFERRED) has been specified.
4. When a backup retry is internally scheduled for a data set, it is the equivalent of a BACKDS command being issued. The settings used on the SETSYS DSBACKUP command affect where the backup is directed. Requests will be directed to tape or DASD based on the settings used in the DASDSELECTIONSIZE parameter.
5. If you specify BACKUP(ANY) on the SETSYS command, DFSMSHsm selects the first nonfull, unallocated, daily backup volume assigned to the current day in the backup cycle. If you want DFSMSHsm to use tape as a daily backup volume and you do not specify restrictions limiting the selection to tape, you must define at least one tape for each of the appropriate days in the backup cycle by using the ADDVOL command. DFSMSHsm does not select a scratch tape if it cannot find any daily or unassigned, nonfull backup volumes that are already defined to DFSMSHsm. If DASD daily backup volumes are not being used in your environment, specify SETSYS BACKUP(TAPE) rather than SETSYS BACKUP(ANY). This allows the flexibility of backing up to a scratch tape if an eligible daily backup volume is not found. You do not have to define tapes as daily backup volumes with the ADDVOL command if you restrict daily backup volumes to tape by:
 - Specifying BACKUP(TAPE) on a SETSYS command.
 - Specifying BACKUPDEVICECATEGORY(TAPE) on a BACKVOL command.
 - Specifying BACKUPDEVICECATEGORY(TAPE) on the ADDVOL command of the nonSMS volume being backed up.

When daily backup volumes are restricted to the tape in one of these ways, DFSMSHsm selects a scratch tape if an eligible daily backup volume is not found.

BACKUPPREFIX: Specifying the prefix for the backup version name or the dump copy data set name

Explanation: **BACKUPPREFIX(prefix)** is an optional parameter specifying the prefix (high-level qualifier) of the data set name DFSMSHsm generates when it backs up a data set or dumps a volume. *prefix* must be defined as 1 to 7 alphanumeric characters; the first character must be alphabetic only.

Attention

Changing this parameter after the DFSMSHsm environment is set could result in failures during the recall and recovery of data sets from tape and SDSs.

The **backup version** name has the following format:

```
prefix.BACK.Tssmmhh.user1.user2.Xydd
```

If patch-enabled, the following dataset name will be generated:

```
prefix.BACK.Tcccchh.user1.user2.Xydd
```

where:

- *prefix* is replaced with the prefix you specify with this command.
- BACK indicates that this is a backup version.
- Tssmmhh is the time when DFSMSHsm backed up the data set; ss is the second, mm is the minute, and hh is the hour. If a duplicate exists after this name is generated, DFSMSHsm changes the first character of the time stamp.
- Tcccchh is the time when DFSMSHsm backed up the data set; cccc is the time in hundredths of seconds from the beginning of the hour converted to four alphabetic characters and hh is hours. For more information, see [“Generating names of backup versions of data sets” on page 204](#).

- *user1* and *user2* are replaced with the first two qualifiers of the data set name. The data set name can be 44 characters long.
- *Xydd* is the date when DFSMSHsm backed up the data set. DFSMSHsm replaces the X with a letter that represents the decade. A–J have the following numeric values:

A–1,	B–2,	C–3,	D–4,	E–5
F–6,	G–7,	H–8,	I–9,	J–0

For example, you specify BACKUPPREFIX(HSMBAK). Your data set name is TERRY.CLIST.TEXT. DFSMSHsm backs up the data set on 30 December 1991 at 9:15 a.m. The backup version name is:

```
HSMBAK.BACK.T001509.TERRY.CLIST.I0364
```

The **dump copy** data set name has the following format:

```
prefix.DMP.dclass.Vvolser.Dyyddd.Tssmmhh
```

where:

- *prefix* is replaced with the prefix you specify with this command
- DMP indicates that this is a dump version
- *dclass* is the dump class name
- *Vvolser* is the source volume serial number
- *Dyyddd* is the date when DFSMSHsm dumped the data set. *yy* is the last two digits of the year of the dump date stamp. *ddd* is the Julian day of the dump date stamp.
- *Tssmmhh* is the time when DFSMSHsm dumped the data set; *ss* is the second, *mm* is the minute, and *hh* is the hour.

If you request it, DFSMSHsm makes a dump VTOC copy data set for each dump generation that is made for a volume.

The **dump VTOC copy** data set name has the following format:

```
prefix.DUMPVTOC.Tssmmhh.Vvolser.Dyyddd
```

where:

- *prefix* is replaced with the prefix you specify with this command
- DUMPVTOC indicates that this is a dump VTOC version
- *Tssmmhh* is the time when DFSMSHsm dumped the data set; *ss* is the second, *mm* is the minute, and *hh* is the hour.
- *Vvolser* is the source volume serial number
- *Dyyddd* is the date when DFSMSHsm dumped the data set. *yy* is the last two digits of the year of the dump date stamp. *ddd* is the Julian day of the dump date stamp.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is the UID parameter you specified in the DFSMSHsm startup procedure. This UID is used as the first qualifier for data set names generated by DFSMSHsm during the BACKUP or MIGRATION functions. Changing this UID after the DFSMSHsm environment is set could result in failures during the recall and recovery of data sets from tape and SDSPs. [z/OS DFSMSHsm Implementation and Customization Guide](#) explains the UID and the DFSMSHsm startup procedure.

CDSVERSIONBACKUP: Specifying whether the control data sets should be backed up to multiple data sets

Explanation: **CDSVERSIONBACKUP** is an optional parameter that you use to specify whether or not DFSMSHsm should back up the control data sets to multiple data sets. The multiple backup copies give you a history of the control data sets and the journal data set. The number of backup copies kept is determined by the BACKUPCOPIES subparameter.

In a multiple-DFSMSHsm-host environment, all hosts sharing DFSMSHsm control data sets must specify the same options for the SETSYS CDSVERSIONBACKUP command, as the information is stored in the MCDS. The last DFSMSHsm host to issue the SETSYS CDSVERSIONBACKUP command controls how all the hosts back up the CDSs. An alternative to having all DFSMSHsm hosts specify the same options for the command is to have only one host (usually the primary host) specify the command. If you use the same ARCCMDxx PARMLIB member for all hosts, you can use the ONLYIF command in that member to restrict the SETSYS parameter to one host.

If you specify CDSVERSIONBACKUP while DFSMSHsm is backing up the control data sets and journal data set, the parameter does not take effect until after DFSMSHsm has finished backing up the control data sets and journal data set.

The subparameters of the CDSVERSIONBACKUP parameter follow this discussion in alphabetical order. The following are optional subparameters:

- BACKUPCOPIES
- BACKUPDEVICECATEGORY
- DATAMOVER
- BCDSBACKUPDSN
- MCDSBACKUPDSN
- OCDSBACKUPDSN
- JRNLBACKUPDSN

Note: The use of the NOCDSVERSIONBACKUP parameter has been disabled.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If any of these parameters or subparameters are not specified, the default value is read from the multiple-host processor control record (MHCR). The record is updated with values specified on the SETSYS CDSVERSIONBACKUP command every time the command is issued. If the MHCR record does not exist or the parameter (or subparameter) has never been specified, the DFSMSHsm defaults are as follows:

- BACKUPCOPIES is 4
- BACKUPDEVICECATEGORY is TAPE
- DATAMOVER is HSM
- NOPARALLEL
- UNITNAME specified on the SETSYS UNITNAME command
- RETENTIONPERIOD (7)
- BCDSBACKUPDSN is *uid*.BCDS.BACKUP. The *uid* is the UID parameter you specified in the DFSMSHsm startup procedure.
- MCDSBACKUPDSN is *uid*.MCDS.BACKUP. The *uid* is the UID parameter you specified in the DFSMSHsm startup procedure.
- OCDSBACKUPDSN is *uid*.OCDS.BACKUP. The *uid* is the UID parameter you specified in the DFSMSHsm startup procedure.

- JRNLBACKUPDSN is *uid*.JRNL.BACKUP. The *uid* is the UID parameter you specified in the DFSMSHsm startup procedure.

CDSVERSIONBACKUP (BACKUPCOPIES): Specifying the number of backup copies to keep for each control data set and journal data set

Explanation: **BACKUPCOPIES**(*backupcopies*) is an optional subparameter of the CDSVERSIONBACKUP parameter specifying the number of backup copies to be cataloged and inventoried by DFSMSHsm for each of the control data sets and the journal data set. For *backupcopies*, specify a decimal number from 1 to 9999 indicating the number of backup copies to be maintained. When the number of copies exceeds this limit, DFSMSHsm removes the oldest from the catalog and if on tape, invokes the ARCTVEXT installation exit when it has been activated by the SETSYS EXITON command.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: See the DFSMSHsm defaults for “CDSVERSIONBACKUP: Specifying whether the control data sets should be backed up to multiple data sets” on page 1109.

CDSVERSIONBACKUP (BACKUPDEVICECATEGORY): Specifying the backup device to which the control data sets and journal will be backed up

Explanation: **BACKUPDEVICECATEGORY** is an optional subparameter of the CDSVERSIONBACKUP parameter that specifies the type of device that receives the backup copies of the DFSMSHsm control data sets and the journal data set when DFSMSHsm backs them up.

Subparameter	Explanation
DASD	DFSMSHsm places the backup copies on DASD.
TAPE	DFSMSHsm places the backup copies on scratch tapes.
PARALLEL NOPARALLEL	<p>Control data set backups to tape are done in parallel (PARALLEL) or one at a time (NOPARALLEL). Backup of the CDSs is always performed in parallel if the output device is DASD. If the output is to tape, DFSMSHsm can be directed to backup the data sets in parallel by using the PARALLEL subparameter. If you prefer to use only a single tape drive at a time, use the NOPARALLEL subparameter.</p> <p>PARALLEL is the subparameter indicating that all control data sets and the journal should be backed up in parallel. By specifying this subparameter, you can cause a separate tape drive to be allocated for each control data set and the journal. Note that if DSS is the datamover, PARALLEL must be used.</p> <p>NOPARALLEL is the subparameter indicating that the control data sets and the journal should be backed up serially. When NOPARALLEL is specified, the control data sets are backed up one at a time followed by the backup of the journal. By specifying this parameter, you can cause only one tape drive to be allocated at a time for all the data set backups. NOPARALLEL is the default.</p>

Subparameter	Explanation
DENSITY (<i>density</i>)	You select the density of the scratch tape that DFSMSHsm is to mount when it backs up the control data sets and the journal data set. For <i>density</i> , specify a value of 2, 3, or 4. The decimal number 2 indicates a tape density of 32 bytes/mm (800 bpi); 3 represents a density of 63 bytes/mm (1600 bpi), and 4 represents a density of 246 bytes/mm (6250 bpi). The DENSITY subparameter applies only to reel-to-reel technology and if specified for cartridge technology, DFSMSHsm ignores it. DENSITY must be specified if the unit name specified with the UNITNAME subparameter is a reel-type tape.
EXPIRATIONDATE (<i>expirationdate</i>) RETENTIONPERIOD (<i>retentionperiod</i>)	<p>You select when the backup copies are no longer to be managed by your tape management product. They result in an expiration date being placed in the tape volume label.</p> <p>For <i>yyyyddd</i>, <i>yyyy</i> and <i>ddd</i> are the year and day of the year for the expiration date of the dump copies. For <i>yyyy</i>, specify a year between the current year and 2155. For <i>ddd</i>, specify a day between 001 and 366.</p> <p>For <i>yy</i>, specify a year between the current year and 99; the <i>yy</i> value is added to 1900 to get the year. For <i>ddd</i>, specify a day between 001 and 366.</p> <p>For <i>retentionperiod</i>, specify a 1- to 4-digit number representing the number of days DFSMSHsm must keep the backup copy before DFSMSHsm can delete it.</p>
UNITNAME (<i>unitname</i>)	You select the type of unit where DFSMSHsm is to allocate the scratch tape when DFSMSHsm backs up the control data sets and the journal data set. For <i>unitname</i> , the types of units you can request for allocating the scratch tape are 3400-3, 3400-4, 3400-5, 3400-6, 3400-9, 3480, 3480X, 3490, 3590-1, or an esoteric name you specify in the USERUNITTABLE parameter of the SETSYS command.

The SETSYS UNITNAME command must be issued prior to issuing the SETSYS CDSVERSIONBACKUP command to identify the type of tape unit used during backup or dump processing. If an esoteric tape unit name is used, the SETSYS USERUNITTABLE command must be issued prior to the SETSYS CDSVERSIONBACKUP command.

If you specify . . .	Then . . .
3400-9	Your 3480 Magnetic Tape Subsystem simulates your 3420 tape drives.
3480 or 3480X	You use all the functions of the 3480 Magnetic Tape Subsystem.
3490	You use all the functions of the 3490 Magnetic Tape Subsystem.
3590-1	You use all the functions of the 3590 Magnetic Tape Subsystem.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: See the DFSMSHsm defaults for “CDSVERSIONBACKUP: Specifying whether the control data sets should be backed up to multiple data sets” on page 1109.

Note:

1. Past dates are not recognized for *expirationdate*.

2. Values for *expirationdate* of 1999365 and 1999366 are recognized as “never expire” dates. Values of 1998000 and 1999000 are recognized as meaningful to certain tape management systems.

CDSVERSIONBACKUP (DATAMOVER): Specifying the type of data movement used when performing CDSVERSIONBACKUP

Explanation: **DATAMOVER(HSM | DSS)** is an optional subparameter of the CDSVERSIONBACKUP parameter specifying the type of data movement to be used when performing CDSVERSIONBACKUP of the DFSMSHsm control data sets. DFSMSdss must be specified as the datamover for CDS backup when you are using RLS mode.

Subparameter	Explanation
HSM	The DFSMSHsm control data sets are backed up using the AMS EXPORT function. The journal data set is backed up using sequential I/O.
DSS	The DFSMSHsm control data sets are backed up by invoking the DFSMSdss logical dump function for each data set. The journal is backed up using sequential I/O. Using DFSMSdss as the datamover allows you to exploit the concurrent copy function. Control data sets and the journal are always backed up in parallel.

When you use DFSMSdss rather than DFSMSHsm as the data mover, concurrent copy can be used and the CDSs will be validated as they are backed up. Concurrent copy allows the CDS backup to complete as soon as the journal has been backed up so that DFSMSHsm can begin processing requests before the CDS backups are completed.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: See the DFSMSHsm defaults for “[CDSVERSIONBACKUP: Specifying whether the control data sets should be backed up to multiple data sets](#)” on page 1109.

CDSVERSIONBACKUP (BCDSBACKUPDSN): Specifying the initial characters of the backup data set name for the backup control data set

Explanation: **BCDSBACKUPDSN(dsname)** is an optional subparameter of the CDSVERSIONBACKUP parameter specifying the initial characters of the data set name to be used when allocating the backup data set for the BCDS. For *dsname*, specify the initial characters of the data set name. You can use up to 35 initial characters including the periods (.); however, the 35 initial characters cannot end with a period. If the BCDS is defined as a multicluster, then only 31 characters can be used. DFSMSHsm appends a final qualifier of .Dnnnnnnn or .Vnnnnnnn to the backup name you choose. DFSMSHsm uses the total name to allocate the backup data set for the BCDS.

Note: With the multicluster CDS support, up to four names for the BCDS may be required, depending on how you have split the BCDS. DFSMSHsm generates these names using the user-supplied name (or default) and appending .DSx before the final qualifier. x will be a number 1–4 representing each cluster. For example, if the backup data set name for the BCDS is:

```
DFHSM.BCDS.BACKUP
```

and you have split the BCDS into 4 clusters, then the generated data set names will be:

```
DFHSM.BCDS.BACKUP.DS1.D0000000
DFHSM.BCDS.BACKUP.DS2.D0000000
DFHSM.BCDS.BACKUP.DS3.D0000000
DFHSM.BCDS.BACKUP.DS4.D0000000
```

If the BCDS is not defined as a multicluster, the user-defined name is used as is.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: See the DFSMSHsm defaults for [“CDSVERSIONBACKUP: Specifying whether the control data sets should be backed up to multiple data sets”](#) on page 1109.

CDSVERSIONBACKUP (MCDSBACKUPDSN): Specifying the initial characters of the backup data set name for the migration control data set

Explanation: **MCDSBACKUPDSN(dsname)** is an optional subparameter of the CDSVERSIONBACKUP parameter specifying the initial characters of the data set name when allocating the backup data set for the MCDS. For *dsname*, specify the initial characters of the data set name. You can use up to 35 initial characters, including the periods (.); however, the 35 initial characters cannot end with a period. If the MCDS is defined as a multicluster, then only 31 characters can be used. DFSMSHsm appends a final qualifier of .Dnnnnnnn or .Vnnnnnnn to the backup name you choose. DFSMSHsm uses the total name to allocate the backup data set for the MCDS.

Note: With the multicluster CDS support, up to four names for the MCDS may be required, depending on how you have split the MCDS. DFSMSHsm generates these names using the user-supplied name (or default) and appending .DSx before the final qualifier. x will be a number 1–4 representing each cluster. For example, if the backup data set name for the MCDS is:

```
DFHSM.MCDS.BACKUP
```

and you have split the MCDS into 2 clusters, then the generated data set names will be:

```
DFHSM.MCDS.BACKUP.DS1.D0000000
DFHSM.MCDS.BACKUP.DS2.D0000000
```

If the MCDS is not defined as a multicluster, the user-defined name is used as is.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: See the DFSMSHsm defaults for [“CDSVERSIONBACKUP: Specifying whether the control data sets should be backed up to multiple data sets”](#) on page 1109.

CDSVERSIONBACKUP (OCDSBACKUPDSN): Specifying the initial characters of the backup data set name for the offline control data set

Explanation: **OCDSBACKUPDSN(dsname)** is an optional subparameter of the CDSVERSIONBACKUP parameter specifying the initial characters of the data set name when allocating the backup data set for the OCDS. For *dsname*, specify the initial characters of the data set name. You can use up to 35 initial characters, including the periods (.); however, the 35 initial characters cannot end with a period. DFSMSHsm appends a final qualifier of .Dnnnnnnn or .Vnnnnnnn to the backup name you choose. DFSMSHsm uses the total name to allocate the backup data set for the OCDS.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: See the DFSMSHsm defaults for [“CDSVERSIONBACKUP: Specifying whether the control data sets should be backed up to multiple data sets”](#) on page 1109.

CDSVERSIONBACKUP (JRNLBACKUPDSN): Specifying the initial characters of the backup data set name for the journal data set

Explanation: **JRNLBACKUPDSN**(*dsname*) is an optional subparameter of the CDSVERSIONBACKUP parameter specifying the initial characters of the data set name when allocating the backup data set for the journal data set. For *dsname*, specify the initial characters of the data set name. You can use up to 35 initial characters, including the periods (.); however, the 35 initial characters cannot end with a period. DFSMSHsm appends a final qualifier of .Dnnnnnnn or .Vnnnnnnn to the backup name you choose. DFSMSHsm uses the total name to allocate the backup data set for the journal data set.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: See the DFSMSHsm defaults for “CDSVERSIONBACKUP: Specifying whether the control data sets should be backed up to multiple data sets” on page 1109.

CLASSTRANSITIONS: Specifying if class transitions will be performed during event-driven migration

Explanation: **CLASSTRANSITIONS** is an optional parameter that specifies settings for class transitions during interval migration and on-demand migration windows. The EVENTDRIVENMIGRATION subparameter, when set to Y (YES, the default), indicates that data sets will be class transitioned during event-driven migration. A setting of N (NO) indicates that class transitions will *not* occur during event-driven migration processing and only occur during primary space management.

The SERIALIZATIONEXITS subparameter, when set to Y (YES) indicates that the user data set serialization error exits will be used during event driven migration. A setting of N (NO, the default) indicates that the user data set serialization error exits will *not* be used during event-driven migration.

SMS relationship: This keyword only applies to SMS managed volumes.

SETSYS default: Same as DFSMSHsm default.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, class transitions will be performed during event-driven migration, but user data set serialization error exits will *not* be used.

CLOUDMIGRATION: Specifying the type of migration to CLOUD

CLOUDMIGRATION is an optional parameter specifying that you want DFSMSHsm to attempt to use fast subsequent migration when migrating to the CLOUD.

The following are required and optional keywords for the CLOUD parameter:

RECONNECT

Data sets eligible for fast subsequent migration can be reconnected to the CLOUD from which they were recalled. A data set can be reconnected if all fast subsequent migration requirements are satisfied. For more information about these requirements, see [Fast Subsequent Migration \(reconnection\) eligibility requirements](#).

NONE

Data sets are not eligible for fast subsequent migration and are not reconnected to the CLOUD from which they were recalled.

ALL

All data sets that are eligible for standard migration and satisfy fast subsequent migration eligibility requirements are reconnected to the CLOUD that the data set was recalled from; including data sets that would have otherwise been migrated to an ML1 or ML2 volume.

Alias: CLM

CLOUD: Specifying CLOUD properties

CLOUD is an optional parameter that allows specification of properties specific to a particular Object Storage that DFSMSHsm uses to store full volume dump and migration copies of data sets. If specified in a DFSMSHsm parmlib member, this parameter is ignored.

The following are required and optional keywords for the CLOUD parameter:

NAME(*cloud_network_connection_name*)

cloud_network_connection_name is the name of a defined SMS Cloud Construct or a CDA provider file or a CDA provider file. This is an optional parameter when REFRESH is specified. Otherwise, this is a required parameter.

If the specified name does not exist in the current SMS configuration nor in the CDA providers directory, the command does not succeed.

CDACREDENTIALS

is an optional parameter that specifying this optional keyword requests that DFSMSHsm obtain the password for the *cloud_network_connect_name* from the CDA (cloud data access) where the password is entered by the security administrator. A *cloud_network_connection_name* previously defined by CCREDS is transitioned to use a password obtained from CDA with the issuance of this command with the CDACREDS keyword.

Also, the reissuance of the command with this keyword for an existing *cloud_network_connect_name* refreshes the stored cloud properties entry with the credentials that are reobtained from CDA. Refreshing these stored entries also have the stored credentials reencrypted. This technique is used to update the DFSMSHsm stored cloud properties when the cloud password is changed by the security administrator or when a cloud network connection name is added to the SMS configuration.

CDACREDS option stores up to 248 *cloud_network_connection_name* entries and CCREDS option stores 7 entries, the combination allows 255 *cloud_network_connection_name* entries to be stored by DFSMSHsm.

Aliases: CDACREDSTORE, CDACREDS

CLOUDCREDENTIALS

Specifying this optional keyword requests that DFSMSHsm request the password associated with the Object Storage account from the storage administrator using WTOR. The reply to the WTOR is suppressed on the console. If the password is mixed case, and the system has a dual-case console, enclosing the password in single quotation marks ensures that it is passed as-is to DFSMSHsm. DFSMSHsm will store the password for future requests to the Cloud Storage. The cloud password must be secured. It is recommended that the security administrator who is administering the cloud storage accounts is the one who enters this password.

A *cloud_network_connection_name* previously defined by CDACREDS is transitioned to use a password obtained from the WTOR with the reissuance of the command with this keyword.

DFSMSHsm can only store seven cloud property entries that are specified with the CCREDS keyword. A transition to a WTOR specified password might not succeed because of the limited number of cloud property entries that can be stored by DFSMSHsm. With the CDACREDS keyword, up to 248 *cloud_network_connection_name* property entries are stored where the security administrator entered the password with CDA. For these reasons, you should request CDACREDS with the SETSYS command.

Aliases: CCREDS, PASSWORD, PW

REMOVECREDENTIALS

Specifying this optional keyword requests that DFSMSHsm delete the information that is related to the Object Storage account from its record. You can use this keyword to remove old invalid entries. The FIXCDS command to display the MHCR record can be used to display the Object Storage accounts known to DFSMSHsm.

Aliases: REMOVE, DELETE, DEL

REFRESH

Specifying this optional keyword requests that DFSMSHsm reload the Cloud credentials into memory from the Migration Control Data Set (MCDS). This option is used on other DFSMSHsm hosts in a sysplex after SETSYS CLOUD(<name> CDACREDENTIALS) was used on one system to change the stored password. You can also use this option if you want DFSMSHsm to re-validate that OMVS is available for DFSMSHsm.

Aliases: REF

CDAPROVIDER and SMSPROVIDER

CDAPROVIDER and SMSPROVIDER are mutually exclusive keywords specifying whether DFSMSHsm should look for cloud information in a CDA provider file or an SMS network connection construct. When REMOVE or REFRESH is specified along with CDAPROVIDER or SMSPROVIDER, CDAPROVIDER and SMSPROVIDER keywords are ignored.

- **CDAPROVIDER** specifies cloud provider properties are defined in a CDA provider file. DFSMSHsm looks for a CDA provider file with the specified CLOUD name. When a valid, nonempty provider file is found, DFSMSHsm will use CDA API for cloud operations. If a valid CDA provider file is not found, the SETSYS CLOUD command fails.

When DFSMSHsm is obtaining information from a CDA provider file, the **tctType** key field is checked to determine how to connect to the cloud object store and transfer data.

- **TAPE-OBJECT**: When tctType value specifies “TAPE-OBJECT” in the CDA provider file, it describes a TS7700 advanced object store. DFSMSHsm supports multiple endpoints for TS7700 advanced object store if the functionality has been enabled. All data is moved through the DS8000 cloud proxy using either FICON or Ethernet connections.
- **TCT**: When tctType value species “TCT” in the CDA provider file, data will be transferred using TCT. All user data is moved through the DS8000 cloud proxy using FICON connections. All metadata and utility operations go through the storage cloud via Ethernet instead of using the DS8000 proxy.
- When tctType is not specified in the CDA provider file, the connection type is **direct to cloud**. DFSMSHsm uses CDA API to transfer both metadata and user data extents via Ethernet connections.

Alias: CDAPROV

- **SMSPROVIDER** specifies cloud provider properties are defined in an SMS network connection construct and DFSMSHsm should not look for a valid, non-empty CDA provider file. When SMSPROVIDER is specified, either CCREDS or CDACREDS must also be specified.

Alias: SMSPROV

Defaults: When neither CDAPROVIDER nor SMSPROVIDER is specified, DFSMSHsm does the following when the designated cloud is a TS7700 TAPE-OBJECT store:

- When multiple endpoints support functionality has been enabled, DFSMSHsm first looks for a valid, non-empty CDA provider file with the name of a TS7700 TAPE-OBJECT store in order to provide multiple endpoints support. If a valid, non-empty CDA provider file is not found, DFSMSHsm will continue to look for an SMS network connection construct for the specified cloud, and multiple endpoints support is unavailable.
- When multiple endpoints support is not enabled, DFSMSHsm uses cloud information defined in the SMS network connection construct.

Related Reading

- For more information about multiple endpoints support, see [Allowing multiple endpoints support for TCT TS7700 advanced object store \(tape object\) in z/OS DFSMSHsm Implementation and Customization Guide](#).
- For more information about using CDA provider files and associated key credentials, see [DFSMSHsm and cloud storage in z/OS DFSMSHsm Implementation and Customization Guide](#).

Restriction: DFSMSHsm can only store seven CLOUD property entries when the CLOUDCREDENTIALS option is used. Up to 248 cloud property entries can be stored with the CDACREDENTIALS keyword. The combination allows 255 cloud property entries to be stored by DFSMSHsm.

Aliases: CLD

COMMONQUEUE: Specifying settings for the common queues

Explanation: **COMMONQUEUE** is an optional parameter that specifies settings for the DFSMSHsm common queues.

The subparameters of the **COMMONQUEUE** parameter follow this discussion.

SMS relationship: Not applicable.

SETSYS default: None.

DFSMSHsm default: None.

COMMONQUEUE (DUMP(CONNECT(*basename*))): Specifying the XCF functional group name suffix for remote dump processing

Explanation: **DUMP(CONNECT(*basename*))** is an optional subparameter of the **COMMONQUEUE** parameter. It specifies the XCF functional group name suffix that this host uses for remote dump processing. When it is specified, this system is allowed to send and receive dumps to and from other systems in the HSMplex that were started with the same *basename*. For *basename*, substitute four characters. The four characters can be numeric, uppercase alphabetic, and national characters. The XCF group name generated by the system from this parameter is **ARCD*basename***. For example, if you specify **DMP1** for *basename*, the resulting XCF group name that this host will become a member of is **ARCD**DMP1****.

This system becomes a candidate for being the common dump queue master scheduler when the **MSC** keyword is not specified, or specified as **MSC** with the **CONNECT** or **MSC(YES)** on another separate command. If this master scheduler candidate system is selected during DFSMSHsm startup or during dump to be the master scheduler of this functional group, this system is considered to be the enabled master scheduler for this functional group of systems.

Subsequent SETSYS commands after a **CONNECT** can be issued to change the **MASTERSCHEDULERCANDIDATE** state of this member of the dump group. A specification of **MSC(NO)** will remove this member as a master scheduler candidate, and if the member was currently active as the master scheduler, it will be stopped. The system will reassign the master scheduler to another dump group member that was defined as a candidate, if one is available. New incoming work will be assigned to run in this new master scheduler member. Active and queued work will be allowed to complete. A specification of **MSC(YES)** will allow this member to become the master scheduler if needed by the dump group.

If it is known at startup that a system is not a candidate for being the master scheduler, but the system needs to be a member of the dump group, the **MSC(NO)** and **CONNECT(*basename*)** subparameters should be specified together in the **DUMP** keyword.

Remote dump processing in the group will not be performed if all of the group members are not allowed to be a master scheduler with the **MSC(NO)** specification.

Use the **HOLD DUMP** command to prevent additional command and automatic dump processing tasks being started by this system. See the **HOLD DUMP** command ([“DUMP: Preventing dumps” on page 902](#)) for more information.

When the **SETSYS COMMONQUEUE(DUMP(CONNECT(*basename*)))** command is specified, the preference by the system will be to utilize the available dump tasks as defined by **MAXDUMPTASKS** on all the dump group members in the HSMplex. The maximum and minimum stack value on the dump class or **BACKVOL** command determines the utilization of the available tasks in the dump group.

SMS relationship: Not applicable.

SETSYS default: None.

DFSMSHsm default: If the DUMP(CONNECT) subparameter is not specified, no XCF dump groups will be defined and remote processing of dumps will not be performed.

Note: A system must disconnect itself from using XCF groups before it attempts to connect to a new XCF group.

For more information: Refer to [“Common dump queue” on page 466](#).

COMMONQUEUE(DUMP(DISCONNECT)): Specifying that a system disconnect itself from using the currently connected XCF functional group for dump processing

Explanation: DUMP(DISCONNECT) is an optional sub-parameter of the COMMONQUEUE parameter which specifies that a system disconnect itself from using the currently connected XCF functional group for dump processing. If the system is the enabled master scheduler for this group, it will be stopped and the master scheduler role will be assigned to another candidate. When you specify the DUMP(DISCONNECT) subparameter, the system performs the following functions:

- Directs all new dump requests to its local queue.
- Stops requesting dumps to be sent to remote systems.
- Stops receiving dumps from remote systems.
- Allows active requests from the common queue running in this system to finish. Also requests submitted by this host and running in the common group in other systems will be allowed to finish.
- The FORCE option, DUMP(DISCONNECT FORCE), allows requests from the common queue running in this system to finish. Requests submitted to the common queue from this system are failed locally on the submitting host but may continue to be processed elsewhere in the CDQ.
- The FORCE option, DUMP(DISCONNECT FORCE), on a master scheduler system will allow requests from the common queue for this function running in the group to finish. However, any request received from remote members in the group on this master scheduler system and are waiting to be processed will be failed.
- If the system was the master scheduler for this function, this role will be assigned to another candidate master scheduler system in the group.

SMS relationship: Not applicable.

SETSYS default: None.

DFSMSHsm default: None.

For more information: Refer to [“Common dump queue” on page 466](#).

COMMONQUEUE (DUMP(MASTERSCHEDULERCANDIDATE)): Specifying whether the host is a master scheduler candidate for grouped function of dump

Explanation: DUMP(MASTERSCHEDULERCANDIDATE)) is an optional subparameter of the COMMONQUEUE parameter. This specifies whether the host is a master scheduler candidate for the common dump queue.

Subsequent SETSYS commands after a CONNECT can be issued to change the MASTERSCHEDULERCANDIDATE state of this member of the dump group. A specification of MSC(NO) will remove this member as a master scheduler candidate, and if the member was currently active as the master scheduler, it will be stopped. The system will reassign the master scheduler to another dump group member that was defined as a candidate, if one is available. New incoming work will be assigned to run in this new master scheduler member. Active and queued work will be allowed to complete. A

specification of MSC(YES) will allow this member to become the master scheduler if needed by the dump group. This stand-alone MSC specification will have no effect until the host is connected to the group.

If it is known at startup that a system is not a candidate for being the master scheduler, but the system needs to be a member of the dump group, the MSC(NO) and CONNECT(*basename*) subparameters should be specified together in the DUMP keyword.

SMS relationship: Not applicable.

SETSYS default: None.

DFSMSHsm default: MASTERSCHEDULERCANDIDATE(Y), but will have no effect until a SETSYS CQUEUE(DUMP(CONNECT(*basename*))) command is issued.

For more information: Refer to [“Common dump queue” on page 466](#).

COMMONQUEUE (RECALL(CONNECT(*basename*))): Specifying the base name of the list structure for CRQ host connection

Explanation: RECALL(CONNECT(*basename*)) is an optional subparameter of the COMMONQUEUE parameter. This subparameter specifies the base name of the list structure that a host connects to for common recall queue (CRQ) activities. The list structure name must be defined in the active CFRM policy. For *basename*, substitute five characters. The five characters can be numeric, uppercase alphabetic, and national characters. The list structure name is SYSARC_*basename*_RCL. For example, if you specify PLEX1 for *basename*, the resulting list structure is SYSARC_PLEX1_RCL.

SMS relationship: Not applicable.

SETSYS default: None.

DFSMSHsm default: None.

Note: A host must disassociate itself from one list structure before it attempts to connect to another structure. To disassociate, a host must disconnect from the list structure, and then you must define the new structure in the active CFRM policy. DFSMSHsm will attempt to connect to the new structure when it is defined in the active CFRM policy.

COMMONQUEUE (RECALL(DISCONNECT)): Specifying disconnection from the CRQ

Explanation: RECALL(DISCONNECT) is an optional subparameter of the COMMONQUEUE parameter which specifies that a host disconnect from the common recall queue (CRQ). When you specify the RECALL(DISCONNECT) subparameter, the host performs the following functions:

- Directs all new recall requests to the local recall queue
- Moves all recall requests that originated on that host from the CRQ to the local queue
- Completes any remote requests that were previously selected from the CRQ
- Stops selecting requests from the CRQ

The host disconnects from the CRQ when the following conditions are met:

- The host has finished processing all the remote requests that were previously selected from the CRQ
- All requests originating on that host have moved from the CRQ to the local queue
- Processing is complete for all requests that originate on that host that have been selected for remote processing

The disconnection must be complete before the host can connect to another CRQ.

SMS relationship: Not applicable.

SETSYS default: None.

DFSMSHsm default: None.

Note: This command does not need to be issued before a DFSMSHsm shutdown. Disconnection from the CRQ is part of the normal shutdown process.

COMMONQUEUE RECOVER(CONNECT(basename)): Specifying the XCF functional group name suffix for remote full volume recover from dump processing

Explanation: RECOVER(CONNECT(basename)) is an optional subparameter of the COMMONQUEUE parameter.

This subparameter specifies the XCF functional group name suffix that this host uses for volume restores from dumps. This includes the FRRECOV COPYPOOL FROMDUMP, FRRECOV TOVOLUME FROMDUMP, and RECOVER * FROMDUMP volume restore commands. When specified, this host is allowed to send volume restores to the common recover queue for processing in the HSMplex with the same basename. For basename, substitute four characters. The 4 characters can be numeric, uppercase alphabetic, and national characters. The XCF group name is ARCVbasename. For example, if you specify REC1 for basename, the resulting XCF group name that this host becomes a member of is ARCVREC1.

This host becomes a candidate for the common recover queue master scheduler when the MSC keyword is not specified, or when specified as MSC with the CONNECT command or MSC(YES) on another separate command. If this master scheduler candidate system is selected during HSM startup or during recovery to be the Master Scheduler of this group, this system is considered to be the Master Scheduler for the group.

Subsequent SETSYS commands after a CONNECT can be issued to change the MASTERSCHEDULERCANDIDATE state of this member of the recover group. A specification of MSC(NO) remove this member as a master scheduler candidate. In addition, if the member was currently active as the master scheduler, it is stopped. The system reassigns the master scheduler to another recover group member that is defined as a candidate. New incoming work is assigned to run in this new Master Scheduler member. Active and queued work is allowed to complete. A specification of MSC(YES) allows this member to become the Master Scheduler if needed by the recover group. This stand-alone MSC specification has no effect when it is issued on a host that is not connected to the group.

If it is known at startup that a host is not a candidate for the master scheduler role, but the host needs to be a member of the recover group, then MSC(NO) and CONNECT(basename) subparameters can be specified together in the RECOVER keyword. Remote recover processing in the group is not performed when none of the group members are master scheduler candidates with the MSC(NO) specification.

Use the HOLD RECOVER command to prevent this system from starting additional recover processing tasks. See HOLD RECOVER command for details.

When the SETSYS COMMONQUEUE(RECOVER(CONNECT(basename))) is specified, the preference by the system preference is to use the available recover tasks as defined by MAXDUMPRECOVERTASKS on all the recover group members in the HSMplex. When this SETSYS is not specified, only local recover tasks, where the command was issued will be utilized. This reduced parallelism might lengthen the total time needed for the volume recovery to complete. In either case, the number of concurrent tasks is further limited by the stacking of the volumes on the dump tapes. For example, if all 100 volumes on a single tape are being recovered, then only a single recover task is used.

SMS relationship: Not applicable.

SETSYS default: None.

DFSMSHsm default: If the RECOVER(CONNECT) subparameter is not specified, no XCF recover groups will be defined. Local processing of volume restores will be performed.

Note: A system must disconnect itself, and stop using XCF groups before it attempts to connect to a new XCF group.

The host will respond with message ARC1566I when it connects to the common recover group, and with message ARC1567I when it takes on the master scheduler responsibilities for it.

For more information: Refer to [“Common recover queue” on page 474](#).

COMMONQUEUE RECOVER(DISCONNECT): Specifying that a system disconnect itself from using the currently connected XCF functional group for recover processing

Explanation: RECOVER(DISCONNECT) is an optional subparameter of the COMMONQUEUE parameter that specifies that a host disconnect itself to stop using the currently connected common recover queue (CVQ) for processing. The following considerations apply to this disconnect process:

- All CVQ requests being processed on this host, and requests that originated from this host and are selected to be processed in the CVQ, are waited upon for completion before the host is disconnected from the CVQ. This host will no longer be selected to process new volume restore work from the CVQ.
- A HOLD RECOVER issued prior to the disconnect command prevents queued requests from being selected to be processed. After the disconnect has completed, a RELEASE RECOVER allows the queued requests to be processed locally.
- RECOVER after the disconnecting allows these requests to be processed locally.
- To verify the disconnection, use the QUERY ACTIVE command and look for message ARC1560I.
- Recover resources available on this host after the disconnection has completed are not known or available to the remaining CVQ members. All new recover requests received are placed on this host's local queue and processed locally.
- For shutdown procedures, a DISCONNECT should first be issued on each host being removed from the HSMplex to allow CVQ requests to complete first.
- The DISCONNECT FORCE option should be reserved for emergency situations. With FORCE specified, requests that originated from this host and are selected to be processed in the CVQ are not waited upon for completion before disconnecting. Messages are issued to indicate that a request has been failed but still may complete in the CVQ.

SMS relationship: Not applicable.

SETSYS default: None.

DFSMSHsm default: None.

The host will respond with message ARC1567I when the host disconnects from the group, and with message ARC1568I if master scheduler responsibilities are lost.

Explanation: SETSYS CQUEUE(RECOVER) with no options specified will parse out with an error.

For more information: Refer to [“Common recover queue”](#) on page 474.

COMMONQUEUE RECOVER(MASTERSCHEDULERCANDIDATE): Specifying whether the host is a master scheduler candidate for grouped function of recover

Explanation: RECOVER(MASTERSCHEDULERCANDIDATE)) is an optional sub-parameter of the COMMONQUEUE parameter. This specifies whether the host is a master scheduler candidate for grouped function of recover.

Subsequent SETSYS commands after a CONNECT can be issued to change the MASTERSCHEDULERCANDIDATE state of this member of the recover group. A specification of MSC(NO) removes this member as a master scheduler candidate. In addition, if the member is currently active as the master scheduler, it is stopped. The system reassigns the master scheduler to another recover group member that is defined as a candidate, if one is available. New incoming work is assigned to run in this new master scheduler member. Active and queued work is allowed to complete. A specification of MSC(YES) allows this member to become the master scheduler if the recover group needs it.. This stand-alone MSC specification has no effect until the host is connected to the group. If it is known at startup that a system is not a candidate for the master scheduler role, but the system needs to be a member of the recover group, the MSC(NO) and CONNECT(basename) sub-parameters should be specified together in the RECOVER keyword.

If it is known at startup that a system is not a candidate for being the Master Scheduler but the system needs to be a member of the recover group, the MSC(NO) and CONNECT(basename) sub-parameters should be specified together in the RECOVER keyword.

SMS relationship: Not applicable.

SETSYS default: None.

DFSMSHsm default: MASTERSCHEDULERCANDIDATE(Y), but will have no effect until a SETSYS CQUEUE(RECOVER(CONNECT(groupname))) is issued.

The host will respond with message ARC15668I if the host lost its Master Scheduler responsibilities and with message ARC1569I if it took them on.

For more information: Refer to [“Common recover queue”](#) on page 474.

COMPACT: Specifying when compaction should be done

Explanation: **COMPACT** is an optional parameter set that you use to specify the type of compaction during migration or backup for all data sets.

The subparameters of the COMPACT parameter follow this discussion in alphabetical order. The following are optional subparameters:

- ALL | NONE
- DASDBACKUP
- DASDMIGRATE
- TAPEBACKUP
- TAPEMIGRATE

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets. This COMPACT parameter is only used for SMS data sets that are not compressed on L0; as for non-SMS data sets, it's always in effect since you cannot have a non-SMS dataset compressed on L0.

SETSYS default: If you specify the COMPACT parameter without specifying any subparameters, the SETSYS default is no compaction.

DFSMSHsm default: If you do not specify a subparameter with this parameter on any SETSYS command, the DFSMSHsm default is no compaction.

COMPACT ALL and NONE: Specifying whether to compact data sets

Explanation: **ALL | NONE** are mutually exclusive, optional subparameters of the COMPACT parameter specifying whether or not to compact a data set during migration or backup.

Subparameter	Explanation
ALL	DFSMSHsm can compact a data set during migration to DASD, migration to tape, backup to tape, and backup to DASD.
NONE	DFSMSHsm does not compact a data set during migration or backup.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify any subparameter of the COMPACT parameter on any SETSYS command, the DFSMSHsm default is NONE.

Note:

1. When you specify the ALL or NONE subparameter with the COMPACT parameter, DFSMSHsm ignores all other subparameters.
2. DFSMSHsm compacts cataloged and uncataloged data sets.
3. Since encrypted data sets do not compress, they will not be compacted during migration or backup.

COMPACT DASDBACKUP and NODASDBACKUP: Specifying whether to compact data sets during backup to DASD

Explanation: **DASDBACKUP** | **NODASDBACKUP** are mutually exclusive, optional subparameters of the COMPACT parameter specifying whether or not to compact a data set when DFSMSHsm backs it up to DASD.

Subparameter	Explanation
DASDBACKUP	DFSMSHsm can compact a data set when DFSMSHsm backs it up to DASD.
NODASDBACKUP	DFSMSHsm does not compact a data set when DFSMSHsm backs it up to DASD.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either subparameter on any SETSYS command, the DFSMSHsm default is NODASDBACKUP.

Note:

1. If you do not want a specific data set to be compacted during volume backup, use the data set backup exit (ARCBDEXT) to prevent compaction.
2. Since compressed format data sets are already compressed, they will not be compacted during backup to DASD.
3. Since encrypted data sets do not compress, they will not be compacted during backup to DASD..

COMPACT DASDMIGRATE and NODASDMIGRATE: Specifying whether to compact data sets during migration to DASD

Explanation: **DASDMIGRATE** | **NODASDMIGRATE** are mutually exclusive, optional subparameters of the COMPACT parameter specifying whether or not to compact a data set during migration to DASD.

Subparameter	Explanation
DASDMIGRATE	DFSMSHsm can compact a data set during migration to DASD.
NODASDMIGRATE	DFSMSHsm does not compact a data set during migration to DASD.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either subparameter on any SETSYS command, the DFSMSHsm default is NODASDMIGRATE.

Note:

1. If you do not want a specific data set compacted during volume migration to DASD, use the data set migration exit (ARCMDEXT) to prevent compaction.

2. If you specified the TAPEMIGRATION(DIRECT) parameter of the SETSYS command, DFSMSHsm ignores the DASDMIGRATE or NODASDMIGRATE subparameter if you specify one of them.
3. Although the MIGRATE and NOMIGRATE subparameters no longer exist, DFSMSHsm does not fail the command if you specify them. Instead, MIGRATE and NOMIGRATE have the same meaning as DASDMIGRATE and NODASDMIGRATE.
4. Since compressed format data sets are already compressed, they will not be compacted during migration to DASD.
5. Since encrypted data sets do not compress, they will not be compacted during migration to DASD.

COMPACT TAPEBACKUP and NOTAPEBACKUP: Specifying whether to compact data sets during backup to tape

Explanation: **TAPEBACKUP** | **NOTAPEBACKUP** are mutually exclusive, optional subparameters of the COMPACT parameter specifying whether or not to compact a data set when DFSMSHsm is backing it up to tape.

Subparameter	Explanation
TAPEBACKUP	DFSMSHsm can compact a data set when DFSMSHsm backs it up to tape.
NOTAPEBACKUP	DFSMSHsm does not compact a data set when DFSMSHsm backs it up to tape.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either subparameter on any SETSYS command, the DFSMSHsm default is NOTAPEBACKUP.

Note:

1. If you do not want a specific data set to be compacted during volume backup, use the data set backup exit (ARCBDEXT) to prevent compaction.
2. Since compressed format data sets are already compressed, they will not be compacted during backup to tape.
3. Since encrypted data sets do not compress, they will not be compacted during backup to tape.

COMPACT TAPEMIGRATE and NOTAPEMIGRATE: Specifying whether to compact data sets during migration to tape

Explanation: **TAPEMIGRATE** | **NOTAPEMIGRATE** are mutually exclusive, optional subparameters of the COMPACT parameter specifying whether or not to compact a data set when DFSMSHsm is migrating it to a tape migration level 2 volume.

Subparameter	Explanation
TAPEMIGRATE	DFSMSHsm can compact a data set when DFSMSHsm migrates it to a tape migration level 2 volume.
NOTAPEMIGRATE	DFSMSHsm does not compact a data set when DFSMSHsm migrates it to a tape migration level 2 volume.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMShsm default: If you do not specify either subparameter on any SETSYS command, the DFSMShsm default is NOTAPEMIGRATE.

Note:

1. If you do not want a specific data set to be compacted during volume migration, use the data set migration exit (ARCMDEXT) to prevent compaction.
2. Since compressed format data sets are already compressed, they will not be compacted during migration to tape.
3. Since encrypted data sets do not compress, they will not be compacted during migration to tape.

COMPACTPERCENT: Specifying the percentage of space saved for compaction

Explanation: **COMPACTPERCENT**(*pct*) is an optional parameter specifying the percentage of space saved if DFSMShsm compacts all data sets. For *pct*, substitute a decimal number from 0 to 99 to specify the least amount of space you want saved if DFSMShsm compacts a data set.

If you request compaction, DFSMShsm compacts a data set when it migrates or backs up the data set for the first time. DFSMShsm then compares the number of bytes written to the total bytes of the original data set and computes the percentage of bytes saved. If the percentage saved is not greater than or equal to *pct*, DFSMShsm does not compact the data set during subsequent migrations or backups. DFSMShsm does not check whether or not the data set was compacted during migration if DFSMShsm is currently backing up the data set. Similarly, DFSMShsm does not check whether or not the data set was compacted during backup if DFSMShsm is currently migrating the data set.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMShsm default: If you do not specify this parameter on any SETSYS command, the DFSMShsm default is 40.

Note:

1. DFSMShsm makes this comparison only for cataloged data sets.
2. DFSMShsm compacts a data set only if it can save at least one track on DASD or the data set migrated to an SDSP data set.
3. Compaction always occurs during backup processing if SETSYS COMPACTPERCENT(0) is specified and DFSMShsm is to compact the data set.

CONVERSION and NOCONVERSION: Specifying whether reblocking is to occur

Explanation: **CONVERSION** | **NOCONVERSION** are mutually exclusive, optional parameters specifying whether DFSMShsm reblocks eligible data sets during recall or recovery. This parameter is not applicable to system-reblockable data sets, whether they are SMS or non-SMS.

CONVERSION specifies that DFSMShsm can reblock the data sets during recall or recovery.

REBLOCKTOANY is an optional subparameter of the CONVERSION parameter specifying the type of reblocking during recall or recovery of data sets that use DFSMShsm as the data mover and also specifies reblocking to any DASD device type supported by DFSMShsm.

NOCONVERSION specifies that DFSMShsm cannot reblock the data sets even if you specified the data set reblock exit.

SMS relationship: Parameter applies in some instances to SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either parameter on any SETSYS command, the DFSMSHsm default is NOCONVERSION.

Note:

1. DFSMSHsm reblocks only nonkeyed, physical sequential data sets with the following record organizations: fixed-blocked, fixed-blocked-standard, variable-blocked, or variable-blocked-spanned. If a data set specified LRECL=X, DFSMSHsm does not support reblocking.

DFSMSdss reblocks only physical sequential and partitioned data sets with the following record organizations: fixed-blocked, fixed-block-standard, and variable-blocked.
2. You must specify the CONVERSION parameter if you want to use the data set reblock exit (ARCCDEXT). You can prevent DFSMSHsm from reblocking user-selected data sets by using the data set reblock exit.

CSALIMITS and NOCSALIMITS: Specifying whether to use CSA limiting for MWE allocation

Explanation: **CSALIMITS** | **NOCSALIMITS** are mutually exclusive, optional parameters that you use to specify whether common service area (CSA) limiting of management work element (MWE) storage allocation is to be used during DFSMSHsm processing. The MWE describes a requested function to be performed by DFSMSHsm.

Note: DFSMSHsm acquires storage in extended CSA (ECSA) for MWE's. Since DFSMSHsm is using ECSA, more CSA storage is available for other applications

CSALIMITS specifies the values for CSA storage allocation used during DFSMSHsm processing.

The subparameters of the CSALIMITS parameter follow this discussion in alphabetical order. These optional subparameters are:

- ACTIVE
- INACTIVE
- MAXIMUM
- MWE

NOCSALIMITS specifies that CSA limiting should not be done during DFSMSHsm processing.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is CSALIMITS.

CSALIMITS (ACTIVE): Specifying the percentage of the maximum limit to be allocated to any type of MWE

Explanation: **ACTIVE(percent1)** is an optional subparameter of the CSALIMITS parameter that you use to specify the percentage of CSA storage that DFSMSHsm can allocate to all types of MWEs when DFSMSHsm is active. After the percentage is reached, only batch WAIT MWEs are added to the CSA queue. All other requests are failed until CSA storage usage drops below the limit or you change the limit. For *percent1*, specify a 1-to 3-character number indicating the percentage of CSA storage to be allocated to all types of MWEs. The number can range from 0 to 100.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this subparameter on any SETSYS command, the DFSMSHsm default is 90.

CSALIMITS (INACTIVE): Specifying the percentage of the maximum limit to be allocated to NOWAIT MWEs

Explanation: **INACTIVE(*percent2*)** is an optional subparameter of the CSALIMITS parameter specifying the percentage of CSA storage that DFSMSHsm can allocate to NOWAIT MWEs while DFSMSHsm is inactive. After the percentage is reached, all requests are failed until DFSMSHsm is started or until you change the limit. For *percent2*, specify a 1-to 3-character number indicating the percentage of CSA storage to be allocated to NOWAIT MWEs while DFSMSHsm is inactive. The number can range from 0 to 100.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this subparameter on any SETSYS command, the DFSMSHsm default is 30.

CSALIMITS (MAXIMUM): Specifying the maximum number of CSA bytes allocated to all types of MWEs

Explanation: **MAXIMUM(*Kbytes*)** is an optional subparameter of the CSALIMITS parameter specifying the maximum number of KBs of CSA storage to be allocated to MWEs. For *Kbytes*, specify a 2- to 5-character decimal number indicating the number of bytes of CSA storage to be allocated to MWEs. You can specify a value from 10 to 16383. If you specify 16384 or higher, no limiting of the number of bytes allocated in CSA is done. If the value for MAXIMUM is exceeded, DFSMSHsm fails all new requests until CSA usage drops below the maximum limit or you change the value for MAXIMUM.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this subparameter on any SETSYS command, the DFSMSHsm default is 100.

CSALIMITS (MWE): Specifying maximum number of NOWAIT MWEs per address space

Explanation: **MWE(*#mwes*)** is an optional subparameter of the CSALIMITS parameter specifying the maximum number of NOWAIT MWEs submitted by a single address space that is to be kept on the CSA queue until completed. NOWAIT MWEs in excess of the maximum number will be removed from the CSA queue as soon as they are copied into the DFSMSHsm address space. For *#mwes*, specify a 1-to 4-character decimal number indicating how many NOWAIT MWEs per address space are kept on the CSA queue until completed. To limit the number of NOWAIT MWEs kept on the CSA queue, specify a number between 0 and 8191. If you specify 0, all NOWAIT MWEs are removed from the CSA queue as soon as they are copied into the address space of DFSMSHsm. If you specify 8192 or higher, the number of MWEs to keep on the CSA queue per address space is limited only by the amount of CSA available, as specified in the MAXIMUM subparameter.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this subparameter on any SETSYS command, the DFSMSHsm default is 4.

Note: If DFSMSHsm is inactive, the NOWAIT MWEs will not be removed from the CSA queue. In that case, the number of NOWAIT MWEs submitted by all address spaces that will be added to the CSA queue is controlled by the INACTIVE subparameter.

DAYS: Specifying the minimum migration age of a data set

Explanation: **DAYS(days)** is an optional parameter specifying the number of contiguous days a data set must remain unreferenced before the data set is eligible for migration. DFSMSHsm uses this parameter to migrate data sets from primary volumes to migration level 1 volumes under the following conditions:

- The primary volume does not already have a minimum migration age.
 - For automatic migration, DFSMSHsm checks the minimum migration age you specified with the ADDVOL command. If you did not specify the MIGRATE(days) parameter of the ADDVOL command, or if you specified MIGRATE(0) with the ADDVOL command, or if you specified MIGRATE(1) with the ADDVOL command in a multiple-DFSMSHsm-host environment and did not specify USERDATASETSERIALIZATION, then DFSMSHsm uses the minimum migration age you specify with the SETSYS DAYS parameter.
 - For command migration, DFSMSHsm checks the minimum migration age you specified with the MIGRATE command. If you did not specify a value for days with the MIGRATE command, DFSMSHsm checks whether you specified the minimum migration age with the ADDVOL command. If you also did not specify the MIGRATE(days) parameter of the ADDVOL command, or you specified MIGRATE(0) with the ADDVOL command, or you specified MIGRATE(1) with the ADDVOL command in a multiple-DFSMSHsm-host environment and did not specify USERDATASETSERIALIZATION, then DFSMSHsm uses the minimum migration age you specify with the SETSYS DAYS parameter.
- For nonmanaged volumes, DFSMSHsm checks whether you used the MIGRATE command to specify the minimum migration age. If you did not, DFSMSHsm uses the age you specify with this parameter.

The value you specify for *days* depends on your environment. If USERDATASETSERIALIZATION has been specified, DAYS can be set between 0 and 999. If not, DAYS can be set between 1 and 999 in a single-DFSMSHsm-host environment, and between 2 and 999 in a multiple-DFSMSHsm-host environment.

SMS relationship: Parameter does not apply to SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is one day if DFSMSHsm is running in a single-DFSMSHsm-host environment or two days if DFSMSHsm is running in a multiple-DFSMSHsm-host environment.

Note: DFSMSHsm uses the DAYS value when you have not defined thresholds of occupancy for a volume. If you have defined thresholds of occupancy for the volume, the DAYS parameter is another way to set a lower limit for migration.

DEBUG and NODEBUG: Specifying debug mode

Explanation: DEBUG and NODEBUG are mutually exclusive, optional parameters specifying whether DFSMSHsm is to operate in debug mode.

DEBUG specifies that DFSMSHsm is to operate in debug mode. A command to process only one data set is not affected by the DEBUG parameter. You use DEBUG to monitor the effect of DFSMSHsm on your computing system. DFSMSHsm does all automatic and command volume space management, backup, dump, and command expiration of backup versions functions without moving or deleting any data sets. DEBUG specifies that DFSMSHsm is not to move any data. Because you can monitor the data sets and volumes that DFSMSHsm would have managed, you can decide which data sets you do not want DFSMSHsm to process.

Debug mode can be entered at any time during DFSMSHsm processing. During automatic volume space management, command volume space management, or backup functions, DFSMSHsm checks for debug mode before processing each data set. During automatic dump, command dump, or volume recovery functions, DFSMSHsm checks for debug mode before processing each volume. During the expiration of backup versions function, DFSMSHsm checks for debug mode at the start of each command. If a SETSYS DEBUG command is issued before the start of the next data set during space management or backup, or before the start of the next volume during dump or recovery, the next data set or volume to be processed will be processed in debug mode, and no data will be moved or deleted. Any processing accomplished before entering debug mode is not affected.

NODEBUG specifies that DFSMSHsm is not to operate in debug mode.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either parameter on any SETSYS command, the DFSMSHsm default is NODEBUG.

Note:

1. Debug mode causes all ABACKUP and ARECOVER commands to be processed with the VERIFY option at the time the command is selected to be started.
2. Debug mode does not affect the BACKVOL CONTROLDATASETS command and the command will be processed as normal.
3. To use the debug mode, decide which volumes you want DFSMSHsm to manage. Then, run DFSMSHsm in debug mode. When you are satisfied that the volumes are being managed as you want, specify NODEBUG. DFSMSHsm will then process the data sets. You can use this gradual conversion procedure when you add more volumes to DFSMSHsm control.

DEFERMOUNT: Specifying defer mounting of tapes

The use of the SETSYS DEFERMOUNT parameter is considered to be nonfunctional and its use is ignored by DFSMSHsm.

DENSITY: Specifying the tape density

The use of the DENSITY parameter is considered to be nonfunctional and its use will result in an ARC1605I parse error.

DFHSMDATASETSERIALIZATION and USERDATASETSERIALIZATION: Specifying data set serialization

Explanation: **DFHSMDATASETSERIALIZATION** | **USERDATASETSERIALIZATION** are mutually exclusive, optional parameters that apply to volume migration and volume backup in a multiple-DFSMSHsm-host environment. These parameters specify whether data set serialization of system resources is provided for all data sets by system facilities.

DFHSMDATASETSERIALIZATION specifies that data set serialization of system resources during volume migration and volume backup in a multiple-image environment is not provided by system facilities, and that DFSMSHsm should implement its requirements for resource serialization.

USERDATASETSERIALIZATION specifies that data set serialization of system resources during volume migration and volume backup in a multiple-DFSMSHsm-host environment is provided by system facilities. Examples of such system facilities are Global Resource Serialization and JES3 data set reservation. In a single DFSMSHsm host, data set enqueue is provided. DFSMSHsm should optimize its requirements for resource serialization with those facilities.

Note:

1. The setting of this parameter affects the value of the DFSMSHsm integrity age. Refer to the “[Integrity age for space management](#)” on page 56 for more information on the relationship between integrity age and DFHSMDATASETSERIALIZATION | USERDATASETSERIALIZATION.
2. In DFSMSHsm Version 1 Release 5, the incremental backup function was restructured in order to improve the performance of that function. This improvement is only effective when USERDATASETSERIALIZATION is specified. Only use the SETSYS DFHSMDATASETSERIALIZATION command if it is required by your environment. Otherwise, it is recommended that you use the SETSYS USERDATASETSERIALIZATION command.
3. The fast subsequent migration function supports reconnection only in a USERDATASETSERIALIZATION environment.

4. Some data sets, such as multivolume physical sequential data sets, are processed only with SETSYS USERDATASETSERIALIZATION.

Attention

In a multiple-DFSMSHsm-host environment, do not specify USERDATASETSERIALIZATION unless you have a data set serialization facility installed and enabled on your system. Otherwise, serious data-integrity problems can occur.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either parameter on any SETSYS command, the DFSMSHsm default is DFHSM DATASET SERIALIZATION.

DISASTERMODE: Specifying the tape operation mode for DFSMSHsm in disaster mode

Explanation: **DISASTERMODE** is an optional parameter that specifies whether DFSMSHsm establishes a tape substitution mode. This command plays an important part during an actual disaster recovery or when you are running a disaster recovery test.

While DFSMSHsm is running in disaster mode, recalls and recovers from tape volumes that are flagged as having disaster alternate volumes dynamically substitute the alternate tape for the original tape. For more information on the use of disaster alternate volumes, refer to [Chapter 9, “Making disaster backup copies of DFSMSHsm-owned tape volumes,”](#) on page 435.

If you specify Y for this parameter on the SETSYS command, DFSMSHsm checks the TTOC record of the original tape volume to see if a disaster alternate volume exists and if so, requests the use of it to return the data. If you specify N for this parameter on the SETSYS command or no disaster alternate volume exists, DFSMSHsm will request the original tape volume and makes no substitution.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: If you specify DISASTERMODE without specifying any subparameter, the default is Y.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is N.

DSBACKUP: Controlling the command data set backup environment

DSBACKUP is an optional parameter that allows you to control the command data set backup environment. You can balance the backup workload between DASD and tape tasks and you can tailor DFSMSHsm tape mounting and demounting for command data set backups. DFSMSHsm can run up to 64 concurrent command data set backup tasks.

If GENVSAMCOMPNames(YES) | GVCN(YES) is in effect, and *dsname* is a VSAM base cluster and *newdsname* is either migrated or uncataloged, DFSMSHsm will process the request, and default names will be assigned to the VSAM data and index components. If GENVSAMCOMPNames(NO)|GVCN(NO) is in effect, and *dsname* is a VSAM base cluster and *newdsname* is either migrated or uncataloged, the data set backup command will fail.

DASDSELECTIONSIZE (*maximum*, *standard*) helps you balance the workload between DASD and tape tasks for all WAIT-type requests that do not target tape. DASDSELECTIONSIZE is only applicable if both tape and ML1 DASD are allowed for command data set backups. *maximum* is the size, in kilobytes, of the largest data set, (a WAIT-type request) that is directed to ML1 DASD. *standard* is the largest size, in kilobytes, that is considered to be a small data set. DFSMSHsm directs small data sets (a WAIT-type request) to DASD if a tape task is not immediately available to process the request. DFSMSHsm directs

NOWAIT requests to tape, if tape tasks are allowed. The values that you can specify for *maximum* and *standard* range from 0 to 999999.

A data set is considered small if it is less than or equal to *standard*. A data set is considered large if it is greater than *maximum*. A data set with a value between *maximum* and *standard* is a medium data set.

To determine whether a data set uses tape or disk, refer to [Table 64 on page 1131](#).

Note: The default is DASDSELECTIONSIZE(3000,250), where 3000 is the *maximum* in kilobytes, and 250 is the *standard* in kilobytes. The categories in the table are based on these default values. If the you change the DASDSELECTIONSIZE(*maximum*,*standard*) settings, then these categories change.

Table 64. Determining data set task targets			
Default criteria	Large	Medium	Small
Data set size	3001 KB and up	251–3000 KB	0–250 KB
WAIT-type requests	Favor tape	First available	Favor disk
NOWAIT-type requests	Favor tape	Favor tape	Favor tape

The following list describes the task targets that are used in [Table 64 on page 1131](#).

This task target . . .	Means . . .
Favor disk	Small data sets that are processed by WAIT-type requests will select ML1 DASD as target. However, if you specify DASD(TASKS(0)), the data set will use tape.
Favor tape	Data set backups will be directed to tape unless you specify TAPE(TASKS(0)).
First available	Data sets will favor the first available task, regardless of disk or tape. If both tasks are available, it will favor the tape task.

Note:

1. If you want command data set backups to go to DASD only if targeted to do so, and all nontargeted command data set backups to go to tape, you can specify DASDSELECTIONSIZE(0 0). This forces all nontargeted command data set backups to go to tape.
2. If only one value is specified for DASDSELECTIONSIZE, it will be interpreted as the maximum size.

DASD(TASKS(nn)) specifies that you want to use ML1 DASD for command data set backups.

TAPE(TASKSnn) DEMOUNTDELAY(MAXIDLETASKS(drives) MINUTES(minutes)) specifies that you want to use tape for command data set backups.

You can also specify both DASD and tape for command data set backup tasks. TASKS(nn) specifies the maximum number of concurrent command data set backup tasks that DFSMSHsm directs to ML1 DASD or to tape. nn is a value between 0 and 64. If the number of DASD or tape tasks specified is 0, all command data set backup requests targeting the backup to DASD or tape fail. The sum of DASD(TASKS(nn)) and TAPE(TASKS(nn)) cannot exceed 64. If the sum is zero, any request fails.

DEMOUNTDELAY allows you to tailor the DFSMSHsm tape mounting and demounting for command data set backup. MINUTES(minutes) is the number of minutes that you want DFSMSHsm to wait before it deallocates the tape associated with continuously inactive (idle) command data set backup tasks. minutes is a value from 0 to 1440. A value of 1440 indicates that DFSMSHsm will not demount the tape until command data set backup tasks are held, a SWITCHTAPES event occurs, or DFSMSHsm shuts down, so this value extends across 24 hours.

If you specify DEMOUNTDELAY(MINUTES(0)), a tape that is mounted for command data set backup remains mounted long enough to support a continuous stream of WAIT-type backup requests to tape from a single job stream even if the queue of work momentarily becomes empty.

Note: The tape will remain mounted for up to 5 seconds if MINUTES(0) is specified.

A change to the DEMOUNTDELAY(MINUTES) value results in a new delay time being set. This new time is calculated from the current time of day. In other words, the new delay does not take into account any time the tape has been idle up to the issuance of this change.

MAXIDLETASKS(drives) is the maximum number of tape drives that DEMOUNTDELAY can accommodate. *drives* is a value from 0 to 64. You can specify a maximum of 64 drives for MAXIDLETASKS, regardless of the number of TAPE tasks specified. However, the effective number of tasks for MAXIDLETASKS is bound by the number of TAPE tasks. So, if you specify MAXIDLETASKS(64) and TAPE(TASKS(5)), the effective MAXIDLETASKS is 5. If at a later time you respecify TAPE(TASKS(7)), the effective MAXIDLETASKS becomes 7.

When you issue the QUERY SETSYS command, DFSMSHsm displays the number of MAXIDLETASKS specified. The QUERY ACTIVE command displays both the effective number of MAXIDLETASKS and the number of current idle tape tasks (that is, drives that are allocated but have no work).

When a command data set backup task writing to tape completes, DFSMSHsm does not deallocate tape units until all queued command data set backup requests have been processed. This enables all consecutive WAIT-type requests by the same batch job to be performed without going through a demount/mount sequence.

DEMOUNTDELAY notes:

1. DEMOUNTDELAY(MINUTES(0)) or MAXIDLETASKS(0) specifies that DFSMSHsm deallocates tapes when there are no requests on the queue that the tape task could select. The tape task can select any requests except those that are restricted to DASD.
2. If a tape drive is idle (waiting for additional backup requests) and is then used to satisfy a command data set backup request, DFSMSHsm resets the DEMOUNTDELAY time specified for that drive. In other words, the DEMOUNTDELAY is per instance, not an accumulation of idle time.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify the DASDSELECTIONSIZE parameter on any SETSYS command, the DFSMSHsm default for *maximum* is 3000 KB, and *standard* is 250 KB. If you do not specify the DASD(TASKS) or TAPE(TASKS) parameters on any SETSYS command, the DFSMSHsm default for *nn* is 2. If you do not specify DEMOUNTDELAY parameter on any SETSYS command, the DFSMSHsm default for MAXIDLETASKS is 0. If idle tape tasks exist and the MINUTES parameter was not specified, then the default for MINUTES is 60 minutes.

Note:

1. You can prevent DFSMSHsm from directing command data set backups to ML1 DASD by specifying DASD(TASKS(0)).
2. You can prevent DFSMSHsm from directing command data set backups to tape by specifying TAPE(TASKS(0)). You should do this if daily backup targets DASD in your installation.
3. You can prevent nontargeted command data set backups from going to ML1 DASD by specifying DASDSELECTIONSIZE(0).
4. A change in TAPE(TASKS(*nn*)) requires DFSMSHsm to start additional tape tasks or stop existing tape tasks (at the end of processing the current command data set).
5. If the sum of tape and DASD tasks exceed the high limit of 64, the command fails.
6. Use care in making a change in the DEMOUNTDELAY parameter. For instance, if a backup to tape task completes its work, the value for MAXIDLETASKS is greater than zero, and DEMOUNTDELAY(10) is in effect, DFSMSHsm sets an internal timer for 10 minutes.
 - If after 10 minutes, no additional work is received, the task begins to deallocate the drive and ends.
 - If during this 10 minute idle time the task is selected to perform a backup, the timer is canceled. Once the task is complete DFSMSHsm again sets a timer value of 10 minutes.

- If during this 10 minute delay, the time is decreased to 5 minutes by using DEMOUNTDELAY(MINUTES(5)), DFSMSHsm cancels the current timer and a new timer is established for 5 minutes (not taking into consideration any previous time).
 - If DEMOUNTDELAY(MINUTES(3)) is in effect and you issue an increase such as DEMOUNTDELAY(MINUTES(10)), DFSMSHsm cancels the current timer value and uses the new value. This resets the countdown to 10 minutes from the time the command is received.
7. If a parsing error occurs, DFSMSHsm fails the SETSYS command with the ARC1605I message. For nonparsing errors but contextual errors, DFSMSHsm fails the parameter in error but continues to process all other parameters in the SETSYS DSBACKUP command. DFSMSHsm treats the TAPE(TASKS) and DASD(TASKS) parameters as a single entity. For example, SETSYS DSBACKUP(DASDSELECTIONSIZE(5000 300) DASD(TASKS(45)) TAPE(TASKS(20))) results in DASDSELECTIONSIZE being set, but DASD(TASKS) and TAPE(TASKS) fail because the sum of both tasks exceeds 64.

DSSXMMODE: Specifying whether DFSMSdss will be loaded in its own address space using the cross memory interface, or in the DFSMSHsm address space, for backup, CDS backup, dump, migration, and full-volume and data set recovery

Explanation: DSSXMMODE is an optional parameter specifying whether DFSMSdss is loaded in its own address space, or in the DFSMSHsm address space, for backup, CDS backup, dump, migration, and full-volume and data set recovery functions.

This parameter can be issued from the ARCCMDxx PARMLIB member only and does not affect FRBACKUP and FRRECOV use of the DFSMSdss cross memory interface.

The following parameters are optional parameters of the DSSXMMODE parameter:

N

DFSMSdss will not be loaded into its own address space for the DFSMSHsm function being invoked. Instead, DFSMSdss will be loaded in the DFSMSHsm address space. This is the default.

Y

DFSMSdss will be loaded into a new address space for the DFSMSHsm function being invoked and will be retained for future invocations of the that function, until DFSMSHsm has been shutdown or restarted.

BACKUP

Controls where DFSMSdss for the DFSMSHsm backup function will be loaded; in its own address space (Y) or in the DFSMSHsm address space (N). The default is N (no).

CDSBACKUP

Controls where DFSMSdss for the DFSMSHsm CDS backup function will be loaded; in its own address space (Y) or in the DFSMSHsm address space (N). The default is N (no).

DUMP

Controls where DFSMSdss for the DFSMSHsm dump function will be loaded; in its own address space (Y) or in the DFSMSHsm address space (N). The default is N (no).

MIGRATION

Controls where DFSMSdss for the DFSMSHsm migration function will be loaded; in its own address space (Y) or in the DFSMSHsm address space (N). The default is N (no).

RECOVERY

Controls where DFSMSdss for the DFSMSHsm full-volume and data set recovery functions will be loaded; in their own address space (Y) or in the DFSMSHsm address space (N). The default is N (no).

Note:

1. When issuing the FRBACKUP or FRRECOV command to back up volumes to disk or to recover volumes and data sets from disk, DFSMSdss will always be loaded in its own address space. Note that FRBACKUP processing, automatic dump processing, and FRRECOV processing all invoke DFSMSdss

to dump from fast replication volumes to tape, or to restore from tape. DFSMSdss address space identifiers can be started optionally, based on the SETSYS DSSXMMODE command in the ARCCMDxx member of the SYS1.PARMLIB.

2. The DFSMSHsm recall function will always run with DFSMSdss loaded in the DFSMSHsm address space.
3. When transitioning or moving Db2 objects, DFSMSHsm will run with DFSMSdss loaded in the DFSMSHsm address space.
4. When migrating, dumping, or restoring data using direct to cloud connections, DFSMSdss will always be loaded in its own address space.

SMS relationship: None.

SETSYS default: If you specify the DSSXMMODE parameter without N (no), Y (yes), or a specific function, then the SETSYS default for this parameter and all unspecified functions is to run with DFSMSdss loaded in the DFSMSHsm address space.

DFSMSHsm default: If you do not specify DSSXMMODE on the SETSYS command during startup, the default is to load DFSMSdss in the DFSMSHsm address space.

DUMPIO: Specifying the DFSMSdss DASD I/O buffering technique

Explanation: **DUMPIO(*n,m*)** is an optional parameter identifying which DFSMSdss DASD I/O buffering technique to use and the number of tracks to read for each EXCP.

The *n* indicates the DFSMSdss DASD I/O buffering technique for reading tracks. This value applies to DFSMSdss physical volume dump, when using the BACKVOL command with the DUMP subparameter.

The *m* indicates the value used for DFSMSdss logical dump. If *m* is not specified, the value will be the same as *n*.

The values to be used for *n* and *m* and their meanings are:

Value

Meaning

- | | |
|----------|-------------------------------------|
| 1 | DFSMSdss reads 1 track at a time |
| 2 | DFSMSdss reads 2 tracks at a time |
| 3 | DFSMSdss reads 5 tracks at a time |
| 4 | DFSMSdss reads 1 cylinder at a time |

Note:

1. Exercise caution when using the DUMPIO parameter because it can have a severe effect on virtual and real storage requirements in a z/OS system. The higher the level of optimization used, the more real storage required for I/O buffers, which are page-fixed. This could result in a limit to the number of concurrent DFSMSHsm tasks, could require that DFSMSHsm address space be expanded, or could cause overall system degradation. Refer to [z/OS DFSMSHsm Implementation and Customization Guide](#) for information on how to calculate storage requirements.
2. DFSMSdss uses three I/O buffers for each active dump task. The size of each of these buffers is determined by the DASD device type and by how many tracks or cylinders are specified in the DUMPIO parameter. For example, if you specify SETSYS DUMPIO(4) and SETSYS MAXDUMPTASKS(15), DFSMSdss gets buffers for 3 cylinders of data for each dump task that is running. The total storage required, if you are using a 3380 DASD device, is 33MB of 31-bit storage. This means that the operating system region size must be larger than the default of 32MB, or an ABEND878 occurs.
3. One other performance consideration is that *each* page of buffer storage will be page-fixed, requiring time and machine cycles.

4. DUMPIO does not apply during aggregate backup and recovery, use the SETSYS ABARSOPTIMIZE parameter instead.
5. DUMPIO applies to migration and full volume dump to DIRECT cloud connections. It is ignored during other cloud operations.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: If you specify DUMPIO without a value for *m*, then *m* defaults to *n*.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default for *n* is one and the default for *m* is four.

DUPLEX: Allowing DFSMSHsm to create two tapes concurrently

Explanation: **DUPLEX** allows DFSMSHsm to create two tapes concurrently, the original tape intended to be kept onsite and the alternate tape taken offsite or written to a remote tape library.

Subparameter	Explanation
BACKUP(Y N)	<p>Duplex alternates will or will not be made for backup volumes. If this subparameter is not specified, no change will be made to the current setting for backup. Y specifies that duplexing will occur for backup tape volumes. N specifies that duplexing will not occur for backup tape volumes.</p> <p>If BACKUP(Y) is specified, then the ERRORALTERNATE subparameter can also be specified:</p> <p>BACKUP(Y ERRORALTERNATE(CONTINUE)) Specifies that if an error occurs on the alternate volume, then the processing will continue on the original tape. This is the default if neither CONTINUE nor MARKFULL are specified.</p> <p>Upon completion of the original tape, either a tapecopy or a recycle is immediately attempted, according to the following subparameter:</p> <p>BACKUP(Y ERRORALTERNATE(CONTINUE(TAPECOPY))) A TCN record for tapecopy is created and written to OCDS. The TCN record indicates that TAPECOPY should be used to create the duplex tape. This is the default if neither TAPECOPY nor RECYCLE are specified.</p> <p>BACKUP(Y ERRORALTERNATE(CONTINUE(RECYCLE))) A TCN record for recycle is created and written to OCDS. The TCN record indicates that the original volume should be recycled in order to create new original and duplex tapes.</p>

Subparameter	Explanation
MIGRATION(Y N)	<p>Duplex alternates will or will not be made for migration volumes. If this subparameter is not specified, no change will be made to the current setting for migration. Y specifies that duplexing will occur for migration tape volumes. N specifies that duplexing will not occur for migration tape volumes.</p> <p>If MIGRATION(Y) is specified, then the ERRORALTERNATE subparameter can also be specified:</p> <p>MIGRATION(Y ERRORALTERNATE(CONTINUE)) Specifies that if an error occurs on the alternate volume, then the processing will continue on the original tape. This is the default if neither CONTINUE nor MARKFULL are specified.</p> <p>Upon completion of the original tape, either a tapecopy or a recycle is immediately attempted, according to the following subparameter:</p> <p>MIGRATION(Y ERRORALTERNATE(CONTINUE(TAPECOPY))) A TCN record for tapecopy is created and written to OCDS. The TCN record indicates that TAPECOPY should be used to create the duplex tape. This is the default if neither TAPECOPY nor RECYCLE are specified.</p> <p>MIGRATION(Y ERRORALTERNATE(CONTINUE(RECYCLE))) A TCN record for recycle is created and written to OCDS. The TCN record indicates that the original volume should be recycled in order to create new original and duplex tapes.</p> <p>MIGRATION(Y ERRORALTERNATE(MARKFULL)) Specifies that both the original and alternate tapes will be marked full if an error occurs on the alternate tape and the failing data set will be retried on a new set of tapes.</p>

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: When either BACKUP or MIGRATION is specified with no subparameter, the default is Y.

DFSMSHsm default: If you do not specify DUPLEX and either of its subparameters, DUPLEXING does not occur.

Note: The SETSYS DUPLEX command is not saved across DFSMSHsm startups, therefore, it is recommended that you specify the SETSYS DUPLEX command in your DFSMSHsm startup member so that duplexing will be your normal environment. Although the SETSYS DUPLEX values can be changed while DFSMSHsm is up and running, the values will not take effect until after any currently running function has completed.

EMERGENCY and NOEMERGENCY: Specifying no data set movement

Explanation: **EMERGENCY** | **NOEMERGENCY** are mutually exclusive, optional parameters specifying whether emergency mode is in effect. Emergency mode stops all DFSMSHsm automatic and command data set processing in both SMS and non-SMS environments and in both primary and secondary address spaces, including functions like aggregate backup, aggregate recovery, audit, migration, backup, recall, recovery and recycle.

EMERGENCY specifies that emergency mode is in effect, and no new DFSMSHsm data set processing can be performed. DFSMSHsm allows any operation in process to finish the currently selected data set and it allows any currently running ABACKUP and ARECOVER commands to continue until completion. However, DFSMSHsm also allows commands that correct or set up options to run. For example, you can issue FIXCDS, QUERY, or SETSYS commands while running in EMERGENCY mode.

NOEMERGENCY specifies that emergency mode is not in effect.

Note:

1. If DFSMSHsm does not resume processing for all functions after you specify SETSYS EMERGENCY and then SETSYS NOEMERGENCY, you may need to issue a RELEASE command, assuming a HOLD command was issued previously.
2. You can start DFSMSHsm in emergency mode by specifying EMERG=YES on the START command.
3. Emergency mode does not prevent a host from placing recall requests in the common recall queue (CRQ), where those requests are then processed by other active hosts. To prevent a host from placing requests in the CRQ, specify HOLD COMMONQUEUE(RECALL(PLACEMENT)).
4. Emergency mode does not prevent a host from placing dump or recover requests onto a common queue, where those requests are then processed by other active hosts. It does prevent a host from accepting any new requests for processing from a common queue.
5. A SETSYS xxEMERGENCY command in the ARCCMDxx startup member would override any EMERG=xxx parameter.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either parameter on any SETSYS command, the DFSMSHsm default is NOEMERGENCY.

ERASEONSCRATCH and NOERASEONSCRATCH: Specifying to check for erasure of DFSMSHsm-owned data sets

Explanation: **ERASEONSCRATCH** | **NOERASEONSCRATCH** are mutually exclusive, optional parameters specifying whether DFSMSHsm should check for erasure of DFSMSHsm-owned data sets that have migrated or been backed up to DFSMSHsm-owned volumes.

ERASEONSCRATCH specifies that DFSMSHsm asks RACF for the erase status of the user's data set when backup versions and migration copies are scratched from DFSMSHsm-owned DASD volumes. The data set is deleted, and if RACF indicates erase-on-scratch, the DASD residual data is overwritten by data management.

NOERASEONSCRATCH specifies that DFSMSHsm does not ask RACF for the erase status of the user's data set when backup versions and migration copies are scratched from DFSMSHsm-owned DASD volumes. The data set is deleted but the DASD residual data is not overwritten by data management.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either parameter on any SETSYS command, the DFSMSHsm default is NOERASEONSCRATCH.

Note:

1. DFSMSHsm always allows data management to perform erase-on-scratch functions for user-owned data sets.
2. ERASEONSCRATCH and NOERASEONSCRATCH affect only backup versions and migration copies of data sets.

EVENTDRIVENMIGRATIONQUIESCE: Specifying quiesce window(s) for Interval and On-demand Migration

Explanation: **EVENTDRIVENMIGRATIONQUIESCE**(*hhmm1-hhmm2/hhmm3-hhmm4*) is an optional parameter specifying the time window(s) of when Interval and On-demand migration should quiesce. The times defined:

- *hhmm1* is the quiesce start time of the first window.
- *hhmm2* is the quiesce end time of the first window.
- *hhmm3* is the quiesce start time of the second window.
- *hhmm4* is the quiesce start time of the second window.

These times represent the window(s) that Interval and On-demand Migration should quiesce, or halt execution. If Interval or On-demand Migration is started outside of the specified window(s) it will be allowed to run until completion.

Note: Time is based on the 24-hour clock and is expressed as a four-digit decimal number in the format *hhmm*. The hour is represented by *hh* and the minutes by *mm*. For example, 1:15 p.m. is 1315 and midnight is 2400. The maximum value you can specify for *hh* is 24, the maximum value you can specify for *mm* is 59, and the maximum value you can specify for *hhmm* is 2400.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None. If specified, at least the first window must contain time values.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the default is no Event Driven Migration Quiesce (for example, Interval or On-demand Migration will run as normal throughout the day).

Note:

1. To reset the time windows, specify all *hhmm*(s) in the first window only as 0000 (for example, 'EVENTDRIVENMIGRATIONQUIESCE(0000 0000)'). Specifying any other combination of 0000 will result in a parse error and neither of the time windows being reset simultaneously. Individual windows cannot be reset while the other is left unchanged. If you desire to keep one window, you must reset as described earlier, and reissue the command with the desired time window.
2. A single time window may span midnight, but not both. This can be specified by the end time < start time (for example, 'EVENTDRIVENMIGRATIONQUIESCE(1315 04340)').
3. Time windows cannot overlap (for example, 'EVENTDRIVENMIGRATIONQUIESCE(1315 0430 0400 0800)').
4. Start and end times within a window, and within a set of windows, cannot be equal to the exception of specifying 0000 (as noted in the first note) in the first time window.

Note: It is imperative that the issuer of this command understand that quiescing Interval and On-demand Migration may result in DASD being filled to capacity because DFSMSHsm is not processing inactive data.

EXITOFF: Specifying inactive installation exits

Explanation: **EXITOFF**(*modname,modname, ...*) is an optional parameter specifying installation exits inactive in DFSMSHsm primary address space. EXITOFF now applies to ABARS exits. For *modname*, substitute the module name of the installation exit you want to be inactive. See [z/OS DFSMS Installation Exits](#) for more information about installation exits.

Valid installation exit module names and their meanings are as follows:

Module Name	Abbreviation	Meaning
ARCADEXT	AD	Data set deletion exit
ARCBDEXT	BD	Data set backup exit

Module Name	Abbreviation	Meaning
ARCBEXT	BE	Aggregate Backup error exit
ARCCBEXT	CB	Control data set backup exit
ARCCDEXT	CD	Data set reblock exit
ARCCREXT	CR	Aggregate Recovery conflict resolution exit
ARCEDEXT	ED	ABARS expiration date setting exit
ARCINEXT	IN	Initialization exit
ARCMDEXT	MD	Data set migration exit
ARCMMEXT	MM	Second level migration data set exit
ARCMVEXT	MV	Space management volume exit
ARCM2EXT	M2	Aggregate Backup ML2 bypass exit
ARCRDEXT	RD	Data set recall exit
ARCRPEXT	RP	Return-priority exit
ARCSAEXT	SA	Space management and backup exit
ARCSDEXT	SD	Shutdown exit
ARCSKEXT	SK	Aggregate Recovery bypass exit
ARCTDEXT	TD	Tape data set exit
ARCTEEXT	TE	Tape ejected exit
ARCTVEXT	TV	Tape volume exit

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMShsm default: If you do not specify an installation exit *modname* on any SETSYS command, the DFSMShsm default is that installation exits will remain in their current state from a previous SETSYS command.

Note:

1. You can delete installation exits while DFSMShsm is running. If you want to delete installation exits, you must use the EXITOFF parameter to specify them.
2. All existing installation exits are supported on the EXITOFF parameter.
3. The *modnames* are not positional. Installation exits not specified remain in their current state.
4. If the EXITS parameter and either the EXITOFF or the EXITON parameter both specify the same installation exit on a SETSYS command, the status specified with the EXITOFF or EXITON parameter has precedence over the status specified with the EXITS parameter.
5. If the same installation exit is specified in both the EXITOFF and the EXITON parameters on a SETSYS command, DFSMShsm leaves that installation exit inactive.
6. The recall exit (ARCRDEXT) and data set deletion exit (ARCADEXT) will not be invoked for SMS-managed data sets.

EXITON: Specifying active installation exits

Explanation: **EXITON(modname,modname, ...)** is an optional parameter specifying active installation exits in DFSMShsm primary address space. EXITON now applies to ABARS exits. For *modname*, substitute the module name of the installation exit you want to be active.

The ARCINEXT exit is passed parameters having 31-bit addresses. This exit may require modification to accept and use the 31-bit addresses. See *z/OS DFSMS Installation Exits* for more information about installation exits.

Valid installation exit module names and their meanings are as follows:

Module Name	Abbreviation	Meaning
ARCADEXT	AD	Data set deletion exit
ARCBDEXT	BD	Data set backup exit
ARCBEEEXT	BE	Aggregate Backup error exit
ARCCBEXT	CB	Control data set backup exit
ARCCDEXT	CD	Data set reblock exit
ARCCREXT	CR	Aggregate Recovery conflict resolution exit
ARCEDEXT	ED	ABARS expiration date setting exit
ARCINEXT	IN	Initialization exit
ARCMDEXT	MD	Data set migration exit
ARCMMEXT	MM	Second level migration data set exit
ARCMVEXT	MV	Space management volume exit
ARCM2EXT	M2	Aggregate Backup ML2 bypass exit
ARCRDEXT	RD	Data set recall exit
ARCRPEXT	RP	Return-priority exit
ARCSAEXT	SA	Space management and backup exit
ARCSDEXT	SD	Shutdown exit
ARCSKEXT	SK	Aggregate Recovery bypass exit
ARCTDEXT	TD	Tape data set exit
ARCTEEXT	TE	Tape ejected exit
ARCTVEXT	TV	Tape volume exit

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify an installation exit *modname* on any SETSYS command, the DFSMSHsm default is that no installation exits are active.

Note:

1. You can dynamically load installation exits while DFSMSHsm is running. If you want to load installation exits, you must specify the exits to be loaded with the EXITON parameter.
2. All existing installation exits are supported on the EXITON parameter.
3. The *modnames* are not positional. Installation exits not specified remain in their current state.
4. If the EXITS parameter and either the EXITOFF or the EXITON parameter both specify the same installation exits on the same SETSYS command, the status specified with the EXITOFF or EXITON parameter has precedence over the status specified with the EXITS parameter.
5. If the same installation exit is specified in both the EXITOFF and the EXITON parameters on a SETSYS command, DFSMSHsm leaves that installation exit inactive.
6. If an installation exit is specified with EXITON and that exit is already active, DFSMSHsm does not load a new copy of the exit.

7. The recall exit (ARCRDTEXT) and data set deletion exit (ARCADEXT) are not invoked for SMS-managed data sets.

EXITS: Specifying the installation exits to be taken

The use of the SETSYS EXITS parameter has been replaced by the SETSYS EXITON and SETSYS EXITOFF parameters. The EXITS parameter is still supported but is no longer documented.

EXPIREDDATASETS: Specifying whether to scratch data sets with expired expiration dates

Explanation: **EXPIREDDATASETS(SCRATCH | NOSCRATCH)** is an optional parameter specifying whether or not DFSMSHsm should scratch data sets having explicit expiration dates when the date has passed (data set has expired). SMS-managed data sets not having explicit expiration dates are expired when they have met their management class expiration criteria.

Note: Explicit expiration dates can be set by JCL, utility parameters, Data Class Expiration parameters, or Data Class Retention parameters. The explicit expiration date for a data set can be found in the data set's VTOC entry.

SCRATCH specifies that DFSMSHsm scratch data sets that have an expired expiration date when it performs space management and migration cleanup.

NOSCRATCH specifies that DFSMSHsm ignore the expiration date. DFSMSHsm processes the data set as if the expiration date has not been reached.

SMS relationship: Parameter applies in some instances to SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is not to scratch the expired data sets.

EXTENDEDTTOC: Specifying whether to use extended tape table of contents (TTOC)

Explanation: **EXTENDEDTTOC(Y|N)** is an optional parameter specifying whether DFSMSHsm should use extended tape table of contents (TTOCs) in order to better utilize tapes with higher capacity volumes in your installation. Extended TTOCs allow DFSMSHsm to write slightly more than one million data sets (potentially) to a migration tape or backup tape.

To use extended TTOCs in your installation, you must define your offline control data set(OCDS) with a maximum record size of 6144 bytes, as described in *z/OS DFSMSHsm Implementation and Customization Guide*. Then enable the support by entering the SETSYS command with optional parameter EXTENDEDTTOC(Y) or its shortened form, EXTTC(Y).

Note: If there is an attempt to specify SETSYS EXTENDEDTTOC(Y) and the OCDS has not been defined with a record size of 6144, DFSMSHsm will issue an error message and force the value of EXTENDEDTTOC to "N".

To return to using non-extended TTOCs, enter the SETSYS command with EXTENDEDTTOC(N) or its shortened form, EXTTC(N).

Note: Users should not specify the SETSYS EXTENDEDTTOC(Y) command on any one host in an HSMplex until the OCDS has been redefined with a record length of 6144 bytes and all hosts in an HSMplex are prepared to issue the SETSYS EXTENDEDTTOC(Y) command.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is not to use extended TTOCs.

FASTREPLICATION: Specifying fast replication methods

Explanation

FASTREPLICATION is an optional parameter that specifies which copy method to use for data set level recovery and other fast replication options.

The following parameters are optional parameters of the FASTREPLICATION parameter:

DATASETRECOVERY

DSR

Fast replication should be used for data set level recovery.

NONE

Fast replication is not used. Only traditional copy methods are to be used. This is the default.

PREFERRED

Fast replication should be used as the copy method for data-set-level recovery whenever possible. For situations in which fast replication cannot be used to recover a data set, recovery is done through traditional copy methods.

REQUIRED

Fast replication must always be used. If fast replication cannot be used, the recovery request fails.

FCRELATION

FCREL

Specifies whether an extent-level or a full-volume-level FlashCopy relationship is to be established for fast replication backup and recovery of volumes.

EXTENT

Extent-level FlashCopy relationships are established during backup and recovery. Free space is not flashed. This is the default.

FULL

Full-volume FlashCopy relationships are established during volume backup and recovery. The entire volume including free space is copied. Therefore, the background copy might take longer to complete.

MESSAGEDATASET

MSGDS

Specifies that messages for each fast replication command (or auto dump of a copy pool) should be directed to a unique fast replication message data set.

NO

A fast replication message data set is not used.

YES

Messages are directed to a fast replication message data set.

HLQ(*hlq*)

Overrides the default high level qualifier of HSMMSG that will be used for a fast replication message data set. The *hlq* value can be a maximum six characters in length, and must meet all other requirements for data set name high level qualifiers.

VOLUMEPAIRMESSAGES

VPM

Controlling FlashCopy volume pairing debug message ARC1809I.

YES

FlashCopy volume pairing debug message ARC1809I is enabled.

NO

FlashCopy volume pairing debug message ARC1809I is disabled.

SMS relationship

Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default

If you specify:

- DATASETRECOVERY without a parameter, then the SETSYS default is to use traditional copy methods. Fast replication is not used (NONE).
- FCRELATION without a parameter, then the SETSYS default is to establish extent-level FlashCopy relationships (EXTENT).
- MESSAGEDATASET without a parameter, then the SETSYS default is to direct messages to a fast replication message data set (YES).

DFSMSHsm default

If you do not specify:

- DATASETRECOVERY on a SETSYS command or FASTREPLICATION on a FRRECOV DSNAMES, the default is to use traditional copy methods. Fast replication is not used (NONE).
- FCRELATION on the SETSYS command, the default is to establish extent-level FlashCopy relationships (EXTENT).
- MESSAGEDATASET on the SETSYS command, the default is to *not* direct messages to a fast replication message data set (NO).
- VOLUMEPAIRMESSAGES on the SETSYS command, the default is to disable ARC1809I messages (NO).

Usage notes:

1. The FASTREPLICATION value specified on the FRRECOV DSNAMES command overrides the SETSYS value.
2. The SETSYS FASTREPLICATION command is applicable for recovery from DASD only. If the recovery is from tape, the DATASETRECOVERY parameter is ignored.
3. DATASETRECOVERY(NONE) cannot be used in combination with FlashCopy targets that are Metro Mirror primary volumes. That is, when the ALLOWPPRCP parameter is specified with: YES, PRESERVEMIRRORNO, PRESERVEMIRRORPREFERRED, or PRESERVEMIRRORREQUIRED.
4. Data set recovery from DASD is not permitted if NOCOPY is used to create the backup copy. The recovery cannot be performed until a dump copy has been created.
5. The combination of the FROMDASD and FASTREPLICATION(DATASETRECOVERY(REQUIRED)) restricts data set recovery to being performed only when fast replication can be used.
6. Specifying FCRELATION does not affect data set recovery.
7. Specifying FCRELATION(EXTENT) to establish extent-level FlashCopy relationships is ignored during FRBACKUP and FRRECOV operations when the copy pool is defined to use a function that requires full-volume FlashCopy (such as fast reverse restore or incremental).

FREQUENCY: Specifying the number of days between backup versions of a data set

Explanation

FREQUENCY is an optional parameter specifying the number of days that must have elapsed since the last time DFSMSHsm backed up a data set before DFSMSHsm will back up the data set again.

The following parameter is an optional parameter of the FREQUENCY parameter:

days

A decimal number from 0 to 999. A value of 0 allows DFSMSHsm to back up data sets every time volume backup runs unless you use the FREQUENCY parameter of the ALTERDS or BACKVOL command to change the frequency.

SMS relationship

Parameter does not apply to SMS-managed DASD volumes or data sets.

SETSYS default

None.

DFSMSHsm default

If you do not specify FREQUENCY parameter on any SETSYS command, the DFSMSHsm default is zero.

Usage notes:

1. The FREQUENCY parameter only applies to data sets that have been backed up.

INCREMENTALBACKUP: Specifying whether to back up only changed data sets during incremental volume backup

Explanation: **INCREMENTALBACKUP** is an optional parameter specifying whether DFSMSHsm should back up only changed data sets during incremental volume backup.

Subparameter	Explanation
CHANGEDONLY	<p>INCREMENTALBACKUP(CHANGEDONLY) specifies that DFSMSHsm backs up the following data sets only if their change bit is on in the data set VTOC entry:</p> <ul style="list-style-type: none"> • Non-VSAM data sets • VSAM data sets cataloged in an integrated catalog facility catalog.
ORIGINAL	<p>INCREMENTALBACKUP(ORIGINAL) specifies that DFSMSHsm creates an initial backup version (if one does not exist) for all non-VSAM and integrated catalog facility VSAM data sets on a primary volume when incremental backup takes place, regardless of the setting of the change bit in the data set VTOC entry.</p>

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: If you do not specify either subparameter on any SETSYS command, the SETSYS default is ORIGINAL.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is ORIGINAL.

Note:

1. VSAM data sets not cataloged in an integrated catalog facility Catalog are backed up during incremental backup by comparing the date of the last update from the catalog record to the date of the last backup from the BCDS.
2. It is suggested that you consider running the INCREMENTALBACKUP command with the ORIGINAL parameter once a month, once a quarter, or when some of the following scenarios are suspected because a backup version might not always exist for all data sets that do not have the change flag on. The scenarios are:

- DFSMSdss or a similar product backed up the volume and reset the change flags before DFSMSHsm was able to back up the data sets.
 - Users may have deleted the backup versions that DFSMSHsm created and, the data sets had not been changed again.
3. The INCREMENTALBACKUP parameter affects only data sets residing on a primary volume when incremental backup is performed. Even if you have specified ORIGINAL, no backup copy will be created for a migrated data set for which the change bit in the data set VTOC entry is off. These data sets have to be backed up individually using the BACKDS command.

INPUTTAPEALLOCATION: Specifying whether to wait for the input tape to be allocated

Explanation: **INPUTTAPEALLOCATION(WAIT | NOWAIT)** is an optional parameter specifying whether DFSMSHsm should wait until the tape unit is allocated for the input tape for recall, recovery, or restore.

Subparameter	Explanation
WAIT	<p>INPUTTAPEALLOCATION(WAIT) specifies that DFSMSHsm waits until the input tape unit is allocated. All DFSMSHsm functions stop until this allocation request is satisfied.</p> <p>When using the WAIT option, caution must be exercised to limit the number of DFSMSHsm tasks that require tape. If more tasks run than there are available tape devices, a deadlock condition will occur because of the exclusive enqueue that MVS allocation will put on the task input/output table (SYSZTIOT) while awaiting the tape device. This condition can be resolved only if another job (not DFSMSHsm) releases a tape device, or if you cancel DFSMSHsm.</p>
NOWAIT	<p>INPUTTAPEALLOCATION(NOWAIT) specifies that DFSMSHsm does not wait until the input tape unit is allocated. Instead, DFSMSHsm reissues the request every 10 seconds up to six times. If the input tape unit is still not allocated after seven tries, DFSMSHsm asks the operator whether DFSMSHsm should cancel the request or repeat the allocation sequence. With the NOWAIT option, dynamic allocation issues message IEF238D. Once answered, other DFSMSHsm tasks can proceed with allocations.</p>

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either subparameter on any SETSYS command, the DFSMSHsm default is NOWAIT.

INTERVALMIGRATION and NOINTERVALMIGRATION: Specifying whether interval migration is performed

Explanation: INTERVALMIGRATION and NOINTERVALMIGRATION are mutually exclusive, optional parameters specifying whether DFSMSHsm should perform interval migration. The purpose of interval migration is to prevent the DFSMSHsm-managed volumes from running out of space during the day. DFSMSHsm normally does a space check every hour. Therefore, if you request interval migration, DFSMSHsm uses this hourly space check to determine on which volumes interval migration is done.

INTERVALMIGRATION specifies that interval migration is performed.

NOINTERVALMIGRATION specifies that interval migration is not performed.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either parameter on any SETSYS command, the DFSMSHsm default is INTERVALMIGRATION.

Note:

1. If you want the operator to decide whether interval migration should be allowed after DFSMSHsm decides it is necessary, specify the INTERVALMIGRATION parameter and the REQUEST parameter. Interval migration does not occur during the DFSMSHsm startup process.
2. With Tape Mount Management (TMM), interval migration can still be performed on SMS volumes in a storage group having the attribute of AUTO MIGRATE=I, regardless of the setting for the SETSYS INTERVALMIGRATION parameter or the SETSYS NOINTERVALMIGRATION parameter.
3. Only primary space management will be performed on SMS volumes in a storage group having the attribute of AM=P. When this attribute is specified, interval migration is not performed even if the SETSYS INTERVALMIGRATION parameter is specified.

ISSUEARC1902: Enable/disable the issue of ARC1902I message to the console

Explanation:ISSUEARC1902(YES|NO DELAYTIME(secs)) is an optional parameter that controls whether DFSMSHsm will issue message ARC1902I when an auto backup function is still running after its specified quiesce/end time. If enabled, ARC1902I will be displayed on the operator console after the user specified amount of time, in seconds, after the quiesce/end time of an autobackup function. The ARC1902I message will be moved from the operator console if the affected automatic function completer normally.

The Sub-parameters of the ISSUEARC1902 parameterSet follow this discussion.

Subparameter	Explanation
Y N	Enable/disable the DFSMSHsm to issuing ARC1902I message to the console.
DELAYTIME(SECS)	Amount of time (seconds) after the quiesce/end time need to display ARC1902I message on the console when autobackup is still running.

SMS relationship:Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default:The following table describes the SETSYS ISSUEARC1902 default.

If.....	then.....
If you specify ISSUEARC1902.	Issue of ARC1902I message is enabled with default delaytime 7200 secs
If you specify DELAYTIME without a value.	SETSYS default is 7200 secs (equivalent to 2 hrs).
If you specify DELAYTIME with a value greater than 50400 secs (equivalent to 14 hrs.)	SETSYS default is 50400 secs (equivalent to 14 hours.)

DFSMSHsm default: The following table describes the SETSYS ISSUEARC1902 DFSMSHsm default.

If.....	then.....
If you specify ISSUEARC1902.	Issue of ARC1902I message is enabled with default delaytime 7200 secs

If.....	then.....
If you specify DELAYTIME without a value.	DFSMSHsm default is 7200 secs (equivalent to 2 hrs).
If you specify DELAYTIME with a value greater than 50400 secs (equivalent to 14 hrs.)	N/A

JES2 and JES3: Specifying the job entry subsystem

Explanation: JES2 and JES3 are mutually exclusive, optional parameters specifying the job entry subsystem that is used with DFSMSHsm.

If you want to use JES3, you must specify the JES3 parameter before you specify the first ADDVOL command. If you do not, DFSMSHsm defaults to JES2. When DFSMSHsm is started in an operating system that has JES3 and when you do not specify JES3 during DFSMSHsm initialization, an error message is written when DFSMSHsm receives the first request from the JES3 converter (interpreter). If you specify JES3, but the operating system uses JES2, DFSMSHsm is not notified of the error. DFSMSHsm, however, uses the rules that govern pool configuration for JES3 and one or both of the following situations can occur:

- Some ADDVOL, SETSYS, and DEFINE commands fail if they are issued when it is unacceptable in a JES3 system.
- Volumes eligible for recall in a JES2 system might not qualify for the DFSMSHsm general pool and, in some cases, are not available for recall in the JES3 system.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either parameter on any SETSYS command, the DFSMSHsm default is JES2.

JOURNAL and NOJOURNAL: Specifying whether to write updated control data set records in the journal data set

Explanation: JOURNAL and NOJOURNAL are mutually exclusive, optional parameters specifying whether MCDS data set records, BCDS data set records, and OCDS data set records are written in the journal data set when DFSMSHsm updates the control data sets. If the MCDS, BCDS, or OCDS is lost or damaged, you can use the journal data set with a backup copy of the control data set to recreate the affected control data set.

JOURNAL specifies that DFSMSHsm write the BCDS, MCDS, and OCDS data set records in the journal data set when DFSMSHsm updates them.

Subparameter	Explanation
SPEED	<p>JOURNAL(SPEED) specifies that the module making the change should wait only until the journaling request has been added to the journaling queue. When you use SPEED, DFSMSHsm does not wait long, because of the following reasons:</p> <ul style="list-style-type: none"> • The journal task has the highest dispatching priority among all DFSMSHsm tasks. • The journal entries are not blocked. • In each DFSMSHsm host, the journal entries are written in the order they are created. <p>The task probably does not lose more than one entry if the system fails, unless you allocate the journal data set on a volume that is used often.</p>
RECOVERY	<p>JOURNAL(RECOVERY) specifies that the module making the change should wait until the journal entry has been written in the journal data set. DFSMSHsm writes each record as it receives the record. Therefore, not more than one entry can be lost if DFSMSHsm abnormally ends. After DFSMSHsm has updated the affected control data set and has written each journal data set entry, DFSMSHsm continues processing.</p>

NOJOURNAL specifies that DFSMSHsm is not to write the updated BCDS, MCDS, and OCDS records in the journal data set.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: If you specify JOURNAL without a subparameter, the SETSYS default is RECOVERY.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is JOURNAL(RECOVERY).

Note:

1. The SPEED option queues the journal updates to be written as soon as possible, but the requesting task does not wait for the journal entry to be written. This can cause ABEND878, ABEND80A, or ABEND106-C during heavy journaling activity, if the logging task cannot keep up with the journaling load. This can happen if the ARCILOG task gets tied up during I/O to the DASD data set. If DFSMSHsm should be abnormally terminated while running this option, all journal updates not yet written will be lost.
2. If JOURNAL(RECOVERY) is specified and DFSMSHsm senses it is waiting too long for the journal entry to be written, DFSMSHsm stops its wait and leaves the request on the journaling queue. This temporary return to SPEED mode helps prevent lockouts caused by resource contention.
3. DFSMSHsm does not write updated entries from the BCDS, MCDS, and OCDS unless you include a JCL DD statement for the journal data set in the DFSMSHsm startup procedure.
4. DFSMSHsm nulls the journal data set every time DFSMSHsm successfully backs up the control data sets.
5. When defined as a large format data set, the DFSMSHsm journal can exceed 65,535 tracks per volume. For information about defining the DFSMSHsm journal, see [z/OS DFSMSHsm Implementation and Customization Guide](#).

MAXABARSADDRESSSPACE: Specifying the maximum number of concurrent secondary address spaces supported

Explanation: **MAXABARSADDRESSSPACE(nn)** is an optional parameter specifying the maximum number of concurrent aggregate backup and recovery address spaces that DFSMSHsm supports. For *nn*,

substitute a decimal number from 1 to 64 to represent the number of secondary address spaces that can run concurrently for aggregate backup and recovery.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is one.

MAXBACKUPTASKS: Specifying the maximum number of concurrent volume backup tasks

Explanation: **MAXBACKUPTASKS(*nn*)** is an optional parameter specifying the maximum number of volume backup tasks DFSMSHsm can concurrently process. For *nn*, substitute a decimal number from 1 to 15 to represent the number of volume backup tasks to be run concurrently.

To decide how many concurrent volume backup tasks DFSMSHsm should run, consider how many tape units are available if you use tape backup volumes and if you are utilizing duplex tape. Also, consider the system work load and how many backup volumes you have available when volume backup is running. Because each volume backup task chooses a unique daily backup volume, it is impractical to specify more volume backup tasks than available daily backup volumes, because a volume backup task waits until a daily backup volume is available.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is two tasks.

MAXCOPYPOOLTASKS: Specifying the maximum number of concurrent DFSMSdss invocations for each fast replication command

Explanation: **MAXCOPYPOOLTASKS** is an optional parameter that you use to define the maximum number of DFSMSdss invocations for each fast replication command that DFSMSHsm can concurrently process. **FRBACKUP tasks:** The maximum number of concurrent fast replication backup volume tasks is the product of the FRBACKUP and DSS parameters. **FRRECOV tasks:** The maximum number of concurrent fast replication recover volume tasks is the product of the FRRECOV and DSS parameters.

Note: When the FRBACKUP COPYPOOL command uses FlashCopy consistency groups, DFSMSHsm processes all the copy pool volumes in one DFSMSdss invocation, regardless of the SETSYS MAXCOPYPOOLTASKS(FRBACKUP(*nn*) DSS(*nnn*)) setting.

Subparameter	Explanation
FRBACKUP	MAXCOPYPOOLTASKS (FRBACKUP(<i>nn</i>)) is an optional parameter that you specify to define the maximum number of DFSMSdss invocations for each FRBACKUP command that DFSMSHsm can concurrently process. For <i>nn</i> , substitute a decimal number from 1 to 64 to represent the number of DFSMSdss invocations for each FRBACKUP command that runs concurrently.
FRRECOV	MAXCOPYPOOLTASKS (FRRECOV(<i>nn</i>)) is an optional parameter that you specify to define the maximum number of DFSMSdss invocations for each FRRECOV command that DFSMSHsm can concurrently process. For <i>nn</i> , substitute a decimal number from 1 to 64 to represent the number of DFSMSdss invocations for each FRRECOV command that runs concurrently.

Subparameter	Explanation
DSS	MAXCOPYPOOLTASKS (DSS(<i>nnn</i>)) is an optional parameter that you specify to define the maximum number of volume pairs that DFSMSdss passes to each DFSMSdss invocation for backup and recover functions. For <i>nnn</i> , substitute a decimal number from 1 to 254 to represent the number volume pairs that DFSMSdss passes to each DFSMSdss invocation.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMShsm default: If you do not specify this parameter on any SETSYS command, the DFSMShsm default for the FRBACKUP parameter is 15 tasks, the FRRECOV parameter is 15 tasks, and the DSS parameter is 24 tasks.

Attention

The default values recommended for these parameters are based on performance tests that determined the values that would provide the optimal throughput. You should realize that increasing the value of the DSS(*nnn*) parameter above the recommended default may have a negative impact on throughput.

MAXDSRECOVERTASKS: Specifying the maximum number of data set recovery tasks from DASD and tape

Explanation: **MAXDSRECOVERTASKS(*nn*)** is an optional parameter specifying the maximum number of data set recovery tasks DFSMShsm can concurrently process for both DASD and tape. This parameter allows an installation to determine the appropriate tasking level to recover individual data sets, based on the amount of disk storage and the number of tape drive resources available. The actual number of effective tasks may be limited if the number of backup resources is less than the total tasks specified. For *nn*, substitute a decimal number from 1 to 64 to represent the number of data set recovery tasks to be run concurrently.

The value you specify for MAXDSRECOVERTASKS applies to data set recovery tasks for both DASD and tape. To limit tape requests to a subset of this value, use the keyword MAXDSTAPERECOVERTASKS instead. The maximum number of tasks from DASD is the value of MAXDSRECOVERTASKS minus the current number of tape tasks specified by MAXDSTAPERECOVERTASKS.

If there are no active tape tasks, the number of disk tasks can reach the value specified by MAXDSRECOVERTASKS. To prevent tape tasks, specify SETSYS MAXDSTAPERECOVERTASKS(0).

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMShsm default: If you do not specify this parameter on any SETSYS command, the DFSMShsm default is two tasks.

MAXDSTAPERECOVERTASKS: Specifying the maximum number of data set recovery tasks from tape

Explanation: **MAXDSTAPERECOVERTASKS(*nn*)** is an optional parameter specifying the maximum number of data set recovery tasks DFSMShsm can concurrently process from tape. This parameter allows you to determine the appropriate tasking level to recover individual data sets, based on the number of tape drives available. The actual number of effective tasks might be limited if the number of backup tape cartridges is fewer than the total tasks specified.

For *nn*, specify a decimal number from 0 to 64 to represent the number of data set recovery tasks to be run concurrently. The value for *nn* cannot exceed the value you specify for the MAXDSRECOVERTASKS parameter.

To prevent any DFSMSHsm data set recoveries from tape, specify SETSYS MAXDSTAPERECOVERTASKS(0).

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is the value of MAXDSRECOVERTASKS.

MAXDUMPRECOVERTASKS: Specifying the maximum number of concurrent volume recovery from dump tasks

Explanation: MAXDUMPRECOVERTASKS(*nn*) is an optional parameter specifying the maximum number of volume recovery from dump tasks DFSMSHsm can concurrently process. This parameter allows you to set the appropriate tasking level to recover individual volumes, based on the number of tape drives available. The actual number of effective tasks will be limited by the number of tape drives available and dump stacking value.

For *nn*, specify a decimal number from 0 to 64 to represent the number of volume recovery from dump tasks to be processed concurrently.

Note:

1. Special care must be taken when considering dump classes and their dump stacking values. A higher dump stacking value requires fewer tapes; however, the higher the number of volumes dumped onto a single tape, the greater the likelihood that a single tape will be needed for multiple recovery tasks. If the specified number of concurrent tasks is greater than the number of tape drives in use, the maximum number of concurrent tasks will be limited.
2. For CVQ processing consider using SETSYS MAXDUMPRECOVERTASKS(0) from the master scheduler, instead of a HOLD RECOVER or FRRECOV, when you want the master scheduler to assign CVQ work, but not use the master scheduler resources for CVQ fast replication or for volume recovery processing. To end this state, use a SETSYS MAXDUMPRECOVERTASKS command with a non zero value.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed volumes.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the default is 1.

MAXDUMPTASKS: Specifying the maximum number of concurrent volume dump tasks

Explanation: MAXDUMPTASKS(*nn*) is an optional parameter specifying the maximum number of volume dump tasks DFSMSHsm can concurrently process. For *nn*, substitute a decimal number from 0 to 64 to represent the number of dump tasks to be run concurrently.

Because multiple classes can be requested for each input volume, MAXDUMPTASKS does not explicitly limit the number of output copies. To decide how many concurrent volume dump tasks DFSMSHsm should run, consider how many tape units are available. Multiple dump classes for an input volume require a separate tape drive for a tape in each class. To determine the required number of tape drives for the volume dump process, multiply the number of classes per volume by the number of dump tasks (*nn*). This number should not exceed the number of tape drives expected to be available during the volume dump process.

MAXDUMPTASKS(0) allows hosts to submit work but the dump tasks available on those hosts are not selected for processing. In a common dump queue, dump tasks available from other hosts in the common

queue are used. To end this state, use a SETSYS MAXDUMPTASKS command with a non zero value, and a RELEASE DUMP command.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is two tasks.

Note:

1. When specifying more than a few tasks, ensure that DFSMSdss is loaded in its own address space by specifying SETSYS DSSXMMODE(DUMP(Y)) in the ARCCMDxx PARMLIB member. Failure to do so may result in 878 abends and related errors.

MAXEXTENTS: Specifying the number of extents to cause extent reduction

Explanation: **MAXEXTENTS(*extents*)** is an optional parameter specifying the number of extents that, if equaled or exceeded, causes DFSMSHsm to reallocate all non-VSAM data sets. For *extents*, substitute a decimal number from 0 to 16 specifying the number of extents to allow before DFSMSHsm does extent reduction. If you specify 0, DFSMSHsm does not do extent reduction.

When volume migration occurs for volumes containing a non-VSAM data set that cannot migrate either because the data set was referred to recently or has reached or exceeded its maximum extents, DFSMSHsm migrates and then immediately recalls the data set.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: If you specify a value larger than 16, the SETSYS default for *extents* is 16.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is 0.

Note:

1. The MAXEXTENTS parameter does not apply to VSAM data sets or to data set organizations not supported by DFSMSHsm.
2. You use this parameter for active, non-VSAM data sets. This parameter only applies to those non-VSAM data sets that are architecturally limited to 16 extents. It does not apply to data sets that are allocated to more than one volume, striped data sets, extended format data sets, PDSE or HFS data sets. Data sets that can be allocated to multiple volumes via the DATACLASS, but are only allocated on one volume, are eligible for EXTENT REDUCTION.
3. DFSMSHsm will not do extent reduction unless the data set is more than one day old in a single-DFSMSHsm-host environment or two days old in a multiple-DFSMSHsm-host environment.
4. Using a low MAXEXTENTS value might cause extent reduction to occur more frequently than you want. If you specify a MAXEXTENTS value, try using a value of 5 or more.

MAXINTERVALTASKS: Specifying the maximum number of automatic interval migration or on-demand migration tasks that can run concurrently

Explanation: **MAXINTERVALTASKS(*nn*)** is an optional parameter specifying the maximum number of automatic interval or event-driven on-demand migration tasks that can run concurrently. It applies to the processing of primary volumes and SMS-managed volumes.

For *nn*, substitute a decimal number from 0 to 15, specifying the maximum number of concurrent tasks. A zero value allows you to restrict the interval migration or on-demand migration task from running on any host that has MAXINTERVALTASKS set to zero. Once MAXINTERVALTASKS is set to a nonzero value, interval migration or on-demand migration processing will resume on the host.

Note: MAXEVENTDRIVENMIGTASKS or MAXEDMT alias can be used instead of MAXINTERVALTASKS parameter.

Tape units must be available to support the maximum number of migration tasks. In a direct-to-tape environment, the number of tape units available must be at least equal to *nn*. The number of SDSP data sets available should be greater than *nn*. In addition, in a duplex tape environment, the number of tape units must be at least 2 times *nn*.

In an environment where data sets can be routed to either DASD or tape, a tape unit is required for each migration task that encounters a data set that is migrated directly to tape. Make sure that you have *nn* tape units available. Once DFSMSHsm has selected a tape unit, that unit will not be released until the automatic volume space management function has completed, or until recall needs the tape. In a duplex tape environment, DFSMSHsm selects two tape units for each migration task and these tape units will not be released until the automatic volume space management function is complete.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS defaults: None.

DFSMSHsm defaults: If you do not specify this parameter on any SETSYS command, the default value for the maximum number of concurrent interval migration or on-demand migration tasks (*nn*) is equal to the value defined for MAXMIGRATIONTASKS. The default value for MAXMIGRATIONTASKS is 2.

MAXMIGRATIONTASKS: Specifying the maximum number of automatic volume space management tasks that can run concurrently

Explanation: MAXMIGRATIONTASKS(*nn*) is an optional parameter specifying the maximum number of automatic volume space management (primary space management, interval migration and on-demand migration) tasks that can run concurrently. It applies to the processing of primary volumes and SMS-managed volumes. You can specify the maximum number of concurrent tasks (*nn*) from 1 to 15.

MAXMIGRATIONTASKS applies only to automatic functions. You can run only one command migration task at a time. Individual commands for data set or volume migrations do not run concurrently.

Tape units must be available to support the maximum number of migration tasks. In a direct-to-tape environment, the number of tape units available must be at least equal to *nn*. The number of SDSP data sets available should be greater than *nn*. In addition, in a duplex tape environment, the number of tape units must be at least 2 times *nn*.

In the environment where data sets can be routed to either DASD or tape, a tape unit is required for each migration task that encounters a data set to be migrated directly to tape. Make sure that you have *nn* tape units available. Once DFSMSHsm has selected a tape unit, it will not be released until the automatic volume space management function has completed. In a duplex tape environment, DFSMSHsm selects two tape units for each migration task and these tape units will not be released until the automatic volume space management function is complete. This does not apply to DASD volumes.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the default value for the maximum number of concurrent migration tasks (*nn*) is 2.

MAXRECALLTASKS: Specifying the maximum number of active recall tasks

Explanation: MAXRECALLTASKS(*nn*) is an optional parameter specifying the number of active recall tasks DFSMSHsm can concurrently process. For *nn*, substitute a decimal number from 1 to 15 for the number of concurrent recall tasks DFSMSHsm can process.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: If you specify a value larger than 15, the SETSYS default for *nn* is 15.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default for *nn* is 15.

Note: The MAXRECALLTASKS parameter is utilized in the processing of deletes initiated by secondary space management.

MAXRECYCLETASKS: Specifying the maximum number of active recycle tasks

Explanation: **MAXRECYCLETASKS(*nn*)** is an optional parameter specifying the maximum number of tape processing tasks initiated by a single RECYCLE request. For *nn*, substitute a decimal number from 1 to 15 for the number of tasks to initiate. The number of tape processing tasks can be changed dynamically, even while DFSMSHsm is processing a RECYCLE request. This allows you to free tape drives for uses other than recycle processing, should the need arise. Each task that moves data requires two tape drives, one for input and one for output. In a duplex tape environment, each task moving data requires three tape drives, one for input and two for output.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default for *nn* is 2.

Note: Only one RECYCLE command is processed at a time when you use the VOLUME parameter of the specific RECYCLE command. An MVS image can process only one RECYCLE command at a time. If you issue a generic RECYCLE command, and multiple volumes are eligible, then MAXRECYCLETASKS is used.

MAXSSMTASKS: Specifying the maximum number of concurrent automatic secondary space management tasks

MAXSSMTASKS(CLEANUP(*nn*) | TAPEMOVEMENT(*mm*) | EMPTYCONTAINERDELETION(*kk*)) is used to define the maximum number of secondary space management tasks that can be run concurrently.

Subparameter	Explanation
CLEANUP(<i>nn</i>)	MAXSSMTASKS(CLEANUP(<i>nn</i>)) specifies the maximum number of secondary space management migration cleanup tasks that can run concurrently. For <i>nn</i> , substitute a decimal number from 0 to 15 for the maximum number of concurrent migration cleanup tasks. A value of 0 indicates that there are no cleanup tasks, and therefore the secondary space management window includes no cleanup processing.
TAPEMOVEMENT(<i>mm</i>)	MAXSSMTASKS(TAPEMOVEMENT(<i>mm</i>)) specifies the maximum number of automatic secondary space management tape migration tasks that can be run concurrently. This parameter applies to the migration of data sets from level 1 volumes to level 2 tape volumes. If you are duplexing migration tapes, each TAPEMOVEMENT task you define will require two tape drives. For <i>mm</i> , substitute a decimal number from 0 to 15 for the maximum number of concurrent tape migration tasks. A value of 0 indicates that there are no tape movement tasks. In that case, DFSMSHsm performs no ML1-to-ML2 data movement. This setting is useful when no tape drives are available.

Subparameter	Explanation
EMPTYCONTAINERDELETION(<i>kk</i>)	MAXSSMTASKS(EMPTYCONTAINERDELETION(<i>kk</i>)) specifies the number of Cloud Storage containers processing tasks. Only 0 or 1 values are acceptable. A value of 0 indicates that Cloud Storage containers deletion task will not be submitted. Alias: ECD

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify the CLEANUP parameter on any SETSYS command, the DFSMSHsm default for *nn* is 2. If you do not specify the TAPEMOVEMENT parameter on any SETSYS command, the DFSMSHsm default for *mm* is 1. If you do not specify the EMPTYCONTAINERDELETION parameter on any SETSYS command, the DFSMSHsm default for *kk* is 1.

MIGDENSITY: Specifying the tape density when allocating scratch tapes for migration

The use of the MIGDENSITY parameter is considered to be nonfunctional, and its use results in an ARC1605I parse error.

MIGRATEPREFIX: Specifying the prefix for the migration copy name

Explanation: **MIGRATEPREFIX(*prefix*)** is an optional parameter specifying the prefix (high-level qualifier) of the data set name that DFSMSHsm generates when it migrates the data set. *prefix* must be defined as 1 to 7 alphanumeric characters; the first character must be alphabetic only.

Attention: Changing this parameter after the DFSMSHsm environment is set could result in failures during the recall and recovery of data sets from tape and SDSPs.

The migration copy name has the following format:

```
prefix.HMIG.Tssmmhh.user1.user2.Xydd
```

If patch-enabled, the following dataset name will be generated:

```
prefix.HMIG.Tcccchh.user1.user2.Xydd
```

where:

- *prefix* is replaced with the prefix you specify with this command.
- HMIG indicates that this is a migrated data set.
- Tssmmhh is the time when DFSMSHsm migrated the data set; *ss* is the second, *mm* is the minute, and *hh* is the hour. If a duplicate exists after this name is generated, DFSMSHsm changes the first character of the time stamp.
- Tcccchh is the time when DFSMSHsm migrated the data set; *cccc* is the time in hundredths of seconds from the beginning of the hour converted to four alphabetic characters and *hh* is hours. For more information, see “Names of migrated data sets” on page 73.
- *user1* and *user2* are replaced with the first two qualifiers of the data set name. The data set name can be 44 characters long.

- *Xydd* is the date when DFSMSHsm migrated the data set. DFSMSHsm replaces the X with a letter that represents the decade. A–J have the following meaning:

```
A-1,  B-2,  C-3,  D-4,  E-5
F-6,  G-7,  H-8,  I-9,  J-0
```

For example, you specify MIGRATEPREFIX(HSMmig). Your data set name is TERRY.CLIST.TEXT. DFSMSHsm migrates the data set on 15 July 1990 at 5:33 p.m. The migration copy name is:

```
HSMmig.HMIG.T003317.TERRY.CLIST.I0198
```

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is the UID you specified in the DFSMSHsm startup procedure. This UID is used as the first qualifier for data set names generated by DFSMSHsm during the BACKUP or MIGRATION functions. Changing this UID after the DFSMSHsm environment is set could result in failures during the recall and recovery of data sets from tape and SDSPs. [Chapter 2, “Space management of SMS-managed storage,” on page 23](#) explains the UID and the DFSMSHsm startup procedure.

MIGRATIONAUTOCLOUD: Allow the host to execute Cloud migration

MIGRATIONAUTOCLOUD ({ALL | CLOUDONLY | NOCLOUD} SELECTIONTHRESHOLD(*nnn*)) defines the possible target tier during the MIGRATE STORAGEGROUP command and automatic migration and the method of CEC thread serialization.

Optional subparameters of the SETSYS MIGRATIONAUTOCLOUD command:

ALL

Allows data set migration to ML1, ML2, transition, and migration to Cloud storage.

CLOUDONLY

Allows data set migration to Cloud storage only.

NOCLOUD

Allows data set migration to ML1, ML2, and transition only. NOCLOUD is the default.

Alias: MAC

SELECTIONTHRESHOLD(*nnn*)

Specifies the expected maximum percentage of data sets on a volume eligible to be migrated to the cloud before DFSMSHsm reserves a data movement thread in the disk storage controller unique to this volume. This parameter only applies when the ALL optional subparameter is specified. It does not apply when the NOCLOUD or CLOUDONLY options are specified.

A finite number of data movement threads is available in the disk controller to move data sets to cloud object storage. This threshold can be tuned to optimize when DFSMSHsm reserves a thread during volume selection based on the number of data sets expected to migrate to cloud object storage from a volume.

Each time a volume is processed, DFSMSHsm records the percentage of data sets that were migrated to cloud object storage. This percentage is used during the subsequent processing of the volume to determine whether a storage controller thread for cloud data movement should be reserved. If the percentage of data sets eligible for cloud migrations on the volume is less than this SETSYS value, then a thread is not reserved during volume selection. If the percentage is greater than the threshold, then a thread is reserved.

Reserving a disk controller data movement thread ensures that the DFSMSHsm volume task can select data sets eligible to migrate to the cloud and immediately process them. If a thread is not reserved, then data sets eligible to migrate to the cloud might have to wait if there are not enough available threads for all of the cloud migration activity. Also, if a DFSMSHsm volume task has reserved a thread

but is not currently using it, then that thread is not available to be used by other DFSMSHsm migration tasks.

Valid values are 0 to 100.

- 0 indicates that if any data set on a volume has migrated to the cloud, then a disk controller data movement thread should always be reserved. Use this value only if it is certain that all migrations will target cloud storage.
- 100 indicates that a data movement thread should never be reserved. This value should only be used if it is certain that migrations will never target cloud storage. In this case, the NOCLOUD parameter should be specified instead.

The default value is 40. This default value will likely need to be tuned based on the activity in your environment.

Using the SETSYS MIGRATIONAUTOCLOUD command without the SELECTIONTHRESHOLD parameter does not change this value.

Alias: ST

Table 65. Summary of DFSMSHsm default values	
DFSMSHsm default value	Result
MIGRATEPSMEARLY(NO)	The actual data set age is used during primary space management.
MIGRATIONAUTOCLOUD(NOCLOUD)	Only data sets that would target ML1 or ML2, or transition will be processed. Any eligible data sets that would target cloud storage will not be migrated by this host during the automatic migration.
MIGRATIONAUTOCLOUD(SELECTIONTHRESHOLD(40))	If the percentage of data sets migrated from a volume to the cloud is not greater than 40, this volume is selected without checking for "free" CEC threads. Otherwise, the volume is selected if a "FREE CEC" thread can be found to process the migrations.

MIGRATIONCLEANUPDAYS: Specifying the number of days to keep MCDS data set records and statistics records

Explanation: **MIGRATIONCLEANUPDAYS(recalldays statdays reconnectdays clouddays)** is an optional parameter specifying the number of days that DFSMSHsm keeps MCDS records for recalled data sets or keeps daily and volume statistics records before it deletes them during migration cleanup. The REPORT command uses the daily and volume statistics records. The IDCAMS DCOLLECT function gathers them when the CAPPLANDATA keyword is specified.

For *recalldays*, substitute a decimal number from 0 to 999 for the number of days since the date of recall that DFSMSHsm keeps MCDS data set records for recalled data sets.

For *statdays*, substitute a decimal number from 1 to 999 for the number of days DFSMSHsm keeps the daily and volume statistics records.

For *reconnectdays*, substitute a decimal number from 0 to 999 for the number of days that DFSMSHsm uses to calculate how long to keep the MCDS data set records for recalled data sets that are candidates for reconnection.

For *clouddays*, substitute a decimal number from 0 to 999 for the number of days that DFSMSHsm should keep old cloud migration copies around after a modified version of the same data set has been remigrated to the cloud.

This algorithm shows the calculation. The predicted remigration date is the date of recall plus the number of days of nonuse when the data set last migrated. For example:

- Date last referenced at time of migration: 99.100

- Date of migration: 99.110
- Date of recall: 99.125

This equals a predicted remigration date of 99.135. The 10 days the data set went unreferenced prior to the migration is added to the recall date to calculate the predicted remigration date. To this predicted remigration date, add the value specified for the *reconnectdays* parameter (in our example, we are using a value of 5). The MCDS data set record is retained through 99.140.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm defaults for *recalldays* is 10, for *statdays* is 30, for *reconnectdays* is 3, and for *clouddays* is 0.

Note:

1. The MCDS record for a reconnectable data set is not deleted until both the *recalldays* and *reconnectdays* criteria are met.
2. The *recalldays* value specifies to DFSMSHsm how long to keep MCDS data set records for recalled data sets that were not compacted or were compacted and met or exceeded the current value of SETSYS COMPACTPERCENT. For data sets that were compacted but did not meet the current value of SETSYS COMPACTPERCENT, the MCDS data set records are retained for 90 days.
3. Specifying a value other than 0, for *clouddays*, will cause DFSMSHsm to create 'Retained' MCA records describing old cloud migrated data sets, which will be kept for the number of days specified, once a newer version of the data set is remigrated to the cloud. Specifying a value of 0 will cause DFSMSHsm to not keep 'Retained' MCA records and the old cloud migrated data sets they describe. As a side effect of specifying 0, after having a non-zero value for a time, all 'Retained MCA' records and the old cloud migration copies they describe will be deleted on the next run of Secondary Space Management.

MIGRATIONLEVEL1DAYS: Specifying the inactive age for data sets migrating from level 1 volumes

Explanation: **MIGRATIONLEVEL1DAYS(days)** is an optional parameter specifying the number of contiguous days a data set must remain unreferenced before the data set is eligible for migration from a level 1 volume to a level 2 volume. For *days*, substitute a decimal number from 0 to 999. This value includes the time the unreferenced data set was on a primary volume. For example, if you specified MIGRATIONLEVEL1DAYS(15) and the minimum migration age is 5, the unreferenced data set remains on the primary volume for 5 days and on the migration level 1 volume for 10 days before DFSMSHsm migrates it to a migration level 2 volume.

SMS relationship: Parameter does not apply to SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter with any SETSYS command, the DFSMSHsm default is 60 calendar days.

Note: MIGRATIONLEVEL1DAYS applies only to migration from level 1 volumes to level 2 volumes.

MIGRATEPSMEARLY: Activate the PSM earlier checking option

MIGRATEPSMEARLY (YES | NO) activates the earlier checking option provided by primary space management (PSM). One is added to the age check, up until midnight.

Required subparameters of the SETSYS MIGRATEPSMEARLY command:

YES

One is added to the age check, up until midnight.

NO

The actual data set age is always used.

Alias: MPE

The default is NO.

MIGRATIONSUBTASKS: Enabling multiple migration subtasks

Explanation: **MIGRATIONSUBTASKS(NO | YES ADDITIONALSUBTASKS(nn))** is an optional parameter that allows DFSMSHsm to run multiple subtasks concurrently. Each subtask manages the migration for a single data set, and these run under migration tasks for primary space management, on-demand migration, and interval migration on level 0 volumes that migrate data sets to ML1 or ML2 volumes. Note that, when MIGRATIONSUBTASKS(YES) is specified, this will apply to *all* migration tasks running in DFSMSHsm.

The ADDITIONALSUBTASKS(nn) subparameter allows you to dynamically change the number of additional subtasks that the system can use, running under each migration task. These additional subtasks add to the number of subtasks that the system already uses when the MIGRATIONSUBTASKS parameter is specified. Note that the actual number of total subtasks used can vary. In general, the total migration subtasks used will be lower if a large value is specified with the maximum migration tasks (MAXMIGRATIONTASKS) parameter. Conversely, the total migration subtasks used will be higher, up to 15, if a smaller value is specified with the maximum migration tasks (MAXMIGRATIONTASKS) parameter.

Enablement occurs at DFSMSHsm startup, with SETSYS MIGRATIONSUBTASKS(YES) specified (or defaulted to YES if SETSYS MIGRATIONSUBTASKS is specified without the YES/NO keyword). Disablement occurs at DFSMSHsm startup with SETSYS MIGRATIONSUBTASKS(NO) specified, or if the command is not specified at all. Additional subtasks can be added or removed dynamically with the ADDITIONALSUBTASKS(nn) subparameter, with no DFSMSHsm startup necessary.

You may find that adding additional subtasks is advantageous, based on different possible factors in your system environment. If tape units limit the maximum number of migration tasks, for instance, then you may find that specifying additional migration subtasks increases the amount of concurrency. As another example, you may find that if many data sets being migrated are small, then additional migration subtasks will provide a improvement in overall throughput.

You must weigh such gains, however, against the possibility that specifying additional subtasks may increase the amount of below the line storage used by DFSMSHsm.

Note that when specifying MIGRATIONSUBTASKS(YES), USERDATASETSERIALIZATION must also be specified. Specifically, SETSYS USERDATASETSERIALIZATION must be specified in the ARCCMDxx parmlib member, prior to the SETSYS MIGRATIONSUBTASKS(YES) command.

Note, also, that when MIGRATIONSUBTASKS(YES) is specified, concurrent cell pool activity may increase in cell pool 5. It is therefore recommended to review the value specified by the CELLS parameter in the DFHSM startup procedure for CELL POOL 5. See "Specifying the size of cell pools" and "Adjusting the size of cell pools" in the *z/OS DFSMSHsm Implementation and Customization Guide* for more information.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is to not use migration subtasks. When MIGRATIONSUBTASKS is specified without the YES or NO keyword, the default is YES. When the ADDITIONALSUBTASKS option is not specified, DFSMSHsm will not use any additional subtasks.

MIGUNITNAME: Specifying the type of unit for allocating a scratch tape during migration

Explanation: **MIGUNITNAME(unitname)** is an optional parameter identifying the type of unit that should be specified the first time DFSMSHsm requests to allocate a scratch tape during migration. You can request several unit names for allocating the scratch tape. For *unitname* specify either 3480, 3480X, 3490, 3590-1, or an esoteric name which you specify in the USERUNITTABLE parameter of the SETSYS

command. If an esoteric tape unit name is used, the SETSYS USERUNITTABLE command must be issued prior to the SETSYS MIGUNITNAME command.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is 3590-1.

Note:

1. You cannot specify an esoteric unit name that represents DASD; it must represent tape.
2. DFSMSHsm does not use MIGUNITNAME when it requests that a scratch volume be allocated while continuing from another volume. Instead, DFSMSHsm uses the same unit the volume was allocated on.
3. If you specify MIGDENSITY and MIGUNITNAME, the density must match the density capabilities for that type of unit. If you specify MIGUNITNAME and do not specify MIGDENSITY, DFSMSHsm uses the highest density for the specified unit.
4. If you specify an esoteric unit name with the MIGUNITNAME parameter, you must also have identified the esoteric unit name to DFSMSHsm with the USERUNITTABLE parameter.
5. You can specify the USERUNITTABLE parameter when you specify the MIGUNITNAME parameter or you could have specified USERUNITTABLE with a previous SETSYS command during this startup.

ML1OVERFLOW: Manage ML1 OVERFLOW volumes

Explanation: **ML1OVERFLOW** is an optional parameter specifying:

- Minimum data set size for ML1 OVERFLOW volume preference
- Threshold for ML1 OVERFLOW volume capacity for automatic secondary space management migration from ML1 OVERFLOW to ML2 volumes

ML1OVERFLOW has the following subparameters:

Subparameter	Explanation
DATASSETSIZE(<i>dssize</i>)	<p>Specifies the minimum size, in K bytes, of the data set for which an ML1 OVERFLOW volume is preferred for migration or backup. This includes invoking inline backup, the HBACKDS or BACKDS commands, or the ARCHBACK macro.</p> <p>SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.</p> <p>SETSYS default: 2000000 K bytes.</p> <p>DFSMSHsm default: If you do not specify this parameter on any SETSYS command, DFSMSHsm will use the value of 2000000 K bytes.</p> <p>If the calculated size of a data set being backed up or migrated is equal to or greater than <i>dssize</i>, DFSMSHsm prefers the OVERFLOW ML1 volume with the least amount of free space that still has enough remaining space for the data set.</p> <p>If the calculated size of the data set is less than the minimum size specified in <i>dssize</i>, DFSMSHsm prefers the NOOVERFLOW ML1 volume with the maximum amount of free space and least number of users.</p>

Subparameter	Explanation
THRESHOLD(<i>threshold</i>)	<p>Specifies the percent of occupied space in the ML1 OVERFLOW volume before migration of data sets to ML2 volumes during automatic secondary space management. DFSMSHsm calculates the percentage of occupied space for each ML1 OVERFLOW volume and then compares the average value with the specified threshold. If the average of the ML1 OVERFLOW volume pool has an occupancy that is equal to or greater than the threshold, then secondary space management is started and moves data from ML1 to ML2.</p> <p>SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.</p> <p>SETSYS default: 80%.</p> <p>DFSMSHsm default: If you do not specify this parameter on any SETSYS command, DFSMSHsm will use the value of 80%.</p>

ML2PARTIALSNOTASSOCIATEDGOAL: Specifying the maximum number of allowed partial ML2 tapes

Explanation: **ML2PARTIALSNOTASSOCIATEDGOAL(*nnn* | NOLIMIT)** is an optional parameter specifying the maximum number of partial ML2 tapes not associated with any migration or recycle task to remain after the generic RECYCLE command is invoked to recycle ML2 tape volumes. A partial tape is one that is not full and not empty. For *nnn*, substitute a decimal number from 0 to 999.

If the number of unassociated ML2 partial tapes is less than or equal to *nnn* when recycle is invoked, no partial tapes are recycled. To recycle all unassociated ML2 partial tapes, use the value of zero (0) for *nnn*. To prevent recycling of all ML2 partial tapes, specify the NOLIMIT subparameter.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, DFSMSHsm will use the value of 10.

Note:

1. This parameter is effective only during recycle processing
2. The allowed number of partial tape volumes applies to your complex of hosts which share the MCDS and OCDS and which define those volumes to DFSMSHsm.

ML2RECYCLEPERCENT: Specifying the maximum percentage of valid data on a migration tape

Explanation: **ML2RECYCLEPERCENT(*pct*)** is an optional parameter specifying the percent-valid criterion DFSMSHsm uses to recycle tape migration level 2 volumes, if you do not specify the PERCENTVALID parameter of the RECYCLE command. For *pct*, substitute a decimal number from 0 to 100. When DFSMSHsm invalidates a data set entry for a full volume and the percentage of valid data on the migration level 2 tape volume becomes less than or equal to *pct*, DFSMSHsm writes the informational message, ARC0365I, in the command activity log.

For a discussion of how DFSMSHsm calculates percentages based on valid blocks, refer to [“Consolidating valid data on tape volumes”](#) on page 537.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, DFSMSHsm will use the value specified with the SETSYS RECYCLEPERCENT parameter.

Note: DFSMSHsm ignores the ML2RECYCLEPERCENT parameter of this command and the PERCENTVALID parameter of the RECYCLE command when you use the RECYCLE command to recycle specific tape migration level 2 volumes.

MONITOR: Specifying which informational messages to print at the system console

Explanation: **MONITOR** is an optional parameter that specifies which informational messages DFSMSHsm is to print at the system console, and the values DFSMSHsm is to use for monitoring space in the journal and control data sets.

The subparameters of the MONITOR parameter are listed in alphabetical order and can be found at the following locations:

Subparameter	See
BACKUPCONTROLDATASET	“MONITOR (BACKUPCONTROLDATASET): Monitoring the space used in the BCDS” on page 1163
JOURNAL	“MONITOR (JOURNAL): Monitoring the space used in the journal data set” on page 1163
MIGRATIONCONTROLDATASET	“MONITOR (MIGRATIONCONTROLDATASET): Monitoring the space used in the MCDS” on page 1163
OFFLINECONTROLDATASET	“MONITOR (OFFLINECONTROLDATASET): Monitoring the space used in the OCDS” on page 1164
SPACE	“MONITOR (SPACE and NOSPACE): Printing volume space-use messages” on page 1164
STARTUP	“MONITOR (STARTUP and NOSTARTUP): Printing DFSMSHsm startup informational messages” on page 1164
VOLUME	“MONITOR (VOLUME and NOVOLUME): Print data set messages during volume processing” on page 1165

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is 80%. No messages are printed to the console about space used during volume processing. No messages are printed to the console from DFSMSHsm commands read from the ARCCMDxx parmlib member during DFSMSHsm initialization.

Note: If you specify MONITOR, the specified level of activity logging controls which messages are written to the system console. For example, if you specify ACTLOGMSGLVL(EXCEPTIONONLY), DFSMSHsm does not write the successful execution messages to the system console.

MONITOR (BACKUPCONTROLDATASET): Monitoring the space used in the BCDS

Explanation: **BACKUPCONTROLDATASET(thresh)** is an optional subparameter of the MONITOR parameter that specifies when DFSMSHsm issues warning messages about the amount of space used in the BCDS.

For *thresh*, substitute a decimal number from 0 to 100 that specifies a percentage value. When the occupied space in the BCDS exceeds this percentage value, DFSMSHsm warns the system operator that the data set is getting full.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify a threshold on any SETSYS command, the DFSMSHsm default is 80%.

MONITOR (JOURNAL): Monitoring the space used in the journal data set

Explanation: **JOURNAL(thresh)** is an optional subparameter of the MONITOR parameter that specifies when DFSMSHsm issues warning messages about the amount of space used in the journal data set.

For *thresh*, substitute a decimal number from 0 to 100 that specifies a percentage value. When the occupied space in the journal data set exceeds this percentage value, DFSMSHsm warns the system operator that the data set is getting full.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this subparameter on any SETSYS command, the DFSMSHsm default is 80%.

Note:

When defined as a large format data set, the DFSMSHsm journal can exceed 65,535 tracks per volume. For information about defining the DFSMSHsm journal, see [z/OS DFSMSHsm Implementation and Customization Guide](#).

MONITOR (MIGRATIONCONTROLDATASET): Monitoring the space used in the MCDS

Explanation: **MIGRATIONCONTROLDATASET(thresh)** is an optional subparameter of the MONITOR parameter that specifies when DFSMSHsm issues warning messages about the amount of space used in the MCDS.

For *thresh*, substitute a decimal number from 0 to 100 that specifies a percentage value. When the occupied space in the MCDS exceeds this percentage value, DFSMSHsm warns the system operator that the data set is getting full.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify a threshold on any SETSYS command, the DFSMSHsm default is 80%.

MONITOR (OFFLINECONTROLDATASET): Monitoring the space used in the OCDS

Explanation: **OFFLINECONTROLDATASET(thresh)** is an optional subparameter of the MONITOR parameter that specifies when DFSMSHsm issues warning messages about the amount of space used in the OCDS.

For *thresh*, substitute a decimal number from 0 to 100 that specifies a percentage value. When the occupied space in the OCDS exceeds this percentage value, DFSMSHsm warns the system operator that the data set is getting full.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify a threshold on any SETSYS command, the DFSMSHsm default is 80%.

MONITOR (SPACE and NOSPACE): Printing volume space-use messages

Explanation

SPACE and NOSPACE are mutually exclusive, optional parameters of the MONITOR parameter that specify whether to print volume space-use messages when DFSMSHsm performs a space check for interval migration, on-demand migration, or primary space management. The three messages printed are: ARC0400I, ARC0401I, and ARC0402I.

SPACE

Volume space-use messages are printed to the system console, the DFSMSHsm log, and the appropriate activity log.

NOSPACE

Volume space-use messages printed to the DFSMSHsm log and the appropriate activity log only.

SMS relationship

The SPACE and NOSPACE parameters have the same meaning when applied to SMS-managed or non-SMS-managed volumes or data sets.

SETSYS default

None.

DFSMSHsm default

If you do not specify the SPACE or NOSPACE parameter on any SETSYS MONITOR command, the DFSMSHsm default is NOSPACE.

MONITOR (STARTUP and NOSTARTUP): Printing DFSMSHsm startup informational messages

Explanation: **STARTUP | NOSTARTUP** are mutually exclusive, optional subparameters of the MONITOR parameter that specify whether or not to print DFSMSHsm startup informational messages at the system console. The messages result from DFSMSHsm commands that are read from the PARMLIB member during DFSMSHsm initialization. You could also specify the STARTUP option on the EXEC PARM options of the DFSMSHsm startup procedure to direct the startup informational messages to the system console.

Subparameters	Explanation
STARTUP	MONITOR(STARTUP) specifies that DFSMSHsm startup informational messages print at the system console and in the DFSMSHsm log.
NOSTARTUP	MONITOR(NOSTARTUP) specifies that DFSMSHsm startup informational messages print only in the DFSMSHsm log, with the exception of messages from the PATCH command, which is printed at the system console.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either subparameter on any SETSYS command, the DFSMSHsm default is NOSTARTUP.

MONITOR (VOLUME and NOVOLUME): Print data set messages during volume processing

Explanation: **VOLUME** | **NOVOLUME** are mutually exclusive, optional subparameters of the MONITOR parameter that specify whether or not to print data set (ARC0734I) messages at the system console.

Subparameter	Explanation
VOLUME	MONITOR(VOLUME) specifies that messages print at the system console, DFSMSHsm log, and appropriate activity log. DFSMSHsm prints messages about data sets on volumes processed by space management, backup, and recovery.
NOVOLUME	MONITOR(NOVOLUME) specifies that messages relating to the data sets on the volumes processed by space management, backup, and recovery print only in the DFSMSHsm log and the appropriate activity log.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either subparameter on any SETSYS command, the DFSMSHsm default is NOVOLUME.

MOUNTWAITTIME: Specifying the time DFSMSHsm waits for a tape mount and open

Explanation: **MOUNTWAITTIME(*minutes*)** is an optional parameter specifying the time, in minutes, that DFSMSHsm waits for the tape volume to be mounted and opened. For *minutes*, substitute a decimal number from 1 to 120 to represent how long DFSMSHsm waits for a tape to be mounted and opened. If the first time period expires, DFSMSHsm sends message ARC0310A to the operator asking whether to mount the tape volume. If the operator answers Y to message ARC0310A, DFSMSHsm resets the timer to *minutes*. If the input volume has not been mounted and opened when the second time period expires, DFSMSHsm automatically ends the task. If the output volume has not been mounted and opened when the second time period expires, DFSMSHsm marks this volume as unavailable and selects another tape volume.

If you have not mounted an output tape dump volume when the second time period expires, DFSMSHsm automatically ends the dump task.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is 15 minutes.

Note:

1. This parameter does not apply to tape mounts performed during aggregate backup and recovery processing.
2. DFSMSHsm sets a mount wait timer for both manual and automatic tape libraries. Appropriate consideration should be given based on which kind of mount DFSMSHsm will be involved with. Unique considerations may exist when using a virtual tape system (VTS).

OBJECTNAMES: Specifying the compaction-control qualifier of the object data set

Explanation: **OBJECTNAMES**(*name1,name2,...*) is an optional parameter specifying the compaction-control qualifier of all data sets that should be compacted with the compaction table for object data sets. For generation data group data sets, this compaction-control qualifier is the next-to-the-last qualifier of the data set name. For all other data sets, this compaction-control qualifier is the last qualifier of the data set name.

For *name1,name2,...*, specify the compaction-control qualifiers of the data set names of those data sets you want to compact with the compaction table for data sets that contain object code. For example, you could specify LINKLIB as a compaction-control qualifier.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is that the general compaction table is used to compact the object data sets.

ONDEMANDMIGRATION: Specifying whether on-demand migration should be performed

Explanation: **ONDEMANDMIGRATION** is an optional parameter specifying whether on-demand migration should be performed on SMS-managed volumes that have exceeded the high threshold and that belong to a storage group defined using AM=Y (Auto Migrate, yes). This parameter can be abbreviated as ODM.

The following parameters are optional parameters of the ONDEMANDMIGRATION parameter:

N

(no) On-demand migration is not performed.

Y

(yes) On-demand migration is performed on eligible SMS-managed volumes.

For more information about on-demand migration, see [“Using on-demand migration” on page 27](#).

SMS relationship: The ONDEMANDMIGRATION parameter applies to SMS-managed volumes only. It is ignored for non-SMS-managed volumes. For non-SMS managed volumes, interval migration is performed instead (if enabled).

SETSYS default: If you specify the ONDEMANDMIGRATION parameter without N (no) or Y (yes), then the SETSYS default for this parameter is N (on-demand migration is not performed).

DFSMSHsm default: If you do not specify ONDEMANDMIGRATION on the SETSYS command during startup, the default is to perform interval migration.

Notes:

1. On-demand migration is performed on a volume when an SMS ENF72 signal is received (indicating the volume has exceeded the high threshold).
2. If you want to perform on-demand migration on TMM storage groups, you must convert AM=I (Auto Migrate, interval) TMM storage groups to AM=Y.
3. On-demand migration is paused when interval migration or primary space management are started on the same DFSMSHsm host performing on-demand migration. On-demand migration will start again after interval migration or primary space management has ended, if there are eligible volumes to be processed.

ODMNOTIFICATIONLIMIT: Specifying an on-demand migration number of concurrently queued volumes notification limit

Explanation: **ODMNOTIFICATIONLIMIT** is an optional parameter specifying a limit before notification of the number of volumes concurrently queued for on-demand migration is issued. When the notification limit is exceeded, highlighted message ARC1901E is issued to the operator's console. When the number of volumes eligible for on-demand migration falls below the notification limit, the message is removed from the operator's console.

The following parameter is an optional parameter of the ODMNOTIFICATIONLIMIT parameter:

limit

Number of volumes (1 to 99999) that must be concurrently queued for on-demand migration before notification is issued.

SMS relationship: The ODMNOTIFICATIONLIMIT parameter applies to SMS-managed volumes being processed by on-demand migration only.

SETSYS default: None.

DFSMSHsm default: If you do not specify ODMNOTIFICATIONLIMIT on the SETSYS command during startup, the default limit is 100.

OPTIMUMDASDBLOCKING and NOOPTIMUMDASDBLOCKING: Specifying whether DFSMSHsm should use its defined optimum block size

Explanation: **OPTIMUMDASDBLOCKING** | **NOOPTIMUMDASDBLOCKING** are mutually exclusive, optional parameters indicating whether DFSMSHsm should use its defined optimum block size when outputting or recovering to DFSMSHsm-owned DASD. Optimum blocking refers to DFSMSHsm writing its output or input in blocks that are multiples of 2 KB and is determined by the device's track size for data being written to DFSMSHsm-owned DASD. For example, all models of 3390 DASD have the same track length and an optimum block size of 18 KB (1 KB equals 1024 bytes). This permits better use of space on DFSMSHsm-owned DASD devices.

OPTIMUMDASDBLOCKING indicates to DFSMSHsm to use its defined optimum block size when writing to DFSMSHsm-owned DASD.

NOOPTIMUMDASDBLOCKING indicates to DFSMSHsm to not use its defined optimum block size when writing to DFSMSHsm-owned DASD. DFSMSHsm writes to DFSMSHsm-owned DASD in 2 KB blocks.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify the NOOPTIMUMDASDBLOCKING parameter on any SETSYS command, DFSMSHsm uses its defined optimum block size when writing to DFSMSHsm-owned DASD as the default.

Note:

1. OPTIMUMDASDBLOCKING does not pertain to small-data-set-packing data sets, dump VTOC copy data sets, or backup VTOC copy data sets.
2. You can change this parameter while DFSMSHsm is running. The change takes effect when the next data set destined for DFSMSHsm-owned DASD is opened for output.

OUTPUTTAPEALLOCATION: Specifying if to wait for output tape to be allocated

Explanation: **OUTPUTTAPEALLOCATION (WAIT | NOWAIT)** is an optional parameter specifying whether DFSMSHsm should wait until the tape unit is allocated for the output tape for migration or backup.

Subparameter	Explanation
WAIT	<p>DFSMSHsm waits until the output tape unit is allocated. Any DFSMSHsm function requiring dynamic allocation services will be unable to proceed until this tape unit is allocated.</p> <p>When using the WAIT option, caution must be exercised to limit the number of DFSMSHsm tasks that require tape. If more tasks run than there are available tape devices, a deadlock condition occurs because of the exclusive enqueue that MVS allocation puts on the task input/output table (SYSZTIOT) while awaiting the tape device. This condition can be resolved only if another job (not DFSMSHsm) releases a tape device, or if you cancel DFSMSHsm.</p>
NOWAIT	<p>DFSMSHsm does not wait until the output tape unit is allocated. Instead, DFSMSHsm reissues the request every 10 seconds up to six times. If the output tape unit still is not allocated after seven tries, DFSMSHsm asks the operator whether DFSMSHsm should cancel the request or repeat the allocation sequence. With the NOWAIT option, dynamic allocation issues message IEF238D. Once answered, other DFSMSHsm tasks can proceed with allocations.</p>

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either subparameter on any SETSYS command, the DFSMSHsm default is NOWAIT.

PARTIALTAPE: Specifying whether to reuse partially full tapes

Explanation: **PARTIALTAPE** is an optional parameter specifying that you want DFSMSHsm to mark a cartridge-type single-file formatted tape volume full when the volume has been demounted.

MARKFULL and REUSE are mutually exclusive parameters of the PARTIALTAPE parameter. One of these parameters must be specified if the PARTIALTAPE parameter is specified. If not, an error message is issued.

Subparameter	Explanation
MARKFULL	<p>DFSMSHsm automatically marks a single-file-formatted tape volume full (except after data set migration or data set backup) independent of the block count when it demounts the tape. These volumes can be marked as full even though the volume is only partially used. DFSMSHsm excludes data set migration or backup to avoid marking a tape volume full after a command migration or after a command backup of a single data set to migration level 2.</p> <p>When running in a PARTIALTAPE(MARKFULL) environment, a generic TAPECOPY command will select, copy, and mark full nonduplexed original tapes that are <i>not</i> marked as full, even if an alternate tape volume serial number is already recorded in the DFSMSHsm inventory (TTOC record). In this case the older alternate is removed from DFSMSHsm's inventory but <i>not</i> explicitly communicated to tape management products as with the ARCTVEXT exit method. DFSMSHsm creates the new alternate because the partial original may have been extended after the old alternate was created by an explicit TAPECOPY. The older alternate is not communicated to tape management products so that the customer can retain alternates in addition to the one DFSMSHsm maintains. DFSMSHsm issues an ARC0436I message to the console and identifies the old alternate, the original, and the new alternate. Customers can update their tape management product if they do not want to retain the old alternates.</p>
REUSE	<p>DFSMSHsm uses the normal process of marking a single-file formatted tape full only when the percent full (specified with the SETSYS TAPEUTILIZATION parameter) is reached.</p>

If you specify the global PARTIALTAPE(MARKFULL | REUSE) parameter, the parameter applies to both migration and backup. If you specify a specific function, the parameter applies only to that function. If you specify a global value and a specific function in a single command, the command will fail.

The PARTIALTAPE(MIGRATION(...)) parameter applies to tape volume migration only. The PARTIALTAPE(BACKUP(...)) parameter applies to tape volume backup only.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: The default is REUSE, meaning that DFSMSHsm marks the tape volume full only when the volume reaches the maximum block count specified with the SETSYS TAPEUTILIZATION parameter.

Note: If you are using a VTS subsystem for migration or backup output, the MARKFULL parameter can improve performance by reducing the need to remount yesterday's partial volume in order to extend it today. Additionally, this usage can somewhat reduce the reclamation process of the VTS subsystem because the physical tape containing the initial partial tape, that was extended, was not invalidated on a true tape.

PDA: Specifying whether the problem determination aid is initiated

Explanation: PDA(NONE | ON | OFF) is an optional subparameter that specifies whether the problem determination aid (PDA) is enabled. The PDA facility gathers diagnostic information and records the information in a storage buffer and in DASD data sets.

You can specify PDA tracing in the DFSMSHsm startup procedure. Specifying the PDA=YES parameter allows the PDA facility to collect trace data prior to the processing of the SETSYS PDA(ON) command.

Subparameter	Explanation
NONE	The PDA facility does not start at DFSMSHsm startup. No space for the storage buffer is requested, and the trace output data sets are not opened. Note: This keyword is effective only at DFSMSHsm startup. If issued after DFSMSHsm startup, NONE has the same results as issuing the OFF keyword.
ON	Storage is requested for the trace buffer and the trace output data sets open. If the trace data sets are not allocated, the problem determination aid function continues to trace in internal storage.
OFF	The trace facilities are suspended but the primary module is left active. The trace buffer storage area remains allocated and the output data sets remain open, but the bit to allow tracing is turned off.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: If you do not specify either the ON or OFF keyword, the default is ON.

DFSMSHsm default: If you do not specify either the ON or OFF keywords, the default is ON.

PLEXNAME: Specifying a name for an HSMplex

Explanation: **PLEXNAME(hsmplex_suffix)** is an optional parameter that allows you to name multiple HSMplexes within a sysplex. This parameter is used during startup of DFSMSHsm and must be specified in an ARCCMDxx member. This parameter must be specified if there are multiple HSMplexes in a sysplex because this HSMplex name is used to distinguish between the separate HSMplexes.

The prefix of ARC is used by DFSMSHsm and you can specify a maximum of five characters as the suffix for the HSMplex name. The default suffix used by DFSMSHsm is PLEX0.

Note:

1. If an HSMplex name other than the default is specified on one host in an HSMplex, then that name must be specified on all other DFSMSHsm hosts in the HSMplex.
2. If data is to be transferred to cloud storage, the HSMplex name should contain only characters from the alphabetic, numeric, and national character sets (A-Z, a-z, 0-9, and #, \$, and @).
3. If utilizing the cloud storage, it is recommended to specify this parameter with an HSMplex name other than the default to ensure the cloud containers created are isolated from visibility to other HSMplexes in your environment that utilize the same cloud. When a cloud container is created, DFSMSHsm uses the HSMplex name as the 2nd qualifier for the cloud container name.
4. If the HSMplex name is changed, the next migration or dump to cloud that occurs will cause a new container to be created utilizing the new HSMplex name as its 2nd qualifier. After the HSMplex name is changed, the LIST CLOUD(cloud_network_connection_name), AUDIT MEDIACONTROLS(CLOUD(cloud_network_connection_name)) and empty container deletion functions will only utilize the current HSMplex name during their processing. These functions do not have visibility to containers created using an HSMplex name other than the current HSMplex name.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: By default, SETSYS uses PLEXNAME(PLEX0), which causes DFSMSHsm to use an HSMplex name of ARCPLEX0.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the default HSMplex name is ARCPLEX0.

PRIMARYSPMGMTSTART: Specifying the start and stop times for automatic primary space management

Explanation: PRIMARYSPMGMTSTART (*hhmm1* *hhmm2*) is an optional parameter specifying the times when automatic primary space management should start. Use this parameter instead of AUTOMIGRATIONSTART to set the start and stop times for automatic primary space management.

Using PRIMARYSPMGMTSTART(*hhmm1* *hhmm2*), you can specify a planned start time and a planned end time. If DFSMSHsm does not start automatic primary space management between the start and stop times, automatic primary space management is not performed for that day.

For *hhmm1*, substitute the planned start time for automatic primary space management. If you specify *hhmm1* as zero, DFSMSHsm does not start automatic primary space management.

For *hhmm2*, substitute the planned stop time when DFSMSHsm no longer starts automatic primary space management on a new volume. If *hhmm2* is set to zero, this is the same as not including the *hhmm2* parameter.

The *hhmm* format expresses time as a four-digit decimal number that is based on the 24-hour clock. *hh* specifies the hour and *mm* specifies the minutes. For example, you can specify 1:15 p.m. as 1315, and you can specify midnight as 2400. The maximum value you can specify for *hh* is 24, the maximum value you can specify for *mm* is 59, and the maximum value you can specify for *hhmm* is 2400.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: If only one time is specified in PRIMARYSPMGMTSTART, DFSMSHsm starts the automatic primary space management functions between the time specified and midnight. Automatic primary space management runs until completion.

DFSMSHsm default: If PRIMARYSPMGMTSTART is not specified, the default is no automatic primary space management (unless AUTOMIGRATIONSTART was specified).

Note:

1. If you do not specify a nonzero value for *hhmm1* during start up of DFSMSHsm, DFSMSHsm does not perform automatic primary space management.
2. The type of automatic primary space management DFSMSHsm does on a particular volume (data set deletion, data set retirement, or migration) depends on the parameter you have specified with the ADDVOL command.
3. If you want the operator to decide whether to start automatic primary space management, specify the REQUEST parameter with the PRIMARYSPMGMTSTART parameter.
4. As with automatic backup, DFSMSHsm serializes access to data sets and volumes for a short period of time. Therefore, select a time for automatic primary space management when the computing system is not very active and there is not much interactive user activity (usually at night).
5. Automatic primary space management usually starts at the planned start time. Assume, however, that DFSMSHsm is not running at the planned start time or the operating system is lost while automatic primary space management is running. When DFSMSHsm restarts, it checks the start (*hhmm1*) and stop (*hhmm2*) times. These start and stop times form a window. If DFSMSHsm restarts during the window, DFSMSHsm also restarts automatic primary space management.
6. PRIMARYSPMGMTSTART fails if *hhmm1* and *hhmm2* are equal.
7. In a test environment, DFSMSHsm can run automatic primary space management multiple times a day. However, this procedure requires certain DFSMSHsm supported patches. Refer to the [z/OS DFSMSHsm Implementation and Customization Guide](#) for more information about running primary space management multiple times a day. If automatic primary space management runs to completion and you want to start automatic primary space management again, use the following procedure:
 - Issue the SETSYS PRIMARYSPMGMTSTART command to define a new start window.
 - Specify a start window that has a planned start time (*hhmm1*) that is after the time that automatic primary space management last ended.

Automatic primary space management starts immediately if the current time is between the start and stop times you specified. If the current time is not between the start and stop times you specified, automatic primary space management starts automatically when the planned start time is reached.

8. If PRIMARYSPMGMTSTART is issued dynamically with a zero value for *hhmm1* to convert to no longer running the function and automatic primary space management is currently running, it runs to completion with the originally established planned stop time. This is true regardless of the *hhmm2* value specified in the newly issued command. DFSMSHsm does not start automatic primary space management again unless another command is issued establishing a new start time. A QUERY SETSYS will show zero for the planned start time and the originally established stop time.

PROFILEBACKUP and NOPROFILEBACKUP: Specifying whether to create backup RACF discrete profiles for cataloged data sets

Explanation: **PROFILEBACKUP** | **NOPROFILEBACKUP** are mutually exclusive, optional parameters that you use to specify whether DFSMSHsm creates a backup RACF discrete profile for all cataloged RACF-indicated data sets during backup.

PROFILEBACKUP specifies that DFSMSHsm creates a backup RACF discrete profile for the cataloged RACF-indicated data set when it backs up the data set. This backup profile applies to all backup versions of the cataloged RACF-indicated data set.

NOPROFILEBACKUP specifies that DFSMSHsm does not create a backup RACF discrete profile when it backs up a cataloged RACF-indicated data set.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either parameter on any SETSYS command, the default is **PROFILEBACKUP**.

Note:

1. If a RACF naming conversion table (NCT) is used, the recover function is not able to re-establish the discrete profile protection.
2. Failure to use **PROFILEBACKUP** allows unauthorized users to have access to data sets. Refer to [Chapter 18, “RACF considerations,” on page 617](#) for more information about backing up RACF discrete profiles for cataloged data sets.

PROMOTE: Specifying whether a host is eligible for promotion

Explanation: **PROMOTE** is an optional parameter that allows users to specify which host in an HSMplex may be promoted and which should not be. Currently, one host in an HSMplex is designated as the Primary host and all other hosts are considered secondary. You should specify the **PROMOTE** parameter on only those hosts that are actually eligible for promotion.

Subparameter	Explanation
PRIMARYHOST (YES NO)	Allows you to designate if a host is eligible to take over the unique functions from a failed primary host. PRIMARYHOST(YES) specifies that this specific host in an HSMplex is eligible to take over the unique functions from a failed primary host. If PRIMARYHOST(YES) is issued from a primary host, it is ignored. PRIMARYHOST(NO) specifies that this specific host in an HSMplex is disabled from being eligible for promotion. For example, this can be done if a host is assigned specific work that would conflict with promotion or the host resides on a slow z/OS image.

Subparameter	Explanation
SSM(YES NO)	Allows you to designate a host's eligibility to take over Secondary Space Management (SSM) functions from a failed host. Secondary Space Management generally runs on a single host. This can be the primary host or a specific secondary host. SSM hosts are not eligible for promotion for other SSM hosts because each SSM host may have different or identical SSM windows and cycles defined. SSM(YES) specifies that this specific non-SSM host in an HSMplex is eligible to take over Secondary Space Management functions from a failed host. If SSM(YES) is issued from a SSM host, the message ARC1521I is issued. SSM(NO) specifies that this specific host in an HSMplex is disabled from being eligible for promotion.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, no hosts in an HSMplex are eligible to take over the Primary or Secondary Space Management functions of a failed host.

Note: The SETSYS PROMOTE parameter only makes the host eligible to be promoted for Primary or SSM hosts that become disabled after the command was issued. If you want to make the host take over for a host that is already disabled, you can issue the SETSYS NOEMERGENCY command on this host, which will cause the host to go and look for hosts that are already disabled and in need of being promoted.

RACFIND and NORACFIND: Specifying whether to put RACF-indication on migration copies and backup versions

Explanation: **RACFIND** | **NORACFIND** are mutually exclusive, optional parameters that you use to specify whether DFSMSHsm puts RACF-indication on all migration copies and backup versions.

RACFIND specifies that DFSMSHsm puts RACF-indication on migration copies and backup versions.

NORACFIND specifies that migration copies and backup versions are not RACF-indicated, including those data sets that are password-protected. Specify this parameter only if generic profile checking is activated and generic profiles are defined for migration and backup qualifiers in all DFSMSHsm hosts.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either parameter on any SETSYS command, the DFSMSHsm default is **RACFIND**.

RECALL: Specifying the target volume to receive recalled data sets

Explanation: **RECALL** is an optional parameter specifying where DFSMSHsm puts the non-SMS-managed recalled data sets.

Subparameter	Explanation
ANYSTORAGEVOLUME	DFSMSHsm recalls a data set to an online primary volume with the use attribute of storage and the primary volume attribute of automatic recall. You specify the primary volume attribute with the ADDVOL command.

Subparameter	Explanation
PRIVATEVOLUME	DFSMSHsm recalls a data set to any online primary volume with the use attribute of public, storage, or private and the primary volume attribute of automatic recall. You specify the primary volume attribute with the ADDVOL command.

LIKE | UNLIKE are mutually exclusive, optional subparameters of the ANYSTORAGEVOLUME or PRIVATEVOLUME subparameters.

Subparameter	Explanation
LIKE	During undirected recall, only primary volumes whose primary volume attributes match the attributes of the primary volume that the data set migrated from are considered as possible target volumes for the recall.
UNLIKE	During undirected recall, volumes whose currently specified primary volume attributes do not match those of the source primary volume are eligible for selection. DFSMSHsm selects the volume for recall from one of three groups of volumes. The following are groups of volumes and how they are ordered: <ul style="list-style-type: none"> • Volumes with like recall attributes • Volumes with unlike recall attributes in automatic backup and backup device category • Volumes with unlike recall attributes in automatic migration

The volumes in each group are ordered according to most-available free space. For more information on defining pools of volumes, refer to [“Defining pools of volumes”](#) on page 105.

SMS relationship: Parameter does not apply to SMS-managed DASD volumes or data sets.

SETSYS default: If you specify RECALL without a subparameter, the SETSYS default is ANYSTORAGEVOLUME. If you do not specify the LIKE or UNLIKE subparameter with the ANYSTORAGEVOLUME or PRIVATEVOLUME subparameter, the SETSYS default is LIKE.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default for data sets is RECALL(ANYSSTORAGEVOLUME).

Note:

1. The LIKE/UNLIKE subparameter does not apply if a data set is SMS-managed when migrated and later is recalled as a non-SMS-managed data set.
2. For BDAM data sets, DFSMSHsm selects only devices that are the same device type as the one the data sets migrated from. The DAOPTION of the RECALL and RECOVER commands can be used to specify how BDAM data sets can be moved to a target volume using relative track or relative block accessing. In addition, target volumes with track sizes different from the last level 0 volume from which the BDAM data set came can be selected.
3. In a JES3 environment, specify the same subparameter for DFSMSHsm hosts that set up jobs and for DFSMSHsm hosts that run the jobs.

RECYCLEINPUTDEALLOCFREQUENCY: Allowing periodic deallocation of input unit during recycle processing

Explanation: **RECYCLEINPUTDEALLOCFREQUENCY(BACKUP(*bfreq*) MIGRATION(*mfreq*))** is an optional parameter that you use to periodically deallocate an input unit during recycle processing. This dynamically changeable parameter prevents DFSMSHsm from possibly keeping an input unit allocated for hours.

Tape Library Relationship: In a tape environment where contention for tape drives may be a consideration, the following table shows BACKUP(*bfreq*) or MIGRATION(*mfreq*) values that are recommended when you recycle single-file-format cartridges:

Type of Environment	Value	Resulting Allocation
A single IBM 3494/3495 Tape Library Dataserver environment having all compatible drives	0	The input unit is allocated for the duration of recycle processing.
An SMS-managed tape environment that has multiple IBM 3494/3495 machines where inputs can come from different ATLS	0	A unique allocation is allowed for each input connected set.
A BTLS-managed environment that has multiple IBM 3494/3495 machines where inputs can come from different ATLS	1	RECYCLE allocates tape drives for each connected set in the correct library.
A multiple non-SMS-managed tape library where not all backup or migration tapes are in a single library (for example, an STK® ACS cluster where you want to prevent pass-through processing)	1	RECYCLE allocates tape drives for each connected set in the correct library.
An environment that has incompatible tapes even though they may appear the same, including when one has a mix of real and emulated devices, such as 3490s and emulators of 3490s	1	RECYCLE allocates tape drives for each connected set.
A tape environment with manual tape operators, but no incompatible mix of real and emulated devices that appear as the same device	5 or 10	New allocations are allowed every 5 to 10 input connected sets.

Subparameter	Explanation
BACKUP(<i>bfreq</i>)	During recycle processing of backup volumes, deallocation of an input unit will occur after the specified number of input connected sets representing single-file-format cartridges have been processed. For <i>bfreq</i> , substitute a decimal number from 1 to 255 for the number of connected sets to process before deallocation of the input unit. Specifying 0 will retain the input unit until recycle processing has completed.
MIGRATION(<i>mfreq</i>)	During recycle processing of migration volumes, deallocation of an input unit will occur after the specified number of input connected sets representing single-file-format cartridges have been processed. For <i>mfreq</i> , substitute a decimal number from 1 to 255 for the number of connected sets to process before deallocation of the input unit. Specifying 0 will retain the input unit until recycle processing has completed.

Note:

- For example, specifying SETSYS RECYCLEINPUTDEALLOCFREQUENCY(BACKUP(20)) will deallocate the input unit every 20 input backup connected sets. Using SETSYS RECYCLEINPUTDEALLOCFREQUENCY(MIGRATION(1)) will deallocate the input unit after each input migration connected set has been processed.
- The input unit will always be deallocated between connected sets when the tape volume is not a single-file-format cartridge.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter (or either subparameter) on any SETSYS command, the DFSMSHsm default is that recycle processing will keep the input unit allocated until the processing of that type of volume (backup or migration) is complete.

RECYCLEOUTPUT: Limiting the selection and allocation of an output volume during recycle processing

Explanation: **RECYCLEOUTPUT(BACKUP MIGRATION)** is an optional parameter that you use to limit the selection and allocation of an output volume during recycle processing.

Tape Library Relationship: A UNITNAME can be used for filtering in the ACS routines. If you specify the unittype for this command, it will be sent to the ACS routines in SMS for the RECYCLEOUTPUT function.

Subparameter	Explanation
BACKUP(<i>unittype</i>)	During recycle processing of a tape backup volume, only tape spill backup volumes that can be mounted and written on the specified type of unit are used for output. In addition, when the tape spill backup volume is allocated for output during recycle processing, the volume is allocated using the unit name specified with the BACKUP subparameter of the RECYCLEOUTPUT parameter, overriding the unit name specified on the ADDVOL command for the tape spill backup volume.
MIGRATION(<i>unittype</i>)	During recycle processing of a tape level 2 migration volume, only tape level 2 migration volumes that can be mounted and written on the specified type of unit will be used for output. In addition, when the tape level 2 migration volume is allocated for output during recycle processing, the volume is allocated using the unit name specified with the MIGRATION subparameter of the RECYCLEOUTPUT parameter, overriding the unit name specified on the ADDVOL command for the tape level 2 migration volume.

For *unittype*, specify a generic or esoteric unit name. The following generic unit names are acceptable: 3480, 3480X, 3490, and 3590-1. If an esoteric unit name is specified, it must have been previously defined to DFSMSHsm using the USERUNITTABLE parameter of the SETSYS command.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: If *unittype* is not specified with the BACKUP parameter, there is no restriction on the type of tape spill backup volume that can be selected for output during the recycle processing of a tape backup volume. If *unittype* is not specified here and a scratch tape is required, the value specified for SETSYS UNITNAME is used when an output tape is allocated for a backup volume.

If *unittype* is not specified with the MIGRATION parameter, there is no restriction on the type of tape level 2 migration volume that can be selected for output during the recycle processing of a tape level 2 migration volume. If *unittype* is not specified here and a scratch tape is required, the value specified for SETSYS MIGUNITNAME is used when an output tape is allocated for a migration volume.

If the RECYCLEOUTPUT parameter is specified without any subparameters, no changes are made to the current DFSMSHsm values.

DFSMSHsm default: None.

RECYCLEPERCENT: Specifying the maximum percentage of valid data on a backup tape

Explanation: **RECYCLEPERCENT(*pct*)** is an optional parameter specifying the percent-valid criteria DFSMSHsm uses to recycle tape backup volumes if you do not specify the PERCENTVALID parameter of the RECYCLE command. For *pct*, substitute a decimal number from 0 to 100.

When DFSMSHsm invalidates a data set entry for a full backup volume and the percentage of valid data on the tape backup volume becomes less than or equal to *pct*, DFSMSHsm writes the informational message, ARC0365I, in the command activity log. You then use the RECYCLE command to recycle all eligible tape backup volumes.

For a discussion of how DFSMSHsm calculates percentages based on valid blocks, refer to [Chapter 13, “Managing DFSMSHsm media,”](#) on page 527.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is 20%.

Note:

1. DFSMSHsm ignores the RECYCLEPERCENT parameter of this command and the PERCENTVALID parameter of the RECYCLE command when you use the RECYCLE command to recycle specific backup volumes.
2. DFSMSHsm also uses this value for migration level 2 tape volumes when the ML2RECYCLEPERCENT parameter of the SETSYS command has not been specified.

RECYCLETAKEAWAYRETRY: Specifying whether to automatically generate a new RECYCLE command for a tape

Explanation: **RECYCLETAKEAWAYRETRY (NO | YES MAXRETRYATTEMPTS(*nn*) DELAY(*ssss*))** is an optional parameter specifying whether DFSMSHsm should automatically generate a new RECYCLE command for a tape when the original recycle must terminate due to the takeaway process, or when the tape is in use by the another DFSMSHsm task.

Note that each tape volume has its own retry count and can be retried up to *nn* times (12 by default). This count will be reset for this tape only when all data sets from this tape are recycled.

If YES is specified, then the following subparameters can also be specified:

MAXRETRYATTEMPTS(*nn*)

sets the maximum number of recycle retry attempts. The value can be 1-99. The default is 12.

DELAY(*ssss*)

sets the delay interval in seconds between recycle attempts. The value can be 1-9999. The default is 300.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do *not* specify this parameter on any SETSYS command, the DFSMSHsm default is to *not* automatically generate a new RECYCLE command for a tape. When RECYCLETAKEAWAYRETRY is specified without the YES or NO keyword, the default is NO. If either the MAXRETRYATTEMPTS or DELAY subparameters are *not* specified, the defaults are 12 and 300, respectively.

RECYCLETAPEALLOCATION: Specifying if to wait for recycle tape to be allocated

Explanation: **RECYCLETAPEALLOCATION (WAIT | NOWAIT)** is an optional parameter specifying whether DFSMSHsm should wait until the tape unit is allocated for the source and target tape volumes.

Subparameter	Explanation
WAIT	<p>DFSMSHsm waits until the recycle tape unit is allocated. All DFSMSHsm functions requesting allocations stop until this allocation request is satisfied.</p> <p>When using the WAIT option, you must exercise caution to limit the number of DFSMSHsm tasks that require tape. If more tasks run than there are available tape devices, a deadlock condition occurs because of the exclusive enqueue that MVS allocation will put on the task input/output table (SYSZTIOT) while awaiting the tape device. This condition can be resolved only if another job (not DFSMSHsm) releases a tape device, or if you cancel DFSMSHsm.</p>
NOWAIT	<p>DFSMSHsm does not wait until the recycle tape unit is allocated. Instead, DFSMSHsm reissues the request every 10 seconds up to six times. If the recycle tape unit is still not allocated after seven tries, DFSMSHsm asks the operator whether to have DFSMSHsm cancel the request or repeat the allocation sequence. With the NOWAIT option, dynamic allocation issues message IEF238D. Once answered, other DFSMSHsm tasks can proceed with allocations.</p>

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either subparameter on any SETSYS command, the DFSMSHsm default is NOWAIT.

RECYCLETAPERESIDENCE: Specifying which IBM VTS tape volumes should be included in RECYCLE processing

Explanation: **RECYCLETAPERESIDENCE (BOTH | INCACHE | NOTINCACHE)** setting indicates which eligible IBM VTS tape volumes will be included in RECYCLE processing. IBM VTS tape volumes that are eligible for recycle and reside either in cache, not in cache, or both in cache and not in cache as specified via the RECYCLETAPERESIDENCE parameter will be included during RECYCLE processing.

SETSYS default: BOTH

DFSMSHsm default: If the **SELECT(TAPERESIDENCE(BOTH | INCACHE | NOTINCACHE))** parameters are specified on the RECYCLE command, they will take precedence over the SETSYS RECYCLETAPERESIDENCE setting.

REMOVECOMPACTNAMES: Removing the compaction-control qualifier for source or object data sets

Explanation: **REMOVECOMPACTNAMES(name1,name2,...)** is an optional parameter specifying the compaction-control qualifier of all data sets to be removed from the SOURCENAMES or OBJECTNAMES table. For *name1,name2,...*, specify the compaction-control qualifiers of those data sets you no longer want to have compacted by the source or object compaction table.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, there is no DFSMSHsm default.

REQUEST and NOREQUEST: Specifying whether the operator's permission is required

Explanation

REQUEST and NOREQUEST are mutually exclusive, optional parameters specifying whether the operator's permission is required before DFSMSHsm starts any of the following actions:

- automatic primary space management
- automatic secondary space management
- interval migration
- automatic backup
- automatic dump

Note: Operator permission is never required for on-demand migration, even if SETSYS REQUEST is specified.

REQUEST

Operator's permission is required before DFSMSHsm starts any of the actions listed above.

NOREQUEST

Operator's permission is not required before DFSMSHsm starts any of the actions listed above.

SMS relationship

Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default

None.

DFSMSHsm default

If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is NOREQUEST.

SCRATCHFREQUENCY: Specifying how long to retain list data sets

Explanation: **SCRATCHFREQUENCY(days)** is an optional parameter specifying the number of days DFSMSHsm should keep list data sets. For *days*, substitute a decimal number from 0 to 9999 specifying how long DFSMSHsm should keep an unused list data set. If you specify 0, DFSMSHsm scratches list data sets during the next space management of the volume. If the last qualifier in a data set name is .LIST, .OUTLIST, or .LINKLIST, the data set is a list data set. DFSMSHsm scratches list data sets during volume space management after the specified number of days have passed since anyone used the data sets.

SMS relationship: Parameter does not apply to SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is 9999 days.

SECONDARYSPMGMTDIRECTIVE: Specifying Secondary Space Management controls pertaining to Cloud and non-Cloud data

Explanation: **SECONDARYSPMGMTDIRECTIVE** is an optional parameter that is used to direct an instance of DFSMSHsm Secondary Space Management to do either one of the following exclusively:

ALL

Secondary Space Management might process data regardless whether it is in the Cloud or not.

CLOUDONLY

Secondary Space Management might only process data in the Cloud and run Empty Container Deletion.

NOCLOUD

Secondary Space Management might not process any data that resides in the Cloud and might not run Empty Container Deletion. All other tasks that Secondary Space Management might run are permissible to run (for example, ML1/ML2 Data Set Expiration, ML1 -> ML2 migration, statistics cleanup, and so on).

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: ALL.

DFSMSHsm default: If you do not specify this parameter, DFSMSHsm defaults to SECONDARYSPMGMTDIRECTIVE(ALL).

Note: Within a given DFSMSHsm SYSPLEX or MASH environment, multiple instances of Secondary Space Management (SSM) might be running. If two, or more, of these instances overlap in run time with mutually exclusive directives declared (for example, SSMDIR(CLOUDONLY) and SSMDIR(NOCLOUD)), the second instance is blocked from executing. Also, message ARC0552I is received indicating that MIGRATION CLEANUP is not performed on that processing unit. Therefore, it is important to make sure SSM instances with mutually exclusive directives do not overlap in run time. More specifically, it is important to ensure that SSM with the CLOUDONLY directive is started at a different time than another SSM with the ALL or NOCLOUD directives, and vice versa.

SECONDARYSPMGMTSTART: Specifying the start and stop time for automatic secondary space management

Explanation: **SECONDARYSPMGMTSTART(hhmm1 hhmm2)** is an optional parameter you use to specify when automatic secondary space management functions are to start and stop. If DFSMSHsm does not start automatic secondary space management between the specified start and stop times, automatic secondary space management functions are not done for that day.

For *hhmm1*, substitute the planned start time for automatic secondary space management. If you specify it as 0000, secondary space management will not start.

For *hhmm2*, substitute the planned stop time for automatic secondary space management. If *hhmm2* is set to zero, this is the same as not including the *hhmm2* parameter.

Note: Time is based on the 24-hour clock and is expressed as a four-digit decimal number in the format *hhmm*. The hour is represented by *hh* and the minutes by *mm*. For example, 1:15 p.m. is 1315 and midnight is 2400. The maximum value you can specify for *hh* is 24, the maximum value you can specify for *mm* is 59, and the maximum value you can specify for *hhmm* is 2400.

The SETSYS SECONDARYSPMGMTSTART command will fail if the start and stop times are the same.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: If only one time is specified in SECONDARYSPMGMTSTART, DFSMSHsm starts the automatic secondary space management functions between the time specified and midnight. Automatic secondary space management runs until completion.

DFSMSHsm default: If you do not specify this parameter, no automatic secondary space management functions are done. ML1 volumes will eventually run out of space.

Note:

1. Any outstanding MWEs for data set deletion that were built by secondary space management up to the stop time, continue to be processed. After the stop time, secondary space management

generates no new MWEs. When many MWEs are waiting for processing, their processing may continue well after secondary space management itself has stopped processing. However, recalls and user-requested deletes have a higher priority than those deletes that are performed from secondary space management.

2. If SECONDARYSPMGMTSTART is issued dynamically with a zero value for *hhmm1* to convert to no longer running the function and automatic secondary space management is currently running, it runs to completion with the originally established planned stop time. This is true regardless of the *hhmm2* value specified in the newly issued command. DFSMSHsm does not start automatic secondary space management again unless another command is issued establishing a new start time. A QUERY SETSYS will show zero for the planned start time and the originally established stop time.

SELECTVOLUME: Specifying whether DFSMSHsm should select a scratch tape volume or a DFSMSHsm tape volume

Explanation: **SELECTVOLUME** is an optional parameter specifying whether DFSMSHsm chooses a tape volume owned by DFSMSHsm or a scratch tape volume when an end-of-volume (EOV) condition occurs while DFSMSHsm is writing on a tape volume. **SELECTVOLUME(SCRATCH | SPECIFIC)** applies to the initial selection for dump tape volumes as well as to the EOV condition.

If you specify the global **SELECTVOLUME(SCRATCH | SPECIFIC)** parameter, the parameter applies to all functions (migration, backup, and dump). If you specify a specific volume type with the **SELECTVOLUME(MIGRATION | BACKUP | DUMP)** parameter, the parameter applies only to that type of function. If you specify a global value and a specific volume type in a single command, the command fails.

Subparameter	Explanation
SCRATCH	A PRIVAT mount request is always sent to the operator when an EOV condition occurs on a tape backup volume, tape migration level 2 volume, or dump tape volume. The operator should mount a private scratch tape volume.
SPECIFIC	DFSMSHsm chooses another tape volume when an EOV condition occurs on a tape backup volume, tape migration level 2 volume, or dump tape volume. DFSMSHsm chooses a tape volume you have already defined to DFSMSHsm with the ADDVOL command. If the EOV condition occurs on a tape backup volume, DFSMSHsm chooses another tape backup volume. If the EOV condition occurs on a tape migration level 2 volume, DFSMSHsm chooses another tape migration level 2 volume. If the EOV condition occurs on a dump tape volume, DFSMSHsm chooses another dump tape volume. DFSMSHsm first attempts to select a dump tape volume that is assigned to the same class as is currently being dumped to. If a dump tape volume with the same class cannot be found, then DFSMSHsm looks for a dump tape volume that is not assigned to any class. When DFSMSHsm chooses the tape volume, the operator receives a message specifying which tape to mount. If DFSMSHsm cannot find an acceptable tape volume, the operator receives a PRIVAT mount request.

DFSMSHsm distinguishes between devices that have the same logical device type but which have different physical devices. There are four types of 3490's:

- Emulated on a 128 track device
- Emulated on a 256 track device
- Emulated on a virtual tape server (VTS) subsystem as a virtual tape volume
- All others

There are three types of 3590's:

- Native 128 track devices

- Native 256 track devices
- Native 384 track devices

DFSMSHsm examines the technology of the restricting output unit name and prefers selecting a partially filled cartridge having that recording format, at initial selection for backup to tape or migration to tape. If no cartridge matching the recording technology is found, then a nonspecific mount is requested.

Note: If a specific volume is specified for output during initial or subsequent (end-of-volume) processing the following requirements apply:

- If a library device is allocated:
 - The tape volume must be in the library for it to be considered eligible for selection. If the tape volume is outside the library, it is marked unavailable in the DFSMSHsm inventory.
 - If a data class is assigned to the DFSMSHsm tape data set name and the ACS COMPACTION attribute is specified (Y or N), the following considerations apply:

A partial tape is eligible for initial tape selection when the compaction status is consistent with the ACS data class COMPACTION attribute, and its device type is consistent with the allocated device type.

If a tape volume is empty, the existing selection rules related to device type eligibility still apply.
 - If a data class is not assigned or a data class is assigned to the DFSMSHsm tape data set name and the ACS COMPACTION attribute is *not* specified (blank), the following considerations apply:

A partial tape is eligible for initial tape selection when its device type is consistent with the allocated device type (the compaction status assigned to a partially full tape does not influence initial tape selection).

If a tape volume is empty, the existing selection rules related to device type eligibility still apply.
- If a non library device is allocated, the tape volume must *not* be in a library for it to be considered eligible for selection. If the tape volume is in a library, it is marked unavailable in the DFSMSHsm inventory.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either parameter on any SETSYS command, the DFSMSHsm default is SCRATCH.

Note:

1. Use the SCRATCH subparameter if you have the cartridge loader of the 3480 Magnetic Tape Subsystem. The cartridge loader provides the operator with the capability to preload multiple tapes used as migration, backup, or dump tapes. The system then writes migration data sets, backup data sets, or dump copies to these tapes without operator intervention.
2. The volume verification exit can reinitialize a tape volume if the tape remains under control of DFSMSHsm. Therefore, to use the volume verification exit effectively, specify SPECIFIC and TAPEDELETION(HSMTAPE).
3. This parameter has no effect when aggregate recovery is recovering data sets to ML2 tape volumes. Aggregate recovery will always request the mount of a non specific (scratch) volume.
4. Repeating the SELECTVOLUME parameter for specific volume types in a single SETSYS command causes conflict. The last entered SELECTVOLUME parameter overrides all other SELECTVOLUME parameters in this single command and is the only parameter processed.

For example, if you enter the following command, only the SELECTVOLUME(DUMP(SCRATCH)) parameter is processed. The SELECTVOLUME(MIGRATION(SPECIFIC)) and the SELECTVOLUME(BACKUP(SCRATCH)) parameters are not processed and their DFSMSHsm defaults are applied.

```
SETSYS SELECTVOLUME(MIGRATION(SPECIFIC)) -
SELECTVOLUME(BACKUP(SCRATCH)) -
SELECTVOLUME(DUMP(SCRATCH))
```

To prevent this from happening, enter the command as follows. In this way, all of the parameters are processed.

```
SETSYS SELECTVOLUME(MIGRATION(SPECIFIC)) -
BACKUP(SCRATCH) -
DUMP(SCRATCH))
```

Another way to enter this command is to repeat the SETSYS command three times with different subparameters for the SELECTVOLUME parameter. Issuing the SELECTVOLUME command in this way allows you to group parameters together in separate sections of your PARMLIB member.

```
SETSYS SELECTVOLUME(MIGRATION(SPECIFIC))
SETSYS SELECTVOLUME(BACKUP(SCRATCH))
SETSYS SELECTVOLUME(DUMP(SCRATCH))
```

SKIPABPRIMARY and NOSKIPABPRIMARY: Specifying whether to skip automatic backup of primary volumes

Explanation: **SKIPABPRIMARY** | **NOSKIPABPRIMARY** are mutually exclusive, optional parameters specifying whether or not to back up data sets on DFSMSHsm-managed volumes with:

- The primary volume attribute of automatic backup, specified with the PRIMARY(AUTOBACKUP) parameter of the ADDVOL command
- The storage group attribute for automatic backup, specified with the AUTOBACKUP=YES for the storage group.

SKIPABPRIMARY specifies that during automatic backup, DFSMSHsm skips the backup of DFSMSHsm-managed volumes with:

- The primary volume attribute of automatic backup
- The storage group attribute of AUTOBACKUP=YES

Therefore, all users must back up their data sets on the DFSMSHsm-managed volumes. DFSMSHsm, however, backs up data sets while the data sets are on migration volumes that migrated from a volume with the primary volume attribute of automatic backup or from a storage group with the attribute of AUTOBACKUP=YES.

NOSKIPABPRIMARY specifies that during automatic backup, DFSMSHsm backs up primary volumes with the automatic backup attribute and storage groups with the attribute of AUTOBACKUP=YES.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either parameter on any SETSYS command, the DFSMSHsm default is **NOSKIPABPRIMARY**.

SMALLDATASETPACKING and NOSMALLDATASETPACKING: Specifying whether DFSMSHsm should use small data set packing

Explanation: **SMALLDATASETPACKING** | **NOSMALLDATASETPACKING** are mutually exclusive, optional parameters specifying whether or not to pack small data sets into predefined VSAM key-sequenced small-data-set-packing data sets on migration level 1 volumes.

SMALLDATASETPACKING specifies that when a small data set migrates, it is eligible to be packed into a predefined VSAM key-sequenced small-data-set-packing data set on a migration level 1 volume.

For *tracks*, substitute a decimal number from 1 to 18 specifying that DFSMSHsm consider any data set using that number of tracks or fewer as a candidate for migration to a small-data-set-packing data set. DFSMSHsm converts the *tracks* value to kilobytes with an assumed track size of device type 3380.

KB(*kilobytes*) specifies the source size of a data set to be considered as a candidate for migration to a small-data-set-packing data set. For *kilobytes*, substitute a decimal number from 1 to 800.

The source size of a DFSMSHsm data set is calculated by multiplying the number of bytes per track for the device type times the number of tracks used by the data set. This calculated value is compared to the value specified in the SMALLDATASETPACKING parameter. If the calculated value is equal to or less than the value specified in the SMALLDATASETPACKING parameter, the data set is a candidate to be migrated to an SDSP. A candidate data set is eligible for migration to an SDSP data set if its estimated size, after compaction, is less than or equal to 400 kilobytes or to the value you specify, whichever is smaller. The number of bytes per track for each DFSMSHsm device type is as follows:

- 3380 is 47,476 bytes per track
- 3390 is 56,664 bytes per track

The compaction size of a DFSMSHsm data set is determined in one of two ways:

1. If compaction during migration is not active, the source size equals the migration size.
2. If compaction for migration is active, an internal default of 50% is used in establishing the estimated compaction size for data sets that are candidates for an SDSP. Previous compaction history is not considered for determining SDSP candidacy.

NOSMALLDATASETPACKING specifies that when small data sets migrate, they are not packed into predefined VSAM key-sequenced small-data-set-packing data sets on a level 1 volume, even if you specified the MIGRATION(SMALLDATASETPACKING) parameter of the ADDVOL command for the volume DFSMSHsm selects.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify *tracks* or KB(*kilobytes*) with the SMALLDATASETPACKING parameter on any SETSYS command, the DFSMSHsm default is 120 KB.

If you do not specify either SMALLDATASETPACKING or NOSMALLDATASETPACKING, the DFSMSHsm default is NOSMALLDATASETPACKING.

Note:

1. This parameter applies only to data sets that migrate from primary volumes to migration level 1 volumes.
2. If both *tracks* and *kilobytes* are specified, only the *kilobyte* value is honored.
3. Small-data-set-packing data sets have the following advantages:
 - The volume table of contents of the migration level 1 volumes are not filled with DSCBs for small data sets.
 - Small data sets become records in the small-data-set-packing data sets, so they do not have to start on track boundaries, giving you a better use of space on the migration level 1 volumes.
 - You get reduced volume fragmentation on the migration level 1 volumes.
4. Specify both primary and secondary extents for the small-data-set-packing data sets. If you want to use small data set packing, you should specify the SMALLDATASETPACKING parameter of the ADDVOL command for at least one migration level 1 volume per migration task. You do not have to specify SMALLDATASETPACKING for all migration level 1 volumes. If a data set is eligible for small data set packing, DFSMSHsm selects a volume that has been added to DFSMSHsm with the SMALLDATASETPACKING parameter.
5. The names of small-data-set-packing data sets have the following format:

uid.SMALLDS.Vvolser

DFSMSHsm replaces *uid* with the UID you specified in the DFSMSHsm startup procedure.

6. Encrypted files will not use the SDSP data sets at targets for migration to ML1 DASD.

Related reading

- For more information about UID and the DFSMSHsm startup procedure, see [Chapter 17, “Operating procedures for DFSMSHsm,”](#) on page 593.
- For more information about small-data-set-packing data sets and how to create them, see [“Managing SDSP data sets”](#) on page 555.

SMF and NOSMF: Specifying whether DFSMSHsm writes SMF records

Explanation: **SMF(*smfid*)** | **NOSMF** are mutually exclusive, optional parameters specifying whether DFSMSHsm writes SMF records that contain DFSMSHsm statistics.

SMF(*smfid*) specifies that DFSMSHsm write SMF records in the SYS1.MANX or SYS1.MANY system data sets. For *smfid*, substitute a record identification. Use SMF user codes for the record identification in the range of 128 to 255.

If you specify *smfid*, DFSMSHsm writes records with SMF identifications of *smfid* and *smfid*+1. Records with an identification of *smfid* contain daily statistics (DSR) and volume statistics (VSR). Records with an identification of *smfid*+1 contain function statistics (FSR) and ABARS function statistics (WWFSR).

Note: When a DFSMSHsm function executes, only selected fields within the FSR record are set. The fields set depend upon the function being performed and the method used to request the function. The fields that are set are required by the DFSMSHsm REPORT command.

NOSMF specifies that no SMF records are to be written.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either parameter on any SETSYS command, the DFSMSHsm default is NOSMF.

Additional information on this subject is available in the [z/OS DFSMSHsm Implementation and Customization Guide](#).

SOURCENAMES: Specifying the compaction-control qualifier of the source data set

Explanation: **SOURCENAMES(*name1,name2,...*)** is an optional parameter specifying the compaction-control qualifier of data sets that should be compacted with the table for source data sets. For *name1,name2,...*, specify the compaction-control qualifiers of the data set names of those data sets you want to compact with the table for data sets that contain source code for programming languages. For example, you could specify BAS and ASM as qualifiers. For generation data group data sets, this compaction-control qualifier is the next-to-last qualifier of the data set name. For all other data sets, this compaction-control qualifier is the last qualifier of the data set name.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is that the general compaction table can compact the source data sets.

SPILL and NOSPILL: Specifying whether DFSMSHsm does spill or cleanup processing on full DASD daily backup volumes

Explanation: **SPILL** | **NOSPILL** are mutually exclusive, optional parameters specifying whether DFSMSHsm can do spill or cleanup processing on full-DASD daily backup volumes during backup volume selection and limiting the selection and allocation of an output volume during spill processing.

SPILL specifies that DFSMSHsm spills full DASD daily backup volumes when a DASD daily backup volume is needed and none is available. Spill processing moves all but the latest backup version of each data set from the daily backup volumes to the spill backup volumes.

Subparameter	Explanation
ANY	Any type of spill backup volume can be used for output during spill processing.
DASD	Only DASD spill backup volumes are used for output during spill processing. TAPE specifies that only tape spill backup volumes be used for output during spill processing. In addition, when a tape spill backup volume is allocated during spill or recycle processing, the volume is allocated using the unit name specified on the ADDVOL command for the volume.
TAPE(<i>unittype</i>)	Only tape spill backup volumes that can be mounted and written on the specified <i>unittype</i> are used during spill processing. In addition, when the tape spill backup volume is allocated during spill processing, the volume is allocated using the unit name specified with the TAPE subparameter of the SPILL parameter, overriding the unit name specified on the ADDVOL command for the tape spill backup volume. For <i>unittype</i> , specify a generic or esoteric unit name. The following generic unit names are acceptable: 3480, 3480X, 3490, and 3590-1. If an esoteric unit name is specified, it must have been previously defined to DFSMSHsm using the USERUNITTABLE parameter of the SETSYS command.

NOSPILL specifies that DFSMSHsm never spills full DASD daily backup volumes. Instead, DFSMSHsm cleans up full DASD daily backup volumes when one is needed and none is available. During cleanup processing, DFSMSHsm scratches the following data sets from the full unallocated DASD daily backup volume that DFSMSHsm has not cleaned up in the longest period of time:

- Unneeded VTOC copy data sets
- Unneeded VCAT copy data sets
- Backup versions without backup-version (MCC) records.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: If you specify SPILL without any value, any previous spill output specification is retained.

DFSMSHsm default: If you do not specify either parameter on any SETSYS command, the DFSMSHsm default is SPILL(ANY).

Note: During spill, DFSMSHsm does not keep the association of a primary volume and a particular backup device category. You specify this association with the PRIMARY(BACKUPDEVICECATEGORY) parameter of the ADDVOL command. For example, if you specify ADDVOL PRIMARY(BACKUPDEVICECATEGORY(DASD)), the backup version can be moved to a tape spill backup volume; however, the latest backup version of each data set on the primary volume remains on a DASD daily backup volume.

STORAGEGROUPAFFINITY: Define the set of host names that have affinity to process a storage group cloud migration

STORAGEGROUPAFFINITY is an optional parameter that specifies a set of hosts that have affinity to process a storage group. Up to 15 host names can be specified.

Required subparameters of the SETSYS STORAGEGROUPAFFINITY command:

A set of hosts that have affinity to process a storage group.

Up to 15 host names can be specified. If a set of hosts name is empty, the list of previously-defined host names is removed.

Alias: SGA

SWAP and NOSWAP: Specifying whether the DFSMSHsm address space can be swapped

Explanation: **SWAP** | **NOSWAP** are mutually exclusive, optional parameters specifying that the DFSMSHsm address space can be swapped.

SWAP specifies that the DFSMSHsm address space can be swapped by the MVS system resource manager. NOSWAP specifies that the DFSMSHsm address space cannot be swapped by the MVS system resource manager.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either parameter on any SETSYS command, the DFSMSHsm default is whatever your computing system would normally do with the DFSMSHsm address space.

Note:

1. DFSMSHsm cannot be swapped while secondary address spaces are processing. While ABARS secondary address spaces are active, DFSMSHsm always sets itself to NOSWAP mode. Once all secondary address spaces have completed processing, DFSMSHsm will reset to the original SETSYS SWAP | NOSWAP setting.
2. To support cross-address space communication, DFSMSHsm cannot be swapped when it is in nonlocal mode. If SETSYS SWAP is issued in the startup PARMLIB member, DFSMSHsm is changed to NOSWAP mode temporarily and message ARC0062I is issued. If SETSYS SWAP is issued while DFSMSHsm is in nonlocal mode, DFSMSHsm is not swapped and message ARC0103I is issued.

SYSOUT: Directing DFSMSHsm output

Explanation: **SYSOUT(class copies forms)** is an optional parameter specifying the class, number of copies, and any special forms used to print output from DFSMSHsm. For *class*, substitute an alphanumeric character for the class that DFSMSHsm uses when it prints output. For *copies*, substitute a decimal number from 1 to 99 for the number of copies to print of DFSMSHsm output. For *forms*, substitute up to 4 alphanumeric characters for the special forms to use when printing DFSMSHsm output.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm defaults are class A, one copy, and no special form.

SYS1DUMP and NOSYS1DUMP: Specifying where DFSMSHsm dumps should be written

Explanation: **SYS1DUMP** | **NOSYS1DUMP** are mutually exclusive, optional parameters specifying whether DFSMSHsm dumps resulting from an abnormal end or error condition in primary or secondary address spaces be written in a system dump data set.

SYS1DUMP specifies that DFSMSHsm dumps be written in a system dump data set. This format is required if using the Interactive Problem Control System (IPCS). When you specify the SETSYS SYS1DUMP command and you have specified the SUPPRESSALL keyword for SVCDUMP in the SYS1.PARMLIB member ADYSETxx, the dump analysis elimination (DAE) function suppresses duplicate SVCDUMPS.

NOSYS1DUMP specifies that when DFSMSHsm abends, the dump produced is directed to the dump related DD statements specified in the DFSMSHsm startup procedure. These DD statements are: SYSABEND, SYSUDUMP, and SYSMDUMP.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is SYS1DUMP.

TAPEDATASETORDER: Specifying order for processing tape

Explanation: **TAPEDATASETORDER** is an optional parameter that specifies the order in which you want DFSMSHsm to recall or recover data sets from a single tape.

PRIORITY | **FBID** are mutually exclusive sub-parameters of the TAPEDATASETORDER parameter. If you specify TAPEDATASETORDER, you must also specify either PRIORITY or FBID, otherwise DFSMSHsm does not make any change to the TAPEDATASETORDER state and issues an error message.

Subparameter	Explanation
PRIORITY	DFSMSHsm processes data sets in the priority order. Data sets within the same priority are processed in the FIFO order.
FBID	DFSMSHsm processes the data sets in the ascending file block id order.

If you specify TAPEDATASETORDER(PRIORITY | FBID) parameter, the parameter applies to both recall and recover processing. If you specify a specific functional parameter, TAPEDATASETORDER applies only to that function. If you specify a general option and a specific function in a single command, the command fails. If you specify the RECALL(PRIORITY | FBID) parameter, the parameter applies to recall processing only. If you specify the RECOVER(PRIORITY | FBID) parameter, the parameter applies to recover processing only.

SETSYS default: None.

DFSMSHsm default: If you do not enter the TAPEDATASETORDER command, the DFSMSHsm default is PRIORITY. DFSMSHsm recalls and recovers data sets from a single tape in priority order. Recall requests with the same priority are processed in FIFO order.

Note:

1. The TAPEDATASETORDER command provides the installation with additional flexibility to handle circumstances in which ascending FBID order offers a significant reduction in tape repositioning, such as when a large number of data sets are being recalled or recovered from a single tape. Specifying FBID might increase throughput, but might cause lower priority requests to be processed prior to a higher priority requests.

2. If a host connected to the Common Recall Queue issues the SETSYS command to change the TAPEDATASETORDER, all hosts connected to the Common Recall Queue adopt the same processing order.
3. If you enter the SETSYS command to change the TAPEDATASETORDER while there are requests residing in the Common Recall Queue, it might take some time before the new processing order takes effect.
4. If you enter the ALTERPRI command to re-prioritize requests residing on the Recall or Recover Queue to HIGH, ALTERPRI takes precedence over FBID.

TAPEDELETION: Specifying what to do with tapes that no longer contain valid data

Explanation: **TAPEDELETION** is an optional parameter specifying whether recycled tape volumes be deleted from DFSMSHsm control and become scratch tapes, or are to remain under DFSMSHsm control as unassigned, available tape backup volumes, migration level 2 volumes, or dump volumes.

Subparameter	Explanation
HSMTAPE	The recycled volumes remain under DFSMSHsm control and become either unassigned backup volumes or available migration level 2 volumes, based on the previous definition of the volume. The tape volume is now available to be selected as a daily or spill backup volume, or as a target volume for data set migration, volume migration, or recycling of tape migration level 2 or dump volumes.
SCRATCHTAPE	Recycled tape volumes are deleted from DFSMSHsm control and become scratch tapes after DFSMSHsm recycles them. The tape volumes are not selected as tape backup or migration level 2 volumes, but an operator can mount them in response to a mount PRIVAT request for a tape backup or migration level 2 volume.

If you specify the global TAPEDELETION(SCRATCHTAPE | HSMTAPE) parameter, the parameter applies to all functions (migration, backup, and dump). If you specify a specific volume type, the parameter applies only to that type of function. If you specify a global value and a specific volume type in a single command, the command fails.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is SCRATCHTAPE.

Note:

1. Although the HSMBACKUPTAPE parameter has been changed to HSMTAPE, if you specify HSMBACKUPTAPE, it has the same meaning as HSMTAPE. The command will not fail.
2. If you choose SCRATCHTAPE and the tape security method that DFSMSHsm used is an expiration date, the DFSMSrmm VLPOOL EXPDTCHECK(N) option should be enough for DFSMSrmm to allow reuse with operator intervention and to allow relabelling to reinitialize the tape before DFSMSHsm or any other user tries to reuse the tape volume.
3. If you choose SCRATCHTAPE and the tape security method that DFSMSHsm used is a password, DFSMSrmm does not support password protection, so you would need to initialize the tapes to avoid problems. You can use the SECCLS parmlib options to specify the requirements to ERASE volumes DFSMSHsm uses before they return to scratch. You can automate this, see Chapter 16, “Initializing and Erasing Volumes” in [z/OS DFSMSrmm Implementation and Customization Guide](#).

4. If you do not use a tape management system, you choose SCRATCHTAPE, and the tape security method that DFSMSHsm used is password or expiration date, you must use the IEHINITT utility to reinitialize the tape before DFSMSHsm or any other user tries to reuse the tape volume.
5. If you choose HSM TAPE, you do not need to reinitialize the tapes that remain under DFSMSHsm control before you reuse them as tape backup or migration level 2 volumes.
6. The disposition of tapes automatically made available for reuse depends on the TAPEDELETION parameter of the SETSYS command. TAPEDELETION(HSM TAPE) is equivalent to issuing a DELVOL UNASSIGN for the tapes. TAPEDELETION(SCRATCHTAPE) is equivalent to issuing a DELVOL PURGE.

TAPEHARDWARECOMPACT and NOTAPEHARDWARECOMPACT: Specifying the data format used when writing to a 3480X tape device

Explanation: TAPEHARDWARECOMPACT | NOTAPEHARDWARECOMPACT are mutually exclusive, optional parameters that specify whether the Improved Data Recording Capability (IDRC) should be used when a 3480X is used as the output device.

IDRC is a form of data compaction that can improve storage capacity for most data sets. The amount of improvement depends upon the data contained within the data set.

TAPEHARDWARECOMPACT specifies that DFSMSHsm *will* request that IDRC be used on eligible 3480 tape cartridges. NOTAPEHARDWARECOMPACT specifies that DFSMSHsm *will not* use IDRC.

The compaction status assigned to a 3480 tape volume occurs at the time the volume is first used for output. This status is determined by the tape unit being used for output and the current specification of SETSYS TAPEHARDWARECOMPACT. DFSMSHsm can be directed to use the 3480X device, but not the IDRC feature by specifying the SETSYS NOTAPEHARDWARECOMPACT command. The following table summarizes how the compaction status is assigned to an empty 3480 tape volume:

SETSYS Parameter	Output Unit (3480)	Output Unit (3480X)	Output Unit (3490)	Output Unit (3590-1)
TAPEHWC	No compaction	Compaction	Compaction	Compaction
NOTAPEHWC	No compaction	No compaction	Compaction	Compaction

When output is restricted to a specific unit, the DFSMSHsm unit name may change. An empty 3480 cartridge can become a 3480X or 3490 cartridge containing compacted data. An empty 3480 or 3480X cartridge can become a 3490 cartridge containing compacted data.

When output is not restricted to a specific unit, DFSMSHsm selects the first available volume. There is no preference between a 3480, 3480X, or 3490 unit. The compaction status assigned to an empty tape volume is based on the following:

- The tape unit associated with the tape volume
- Whether or not 3480X or 3490 tape units are installed on the system
- The SETSYS command parameters TAPEHARDWARECOMPACT or NOTAPEHARDWARECOMPACT

The TAPEHARDWARECOMPACT parameter used with the following unit-restriction parameters causes control unit compaction to be requested:

- ABACKUP UNIT(*unittype*)
- ARECOVER TARGETUNIT(*unittype*)
- DEFINE DUMPCLASS(*class* UNIT(*unittype*))
- SETSYS ARECOVERUNITNAME(*unittype*)
- SETSYS ARECOVERML2UNIT(*unittype*)
- SETSYS ABARSUNITNAME(*unittype*)
- SETSYS BACKUP(TAPE(*unittype*))
- SETSYS CDSVERSIONBACKUP (BACKUPDEVICECATEGORY (TAPE(UNITNAME(*unittype*))))

- SETSYS MIGUNITNAME(*unittype*)
- SETSYS RECYCLEOUT(BACKUP(*unittype*))
- SETSYS SPILL(TAPE(*unittype*))
- SETSYS TAPEMIGRATION(DIRECT(TAPE(*unittype*)))
- SETSYS TAPEMIGRATION(ML2TAPE(TAPE(*unittype*)))
- SETSYS TAPEMIGRATION(NONE(ROUTETOTAPE(*unittype*)))
- SETSYS UNITNAME(*unittype*)

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either TAPEHARDWARECOMPACT or NOTAPEHARDWARECOMPACT, the DFSMSHsm default is NOTAPEHARDWARECOMPACT.

TAPEINPUTPROMPT: Specifying whether to suppress input tape messages

Explanation: TAPEINPUTPROMPT specifies whether DFSMSHsm should issue action messages to the operator asking if input tapes needed by DFSMSHsm are available. Each function using tapes (backup, migration, dump) is handled separately.

TAPEINPUTPROMPT(...TAPES(YES)) allows DFSMSHsm to continue normal operation, which is to issue action messages ARC0313A, ARC0314A, and ARC0366A. These messages prompt the operator to check that the tapes requested by DFSMSHsm are available.

Note: If all of the requested tapes are in an IBM automated tape library managed by SMS tape, messages ARC0313A, ARC0314A, and ARC0366A are not issued even though (...TAPES(YES)) has been specified.

TAPEINPUTPROMPT(...TAPES(NO)) allows you to suppress the input messages, if they are not necessary in your system configuration.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify TAPEINPUTPROMPT(...TAPES(NO)) for a category of tapes (backup, migration, dump), DFSMSHsm issues all messages related to input tapes for that category.

TAPELIBRARYPRESELECT: Preselecting output tape volumes in IBM Tape Library tape environment

Explanation: By default in an IBM Tape Library environment, DFSMSHsm waits to select an output tape until after the tape device has been allocated. This ensures the tape can be mounted and read on the allocated tape device and is resident in the same library as the allocated tape device. Because a tape volume is not selected at allocation time, the volser request at allocation time will be set to PRIVAT (scratch) and later update for open/mount. Some hardware features or configurations may require that the tape volume serial be provided at allocation time. This would require DFSMSHsm to first select the tape volume to which it will write prior to the tape device allocation.

This SETSYS parameter will allow users to have DFSMSHsm preselect tape volumes for output in an IBM Tape Library environment. If an existing tape is selected, its volser will be specified to the allocation.

The TAPELIBRARYPRESELECT (YES) option may not be necessary in environments where the following SETSYS commands are specified. In such an environment, all volumes DFSMSHsm requests for output will be SCRATCH volumes and thus the volser cannot be specified at the allocation time.

```
SELECTVOLUME(SCRATCH)
PARTIALTAPE(MARKFULL)
TAPEDELETION(SCRATCH)
DSBACKUP(TAPE(TASKS(0))) DASD(TASKS(n)))
```

Note: When configured to preselect output tape volumes, DFSMSHsm will no longer be able to verify that a tape volume is compatible with the tape drive that will be allocated nor that the tape volume is resident in the same library that contains the allocated tape drive. In environments where only one tape device type is written to by DFSMSHsm or where SMS is configured to direct allocations to appropriate libraries, such limitation will not impact DFSMSHsm's ability to use tape as expected.

SETSYS default: If you specify TAPELIBRARYPRESELECT without mentioning any sub parameter, the default is Y.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is N.

TAPEMAXRECALLTASKS: Specifying the maximum number of concurrent tape recall tasks

Explanation: **TAPEMAXRECALLTASKS(*tasks*)** is an optional parameter specifying the maximum number of tape recall tasks that can concurrently request tape mounts. For *tasks*, specify a decimal number from 1 to 15. The value you specify must be greater than 0 and less than or equal to the value you specify with the MAXRECALLTASKS parameter.

TAPEMAXRECALLTASKS is a subset of the MAXRECALLTASKS parameter. For example, if you specify MAXRECALLTASKS(10) and TAPEMAXRECALLTASKS(6), DFSMSHsm processes up to ten recall tasks concurrently, but only six can be recalls from tape migration level 2 volumes. You cannot specify a value for TAPEMAXRECALLTASKS that is greater than MAXRECALLTASKS; for example, MAXRECALLTASKS(10) and TAPEMAXRECALLTASKS(11).

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is 1 tape recall task.

Note:

1. DFSMSHsm allows only a maximum of 15 recall tasks concurrently. Also, all recall tasks can process recalls from DASD migration volumes. For example, if you specify TAPEMAXRECALLTASKS(6) and fewer than six tape recall tasks are active, DFSMSHsm can process DASD recall tasks instead.
2. If you specify the same number for TAPEMAXRECALLTASKS as MAXRECALLTASKS, you may find that all tasks are waiting for tape drives and that many recalls from ML1 DASD are waiting in the queue. Specifying a value for TAPEMAXRECALLTASKS that is smaller than MAXRECALLTASKS in effect reserves a set of tasks to be always available to handle recalls from ML1 volumes.

TAPEMIGRATION: Specifying the type of migration to tape

Explanation

TAPEMIGRATION is an optional parameter specifying that you want DFSMSHsm to use migration level 2 (ML2) tape volumes, to limit the selection and allocation of an output volume during tape migration processing, and to attempt fast subsequent migration.

The following are required or optional parameters of the TAPEMIGRATION parameter:

DIRECT

Data sets on DFSMSHsm-managed primary volumes are migrated directly to ML2 tape volumes. If the primary volume is defined with the AUTOBACKUP attribute, data sets on the primary volume with the change flag set to 1 will not be migrated to an ML2 tape volume.

ML2TAPE

Data sets on ML1 volumes are migrated to ML2 tape volumes.

NONE

Data sets are not migrated to ML2 tape volumes unless migration to an ML2 tape volume is indicated by an external-to-DFSMSHsm factor. An ML2 tape volume is selected when:

- The ARCMDEXT exit is used to select migration to an ML2 tape volume from a primary volume (level 0).
- An SMS-managed data set that belongs to a management class indicating that the data set is to be migrated directly to an ML2 tape volume.

**ROUTETOTAPE
TAPE**

Specify a tape volume.

ANY

Any available tape volume is selected. If no tape volumes are available, then the value of the SETSYS MIGUNITNAME system setting is used to allocate a scratch tape.

unittype

An ML2 tape volume that is compatible with the specified unit type is selected. If no tape volumes of that unit type are available, then a scratch tape of that unit type is selected.

The following are valid types of tape units:

- 3480
- 3480X
- 3490
- 3590-1

You can substitute an esoteric tape unit defined with the SETSYS USERUNITTABLE command. If you specify an esoteric tape unit name that does not exist in the user unit table, the command fails. If you specify:

- 3480 or 3480X, you use all the functions of the 3480 Magnetic Tape Subsystem.
- 3490, you use all the functions of the 3490 Magnetic Tape Subsystem.
- 3590-1, you use all the functions of the 3590 Magnetic Tape Subsystem.

RECONNECT

Data sets eligible for fast subsequent migration can be reconnected to the ML2 tape volume from which they were recalled. A data set can be reconnected if *all* fast subsequent migration requirements are satisfied. For more information about these requirements, see [Fast subsequent migration \(reconnection\) eligibility requirements](#).

NONE

Data sets are not eligible for fast subsequent migration and are not reconnected to the ML2 tape volume from which they were recalled.

ALL

All data sets that are eligible for standard migration and satisfy fast subsequent migration eligibility requirements are reconnected to the ML2 tape volume the data set was recalled from; including data sets that would have otherwise been migrated to an ML1 volume.

ML2DIRECTEDONLY

Data sets that are eligible for direct migration to ML2 tape volumes and satisfy fast subsequent migration eligibility requirements are reconnected to the ML2 tape volume the data set was recalled from. Data sets not eligible for direct migration to ML2 tape volumes are processed using the standard migration method.

SMS relationship

The TAPEMIGRATION parameter applies in some instances to SMS-managed DASD volumes or data sets. SMS-managed data sets with the LEVEL 1 DAYS NON-USAGE = NOLIMIT management class attribute are specifically prohibited from migrating to tape.

Tape library relationship

A tape unit name can be used for filtering in the ACS routines. If you specify a unit type, it will be sent to the ACS routines in SMS for the tape migration function.

SETSYS default

If you specify:

- DIRECT or ML2TAPE with no parameter, the default is TAPE(ANY).
- DIRECT or ML2TAPE with TAPE but no parameter, the default is ANY.
- NONE with no parameter, the default is ROUTETOTAPE(ANY).
- NONE with ROUTETOTAPE but no parameter, the default is ANY.
- RECONNECT with no parameter, the default is NONE.

DFSMSHsm default

If you do not specify the TAPEMIGRATION parameter on any SETSYS command, DFSMSHsm does not migrate data sets to ML2 tape volumes unless migration to an ML2 tape volume is indicated by an external-to-DFSMSHsm factor. Any tape volume is used. Fast subsequent migration is disabled. This is the equivalent to SETSYS TAPEMIGRATION(NONE(ROUTETOTAPE(ANY)) RECONNECT(NONE)).

TAPEOUTPUTPROMPT: Specifying whether to suppress output tape messages

Explanation: **TAPEOUTPUTPROMPT(TAPECOPY(YES | NO))** is an optional parameter that allows correct decisions by the operator when mounting a tape during TAPECOPY. It eliminates failures caused from mounting a standard capacity cartridge instead of an enhanced capacity cartridge or vice versa, since the operator does not always know which type of tape cartridge is required.

Subparameter	Explanation
YES	<p>DFSMSHsm issues a message to the operator during TAPECOPY processing indicating which type of target tape be mounted on a particular device; however, this message goes away after the tape has been mounted.</p> <p>Because using cartridge loaders for TAPECOPY causes the tape to be mounted by the cartridge load device before the operator verifies that the proper tape is mounted, an option to have the message issued for TAPEOUTPUTPROMPT as a write-to-operator-with-reply (WTOR) is available, allowing the operator to ensure that the proper tape is mounted even if cartridge load devices are being used. This option is available with a patch of the MCVT.</p> <p>For a description of how to patch the MCVT for this option, refer to Tuning DFSMSHsm in z/OS DFSMSHsm Implementation and Customization Guide.</p>
NO	<p>DFSMSHsm issues no message to the operator during TAPECOPY processing indicating which type of target tape is to be mounted on a particular device.</p>

SMS relationship: Parameter does not apply to SMS-managed DASD volumes or data sets.

SETSYS default: If you do not specify this parameter on the SETSYS command, the default is NO. If you do specify this parameter on the SETSYS command, a message is issued without requesting a reply when the option to patch the MCVT is not used. If the option to patch the MCVT is used, a message is issued requesting a reply.

TAPERECALLLIMITS: Specifying limits to continuously mounted ML2 tapes during multiple recalls

Explanation: **TAPERECALLLIMITS(TASK(*time*) TAPE(*time*))** is an optional parameter specifying the total time that a recall task can utilize a single tape mount for processing recall requests before criteria is used to possibly demount the tape. This parameter does not apply to tape devices prior to 3480 tape devices.

Suparameter	Explanation
TASK(<i>time</i>)	Allows you to specify the number of minutes that a DFSMSHsm recall task can process recall requests from a single tape mount before DFSMSHsm decides whether to demount the tape or to continue processing. Once that time is exhausted, each time the recall task completes the processing of its current recall request, DFSMSHsm decides whether to demount the tape or to continue processing. If the maximum number of tape recall tasks within the host are running and a higher priority tape recall request exists that can be attempted immediately, then the task is freed up to process other requests.
TAPE(<i>time</i>)	Allows you to specify the number of minutes that a recall task can process recalls from a single tape mount before additional criteria are considered. Once this time is exhausted, the recall task completes processing of its current recall request and then DFSMSHsm determines whether to demount the tape or to continue processing. If another DFSMSHsm host requires the mounted tape for a higher priority recall, then the tape is demounted. This results in a tape take-away from recall.

Once the recall processing stops for a specific recall task on a DFSMSHsm host, then all queued recall requests on that host that require the demounted tape volume are excluded from consideration for five minutes. This allows other hosts an opportunity to retry their delayed requests for the demounted tape volume.

When DFSMSHsm processes multiple recall requests that utilize one tape mount, the recall task processes the highest priority tape recall request which requires the currently mounted tape. If DFSMSHsm does force a demount of the tape volume, then the task and the tape are freed up to process other higher priority recalls.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either of the TAPERECALLLIMITS subparameters, then the default time used is 15 minutes for TASK and 20 minutes for TAPE.

Note:

1. TAPE(*time*) is longer than TASK(*time*) because TAPE(*time*) requires delaying additional queued requests.
2. The Storage Administrator is able to disable the TAPERECALLLIMIT function by setting both the TASK and the TAPE time to large values, such as 1000 or even 65535 minutes.

TAPESECURITY: Specifying the type of security for tape volumes

Explanation: **TAPESECURITY** is an optional parameter that you use to specify the type of security for your tape backup, migration level 2, and dump volumes. You can choose more than one tape security option. CDS backup tapes are not affected by this command.

Subparameter	Explanation
EXPIRATION	<p>DFSMSHsm protects each tape backup, migration level 2, and dump volume with an expiration date. Each backup version, migration copy, or dump copy on the tape volume is protected by an expiration date by placing an expiration date of 99365 in the IBM Standard Data Set Label 1 (HDR1, EOVS1, and EOF1). For backup or migration, however, you can use the tape data set exit, ARCTDEXT, to change the expiration date. You can change the expiration date of a dump tape volume using the TAPEEXPIRATIONDATE optional parameter of the DEFINE command.</p> <p>DFSMSHsm does not place a backup version or migration copy of a password-protected data set on a tape volume that is not password protected unless you specify the EXPIRATIONINCLUDE or RACFINCLUDE subparameter. Therefore, if the only tape security subparameter you specify is EXPIRATION, DFSMSHsm fails the backup or migration of a password protected data set to a tape backup or migration level 2 volume.</p>
EXPIRATIONINCLUDE	DFSMSHsm protects each tape backup, migration level 2, and dump volume with an expiration date. In addition, DFSMSHsm backs up or migrates a password-protected data set to a tape volume that is not password protected.
PASSWORD	DFSMSHsm protects each tape backup, migration level 2, and dump volume with a password. To password protect, place an X'F1' in the data set security byte in the IBM Standard Data Set Label (HDR1, EOVS1, and EOF1).
RACF	<p>DFSMSHsm protects with RACF each tape backup, migration level 2, and dump volume. DFSMSHsm protects the tape volume with RACF by adding it to a RACF tape volume set of DFSMSHsm (HSMHSM or DFHSMx). The <i>z/OS DFSMSHsm Implementation and Customization Guide</i> contains information about how to define RACF tape volume sets for DFSMSHsm and ABARS.</p> <p>If TAPESECURITY RACF RACFINCLUDE is specified, ABACKUP output tapes and ARECOVER input tapes are RACF protected, if RACF is active and if an ABARS tape volume set of HSMABR is defined.</p> <p>DFSMSHsm does not place a backup version or migration copy of a password-protected data set on a tape volume that is not password protected unless you specified the RACFINCLUDE or EXPIRATIONINCLUDE subparameter. Therefore, if you specify only the RACF subparameter, DFSMSHsm fails the backup or migration of a password-protected data set to a tape backup or migration level 2 volume.</p>
RACFINCLUDE	DFSMSHsm protects each tape backup, migration level 2, and dump volume with RACF. In addition, DFSMSHsm backs up or migrates a password-protected data set to a tape volume that is not password protected.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the default is PASSWORD.

Note:

1. Although the D parameter has been changed to EXPIRATION, if you specify D, it has the same meaning as EXPIRATION. If you specify DI, it has the same meaning as EXPIRATIONINCLUDE. If you specify the PD or PE parameter, it has the same meaning as if you specify both the PASSWORD parameter and the EXPIRATION parameter.
2. If no RACF tape volume sets are defined for DFSMSHsm, but all tapes are protected by an existing RACF generic profile, then SETSYS TAPESECURITY(RACF | RACFINCLUDE) should be specified.
3. If you want to specify RACF or RACFINCLUDE, your computing system must meet the following conditions:
 - A sufficient level of DFSMSdfp must be installed, or you must specify the PASSWORD tape security option.
 - RACF must be installed.
 - The RACF TAPEVOL resource class must be defined in the RACF class descriptor table (CDT).
 - If you do not have a sufficient level of DFSMSdfp installed and you want to RACF-protect your tape, you must specify PASSWORD with RACF in the TAPESECURITY parameter of the SETSYS command.
4. If RACF is inactive or the RACF TAPEVOL resource class is inactive, DFSMSHsm issues a message (ARC0099I).
5. The restriction about putting password-protected data sets on non password-protected tape volumes does not apply to dump volumes. Therefore, EXPIRATION and EXPIRATIONINCLUDE are equivalent options for dump processing, as are RACF and RACFINCLUDE.
6. VSAM password protected data sets are no longer supported, so DFSMSHsm checking for password protection has been removed. Thus, EXPIRATION and EXPIRATIONINCLUDE are equivalent options for migration and backup processing, as are RACF and RACFINCLUDE for VSAM data sets.

TAPESPANSIZE: Reducing tape volume spanning

Explanation: **TAPESPANSIZE(nnnn)** is an optional parameter used to reduce the occurrences of data sets spanning migration or backup tape volumes. For *nnnn*, specify a value between 0 and 9999 in units of megabytes (MB). This value represents the maximum number of megabytes of tape (ML2 or backup) that DFSMSHsm may leave unused while it tries to eliminate spanning of data sets. To state this differently, this value is the minimum size of a data set that is allowed to span tape volumes. Data sets whose size is less than the value do not normally span volumes. Only those data sets whose size is greater than or equal to the specified value are allowed to span volumes.

This parameter offers a trade-off: to reduce the occurrences of a user data set spanning tapes in exchange for some unused media at the end of each cartridge. The amount of unused media can vary from 0 to *nnnn* physical megabytes, but roughly averages 50% of the customer's median data set size. For example, if you specify 4000MB and your customer's median-sized data set is 2MB, then on average only 1MB of media is unused per cartridge.

If the SETSYS TAPEUTILIZATION parameter is set to NOLIMIT, DFSMSHsm makes no attempt to reduce data set tape volume spanning. If the SETSYS TAPEUTILIZATION parameter is set to a percent, then DFSMSHsm performs reduced data set spanning.

DFSMSHsm calculates a target data set size to use when it is determining whether a data set should fit entirely on the currently mounted tape volume. The size is calculated based on the used tracks of the data set and an estimated IDRC compaction accomplishment. If data is written to tape in IDRC format and software compaction is not being used (by either DFSMSHsm or CPU) for the data set, DFSMSHsm assumes a 2.5 to 1 compaction savings for the data set. If you want to use a different compaction assumption, see *Tuning DFSMSHsm in z/OS DFSMSHsm Implementation and Customization Guide*. If IDRC format is not used or software compaction is used for the data set, then DFSMSHsm does not consider any compaction accomplishments when it estimates the amount of tape media the data set requires.

DFSMSHsm recommends a value of 4000MB for all IBM 3490 and 3590 tape cartridges.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify TAPESPANSIZE, the default is 500MB.

TAPETYPE: Specifying whether to use WORM media for non-ABARS functions

Explanation: **TAPETYPE(WORM | NOWORM)** is an optional parameter that specifies that you want DFSMSHsm to use WORM media for non-ABARS functions.

The following are required or are optional parameters of the TAPEMIGRATION:

TAPETYPE parameter:

NOWORM

Specifies that DFSMSHsm should not use WORM media for non-ABARS functions.

WORM

Specifies that DFSMSHsm should allow non-ABARS functions to use WORM media.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: NOWORM.

DFSMSHsm default: If you do not specify the TAPETYPE parameter on any SETSYS command, DFSMSHsm does not use WORM media for non-ABARS functions by default.

Note:

To begin using WORM tape for all HSM functions, issue SETSYS TAPETYPE(WORM), otherwise, the default is NOWORM.

It is up to the Storage Administrator to decide whether using WORM media with DFSMSHsm functions is appropriate. These functions were not designed to be archival and so have some limitations users should consider before implementing them.

Since the support is passive, HSM treats WORM media the same way it treats R/W tapes.

Migration allows recall with subsequent remigration of data sets by using the same data set names. Even though the original form of a data set remains on tape, only the last version is known to DFSMSHsm.

Data sets on tape tend to move from one tape volume to another by using the Recycle function. If Recycle is allowed, there is no guaranteed relationship between a data set and tape volser.

If the storage administrator begins to use TAPETYPE(WORM) for all HSM functions and then later decides to change back to TAPETYPE(NOWORM), all WORM tapes must be marked full so they are not selected for output.

TAPEUTILIZATION: Specifying the desired tape utilization

Explanation: **TAPEUTILIZATION** is an optional parameter you can use to specify the desired tape utilization for a backup or migration tape volume written in single-file format. When a single-file format tape volume has reached the desired level of utilization (fullness), DFSMSHsm forces an end-of-volume (EOV). With this parameter, you can limit the amount of media used.

LIBRARYBACKUP is a mutually exclusive, required subparameter used to specify the desired tape utilization for a backup tape stored in an SMS-managed tape library. Because esoteric unit names are ignored in an SMS-managed tape library, this is the only vehicle by which you may limit the amount of media used in a library backup cartridge. PERCENTFULL(*pct*) and NOLIMIT are mutually exclusive, optional subparameters that can be used with LIBRARYBACKUP.

LIBRARYMIGRATION is a mutually exclusive, required subparameter used to specify the desired tape utilization for a migration tape stored in an SMS-managed tape library. Because esoteric unit names are ignored in an SMS-managed tape library, this is the only vehicle by which you may limit the amount

of media used in a library migration cartridge. PERCENTFULL(*pct*) and NOLIMIT are mutually exclusive, optional subparameters that can be used with LIBRARYMIGRATION.

UNITTYPE(*unittype*) is a mutually exclusive, required subparameter used to specify the desired tape utilization for a backup or migration tape written in single-file format outside of any library. PERCENTFULL(*pct*) and NOLIMIT are mutually exclusive, optional subparameters that can be used with UNITTYPE.

This command can be issued multiple times, once for each *unittype* required. You must issue this command for each unique unit type that needs a percentage different from the default. For example, if both 3480s and 3490s exist, issue a separate SETSYS TAPEUTILIZATION command. Issue a separate command for a different esoteric *unittype*. For example, if separate esoteric unit names are used for backup and migration, each one can have a different tape utilization value.

For *unittype*, specify one of the following unit names:

- 3480, which is a 3480 **without** the IDRC
- 3480X, which is a 3480 **with** the IDRC
- 3490
- 3590-1
- Any esoteric name that has been identified to DFSMSHsm through the SETSYS USERUNITTABLE command.

If NOLIMIT is specified, there is no tape limiting, no action is taken to reduce data set tape volume spanning and DFSMSHsm writes data until the end-of-volume is reached. It is recommended that you specify PERCENTFULL(100) on the SETSYS TAPEUTILIZATION command when reduced data set tape volume spanning is needed. Specifying NOLIMIT will disable reduced data set tape volume spanning.

CAPACITYMODE(COMPATIBILITY | EXTENDED) is an optional subparameter you can use to specify the maximum capacity to which a tape is filled. COMPATIBILITY specifies that an IBM 3590 that emulates an IBM 3490 fills a tape to no more than the capacity allowed by an IBM 3590 that emulates an IBM 3490 that is not operating in extended capacity mode. Data on these tapes is accessible to IBM 3590 drives that emulate IBM 3490 drives, regardless of whether they are CAPACITYMODE switchable. EXTENDED specifies that an IBM 3590 that emulates an IBM 3490 fills a tape to the same capacity as 3590 drives allow. Data on these tapes is accessible only to tape units that are CAPACITYMODE switchable.

The CAPACITYMODE subparameter is valid when all the following are true:

- CAPACITYMODE is used in conjunction with UNITTYPE
- The subparameter of UNITTYPE is an esoteric that is specified through SETSYS USERUNITTABLE
- The UNITTYPE contains only IBM 3590 drives that are emulating IBM 3490 drives that are CAPACITYMODE switchable.

When you specify CAPACITYMODE incorrectly, DFSMSHsm ignores the subparameter. For example, if you specify CAPACITYMODE when the UNITTYPE is a generic, such as 3490, DFSMSHsm ignores the CAPACITYMODE subparameter. Also, if you specify CAPACITYMODE for an esoteric capable of CAPACITYMODE(EXTENDED), but you do not specify COMPATIBILITY or EXTENDED, CAPACITYMODE is ignored.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: For TAPEUTILIZATION the DFSMSHsm default value is 97%. If you use the DFSMSHsm default value, the data on one cartridge can most likely be copied to another cartridge of the same category. If you do not plan to copy cartridges, you might specify NOLIMIT to use the entire cartridge capacity. However, it is recommended that you instead specify PERCENTFULL(100) to get the benefits of reduced tape spanning.

For TAPEUTILIZATION CAPACITYMODE, the DFSMSHsm default is COMPATIBILITY. During an input operation, DFSMSHsm temporarily switches the unit to CAPACITYMODE(EXTENDED) if it is given a tape in

that mode. If you do not specify CAPACITYMODE for an esoteric capable of CAPACITYMODE(EXTENDED), during a DFSMSHsm output function, the drives operate in CAPACITYMODE(COMPATIBILITY).

Note:

1. In a duplex tape environment, DFSMSHsm uses the default PERCENTFULL value of 97 percent. This value is not likely to be a problem unless you are targeting a 3590-Bx or vendor drive in 3490 emulation mode. These drives need a percent value of a few hundred to fully utilize the tape's capacity. A value of 97 percent is appropriate, however, for targeting a 3590-Ex drive, even if in 3490 emulation mode.
2. Issuing the SETSYS USERUNITTABLE command will reset the TAPEUTILIZATION for all esoteric devices to the DFSMSHsm default of 97 percent. For the command to be effective, you must enter the SETSYS USERUNITTABLE command before the SETSYS TAPEUTILIZATION command.
3. UNITTYPE(*unittype*), LIBRARYBACKUP, and LIBRARYMIGRATION are mutually exclusive subparameters. A separate SETSYS command must be issued for each subparameter. For example, to use 100% of the capacity but retain the reduced tape spanning, issue the following commands:

```
SETSYS TAPEUTILIZATION(UNITTYPE(unittype) PERCENTFULL(100))
SETSYS TAPEUTILIZATION(LIBRARYBACKUP PERCENTFULL(100))
SETSYS TAPEUTILIZATION(LIBRARYMIGRATION PERCENTFULL(100))
```

4. For drives prior to the IBM 3590 Model E1x, DFSMSHsm based the PERCENTFULL value on the cartridge type of the reported logical device type in emulation mode. For IBM 3590 Model E1x drives, DFSMSHsm uses the reported cartridge type of the physical device to determine the tape capacity. When using these tape drives, you do not need to supply a percentage greater than 100 to reasonably fill the tapes. As a result, DFSMSHsm has improved the ability to fill migration and backup tape cartridges when using IBM 3590 Model E1x drives.
5. If you have tape cartridges that have a capacity larger than the IBM enhanced-capacity tape cartridges, it is recommended that you specify the PERCENTFULL(*pct*) parameter for the unit type when those tapes will be used instead of specifying NOLIMIT. For *pct*, specify a value between 1 and 9999.

For example, if you have tape cartridges that are approximately 25% larger, using a value of PERCENTFULL(122) on the SETSYS TAPEUTILIZATION command is recommended for the following reasons:

- You want to avoid hitting the natural EOVS because that would tie tapes together and until the spanning data set is invalidated, all the tapes containing the desired data set must be handled to access the one spanning data set.
 - RECYCLE has to treat the connected tapes together until the spanning data set is invalidated. This process generally delays the tapes from being returned to scratch.
 - A chain of 240 connected tapes will likely be created if TAPEUTILIZATION is not used. If you have an error and need to take some explicit corrective action on one tape, you may have to process a very long chain of tapes.
 - The TAPECOPY function will probably be able to copy these tapes but only to similar or larger tapes. However, the use of 122% rather than 125% increases the possibility of a successful tape copy by maintaining an equivalent 97% tape utilization.
6. IBM 3590 drives introduce a new microcode support; see [Table 66 on page 1200](#) for the percent values to use with the SETSYS TAPEUTILIZATION command:

Table 66. Tape Utilization Capacity for MEDIA3 or Greater.		
Percent to use	3490 Mode	3590 Mode
3590B with MEDIA3 or MEDIA4	2200. If any of the 3590B drive controllers are running with a level of microcode prior to 1.9.19.0, use a value of 1100 instead.	97

Table 66. Tape Utilization Capacity for MEDIA3 or Greater. (continued)		
Percent to use	3490 Mode	3590 Mode
All others	97	97

7. DFSMSHsm writes to 97% of the capacity of MEDIA5, MEDIA6, MEDIA7, MEDIA8, MEDIA9, MEDIA10, MEDIA11, MEDIA12, and MEDIA13 tapes unless otherwise specified by the installation. Other percentages can be specified through the SETSYS TAPEUTILIZATION command, depending on the particular needs of the installation. DFSMSHsm uses the reported cartridge type on the physical device to determine the tape's capacity.
8. The 3490 architecture that the TS7700 emulates has maximum number of blocks, approximately 4.1 million (22 bits = 4,194,304) that can be written to a single tape volume. Writing beyond this limit results in an end of volume (EOV) condition. DFSMSHsm migration and backup processing write to tape using a 16k block size. Due to the 3490 block limit and the use of 16k blocks, if larger logical volume sizes such as 25GB or 65GB are defined for HSM use in the TS7700, the block limit may be reached prior to the full capacity of the volume being utilized.

UNITNAME: Specifying the type of unit for mounting a scratch tape during backup or dump

Explanation: **UNITNAME**(*unitname*) is an optional parameter identifying the type of unit that should be specified the first time DFSMSHsm requests that a scratch tape be mounted during backup or dump.

The BACKUP and DUMP functions use the same types of tape units. For *unitname*, substitute the type of tape unit.

The following are valid types of tape units:

- 3480
- 3480X
- 3490
- 3590-1

You can substitute an esoteric tape unit defined with the SETSYS USERUNITTABLE command. If you specify an esoteric tape unit name that does not exist in the user unit table, the command fails. If you specify:

- 3480 or 3480X, you use all the functions of the 3480 Magnetic Tape Subsystem.
- 3490, you use all the functions of the 3490 Magnetic Tape Subsystem.
- 3590-1, you use all the functions of the 3590 Magnetic Tape Subsystem.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is 3590-1.

Note:

1. For DUMP functions, if you want to specify a reel-type tape, you must use the DEFINE DUMPCCLASS command.
2. For the CDS Backup function, if you want to specify a reel-type tape, you must use the SETSYS CDSVERSIONBACKUP (BACKUPDEVICECATEGORY(TAPE(UNITNAME))) command.
3. You cannot specify an esoteric unit name that represents DASD; it must represent tape.
4. DFSMSHsm does not use UNITNAME when it requests that a scratch volume be mounted while continuing from another volume. Instead, DFSMSHsm uses the same unit the volume was mounted on.

UNLOAD and NOUNLOAD: Specifying whether to unload MSS virtual DASD volumes

The use of the UNLOAD and NOUNLOAD parameters are considered to be nonfunctional and their use is ignored by DFSMSHsm.

USECYLINDERMANAGEDSPACE: Specifying whether to allow use of cylinder managed space for migration copies and backup versions

Explanation: USECYLINDERMANAGEDSPACE is an optional parameter specifying whether you want to allow use of the cylinder-managed space for migration copies and backup versions. USECYLINDERMANAGEDSPACE can be abbreviated as USECMS.

The parameters of the USECYLINDERMANAGEDSPACE parameter are explained:

Y

specifies that migration copies and backup versions can reside in EAS. For allocation, DFSMSHsm uses EATTR=OPT for its migration copy or backup version.

N

specifies that migration copies and backup versions cannot reside in EAS. For allocation DFSMSHsm does not specify an EATTR value.

SMS relationship: This parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: N (no).

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is N (no).

Note:

1. When using the ARECOVER command, the specified USECYLINDERMANAGEDSPACE parameter will determine allocation of migrated data sets specified in the INCLUDE list.
2. When using the FREEVOL command, if USECYLINDERMANAGEDSPACE(Y) was specified and migration copies, backup versions, or VTOC copies are going to be moved, then EATTR=OPT is specified. Otherwise, an EATTR value is not specified.
3. When you issue the QUERY SETSYS command, the value of the USECYLINDERMANAGEDSPACE is displayed as USECMS=*value*.

USERUNITTABLE and NOUSERUNITTABLE: Specifying esoteric tape unit names to DFSMSHsm

The SETSYS USERUNITTABLE command has two functions:

- to identify esoteric tape unit names to DFSMSHsm.
- to control translation of esoteric output unit names.

The SETSYS USERUNITTABLE command must always be coded for esoteric unit names used by DFSMSHsm whether translation is required or not. All esoterics identified to DFSMSHsm with the SETSYS USERUNITTABLE command must appear in a single command.

To identify esoteric tape unit names to DFSMSHsm, you must first define these esoteric tape unit names to MVS during system I/O generation. Then, you must include the esoteric tape unit names in a DFSMSHsm SETSYS USERUNITTABLE command. Only after they have been successfully specified with the SETSYS USERUNITTABLE command can they be recognized and used as valid unit names with subsequent DFSMSHsm commands.

For the DFSMSHsm commands required to restrict device selection, see topic about [Implementing tape environments in z/OS DFSMSHsm Implementation and Customization Guide](#), specifically:

- For SMS-managed tape libraries, see the topic about [Information passed to an ACS routine](#).
- For other tape libraries (such as non-SMS or nonlibrary), see the topic about [Tape device selection](#).

To control the translation of output unit names, you can use the SETSYS USERUNITTABLE specifications of output unit names to input unit names. Translation occurs for translation-eligible esoteric groups. These include:

- 3480 device types with all online units of the esoteric group having cartridge loaders
- 3490 device types
- 3590 device types

Translation occurs during output processing so that when the tape units are used for input, the translated unit name is used for allocation.

There are three forms of specifications you can use to identify esoteric tape unit names to DFSMSHsm:

- first, translation is not specified (*es1*)
- second, translation is specified to a different unit name (*es2out:es2in*)
- third, translation is specified to the same unit name (*es3:es3*)

Explanation: When you specify USERUNITTABLE(*es1*, *es2out:es2in*, *es3:es3*), you are identifying four separate esoteric tape unit names in three independent specifications. You can use any of these forms of specification to identify esoteric tape unit names to DFSMSHsm. You can combine specifications as we have shown here, but remember that all esoterics used in another DFSMSHsm command must appear in a single SETSYS USERUNITTABLE command. Each separate form of specification is explained below.

When you specify a single esoteric (*es1*), the esoteric tape unit name *es1* is identified to DFSMSHsm as valid. Output allocations are made to units associated with the particular esoteric tape unit name requested for the output function. Any cartridge loader esoteric translation is assigned to the generic unit name equivalent to the type of units associated with the esoteric tape unit name. Substitute your esoteric name for *es1*.

When you specify an out-and-in esoteric pair (*es2out:es2in*), the esoteric unit names *es2out* and *es2in* are identified to DFSMSHsm as valid. Translation to an esoteric can take place. The esoteric unit name requested for the output allocation (*es2out*) may be translated to the esoteric tape unit name specified to the right of the colon (*es2in*) when output processing is completed. If translation occurs, then when the tape volume is requested to be read, input allocations are made to units associated with *es2in*. The purpose of this translation is to allow the user to use different devices for input than output. Substitute your esoteric names for *es2out* and *es2in*.

When you specify (*es3:es3*), the esoteric unit name *es3* is identified to DFSMSHsm as valid. Since the same esoteric unit name is specified for both input and output, the same units are candidates for input allocations and output allocations. Substitute your esoteric name for *es3*.

The following discussion presents two examples. One is very general and one is specific. Please note that any values specified here are only examples and should not be interpreted as the values to be used for your system.

General example

```
SETSYS USERUNITTABLE(es1, es2out:es2in, es3:es3)
```

If, for example, backup is restricted to *es1* by using the SETSYS BACKUP(TAPE(*es1*)) command, migration is restricted to *es2out* by using the SETSYS TAPEMIGRATION(ML2TAPE(TAPE(*es2out*))) command, and spill is restricted to *es3* by using the SETSYS SPILL(TAPE(*es3*)) command, then the following occurs:

- Backup output allocations are made to units associated with *es1*. If *es1* is translation-eligible, input allocations for recover are allocated using the generic unit name equivalent to *es1*.
- Migration output allocations are made to units associated with esoteric tape unit name *es2out*. If *es1* is translation-eligible, input allocations for recall are made to units associated with *es2in*.

- Dump output allocations are made to units associated with esoteric tape unit name `es3`, and input allocations for restore from the tapes written in the dumping process are also made to units associated with `es3`.

Specific example

```
USERUNITTABLE(SPOUT,DPOUT,MIGOUT:RECIN,BACKUP:RECIN)
```

This example specifies five esoteric tape unit names. When you specify single esoteric tape unit names (without a colon, like `SPOUT` and `DPOUT`), any translations that occur are allocated to generic tape units. When you specify paired esoteric tape unit names (with colon separators, like `MIGOUT:RECIN` and `BACKUP:RECIN`), any translations that occur are to the specified tape unit name (`RECIN` in this case) and that is what will be used during later input allocations.

`NOUSERUNITTABLE` specifies that no esoteric tape unit names are identified to DFSMSHsm. Any previously defined esoteric names are no longer known to DFSMSHsm.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

Tape Library Relationship: Translation can occur for SMS tapes. However, the ACS routines can modify the resulting tape devices used. Tapes are read back on drives available to the library where the tape is resident.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is `NOUSERUNITTABLE`.

Note:

1. If there is no unit online and available for the esoteric when the SETSYS USERUNITTABLE is issued, you will receive message ARC0103I indicating the USERUNITTABLE is invalid.
2. For IBM 3490 and 3590 tape devices, esoteric translation always occurs, regardless of the existence of cartridge loaders. If you specify a 3490 or 3590-1 esoteric unit name to direct output tape allocations, a translation of that esoteric unit name occurs. Subsequent input allocations use that translated unit name. Therefore for 3490 or 3590-1, if you specify an output esoteric unit name and want the same esoteric unit name to be used for that tape's input allocations, you must specify a translation to itself. For example, SETSYS USERUNITTABLE(TAPE:TAPE).
3. The 3490 control units (models A01, A02, A10, A20, D31, and D32) have the same read and write capabilities as the 3480X control unit.
4. You must ensure that each tape unit belonging to the esoteric group you specify can read and write on any tape written by any other tape unit that belongs to the same esoteric group. If the esoteric group contains both 3480 and 3480X devices, DFSMSHsm treats both types of devices as 3480s.
5. If an esoteric group includes one set of the tape drives defined with compaction on and another set defined with compaction off, this latter group of drives will not be able to read compacted data by the first group. Thus, the esoteric is considered invalid and message ARC0103I will be received when the SETSYS USERUNITTABLE command is issued.
6. You must define all esoteric tape unit names during system I/O generation. Do not remove from a subsequent system I/O generation those esoteric tape unit names DFSMSHsm already has used during its tape processing. If you do, DFSMSHsm cannot allocate the tape volume whose esoteric unit name you specified when you issued the ADDVOL command. Basically, by removing the esoteric name, you make the esoteric name an invalid unit name.
7. DFSMSHsm rejects mixed combinations of device names in an esoteric group, with the following exception: it allows the use of both 3480 and 3480X device names in a single group. Improved Data Recording Capability (IDRC), however, is not used with such a group because all devices in the group are treated as 3480s. If an esoteric group associated only with 3480Xs exists, 3480s should not be added to it, because the data already written using this esoteric tape unit name may create IDRC incompatibilities. 3592-1, 3592-2 and 3592-2E tape units are allowed into the same esoteric since

they share common write formats. 3592-2, 3592-2E, and 3592-3E tape units are allowed into the same esoteric since they also share common write formats. 3592-3E and 3592-4E tape units are allowed into the same esoteric since they also share common write formats. It is up to the user to ensure the drives in the mixed esoteric will be used with a common recording technology write using the same recording technology. For example, if any 3592-1 drives are included, then all drives in the esoteric must use EMFT1 for output. If the esoteric mixes 3592-2 and 3592-2E drives, then all drives must be setup to use EFMT1 or EFMT2. If the esoteric contains mixed 3592-3E and 3592-2E tape units, then all drives must be set up to use EFMT2 or EEFMT2, the write formats they have in common. If the esoteric contains mixed 3592-4E and 3592-3E tape units, then all drives must be set up to use EFMT3 or EEFMT3, the write formats they have in common.

If DFSMSHsm rejects an esoteric tape unit name, it does not reject the rest of the valid esoteric names specified in the USERUNITTABLE command. Those names are now recognized by DFSMSHsm as valid esoteric tape unit names. Each time you specify USERUNITTABLE, the valid esoteric tape unit names identified with this parameter replaces any esoteric tape unit names identified with a previous USERUNITTABLE parameter of the SETSYS command.

8. If you define both 3592-E05 and 3592-J1A to the same esoteric group, the E05 must use the EFMT1 recording format.
9. You can define a 3592-E05 or 3592-J1A to the 3590-1 generic group. If so, you must ensure drive compatibility or segmentation when using the 3590-1 in a non-SMS environment.
10. If an esoteric group includes a mixture of cartridge loader and non cartridge loader units, the esoteric name translation does not take place. It is important to note that for translation to occur, at least one unit associated with the esoteric tape unit name *es2out* must be varied online, and all online units associated with *es2out* must have cartridge loaders or be 3490s. The unit name used by DFSMSHsm for input is described in [Implementing tape environments in z/OS DFSMSHsm Implementation and Customization Guide](#).
11. If you reenter a SETSYS USERUNITTABLE command be aware that the prior table is entirely deleted and a new one is built from the new command and the MVS esoteric definitions. This will likely necessitate that you also enter the SETSYS TAPEUTILIZATION command because defaults are again in use. If you have removed an esoteric that is used in a tape output restriction specification, such as SETSYS BACKUP(TAPE(es1)), then you will also need to change those specifications.
12. To remove cartridge loader as a condition for device type 3480 esoteric unit name translation, refer to [Tuning DFSMSHsm in z/OS DFSMSHsm Implementation and Customization Guide](#).
13. For a summary of esoteric translation results, refer to the topic [Summary of esoteric translation results for various tape devices in z/OS DFSMSHsm Implementation and Customization Guide](#).
14. The esoteric values specified for certain SETSYS parameters cannot resolve to reel-type tapes. See Chapter 13, “Managing DFSMSHsm media,” on page 527 for details.

VERSIONS: Specifying the maximum number of backup versions to keep for any data set

Explanation: **VERSIONS(limit)** is an optional parameter specifying the maximum number of backup versions DFSMSHsm keeps for any one data set. The maximum number of backup versions is limited to either 29 versions or 100 versions based on the BCDS record length. The following values are the valid maximum allowable number of backup versions for different BCDS record lengths:

- Record length of 2040 to 6543 — 29 versions maximum
- Record length of 6544 or more — 100 versions maximum

For *limit*, substitute a decimal number from 0 to 100. A zero (0) specifies that DFSMSHsm does not create backup versions for any non-SMS-managed data set unless you specify the ALTERDS VERSIONS command.

SMS relationship: Parameter does not apply to SMS-managed DASD volumes or data sets.

SETSYS default: If you specify a value larger than the valid maximum allowable for that BCDS record length, the maximum value for that record length will be used. For example, if you specify SETSYS

VERSIONS(50) and you have a BCDS record length of 2040 to 6543, the maximum allowable number of backup versions for this record length, which is 29, will be used.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default for *limit* is 2.

Note:

1. The SETSYS VERSIONS parameter is used to specify the number of backup versions for all your non-SMS-managed data sets. An authorized user, however, can specify the VERSIONS parameter of the ALTERDS command to change that number of backup versions for a specific data set. An unauthorized user can specify the VERSIONS parameter of the HALTERDS command to change that number of backup versions for a specific data set with the same high-level qualifier as the unauthorized user.
2. For more information about cataloged and uncataloged data sets, see [“Backing up cataloged and uncataloged data sets with the same name” on page 307](#).
3. If the number of versions in the VERSIONS parameter is decreased, and the EXPIREBV command is executed prior to the time the next version is created, all excess versions—whether cataloged or uncataloged—are deleted.

VOLCOUNT: Specifying the method for determining volume count for SMS target data set allocations when performed by DFSMSdss

Explanation: VOLCOUNT(ANY | NONE) is an optional parameter that affects how DFSMSHsm will invoke DFSMSdss for the recall and recover of data sets moved by DFSMSdss. Refer to [z/OS DFSMSdss Storage Administration](#) for more specific information about the restrictions and limitations of the DFSMSdss VOLCOUNT parameter.

Subparameter	Explanation
ANY	DFSMSHsm passes the VOLCOUNT(ANY) parameter to DFSMSdss during the recall or recover of data moved by DFSMSdss. This results in the allocation of the target data set on as many volumes as required, to a maximum of 59.
NONE	The VOLCOUNT parameter is not passed to DFSMSdss. Issuing SETSYS VOLCOUNT(NONE) will reset the associated DFSMSHsm indicators and DFSMSHsm will operate as it did prior to the VOLCOUNT support being added. If, for example, VOLCOUNT(ANY) had been previously specified, issuing SETSYS VOLCOUNT(NONE) resets the associated DFSMSHsm indicators.

The VOLCOUNT parameters of ANY or NONE are ignored if specified for data types to which they do not apply. Refer to the [z/OS DFSMSHsm Implementation and Customization Guide](#) to determine data set types moved by DFSMSdss for DFSMSHsm.

SMS relationship: Parameter applies in some instances to SMS-managed DASD volumes or data sets.

SETSYS default: There is no SETSYS default.

DFSMSHsm default: If you do not specify SETSYS VOLCOUNT, the default is NONE.

VOLUMEDUMP: Specifying concurrent copy options for dump volumes

Explanation: VOLUMEDUMP is an optional parameter specifying whether DFSMSHsm will request that DFSMSdss use a type of Concurrent Copy function for dump volumes or no Concurrent Copy function for dump volumes.

Subparameter	Explanation
CC	DFSMSHsm specifies Concurrent Copy when DFSMSdss dumps volumes. DFSMSdss determines if the device and microcode can support this operation. Customers can specify SETSYS DUMPVOLUME(CC). CC is an alias of PREFERRED and can be added next to the word PREFERRED like the other aliases.
STANDARD (NOCC)	STANDARD indicates Concurrent Copy will not be used when DFSMSHsm dumps the volumes. Control returns to the requestor at the end of the physical copy.
REQUIRED (ANYREQUIRED)	DFSMSHsm requests DFSMSdss to use concurrent copy to perform the dump. If virtual concurrent copy is unavailable DFSMSdss uses cache-based concurrent copy. If both types of concurrent copy are unavailable, the dump fails.
PREFERRED (ANYPREFERRED)	DFSMSHsm requests DFSMSdss to use concurrent copy to perform the dump. If virtual concurrent copy is unavailable, DFSMSdss uses cache-based concurrent copy. If both types of concurrent copy are unavailable, the dump continues as if the CC keyword was not specified.
VIRTUALREQUIRED (VREQ)	DFSMSHsm requests DFSMSdss to use virtual concurrent copy to dump volumes. If virtual concurrent copy is unavailable, the dump fails.
VIRTUALPREFERRED (VPREF)	DFSMSHsm requests DFSMSdss to use virtual concurrent copy to dump volumes. If virtual concurrent copy is unavailable, the dump continues as if the CC keyword was not specified.
CACHEREQUIRED (CREQ)	DFSMSHsm requests DFSMSdss to use cache-based concurrent copy to dump the data sets. If cache-based concurrent copy is unavailable, the dump fails.
CACHEPREFERRED (CPREF)	DFSMSHsm requests DFSMSdss to use cache-based concurrent copy to dump the data sets. If cache-based concurrent copy is unavailable, the data set dump continues as if the CC keyword was not specified.

Note:

1. The correct level of hardware and microcode must be present in your system environment for the Concurrent Copy function to work.
2. In a mixed hardware environment, where some volumes are capable of Concurrent Copy and others are not, specifying a type of Concurrent Copy will be accepted and only apply to those volumes capable of this process, and the noncapable volumes will be dumped using traditional methods.

SMS relationship: Parameter has the same meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify this parameter on any SETSYS command, the DFSMSHsm default is NOCC.

ZCOMPRESS: Specifying when compression with zEDC should be done

Explanation: **ZCOMPRESS** is an optional parameter set that you use to specify the type of compression used during migration or backup for all data sets.

The subparameters of the ZCOMPRESS parameter follow this discussion in alphabetical order. The following are optional subparameters:

- ALL | NONE
- CLOUDMIGRATE(YES | NO)
- DASDBACKUP (YES | NO)
- DASDMIGRATE (YES | NO)
- TAPEBACKUP (YES | NO)
- TAPEMIGRATE (YES | NO)

SMS relationship:

Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets. This ZCOMPRESS parameter is used only for SMS data sets that are not compressed on LO; for non-SMS data sets, it is always in effect, as you cannot have a non-SMS data set compressed on LO.

SETSYS default: If you do not specify the ZCOMPRESS parameter, the SETSYS default is no compression with zEDC.

DFSMShsm default: If you do not specify a subparameter with this parameter on any SETSYS command, the DFSMShsm default is no compression with zEDC.

ZCOMPRESS (NONE | ALL): Specifying whether to use zEDC Services for data sets

Explanation: ALL | NONE are mutually exclusive, optional subparameters of the ZCOMPRESS parameter, specifying whether or not to use zEDC Services during migration or backup.

Subparameter	Explanation
NONE	DFSMShsm does <i>not</i> use zEDC for a data set during migration or backup. DFSMShsm will use the SETSYS COMPACT settings.
ALL	DFSMShsm will use zEDC during migration and backup, if this function is supported by the system. If zEDC Services are <i>not</i> available, DFSMShsm will use the SETSYS COMPACT settings to determine what type of software compaction is used for migration and backup.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMShsm default: If you do not specify any subparameter of the ZCOMPRESS parameter on any SETSYS command, the DFSMShsm default is NONE and the SETSYS COMPACT settings will be used.

Note:

1. DFSMShsm does *not* use zEDC for partitioned data sets.
2. When you specify the ALL or NONE subparameter with the ZCOMPRESS parameter, DFSMShsm ignores all other subparameters.

ZCOMPRESS(CLOUDMIGRATE(NO | YES)): Specifying whether to use CDA compression for data sets during migration to DIRECT cloud connections

Explanation: CLOUDMIGRATE (NO | YES) are mutually exclusive, optional subparameters of the ZCOMPRESS parameter, specifying whether or not to use CDA compression with zEDC Services when DFSMShsm migrates to DIRECT cloud.

Subparameter	Explanation
CLOUDMIGRATE(NO)	DFSMSHsm does not use CDA compression for migration to DIRECT cloud connections.
CLOUDMIGRATE(YES)	DFSMSHsm will use CDA compression with zEDC Services during migration to DIRECT cloud connections, if this function is supported by the system. If CDA compression is unavailable, the data sets will not be compressed during migration to DIRECT cloud connections.

SMS relationship: SMS-managed data sets are supported for migration to CLOUD. This parameter is inapplicable for non-SMS-managed data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either subparameter on any SETSYS ZCOMPRESS command, the DFSMSHsm default is CLOUDMIGRATE(NO).

Note:

1. As compressed-format data sets are already compressed, they are not compressed with CDA compression during migration to DIRECT cloud connections.
2. Since encrypted data sets do not compress, CDA compression will not be used during migration to DIRECT cloud connections.
3. You can run the SETSYS ZCOMPRESS(CLOUDMIGRATE(NO|YES)) command in the ARCCMDxx parmlib member conditionally by specifying ONLYIF HSMHOST. This allows you to run the command only on designated DFSMSHsm hosts.

Related Reading: For more information about the ONLYIF command, see [Chapter 56, “ONLYIF command: Running commands in ARCCMDxx conditionally,”](#) on page 973

ZCOMPRESS (DASDBACKUP (NO | YES)) : Specifying whether to use zEDC Services for data sets during backup to DASD

Explanation: DASDBACKUP (NO | YES) are mutually exclusive, optional subparameters of the ZCOMPRESS parameter, specifying whether or not to use zEDC Services when DFSMSHsm backs up to DASD.

Subparameter	Explanation
DASDBACKUP (NO)	DFSMSHsm does <i>not</i> use zEDC for a data set backup to DASD. DFSMSHsm will use the SETSYS COMPACT settings.
DASDBACKUP (YES)	DFSMSHsm will use zEDC Services during backup to DASD, if this function is supported by the system. If zEDC is <i>not</i> available, DFSMSHsm will use the SETSYS COMPACT settings to determine what type of software compaction is used for backup.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either subparameter on any SETSYS command, the DFSMSHsm default is DASDBACKUP(NO).

Note:

1. If you do not want a specific data set to be compressed with zEDC during volume backup to DASD, use the data set backup exit (ARCBDEXT) to prevent compression.
2. As compressed-format data sets are already compressed, they are not compressed with zEDC Services during backup to DASD.

3. Since encrypted data sets do not compress, zEDC compression services will not be used during backup to DASD.

ZCOMPRESS (DASDMIGRATE (NO | YES)) : Specifying whether to use zEDC Services for data sets during migration to DASD

Explanation: **DASDMIGRATE (NO | YES)** are mutually exclusive, optional subparameters of the ZCOMPRESS parameter, specifying whether or not to use zEDC Services when DFSMSHsm migrates to DASD.

Subparameter	Explanation
DASDMIGRATE (NO)	DFSMSHsm does <i>not</i> use zEDC for a data set migration to DASD. DFSMSHsm will use the SETSYS COMPACT settings.
DASDMIGRATE (YES)	DFSMSHsm will use zEDC Services during migration to DASD, if this function is supported by the system. If zEDC is <i>not</i> available, DFSMSHsm will use the SETSYS COMPACT settings to determine what type of software compaction is used for migration.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either subparameter on any SETSYS command, the DFSMSHsm default is DASDMIGRATE(NO).

Note:

1. If you do not want a specific data set to be compressed with zEDC during volume migration to DASD, use the data set migration exit (ARCMDEXT) to prevent compression.
2. As compressed-format data sets are already compressed, they are not compressed with zEDC Services during migration to DASD.
3. Since encrypted data sets do not compress, zEDC compression services will not be used during migration to DASD.

ZCOMPRESS (TAPEBACKUP (NO | YES)) : Specifying whether to use zEDC Services for data sets during backup to tape

Explanation: **TAPEBACKUP (NO | YES)** are mutually exclusive, optional subparameters of the ZCOMPRESS parameter, specifying whether or not to use zEDC Services when DFSMSHsm backs up to tape.

Subparameter	Explanation
TAPEBACKUP (NO)	DFSMSHsm does <i>not</i> use zEDC for a data set backup to tape. DFSMSHsm will use the SETSYS COMPACT settings.
TAPEBACKUP (YES)	DFSMSHsm will use zEDC Services during backup to tape, if this function is supported by the system. If zEDC is <i>not</i> available, DFSMSHsm will use the SETSYS COMPACT settings to determine what type of software compaction is used for backup.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either subparameter on any SETSYS command, the DFSMSHsm default is TAPEBACKUP(NO).

Note:

1. If you do not want a specific data set to be compressed with zEDC during volume backup to tape, use the data set backup exit (ARCBDEXT) to prevent compression.
2. As compressed-format data sets are already compressed, they are not compressed with zEDC Services during backup to tape.
3. Since encrypted data sets do not compress, zEDC compression services will not be used during migration to DASD.

ZCOMPRESS (TAPEMIGRATE (NO | YES)) : Specifying whether to use zEDC Services for data sets during migration to tape

Explanation: TAPEMIGRATE (NO | YES) are mutually exclusive, optional subparameters of the ZCOMPRESS parameter, specifying whether or not to use zEDC Services when DFSMSHsm migrates to tape.

Subparameter	Explanation
TAPEMIGRATE (NO)	DFSMSHsm does <i>not</i> use zEDC for a data set migration to tape. DFSMSHsm will use the SETSYS COMPACT settings.
TAPEMIGRATE (YES)	DFSMSHsm will use zEDC Services during migration to tape, if this function is supported by the system. If zEDC is <i>not</i> available, DFSMSHsm will use the SETSYS COMPACT settings to determine what type of software compaction is used for migration.

SMS relationship: Parameter differs in meaning when applied to SMS-managed or non-SMS-managed DASD volumes or data sets.

SETSYS default: None.

DFSMSHsm default: If you do not specify either subparameter on any SETSYS command, the DFSMSHsm default is TAPEMIGRATE(NO).

Note:

1. If you do not want a specific data set to be compressed with zEDC during volume migration to tape, use the data set migration exit (ARCMDEXT) to prevent compression.
2. As compressed-format data sets are already compressed, they are not compressed with zEDC Services during migration to tape.
3. Since encrypted data sets do not compress, zEDC compression services will not be used during migration to tape.

Examples of how to code the SETSYS command

The following examples present common user scenarios that you can use to code the SETSYS command for your installation. Both main functions and supporting functions are illustrated in the examples. The functions are arranged in alphabetical order.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Specifying the SETSYS parameters for ABARS processing

In this example, the SETSYS parameters associated with both ABACKUP and ARECOVER processing are specified. Where appropriate, default values or recommended values are used in the example. These parameters are in effect until another SETSYS command is issued to change them.

For ABARS Processing:

- All DFSMSdss messages are intercepted and written in the ABARS activity log. Parameter used is ABARSACTLOGMSGLVL(FULL).
- The ABARS activity log is written to DASD. Parameter used is ABARSACTLOGTYPE(DASD).
- Allow ABARS to use the default number of I/O buffers. Parameter used is ABARSBUFFERS(1).
- DFSMSHsm is to delete the ABARS activity log during ABARS roll-off processing or EXPIREBV ABARSVERSIONS processing. Parameter used is ABARSDELETEACTIVITY(Y).
- Allow ABARS to use the default base procedure name when starting the ABARS secondary address space. Parameter used is ABARSPROCNAME(DFHSMABR).
- Allow DFSMSHsm to stack the ABACKUP output. Parameter used is ABARSTAPES(STACK).
- Use 3590-1 as a unit name for ABARS. Parameter used is ABARSUNITNAME(3590-1).
- Use the default number of concurrent secondary addresses supported by DFSMSHsm. Parameter used is MAXABARSADDRESSSPACE(1).
- The following DFSMSHsm installation exits are active: ABARS expiration date setting exit, aggregate backup error exit, aggregate backup ML2 bypass exit, aggregate recovery conflict resolution exit, aggregate recovery bypass exit, and ABARS tape volume exit. Parameter used is EXITON(ED BE M2 CR SK TV).

For ABACKUP Processing:

- Use the default OPTIMIZE value when ABACKUP invokes DFSMSdss to backup level 0 DASD data sets. Parameter used is ABARSOPTIMIZE(3).
- Data sets on volumes protected by peer-to-peer remote copy or extended remote copy are backed up by ABACKUP processing. Parameters used are ABARSKIP(NOPPRC NOXRC).

For ARECOVER Processing:

- Allow DFSMSHsm to pass the VOLCOUNT parameter to DFSMSdss during the ARECOVER of L0 data sets. You want to allocate as many volumes as required for the target data set. Parameter used is ABARSVOLCOUNT(ANY).
- Use 3590-1 tape units when recovering user tape volumes. Parameter used is ARECOVERUNITNAME(3590-1).
- Use 3590-1 tape units when recovering migrated data sets to ML2 tape volumes. Parameter used is ARECOVERML2UNIT(3590-1).
- Use the default percentage of DASD space when filling non-SMS-managed recovery volumes. Parameter used is ARECOVERPERCENTUTILIZED(80).
- Allow DFSMSHsm to pass the TGTGDS parameter to DFSMSdss during restore processing of SMS-managed generation data sets to level 0 DASD. Parameter used is ARECOVERTGTGDS(SOURCE).

```

SETSYS ABARSACTLOGMSGLVL(FULL)  +
       ABARSACTLOGTYPE(DASD)    +
       ABARSBUFFERS(1)          +
       ABARSDELETEACTIVITY(Y)   +
       ABARSPROCNAME(DFHSMABR)  +
       ABARSTAPES(STACK)        +
       ABARSUNITNAME(3590-1)    +
       MAXABARSADDRESSSPACE(1)  +
       EXITON(ED BE M2 CR SK TV) +
       ABARSOPTIMIZE(3)         +
       ABARSKIP(NOPPRC NOXRC)   +
       ABARSVOLCOUNT(ANY)      +
       ARECOVERUNITNAME(3590-1) +
       ARECOVERML2UNIT(3590-1)  +
       ARECOVERPERCENTUTILIZED(80) +
       ARECOVERTGTGDS(SOURCE)

```

Specifying the SETSYS parameters for backup processing

In this example, the SETSYS parameters associated with backup processing are specified. Where appropriate, default values or recommended values are used in the examples. These parameters are in effect until another SETSYS command is issued to change them.

- Automatic backup can start between 0030 (12:30 a.m.) and 0400 (4:00 a.m.) hours. DFSMSHsm does not begin on additional volumes after 0730 (7:30 a.m.) hours. Parameter used is AUTOBACKUPSTART(0030 0400 0730).
- If the backup processing finds a data set in use, DFSMSHsm is to retry the backup after a delay of 60 minutes, and accept the backup version even if the data set is still in use. Parameter used is BACKUP(INUSE (RETRY(Y) DELAY(60) SERIALIZATION(PREFERRED))).
- DFSMSHsm can compact a data set during backup processing to DASD. Parameter used is COMPACT(DASDBACKUP).
- You want DFSMSHsm to use the backup prefix name of HSM. Parameter used is BACKUPPREFIX(HSM).
- DFSMSHsm does not compact a data set unless 40% of the total space is saved. Parameter used is COMPACTPERCENT(40).
- DFSMSHsm creates original backup tapes that will be kept on site and alternate backup tapes that will be written at a remote site. Parameter used is DUPLEX(BACKUP(Y)).
- The following installation exits are active: data set backup exit and space management and backup exit. Parameter used is EXITON(BD SA).
- DFSMSHsm creates backup versions when data sets are changed. Parameter used is INCREMENTALBACKUP(CHANGEDONLY).
- DFSMSHsm can backup eight DASD volumes concurrently on this host. Parameter used is MAXBACKUPTASKS(8).
- DFSMSHsm retains two tape allocations for 120 minutes of inactivity, until command data set backups directed to tape are held, or until DFSMSHsm shuts down before deallocating the drives. Parameter used is DSBACKUP(TAPE(DEMOUNTDELAY(MAXIDLETASKS(2) MINUTES(120)))).

```
SETSYS AUTOBACKUPSTART(0030 0400 0730) +
BACKUP(INUSE (RETRY(Y) DELAY(60) SERIALIZATION(PREFERRED))) +
BACKUPPREFIX(HSM) +
COMPACT(DASDBACKUP) +
COMPACTPERCENT(40) +
DUPLEX(BACKUP(Y)) +
EXITON(BD SA) +
INCREMENTALBACKUP(CHANGEDONLY) +
MAXBACKUPTASKS(8) +
DSBACKUP(TAPE(DEMOUNTDELAY(MAXIDLETASKS(2) MINUTES(120)))))
```

Specifying the SETSYS parameters for DFSMSHsm control data sets

In this example, the SETSYS parameters associated with DFSMSHsm control data sets processing are specified. Where appropriate, default values or recommended values are used in the examples. These parameters are in effect until another SETSYS command is issued to change them.

- DFSMSHsm invokes the DFSMSdss logical dump function for each control data set backed up. Parameter used is CDSVERSIONBACKUP(DATAMOVER(DSS)).
- DFSMSHsm backs up control data sets and the journal data set to scratch tapes. Parameter used is CDSVERSIONBACKUP(BACKUPDEVICECATEGORY(TAPE)).
- DFSMSHsm keeps twenty backup copies for each control data set and journal data set. Parameter used is CDSVERSIONBACKUP(BACKUPCOPIES(20)).
- You want DFSMSHsm to use HSM.BCDS.BACKUP as the initial characters when allocating the backup data set for the BCDS. Parameter used is CDSVERSIONBACKUP(BCDSBACKUPPSN(HSM.BCDS.BACKUP)).

- You want DFSMSHsm to use HSM.MCDS.BACKUP as the initial characters when allocating the backup data set for the MCDS. Parameter used is CDSVERSIONBACKUP(MCDSBACKUPDSN(HSM.MCDS.BACKUP)).
- You want DFSMSHsm to use HSM.OCDS.BACKUP as the initial characters when allocating the backup data set for the OCDS. Parameter used is CDSVERSIONBACKUP(OCDSBACKUPDSN(HSM.OCDS.BACKUP)).
- You want DFSMSHsm to use HSM.JRNL.BACKUP as initial characters when allocating the backup data set for the journal data set. Parameter used is CDSVERSIONBACKUP(JRNLBACKUPDSN(HSM.JRNL.BACKUP)).
- The control data set backup exit is active. Parameter used is EXITON(CB).
- No startup, space use, or data set messages appear at the system console. Parameter used is MONITOR(NOSTARTUP NOSPACE NOVOLUME).
- DFSMSHsm writes the BCDS, MCDS, and OCDS data set records in the journal data set when updated. Parameter used is JOURNAL(RECOVER).

```
SETSYS CDSVERSIONBACKUP(DATAMOVER(DSS) +
                        BACKUPDEVICECATEGORY(TAPE) +
                        BACKUPCOPIES(20) +
                        BCDSBACKUPDSN(HSM.BCDS.BACKUP) +
                        MCDSBACKUPDSN(HSM.MCDS.BACKUP) +
                        OCDSBACKUPDSN(HSM.OCDS.BACKUP) +
                        JRNLBACKUPDSN(HSM.JRNL.BACKUP)) +
                        EXITON(CB) +
                        MONITOR(NOSTARTUP NOSPACE NOVOLUME)+
                        JOURNAL(RECOVER)
```

Specifying the SETSYS parameters for dump processing

In this example, the SETSYS parameters associated with dump processing are specified. Where appropriate, default values or recommended values are used in the example. These parameters are in effect until another SETSYS command is issued to change them.

- Automatic dump can start between 0100 (1:00 a.m.) and 0400 (4:00 a.m.) hours. DFSMSHsm does not begin additional volumes after 0630 (6:30 a.m.). Parameter used is AUTODUMPSTART(0100 0400 0630).
- You intend to use the following DFSMSHsm functions: backup, dump, recovery, and expiring backup versions. Parameter used is BACKUP.
- You want DFSMSHsm to use HSM as the first qualifier in the dump copy name. Parameter used is BACKUPPREFIX(HSM).
- DFSMSHsm specifies to DFSMSdss that the fourth buffering technique is used for DFSMSdss DASD I/O for a full-volume dump. The fourth buffering technique has DFSMSdss read one cylinder at a time. DFSMSHsm specifies to DFSMSdss that the third buffering technique is used for DFSMSdss DASD I/O, and DFSMSdss is to read five tracks at a time. Parameter used is DUMPIO(4,3).
- DFSMSHsm can concurrently process two volume dump tasks. Parameter used is MAXDUMPTASKS(2).
- DFSMSHsm requests that DFSMSdss use the Concurrent Copy function for dump volumes because they have adequate cache for the changed data at the time volume dumps are running. Parameter used is VOLUMEDUMP(PREFERRED). DFSMSdss prefers to use virtual concurrent copy if available. If virtual concurrent copy is not available cache-based concurrent copy is attempted. If both types of concurrent copy are unavailable, the data set dump continues as if the Concurrent Copy keyword was not specified.
- The DFSMSHsm host is connected to the XCF group ARCDMP1 for common dump queue processing. This host is eligible to be the master scheduler for that functional group. All available dump tasks in the HSMplex hosts that are connected to the group as members can be used to process dump copy requests as they are received on this local host. The parameter used is COMMONQUEUE(DUMP(CONNECT(DMP1))).

```
SETSYS AUTODUMPSTART(0100 0400 0630) +
      BACKUP +
      BACKUPPREFIX(HSM) +
      DUMPIO(4,3) +
      MAXDUMPTASKS(2) +
      VOLUMEDUMP(PREFERRED)
      COMMONQUEUE(DUMP(CONNECT(DMP1)))
```

Specifying the SETSYS parameters for expiration processing

In this example, the SETSYS parameter associated with expiration processing is specified. Where appropriate, default values or recommended values are used in the example. This parameter is in effect until another SETSYS command is issued to change it.

- DFSMSHsm scratches data sets that have an expired expiration date when performing space management and migration cleanup. Parameter used is EXPIREDDATASETS(SCRATCH).

```
SETSYS EXPIREDDATASETS(SCRATCH)
```

Specifying the SETSYS parameters for extent reduction processing

In this example, the SETSYS parameter associated with extent reduction processing is specified. Where appropriate, default values or recommended values are used in the example. This parameter is in effect until another SETSYS command is issued to change it.

- DFSMSHsm reallocates all non-VSAM data sets that equal or exceed five extents. Parameter used is MAXEXTENTS(5).

```
SETSYS MAXEXTENTS(5)
```

Specifying the SETSYS parameters for fast replication processing

In this example, the SETSYS parameters that are associated with fast replication processing are specified. Where appropriate, default values or recommended values are used in the example. These parameters are in effect until another SETSYS command is issued to change them.

- The maximum number of DFSMSdss invocations for each FRBACKUP command that DFSMSHsm can process concurrently is 15.
- The maximum number of DFSMSdss invocations for each FRRECOV command that DFSMSHsm can process concurrently is 15.
- The maximum number of volume pairs that DFSMSHsm passes to each DFSMSdss invocation concurrently for backup and recover functions is 24.

```
SETSYS MAXCOPYPOOLTASKS(FRBACKUP(15) FRRECOV(15) DSS(24))
```

Specifying the SETSYS parameters for interval migration processing

In this example, the SETSYS parameters associated with interval migration processing are specified. Where appropriate, default values or recommended values are used in the example. These parameters are in effect until another SETSYS command is issued to change them.

- The space management volume exit is active. Parameter used is EXITON(MV).
- DFSMSHsm does interval migration if the occupied space on a primary volume is equal to or exceeds a high threshold level when the periodic hourly space check is performed. Parameter used is INTERVALMIGRATION.
- DFSMSHsm can concurrently process eight automatic interval migration tasks. Parameter used is MAXINTERVALTASKS(8).

```
SETSYS EXITON(MV) +
      INTERVALMIGRATION +
      MAXINTERVALTASKS(8)
```

Specifying the SETSYS parameters for DFSMSHsm logging and diagnosis

In this example, the SETSYS parameters associated with DFSMSHsm logging and diagnosis are specified. Where appropriate, default values or recommended values are used in the example. These parameters are in effect until another SETSYS command is issued to change them.

- DFSMSHsm generates and logs messages for all activities. Parameter used is ACTLOGMSGVL(FULL).
- DFSMSHsm dynamically allocates DASD data sets as the type of output data sets to receive messages. Parameter used is ACTLOGTYPE(DASD).
- DFSMSHsm is not operating in debug mode. Parameter used is NODEBUG.
- DFSMSHsm is not operating in emergency mode. Parameter used is NOEMERGENCY.
- Migration cleanup deletes the MCDS data set records for data sets that are recalled more than 10 days ago and deletes daily and volume statistics records that were created more than 90 days ago. The records cleaned up by MIGRATIONCLEANUP are used by the REPORT command and by DCOLLECT. Parameter used is MIGRATIONCLEANUP(10 90).
- No startup, space use, or data set messages appear at the system console. Parameter used is MONITOR(NOSTARTUP NOSPACE NOVOLUME).
- The problem determination aid is enabled. Parameter used is PDA.
- DFSMSHsm writes SMF records that contain DFSMSHsm statistics. Parameter used is SMF(240).
- The output from DFSMSHsm goes to system output class D, with one copy printed on a form identified by 6LPI. Parameter used is SYSOUT(D 1 6LPI).
- DFSMSHsm dumps are written to a system dump data set. Parameter used is SYS1DUMP.
- DFSMSHsm will use a fast replication message data set.

```
SETSYS ACTLOGMSGVL(FULL) +
      ACTLOGTYPE(DASD) +
      NODEBUG +
      NOEMERGENCY +
      MIGRATIONCLEANUPDAYS(10 90) +
      MONITOR(NOSTARTUP NOSPACE NOVOLUME) +
      PDA +
      SMF(240) +
      SYSOUT(D 1 6LPI)+
      SYS1DUMP
      FASTREPLICATION(MESSAGE DATASET(YES HLQ(MYHLQ)))
```

Specifying the SETSYS parameters for migration processing

In this example, the SETSYS parameters associated with migration processing are specified. Where appropriate, default values or recommended values are used in the example. These parameters are in effect until another SETSYS command is issued to change them.

- DFSMSHsm can compact data sets during migration processing to DASD. Parameter used is COMPACT(DASDMIGRATE).
- DFSMSHsm does not compact a data set unless 40% of the total space is saved. Parameter used is COMPACTPERCENT(40).
- The following installation exits are active: data set migration exit, second level migration data set exit, space management volume exit, and space management and backup exit. Parameter used is EXITON(MD MM MV SA).
- DFSMSHsm deletes data sets that have an expired expiration date. Parameter used is EXPIREDDATASETS(SCRATCH).

- DFSMSShsm runs up to eight automatic volume space management tasks concurrently. Parameter used is MAXMIGRATIONTASKS(8).
- You want DFSMSShsm to use the migration prefix name of HSM. Parameter used is MIGRATEPREFIX(HSM).
- Automatic primary space management begins if DFSMSShsm is running at 0230 (2:30 a.m.). DFSMSShsm ends automatic primary space management at 0630 (6:30 a.m.). Parameter used is PRIMARYSPMGMTSTART(0230 0630).
- All eligible data sets with a data set source size of 100 KB or less are considered as candidates for migration to a small-data-set-packing data set. Parameter used is SMALLDATASETPACKING(KB(100)).

```
SETSYS COMPACT(DASDMIGRATE) +
        COMPACTPERCENT(40) +
        EXITON(MD MM MV SA) +
        EXPIREDDATASETS(SCRATCH) +
        MAXMIGRATIONTASKS(8) +
        MIGRATEPREFIX(HSM) +
        PRIMARYSPMGMTSTART(0230 0630) +
        SMALLDATASETPACKING(KB(100))
```

Specifying the SETSYS parameters for DFSMSShsm processing in an MVS environment

In this example, the SETSYS parameters associated with DFSMSShsm processing in an MVS environment are specified. Where appropriate, default values or recommended values are used in the example. These parameters are in effect until another SETSYS command is issued to change them.

- DFSMSShsm uses the defaults for CSA limiting. Parameter used is CSALIMITS(ACTIVE(90) INACTIVE(30) MAXIMUM(100) MWE(4)).
- The following installation exits are active: initialization exit and shutdown exit. Parameter used is EXITON(IN SD).
- DFSMSShsm uses job entry subsystem 2. Parameter used is JES2.
- The DFSMSShsm address space cannot be swapped by the MVS system resource manager. Parameter used is NOSWAP.
- DFSMSShsm uses the default HSMplex name of ARCPLEX0. Parameter used is PLEXNAME(PLEX0).
- DFSMSShsm considers all host in an HSMplex eligible for promotion to take over the primary functions of a failed host. Parameter used is PROMOTE(PRIMARYHOST(YES)).
- During volume backup or migration in a multiple-DFSMSShsm-host environment, system facilities like GRS, perform data set serialization of system resources. Parameter used is USERDATASETSERIALIZATION.

```
SETSYS CSALIMITS(ACTIVE(90) INACTIVE(30) MAXIMUM(100) MWE(4)) +
        EXITON(IN SD) +
        JES2 +
        NOSWAP +
        PLEXNAME(PLEX0) +
        PROMOTE(PRIMARYHOST(YES)) +
        USERDATASETSERIALIZATION
```

Specifying the SETSYS parameters for recall processing

In this example, the SETSYS parameters associated with recall processing are specified. Where appropriate, default values or recommended values are used in the example. These parameters are in effect until another SETSYS command is issued to change them.

- The DFSMSShsm host is connected to the SYSARC_PLEX1_RCL common recall queue list structure. The parameter that is used is COMMONQUEUE(RECALL(CONNECT(PLEX1))).
- DFSMSShsm can reblock data sets during recall processing. The parameter that is used is CONVERSION.
- The return-priority installation exits are active. Parameter used is EXITON(RP).

- A maximum of fifteen recall tasks can process concurrently. The parameter that is used is MAXRECALLTASKS(15).
- A maximum of five tape recall tasks that can concurrently request tape mounts. The parameter that is used is TAPEMAXRECALLTASKS(5).
- DFSMSHsm passes the volume count parameter to DFSMSdss during the recall or recover of data that is moved by DFSMSdss. The parameter that is used is VOLCOUNT(ANY).

```
SETSYS COMMONQUEUE(RECALL(CONNECT(PLEX1))) +
      CONVERSION +
      EXITON(RP) +
      MAXRECALLTASKS(15) +
      TAPEMAXRECALLTASKS(5) +
      VOLCOUNT(ANY)
```

Specifying the SETSYS parameters for recover processing

In this example, the SETSYS parameters associated with recover processing are specified. Where appropriate, default values or recommended values are used in the example. These parameters are in effect until another SETSYS command is issued to change them.

- A maximum of two dump recover tasks can be used for FRRECOV and RECOVER FROMDUMP volume recovers.
- The DFSMSHsm host is connected to the XCF group ARCVREC1 for common recover queue processing.
- This host is eligible to be the master scheduler for the common recover queue.
- All available dump recover tasks in the HSMplex hosts that are connected to the group as members, can be used to process volume restores when the local host receives them. Parameter used is: COMMONQUEUE(RECOVER(CONNECT(REC1) MSC)).

```
SETSYS MAXDUMPRECOVERTASKS(2) +
      COMMONQUEUE(RECOVER(CONNECT(REC1) MSC))
```

Specifying the SETSYS parameters for recycle processing

In this example, the SETSYS parameters associated with recycle processing are specified. Where appropriate, default values or recommended values are used in the example. These parameters are in effect until another SETSYS command is issued to change them.

- A maximum of two recycle tasks can process concurrently. Parameter used is MAXRECYCLETASKS(2).
- When recycling tape volumes, each DFSMSHsm recycle task deallocates its input unit after each 5 connected sets of backup volumes, and after each 5 connected sets of ML2 volumes. Note: the values specified here are considered to be safe compromise values in single technology environments and you should refer to this parameters description before deciding what values to use for your installation. Parameter used is RECYCLEINPUTDEALLOCATION(BACKUP(5) MIGRATION(5)).
- During recycle processing of a tape backup volume or a tape level 2 volume, only tape spill backup volumes or tape level 2 migration volumes that can be mounted and written on the specified unit type are used for output. Parameter used is RECYCLEOUTPUT(BACKUP(3590-1) MIGRATION(3590-1)).
- DFSMSHsm uses the percent valid criteria to recycle both backup and migration tape volumes. Parameter used is RECYCLEPERCENT(20).
- DFSMSHsm does not wait for the recycle tape unit to be allocated for the source and target tape volumes. Parameter used is RECYCLETAPEALLOCATION(NOWAIT).

```
SETSYS MAXRECYCLETASKS(2) +
      RECYCLEINPUTDEALLOCATION(BACKUP(5) MIGRATION(5)) +
      RECYCLEOUTPUT(BACKUP(3590-1) MIGRATION(3590-1)) +
      RECYCLEPERCENT(20) +
      RECYCLETAPEALLOCATION(NOWAIT)
```

Specifying the SETSYS parameters for secondary space management

In this example, SETSYS parameters associated with Secondary Space Management processing are specified. Where appropriate, default values or recommended values are used in the example. These parameters are in effect until another SETSYS command is issued to change them.

- Automatic secondary space management begins if DFSMSHsm is running at 0800 (8:00 a.m.). DFSMSHsm ends automatic secondary space management at 1700 (5:00 p.m.). Note: MWEs built by secondary space management up to 1700 continue to process. If a large number of data sets needs deletion, MWE processing continues after secondary space management stops. Parameter used is SECONDARYSPMGMTSTART(0800 1700).
- DFSMSHsm keeps MCDS records for recalled data sets for 10 days. Volume statistics records are kept for 30 days and MCDS records for reconnection are kept for 3 days. Parameter used is MIGRATIONCLEANUPDAYS(10 30 3).
- A maximum of fifteen recall tasks can process concurrently. The parameter that is used is MAXRECALLTASKS(15).
- The maximum number of automatic secondary space management Statistics and Migration cleanup tasks that can run concurrently is 2.
- The maximum number of automatic secondary space management migration tasks for data sets from level 1 volumes to level 2 tape volumes that can run concurrently is 1.

```
SETSYS SECONDARYSPMGMTSTART(0800 1700) +
        MIGRATIONCLEANUPDAYS(10 30 3) +
        MAXRECALLTASKS(15) +
        MAXSMTASKS(CLEANUP(2) TAPEMOVEMENT(1))
```

Specifying the SETSYS parameters for DFSMSHsm processing in a security environment

In this example, the SETSYS parameters associated with DFSMSHsm processing in a security environment are specified. Where appropriate, default values or recommended values are used in the example. These parameters are in effect until another SETSYS command is issued to change them.

- DFSMSHsm asks RACF for the erase status of a users data set when backup versions and migration copies are scratched from DFSMSHsm-owned DASD volumes and if so requested, causes data management to overwrite the storage of the owned copy. Parameter used is ERASEONSCRATCH.
- DFSMSHsm does not create a backup RACF discrete profile when it backs up a cataloged RACF-indicated data set. Parameter used is NOPROFILEBACKUP.
- DFSMSHsm does not put RACF-indication on backup versions and migration copies. Parameter used is NORACFIND.
- DFSMSHsm protects tapes with RACF. In addition, DFSMSHsm backups up or migrates a password-protected data set to a tape volume that is not password-protected. Parameter used is TAPESECURITY(RACFINCLUDE).

```
SETSYS ERASEONSCRATCH +
        NOPROFILEBACKUP +
        NORACFIND +
        TAPESECURITY(RACFINCLUDE)
```

Specifying the SETSYS parameters for DFSMSHsm processing in a tape environment

In this example, the SETSYS parameters associated with DFSMSHsm processing in a tape environment are specified. Where appropriate, default values or recommended values are used in the example. These parameters are in effect until another SETSYS command is issued to change them.

- DFSMSHsm specifies to DFSMSdss that the fourth buffering technique is used for DFSMSdss DASD I/O for a full-volume dump. The fourth buffering technique has DFSMSdss read one cylinder at a time.

DFSMSHsm specifies to DFSMSdss that the third buffering technique is used for DFSMSdss DASD I/O, and DFSMSdss is to read five tracks at a time. Parameter used is DUMPIO(4,3).

- DFSMSHsm creates original backup tapes and migration tapes that will be kept on site and alternate tapes that will be written at a remote site. Parameter used is DUPLEX(BACKUP(Y) MIGRATION(Y)).
- The following installation exits are active: tape data set exit, and tape ejected exit. Note: the TV exit is not included because most customers are using DFSMSrmm. Parameter used is EXITON(TD TE).
- DFSMSHsm does not wait for an input tape unit to be allocated because in this example, the customer has plenty of tape units generally available. Parameter used is INPUTTAPEALLOCATION(NOWAIT).
- The number of allowable, not associated ML2 partial tapes is five. You want to recycle all not associated ML2 partial tapes. Parameter used is ML2PARTIALSNOTASSOCIATEDGOAL(5).
- DFSMSHsm waits 15 minutes for a tape to be mounted on a nonlibrary allocated drive. Parameter used is MOUNTWAITTIME(15).
- DFSMSHsm does not mark cartridge-type single-file formatted tape volumes full when the volume has been demounted. Parameter used is PARTIALTAPE(REUSE).
- DFSMSHsm requests scratch tape volumes when an end-of-volume condition occurs on a tape volume. Parameter used is SELECTVOLUME(SCRATCH).
- The recycled tape volumes are deleted from DFSMSHsm control and become scratch tapes. Parameter used is TAPEDELETION(SCRATCHTAPE).
- DFSMSHsm migrates data sets to 3590-1 tape volumes when migrating the volumes to ML2. DFSMSHsm attempts reconnection to ML2 tape on all data sets eligible to migrate. Parameter used is TAPEMIGRATION(ML2TAPE RECONNECT(ALL)).
- DFSMSHsm does issue action messages to the operator asking if tapes needed by DFSMSHsm recall, recover, and recycle input are available because a customer has nonrobotic tape mounting. Parameter used is TAPEINPUTPROMPT(BACKUPTAPES(NO) DUMPTAPES(NO) MIGRATIONTAPES(NO)).
- DFSMSHsm issues a message to the operator during TAPECOPY processing. Parameter used is TAPEOUTPUTPROMPT(TAPECOPY(YES)).
- DFSMSHsm reduces the occurrence of data set spanning tape volumes. The subparameter value of 1000 is well suited for 3590-1. Parameter used is TAPESPANSIZE(1000).
- DFSMSHsm allows a recall task to be used continuously for tape recalls for at least 10 minutes and have a tape allocated and mounted for at least 5 minutes before allowing another DFSMSHsm host to take the tape away for a higher priority request. Parameter used is TAPERECALLLIMITS(TASK(10) TAPE(5)).
- The 3590-1 tape unit is allocated to initially select scratch tapes during backup or dump. Parameter used is UNITNAME(3590-1).
- Identify an esoteric tape unit name to DFSMSHsm for output allocations of 3590-1 tape drives. Parameter used is USERUNITTABLE(TAPE).
- DFSMSHsm forces an end-of-volume (EOV) when a tape volume has reached the desired level of utilization (fullness). You want to use 97% of the capacity but retain the reduced tape spanning. Three separate SETSYS commands are required to specify each unit type to be defined. Parameters used are TAPEUTILIZATION(UNITTYPE(3590-1) PERCENTFULL(97)) and TAPEUTILIZATION(LIBRARYBACKUP PERCENTFULL(97)) and TAPEUTILIZATION(LIBRARYMIGRATION PERCENTFULL(97)).

```

SETSYS DUMPIO(4,3) +
        DUPLEX(BACKUP(Y) MIGRATION(Y)) +
        EXITON(TD TE) +
        INPUTTAPEALLOCATION(NOWAIT) +
        ML2PARTIALSNOTASSOCIATEDGOAL(0) +
        MOUNTWAITTIME(15) +
        PARTIALTAPE(REUSE) +
        SELECTVOLUME(SCRATCH) +
        TAPEDELETION(SCRATCHTAPE) +
        TAPEMIGRATION(ML2TAPE RECONNECT(ALL)) +
        TAPEINPUTPROMPT(BACKUPTAPES(NO) +
                        DUMPTAPES(NO) +
                        MIGRATIONTAPES(NO)) +
        TAPEOUTPUTPROMPT(TAPECOPY(YES)) +
        TAPESPANSIZE(1000) +
        TAPERECALLLIMITS(TASK(10) TAPE(5)) +
        UNITNAME(3590-1) +
        USERUNITTABLE(TAPE)
SETSYS TAPEUTILIZATION(UNITTYPE(3590-1) PERCENTFULL(97))
SETSYS TAPEUTILIZATION(LIBRARYBACKUP PERCENTFULL(97))
SETSYS TAPEUTILIZATION(LIBRARYMIGRATION PERCENTFULL(97))

```

Chapter 66. STOP command: Shutting down DFSMSHsm

The STOP command causes an orderly shutdown of DFSMSHsm. An orderly shutdown occurs when DFSMSHsm ends each attached subtask and ends all started secondary address spaces. Because many DFSMSHsm commands and automatic functions can run for a long time, DFSMSHsm periodically checks whether you issued a STOP command. This allows DFSMSHsm to shut down as soon as possible. After DFSMSHsm detaches all subtasks and all secondary address spaces end, DFSMSHsm issues a message indicating that shutdown is complete. DFSMSHsm then returns control to the system. The STOP command should be entered only once.

If the DUMP parameter is specified with the STOP command, DFSMSHsm ends processing immediately for all primary and secondary address spaces, and there is no orderly shutdown. All secondary address spaces currently processing are canceled immediately.

When the STOP command is issued without any parameters in a sysplex environment, DFSMSHsm assumes that no promotion is desired on that host.

Another way to shut down DFSMSHsm is to use the MVS STOP command.

Syntax of the STOP command

Optional parameters of the STOP command

This topic describes the optional parameters of the STOP command.

DUMP: Requesting a dump of the DFSMSHsm address space

Explanation

DUMP is an optional parameter requesting a dump of the DFSMSHsm address space before DFSMSHsm stops processing. The SYSUDUMP, SYSMDUMP, or SYSABEND DD statement you specify in the DFSMSHsm startup procedure determines where DFSMSHsm sends the dump. If, however, you specify SETSYS SYS1DUMP, the DFSMSHsm dumps resulting from an abnormal end or error condition are written in a system dump data set. Use caution when specifying the DUMP parameter on the STOP command when there is processing going on in a secondary address space. There is a large expenditure of system resources when processing in a secondary address space, and the DUMP parameter causes all secondary address spaces to end processing immediately.

Defaults

None.

Usage notes:

1. When the STOP command is issued with the DUMP parameter in a sysplex environment, this host is eligible to have its functions taken over by another host.

PROMOTE: Specifying that a specific host in a sysplex is eligible to be promoted for another host

Explanation

PROMOTE is an optional parameter requesting that this host in a sysplex is eligible to have its primary functions or secondary space management functions taken over by another host.

Defaults

None.

Example of how to code the STOP command

The following example shows how to code the STOP command.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Stopping DFSMSHsm with a dump

In this example, DFSMSHsm is stopped and a dump is taken.

```
STOP DUMP
```

Chapter 67. SWAPLOG command: Switching between the DFSMSHsm log or PDA data sets

The SWAPLOG command is used to swap the two log data sets or swap the two PDA data sets. You can choose which data sets to swap by using the LOG or PDA optional parameters. If no optional parameter is specified on the SWAPLOG command, only the log data sets are swapped.

Syntax of the SWAPLOG command

Optional parameters of the SWAPLOG command

This topic describes the optional parameters of the SWAPLOG command.

LOG: Specifying to swap the log data sets

The two DFSMSHsm log data sets are called the LOGX data set and the LOGY data set. The names of the data sets are specified in the procedure used to start DFSMSHsm and also in the procedure used to print the LOGY data set.

DFSMSHsm always writes information in the LOGX data set. When the LOGX data set becomes full, DFSMSHsm automatically swaps the two log data sets. You can use the SWAPLOG command to swap the two log data sets. In addition, you can specify the LOGSW=YES parameter on the START DFSMSHsm command to cause DFSMSHsm to swap the log data sets during DFSMSHsm initialization. When the log data sets are swapped, DFSMSHsm does the following:

1. Stops writing information in the LOGX data set
2. Closes the LOGX data set
3. Renames the LOGX data set to a temporary name
4. Renames the LOGY data set to LOGX
5. Renames the temporary data set name to LOGY
6. Opens the new LOGX data set
7. Resumes writing information in the new LOGX data set.

After the DFSMSHsm log data sets have been swapped, start the HSMLOG procedure that is supplied with the DFSMSHsm licensed program. This procedure normally resides in PARMLIB. The HSMLOG procedure runs the ARCPRLLOG program to do an initial formatting of the information in the LOGY data set and to print the log data set. After running the ARCPRLLOG program, the HSMLOG procedure deletes the old LOGY data set and reallocates a new LOGY data set. The ARCPRLLOG program is also supplied with the DFSMSHsm licensed program.

If you do not print the information in the LOGY data set after the log data sets are swapped and a later swap occurs, you do not have a copy of that information because DFSMSHsm writes over the old information in the LOGY data set.

The Chapter 8, “Aggregate backup and recovery support (ABARS),” on page 319 contains additional information about the contents of the DFSMSHsm log data sets and how to print information in the DFSMSHsm log.

PDA: Specifying to swap the PDA data sets

The two DFSMSHsm PDA data sets are called the ARCPDOY data set and the ARCPDOX data set.

DFSMSHsm always writes information in the ARCPDOX data set. When the ARCPDOX data set becomes full, DFSMSHsm automatically swaps the two PDA data sets. You can use the SWAPLOG command to swap the two PDA data sets.

The [*z/OS DFSMSHsm Diagnosis*](#) contains additional information about the PDA facility.

Examples of how to code the SWAPLOG command

The following examples present how to code the SWAPLOG command.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Swapping the DFSMSHsm LOGX and LOGY data sets (example 1)

In this example, since no optional parameter is specified, the DFSMSHsm log data sets are swapped.

```
SWAPLOG
```

Swapping the DFSMSHsm LOGX and LOGY data sets (example 2)

In this example, the DFSMSHsm log data sets are swapped.

```
SWAPLOG LOG
```

Swapping the DFSMSHsm PDA data sets

In this example, the DFSMSHsm PDA data sets are swapped.

```
SWAPLOG PDA
```

Swapping both the DFSMSHsm log and PDA data sets

In this example, both the DFSMSHsm log and PDA data sets are swapped.

```
SWAPLOG LOG PDA
```

Chapter 68. TAPECOPY command: Making copies of selected cartridge-type tape volumes

The TAPECOPY command provides a way of copying migration level 2 and backup cartridge-type single-file tape volumes. It is an alternative method to tape duplexing, which creates two tapes during the migration, backup, or recycle processes. To distinguish between copies, the input tape is called the original, and the output tape is called the alternate.

You can issue the TAPECOPY command generically for a functional category of tape volumes. Generic processing selects only those tapes that are marked full and do not already have an alternate tape copy. When processing one or more specific volumes, tapes do not have to be already marked full, and they can have a previous tape copy alternate.

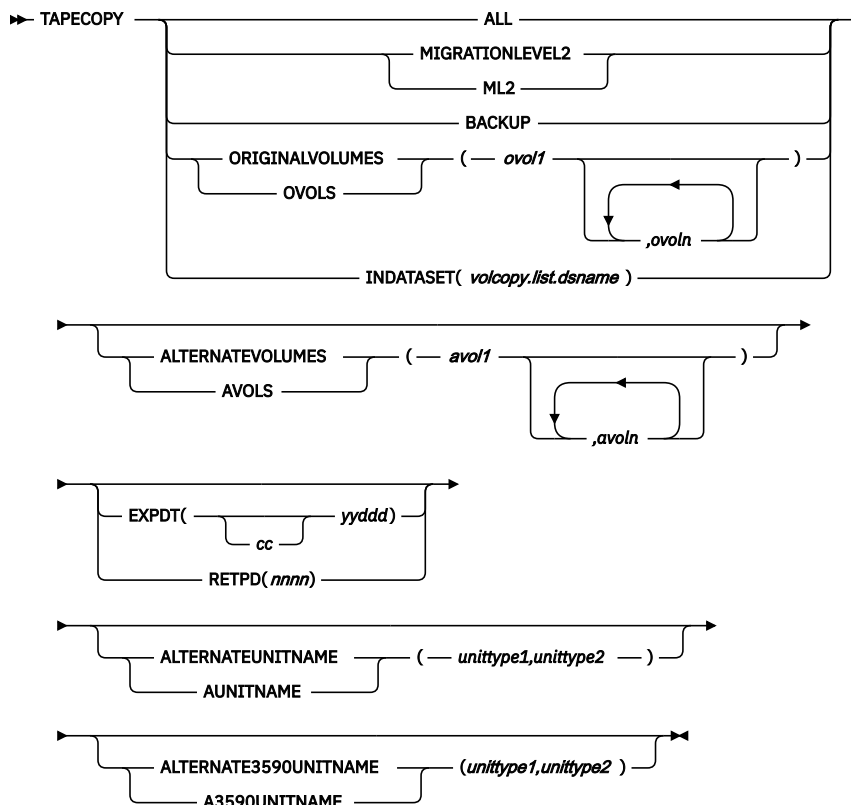

DFSMSHsm gives special consideration to migration level 2 tapes in a SETSYS PARTIALTAPE(MARKFULL) environment. When DFSMSHsm migrates data sets versus volumes; it does not mark output tapes as full even when running in a PARTIALTAPE(MARKFULL) environment. To allow these tapes to be copied, generic processing marks all partial tapes as full so that the tapes are selected.

The source volume for TAPECOPY can reside inside or outside a system-managed tape library. The ACS routines can be used to control whether a system-managed tape volume is used for TAPECOPY output.

Note: If *unittype* is not specified on the TAPECOPY command, it is not provided as input when DFSMSHsm invokes the ACS routines for the TAPECOPY command.

See [Set up the ACS routines in z/OS DFSMSHsm Implementation and Customization Guide](#) for more information on configuring your SMS environment with HSM.

Syntax of the TAPECOPY command

Required parameters of the TAPECOPY command

This topic describes the required parameters of the TAPECOPY command.

ALL: Specifying to copy all eligible cartridge-type single-file tape volumes

Explanation: ALL specifies that all cartridge-type single-file tape volumes that are marked as full in the OCDS TTOC record and do not have an alternate volume are to be copied. If the environment is PARTIALTAPE(MARKFULL) when this command is issued, all partially full migration level 2 tapes will be marked full.

Tape library relationship: A UNITNAME can be used for filtering in the ACS routines. If you specify the unit type for this command, it will be sent to the ACS routines in SMS for the TAPECOPY function.

When ALL is specified, DFSMSHsm uses scratch tapes for the output or target volumes.

Defaults: None.

MIGRATIONLEVEL2: Specifying to create copies of all eligible migration level 2 volumes

Explanation: MIGRATIONLEVEL2 specifies that all cartridge-type single-file migration level 2 tape volumes that are marked as full in the OCDS TTOC record and do not have alternate volumes are to be copied. If the environment is PARTIALTAPE(MARKFULL) when this command is issued, all partially full migration level 2 tapes will be marked full.

When MIGRATIONLEVEL2 is specified, DFSMSHsm uses scratch tapes for the output or target volumes.

Defaults: None.

BACKUP: Specifying to create copies of all eligible backup tape volumes

Explanation: BACKUP specifies that all cartridge-type single-file backup tape volumes that are marked as full in the OCDS TTOC record and do not have alternate volumes are to be copied. When BACKUP is specified, DFSMSHsm uses scratch tapes for the output or target volumes.

Defaults: None.

ORIGINALVOLUMES: Copying specified volumes

Explanation: ORIGINALVOLUMES(*ovol1...ovoln*) is a required parameter (if you are specifying which volumes are to be copied) requesting that alternate tape volume copies be created. The volumes to be copied are specified by their volume serial numbers (*ovol*). The alternate tape volumes are made even though the original volumes may not be marked full or may already have an alternate tape volume reference in the OCDS TTOC record.

The optional parameter ALTERNATEVOLUMES may be used to specify which output volumes are to be used in place of using scratch tapes. If specified, the number of entries in ORIGINALVOLUMES and ALTERNATEVOLUMES must match. The TAPECOPY function will maintain a one-for-one correspondence between the two sets of entries.

Defaults: None.

INDATASET: Specifying to use a data set containing a volume list

Explanation: INDATASET(*volcopy.list.dsname*) is a required parameter specifying to use a list of original tape volumes contained in the data set supplied and create alternate tape volume copies of them. The alternate tape volumes are made even though the original volumes may not be marked as full.

volcopy.list.dsname is the data set name of the cataloged data set. This data set must *not* be a migrated data set when the command is issued.

When allocating the volume list data set, use the following parameters for:

RECFM

Specify F, FB, FS, or FBS

LRECL

Specify 80

BLKSIZE

Specify a multiple of LRECL

DSORG

Use physical sequential (PS) organization.

When building the volume list contents, use the following entry format:

Columns**Contents****1-6**

Original volume source to be copied. Specify this volume by its volume serial number.

8-13

Alternate volume target specified by its volume serial number. You can also use a volume serial number of PRIVAT, meaning that DFSMSHsm is to use a scratch tape for the target. If a volume serial number is not specified, the default is the value found in the alternate volume field of the OCDS TTOC record.

15-21

This field is used to specify an alternate tape volume expiration date. The date is placed in the tape label but has no relation to when DFSMSHsm will remove the tape from its inventory. The alternate tape is deleted by DFSMSHsm at the same time the original tape is deleted. Use the format as *ccyyddd* and right justify the date within the field. If no expiration date is specified in this field, the expiration date specified or defaulted for the command is used.

The date is checked for validity, and the tape listed in the input record is not copied if the check fails. If the *cc* field (below) is blank, the date limits are the current date to 31 December 1999. Date limits are otherwise the current date to 31 December 2155.

cc

This is a field used to specify the first two digits of the year. If the current date is before 1 January 2000, this field can be left blank; the year will be interpreted as 19yy.

yy

This field specifies the last two digits of the year.

ddd

This field specifies the Julian day in the year.

Note:

1. If an expiration date is supplied, it is processed as described under the EXPDT parameter. The exception is that if an expiration date is invalid, only the tape listed in the input record is failed.
2. If the expiration date is not supplied in an input record, the EXPDT parameter on the TAPECOPY command is used.
3. Past dates are not recognized as expiration dates.
4. Values for *ccyyddd* of 1999365 and 1999366 are recognized as “never expire” dates. Values of 1998000 and 1999000 are recognized as meaningful to certain tape management systems.
5. If no expiration date is supplied, DFSMSHsm uses the expiration date specified or defaulted for the command.

Defaults: None.

Example: The following is an example of the format for the input volume list data set:

```

Columns:1----6 8---13 15---21
Format: source target ccyyddd

      * * * Top of Data * * *
Line 1: JHG191 DBK001 2101001
Line 2: ML1002 PRIVAT 2101059
Line 3: ML2100 DBK070
Line 4: ML2101
      * * * End of Data * * *

```

Legend:**Line 1**

JHG191 is the source volume, DBK001 is the target volume and retain the target volume until January 1, 2101.

Line 2

ML1002 is the source volume, use a scratch tape for the target volume and retain the target volume until February 28, 2101.

Line 3

ML2100 is the source volume, DBK070 is the target volume and retain until the date (if any) specified with the EXPDT parameter.

Line 4

ML2101 is the source volume, use a scratch tape and retain the target volume until the date (if any) specified with the EXPDT parameter.

Optional parameters of the TAPECOPY command

This topic describes the optional parameters of the TAPECOPY command.

ALTERNATEUNITNAME: Specifying alternate unit names for a tape copy

Explanation: ALTERNATEUNITNAME(*unittype1*,*unittype2*) is used to specify the unit name associated with only a 3480, 3480X or 3490 cartridge-type single-file tape. When ALTERNATEUNITNAME is specified, the alternate tape will be allocated using the specified unit name. This will be done as long as there is no incompatibility in the unit name.

If there are two unit names specified with ALTERNATEUNITNAME, DFSMSHsm will use *unittype1* when the source volume is a standard cartridge, and it will use *unittype2* when the source volume is an enhanced capacity cartridge.

Defaults: None.

Note:

1. The following table shows the compatibility between original volume unit names and alternate volume unit names. This table applies when TAPECOPY output is being directed outside a system managed tape library.

Table 67. Compatibility between original volume unit names and alternate volume unit names					
Original Volume Unit Name	Alternate Volume Unit Name				
	3480	SETSYS NOTAPEHWC 3480X	SETSYS TAPEHWC 3480X	3490	3590-1
3480	C	C	I	I	I
3480X (non-IDRC)	C	C	I	I	I
3480X (IDRC)	I	I	C	I	I
3490	I	I	I	C	I

Table 67. Compatibility between original volume unit names and alternate volume unit names (continued)

Original Volume Unit Name	Alternate Volume Unit Name				
	3480	SETSYS NOTAPEHWC 3480X	SETSYS TAPEHWC 3480X	3490	3590-1
3590-1	I	I	I	I	C
Note: C = Compatible I = Incompatible					

Important Note:

You can force DFSMSHsm to use a unit specified with ALTERNATEUNITNAME regardless of compatibility as per the table above, by using the following PATCH:

```
PATCH .MCVT.+1BC BITS(..1.....)
```

Note, however, that you can force DFSMSHsm to use this unit only if the following conditions are met:

- The alternate unit name is a native device (*not* virtual).
- The unit name is *not* defined as an esoteric to DFSMSHsm (in other words, SETSYS UUT is *not* used to define the unit name).
- The unit name does *not* contain mixed device types (for example, 3590 and 3592).

If all of these conditions above are true and you have the patch set in the MCVT, DFSMSHsm will allow replacement of the tape using the alternate unit name specified, regardless of the existing original unit. All records associated with the original volume and its data sets will be updated to reflect the new unit name and type.

2. The 3480, 3480X, and 3490 can be considered valid generic unit names for the ALTERNATEUNITNAME parameter.

ALTERNATE3590UNITNAME: Specifying 3590 alternate unit name for a tape copy

Explanation: ALTERNATE3590UNITNAME(*unittypel*,*unittypel2*) is used to specify the unit name associated with only the IBM 3590 tape subsystem. When ALTERNATE3590UNITNAME is specified, the alternate tape will be allocated using the specified unit name. This will be done as long as there is no incompatibility in the unit name.

Defaults: None.

ALTERNATEVOLUMES: Specifying which volumes to copy

Explanation: ALTERNATEVOLUMES(*avol1*,...*avoln*) is an optional parameter that defines which output volumes are to be used in place of scratch tapes. These tape volumes are indicated by their volume serial numbers *avol*. If specified, the number of entries in ORIGINALVOLUMES and ALTERNATEVOLUMES must match. The TAPECOPY function will maintain a one-for-one correspondence between the two sets of entries. The alternate tape volumes are made even though the original volumes may not be marked as full.

When considering 3480, 3480X, and 3490 volumes, the original volumes and the alternate volumes must use the same recording technology. If the original volume is written using the Improved Data Recording Capability (IDRC) of the 3480X, then the alternate volumes must be written using the IDRC. The reverse is true as well.

For 3490 volumes or 3590-1 volumes, the original volumes and alternate volumes must use the same media type. If the original volume is written using a standard capacity cartridge, then the alternate volume must be written with a standard capacity cartridge (an enhanced capacity cartridge cannot be used). The reverse is true as well.

Defaults: None.

EXPDT and RETPD: Specifying a tape expiration date or a retention period

Explanation: EXPDT(ccyyddd) and RETPD(nnnn) are mutually exclusive, optional parameters specifying either an expiration date or a retention period for the alternate tape volume. The date is placed in the tape label but has no relation to when DFSMSHsm will remove the tape from its inventory. The alternate tape is deleted by DFSMSHsm at the same time the original is deleted.

It is important for you to understand that specifying an expiration date for the alternate tape volume that would cause the alternate tape volume to return to scratch before the original tape volume returns to scratch can result in data loss. For example, consider the following scenario:

- Tape 1 is an original volume that has Tape 2 as its alternate volume.
- Tape 2 is returned to scratch by the Tape Management System because the specified expiration date is reached. Tape 2 is now known to the Tape Management System as a scratch tape; however, DFSMSHsm regards this tape as a valid alternate of Tape 1. (The expiration date does not relate to when the tape is removed from the DFSMSHsm inventory.)
- Tape 2 is now mounted in response to a scratch request from either DFSMSHsm or another user request. After it has been written to, Tape 2 is not a valid alternate for Tape 1 anymore because it has been overwritten; however, DFSMSHsm still considers Tape 2 a valid alternate of Tape 1. This, in itself, poses a problem if the alternate tape is needed, but the potential for problems continues.
- Tape 1 is now returned to scratch by the ARCTVEXT exit, which also results in Tape 2 being returned to scratch. Now, Tape 2 is again a scratch volume and the data written to Tape 2 after its return to scratch the first time can be overwritten again if mounted in response to a scratch request.

EXPDT is an optional parameter that specifies a different expiration date (other than 1999365) for the alternate tape volume. The date is checked for validity, and the entire command is rejected if the test fails. Date limits for ccyyddd are from the current date to 31 December 2155.

Values for ccyyddd of 1999365 and 1999366 are recognized as “never expire” dates. Values of 1998000 and 1999000 are recognized as meaningful to certain tape management systems.

RETPD is an optional parameter that sets the expiration date by specifying a retention period. The valid range is 0–9999. RETPD is converted to an expiration date and is processed as described under EXPDT.

Defaults: None.

Table 68 on page 1232 shows all of the conditions for *each* tape volume processed by DFSMSHsm. If the tape data set exit (ARCTDTEXT) is in effect, DFSMSHsm invokes the exit after processing any of the conditions shown in Table 68 on page 1232 and puts the date specified by the exit on the tape being copied.

Table 68. DFSMSHsm Processing by Condition				
Conditions				
Is an expiration date specified in the INDATASET record?	Is an expiration date specified on the TAPECOPY command?	Is the SETSYS TAPESECURITY (EXPIRATION) command in effect?	Is an expiration date specified for the original volume?	DFSMSHsm...
no	no	no	no	Does not protect the alternate volume with an expiration date.
no	no	no	yes	Uses its default date of 1999365.
no	no	yes	no	
no	no	yes	yes	

Table 68. DFSMSHsm Processing by Condition (continued)

Conditions				
no	yes	no	no	Uses the expiration date specified on the TAPECOPY command.
no	yes	no	yes	
no	yes	yes	no	
no	yes	yes	yes	
yes	no	no	no	Uses the expiration date specified in the INDATASET record.
yes	no	no	yes	
yes	no	yes	no	
yes	no	yes	yes	
yes	yes	no	no	
yes	yes	no	yes	
yes	yes	yes	no	
yes	yes	yes	yes	

Examples of how to code the TAPECOPY command

The following examples present different ways to code the TAPECOPY command:

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Specifying to copy all eligible cartridge-type single-file tape volumes

The following example illustrates how to make a copy of all the cartridge-type single-file migration and backup tapes that do not already have a copy:

```
TAPECOPY ALL
```

Specifying to copy a set of tape volumes

The following example illustrates how to make a copy of more than one original volume on specific alternate volumes:

```
TAPECOPY ORIGINALVOLUMES(JHG191,JHG195,JHG198) +  
ALTERNATEVOLUMES(DBK001,DBK005,DBK008)
```

Specifying to copy a list of original volumes

This example illustrates using a data set containing a list of volumes to process that are to be retained until December 31, 2010. The expiration date for the alternate tape volume does not relate to when the tape volume is removed from the DFSMSHsm inventory. In this example, if the original volume is removed from the DFSMSHsm inventory after December 31, 2010, there can be an exposure to data loss.

```
TAPECOPY INDATASET(G737495.VOLIST.DATA) +  
EXPDT(2010365)
```

Specifying the TAPECOPY command with enhanced capacity cartridge support

The 3490E backup and migration volumes residing on standard tape cartridges are copied using the esoteric tape unit name ES1. Those backup and migration volumes residing on enhanced capacity cartridges are copied using the esoteric tape unit name ES2. The 18-track format cartridges are copied to units allocated using ES1.

```
TAPECOPY BACKUP ALTERNATEUNITNAME(ES1, ES2)
```

All backup volumes are copied using esoteric tape unit name ES1, regardless of the type of cartridge (standard vs enhanced capacity). If only one unit is specified with ALTERNATEUNITNAME, it is the device type used for all TAPECOPY processing for backup volumes. In this case, potential exists for TAPECOPY failures if a 3490E backup volume is an enhanced capacity cartridge, and ES1 is an esoteric tape unit that is being used for output to standard tapes (for example, devices are preloaded with standard tapes).

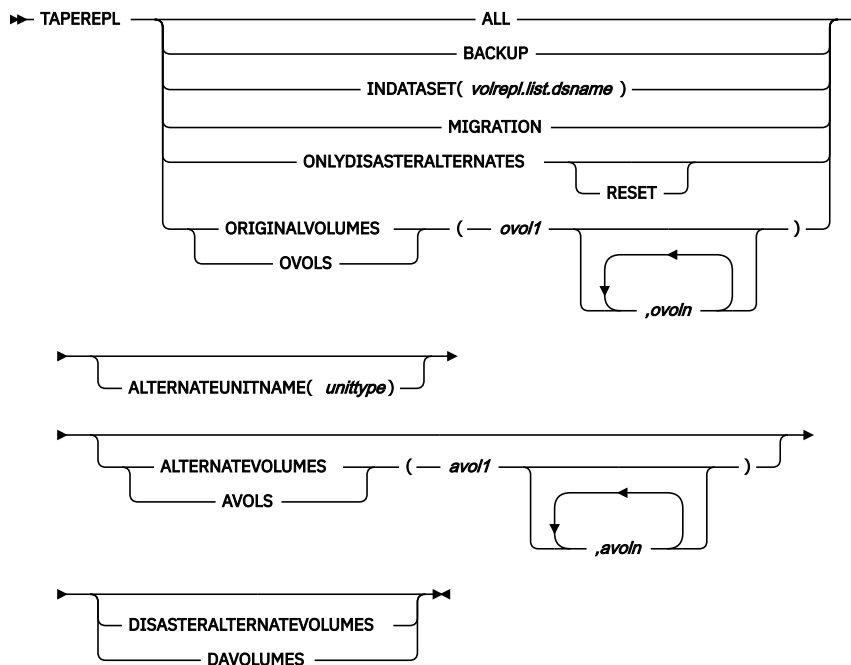

```
TAPECOPY BACKUP ALTERNATEUNITNAME(ES1)
```

Chapter 69. TAPEREPL command: Replacing cartridge-type tape volumes with their alternate volumes

The TAPEREPL command provides a way of replacing an original migration level 2 volume or a backup volume with its alternate volume. It also plays an important part during an actual disaster recovery or when you are running a disaster recovery test by allowing you to replace original volumes with their alternate volumes.

For a discussion of the steps to follow when making disaster backup copies of DFSMSHsm-owned tape volumes, see “Disaster alternate volumes” on page 442.

Syntax of the TAPEREPL command

Required parameters of the TAPEREPL command

This topic describes the required parameters of the TAPEREPL command.

ALL: Specifying replacement of all cartridge-type single-file tape volumes

Explanation: ALL is a required parameter specifying replacement of all cartridge-type single-file tape volumes that have alternate-tape-volume references in their OCDS TTOC records.

Defaults: None.

BACKUP: Specifying replacement of all cartridge-type single-file backup tape volumes

Explanation: BACKUP is a required parameter specifying that all references to cartridge-type single-file backup tapes with alternate volumes be replaced with references to the alternate tape volumes.

Defaults: None.

INDATASET: Specifying the use of a data set containing a volume list

Explanation: INDATASET is a required parameter that causes a list of original tape volume references in the supplied data set to be replaced with a list of alternate tape volume references. *volrepl.list.dsname* is the data set name of the cataloged data set. This data set must *not* be a migrated data set when the command is issued.

When allocating the volume list data set, use the following parameters for:

RECFM

Specify F, FB, FS, or FBS

LRECL

Specify 80

BLKSIZE

Specify a multiple of LRECL

DSORG

Use physical sequential (PS) organization.

When building the volume list contents, use the following entry format:

Columns

Contents

1-6

Original tape volume serial number to be replaced.

8-13

Alternate tape volume serial number to use. If an alternate tape volume serial number is not specified, the value found in the alternate volume field of the original volume's OCDS TTOC record is used.

Defaults: None.

Example: The following is an example of the format for the input volume list data set:

```
Columns: 1---6 8---13
Content: orig.  alt.
         volser volser

         * * * Top of Data * * *
Line 1:  ML1100 DBK070
Line 2:  ML2101
         * * * End of Data * * *
```

Legend:

Line 1

specifies replacement of the original tape volume labeled ML1100 with the alternate tape volume DBK070.

Line 2

specifies replacement of the original tape volume labeled ML2101 with the alternate tape volume specified in the OCDS TTOC record for volume ML2101.

MIGRATION: Specifying replacement of all cartridge-type single-file migration tape volumes

Explanation: MIGRATION is a required parameter specifying that all references to cartridge-type single-file migration tapes with alternate volumes be replaced with references to the alternate tape volumes.

Defaults: None.

ONLYDISASTERALTERNATES: Converting disaster alternate volumes to original volumes

Explanation: ONLYDISASTERALTERNATES is a required parameter that converts all disaster alternate volumes to original volumes. No optional parameters are used with ONLYDISASTERALTERNATES.

RESET is an optional subparameter that changes original volumes flagged as having disaster alternates back to the status of original volumes having normal alternates.

Defaults: None.

ORIGINALVOLUMES: Specifying volumes to be replaced

Explanation: ORIGINALVOLUMES is a required parameter specifying that all references to the original tape volume be replaced with references to the alternate tape volume. The alternate tape volume can be specified using the ALTERNATEVOLUMES parameter or, in its absence, the one found in the original volume's OCDS TTOC record.

Defaults: None.

Optional parameters of the TAPERREPL command

This topic describes the optional parameters of the TAPERREPL command.

ALTERNATEUNITNAME: Specifying an alternate unit name for a tape replacement

Explanation: ALTERNATEUNITNAME (*unittype*) is used to specify the unit name associated with 3480, 3480X or 3490 cartridge-type single-file tape. When ALTERNATEUNITNAME is specified, the tape unit name will be changed in the OCDS TTOC. This will be done as long as there is no incompatibility in the unit name.

Defaults: None.

Note:

1. The following table shows the compatibility between original volume unit names and alternate volume unit names.

Table 69. Compatibility between original volume unit names and alternate volume unit names					
Original Volume Unit Name	Alternate Volume Unit Name				
	3480	SETSYS NOTAPEHWC 3480X	SETSYS TAPEHWC 3480X	3490	3590-1
3480	C	C	I	I	I
3480X (non-IDRC)	C	C	I	I	I
3480X (IDRC)	I	I	C	I	I
3490	I	I	I	C	I
3590-1	I	I	I	I	C
Note: C = Compatible I = Incompatible					

2. The 3480, 3480X, and 3490 can be considered valid generic unit names for the ALTERNATEUNITNAME parameter.

3. If DISASTERALTERNATEVOLUMES is also specified, then the ALTERNATEUNITNAME will only be used with the DAVOLUMES while in DISASTERMODE. The ALTERNATEUNITNAME does *not* permanently replace the original unit. The LIST TTOC command will still show the original unit.

When the time comes to permanently replace the original volumes with the alternate volumes, and you issue a TAPERREPL command without DAVOLUMES, the ALTERNATEUNITNAME must be specified again or the original unit name will be used. The original unit name is used if ALTERNATEUNITNAME is not specified on the command.

ALTERNATEVOLUMES: Specifying the replacement volumes to use

Explanation: ALTERNATEVOLUMES is an optional parameter that identifies specific alternate tape volumes to substitute for the original tape volumes. The alternate tape volumes are selected by their volume serial numbers *avol*. If specified, the number of entries in ORIGINALVOLUMES and ALTERNATEVOLUMES must match. The TAPERREPL function maintains a one-for-one correspondence between the two sets of entries.

Attention: The volumes that are specified in the ALTERNATEVOLUMES parameter will replace the volumes in ORIGINALVOLUMES even if they do not contain valid DFSMSHsm data.

Defaults: None.

DISASTERALTERNATEVOLUMES: Identifying the alternate volume as the disaster alternate volume

Explanation: DISASTERALTERNATEVOLUMES is an optional parameter that causes each alternate volume to be flagged as a disaster alternate volume. If DISASTERALTERNATEVOLUMES is specified, a flag is set for each ML2 tape and backup tape that has an alternate volume. The designation of "disaster alternate volume" helps distinguish between alternate volumes initially present at the recovery site and alternate volumes created later at the recovery site. If DISASTERALTERNATEVOLUMES is not specified, each original volume is replaced by its alternate volume in any of the DFSMSHsm volume and data set records that refer to it. For more information on the use of disaster alternate volumes, refer to the [Chapter 9, "Making disaster backup copies of DFSMSHsm-owned tape volumes,"](#) on page 435.

Defaults: None.

Examples of how to code the TAPERREPL command

The following examples present different ways to code the TAPERREPL command.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Specifying replacement of a damaged tape

The following example illustrates how to replace a damaged tape by its alternate, which is identified in the OCDS TTOC record for the damaged tape:

```
TAPERREPL ORIGINALVOLUMES(HB0123)
```

Specifying replacement of a set of tape volumes

The following example illustrates how to replace more than one original tape volume with respective alternate volumes:

```
TAPERREPL ORIGINALVOLUMES(JHG191,JHG195,JHG198) +  
ALTERNATEVOLUMES(DBK001,DBK005,DBK008)
```

Specifying replacement of a list of original volumes

This example illustrates the use of a data set containing a list of volumes to process.

```
TAPERREPL INDATASET(G737495.VOLIST.DATA)
```

Chapter 70. TRAP command: Requesting a dump when a specified error occurs

The TRAP command is to be used only for maintenance purposes and is explained in the [*z/OS DFSMSHsm Diagnosis*](#).

Chapter 71. UPDATEC command: Recovering the control data sets

The UPDATEC command rebuilds an updated control data set and combines the entries in the specified journal data set with the restored backup copy of the backup control data set (BCDS), migration control data set (MCDS), or offline control data set (OCDS). Use the UPDATEC command to fix any major problems that occur in the control data sets.

When you issue the UPDATEC command, DFSMSHsm places itself in emergency mode and does not write in the journal data set.

Note: For performance reasons, the enhanced CDS recovery function should be used to recover control data sets instead of the UPDATEC command. For information on using enhanced CDS recovery functions, see [“Recovering control data sets using the enhanced CDS recovery function”](#) on page 508.

Syntax of the UPDATEC command

Required parameters of the UPDATEC command

This topic describes the required parameters of the UPDATEC command.

ALL, BACKUPCONTROLDATASET, MIGRATIONCONTROLDATASET, and OFFLINECONTROLDATASET: Specifying which control data set to update

Explanation

ALL, BACKUPCONTROLDATASET, MIGRATIONCONTROLDATASET, OFFLINECONTROLDATASET are mutually exclusive, required parameters that specify which control data sets DFSMSHsm should update.

ALL

DFSMSHsm combines the entries from the journal data set with the restored copies of all three control data sets.

BACKUPCONTROLDATASET

DFSMSHsm combines the entries from the specified journal data set with the restored backup copy of the BCDS.

MIGRATIONCONTROLDATASET

DFSMSHsm combines the entries from the specified journal data set with the restored backup copy of the MCDS.

OFFLINECONTROLDATASET

DFSMSHsm combines the entries from the specified journal data set with the restored backup copy of the OCDS.

Defaults

None.

Optional parameters of the UPDATEC command

This topic describes the optional parameters of the UPDATEC command.

JOURNAL: Specifying the journal data set to use

Explanation

JOURNAL(*dsname*) is an optional parameter specifying the fully qualified name of the journal data set to use with UPDATEC. The parameter variable is explained:

dsname

Fully qualified name of the journal data set that DFSMSHsm should use when it updates the BCDS, MCDS, and OCDS.

Defaults

If you do not specify JOURNAL, DFSMSHsm uses the journal data set identified with the JOURNAL DD statement in the DFSMSHsm startup procedure.

Usage notes:

1. Specify JOURNAL only if you do not want to use the journal data set identified with the JOURNAL DD statement in the DFSMSHsm startup procedure.
2. If a journal is used other than the one currently identified in the journal DD statement (a journal other than the current journal means a backup journal), and if that journal is on tape, the following procedure is required:
 - a. The tape must be mounted without the write-protect ring.
 - b. After mounting the tape, you will receive a message (IEC510D) stating that the program is attempting to write on the tape, but the write-protect ring is not inserted. Reply to this message with Rnn,F which rewinds the tape. After the tape rewinds, insert the write-protect ring and remount the tape. After the tape is remounted, ready the device.

Examples of how to code the UPDATEC command

The following examples present different ways to code the UPDATEC command.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Updating the MCDS, BCDS, and OCDS with a specified journal data set

In this example, the MCDS, BCDS, and OCDS are updated by using a specified journal data set.

```
UPDATEC ALL JOURNAL(ALT.JRNL)
```

Updating the MCDS

In this example, the MCDS is updated using the journal data set identified by the journal DD statement in the DFSMSHsm startup procedure.

```
UPDATEC MIGRATIONCONTROLDATASET
```

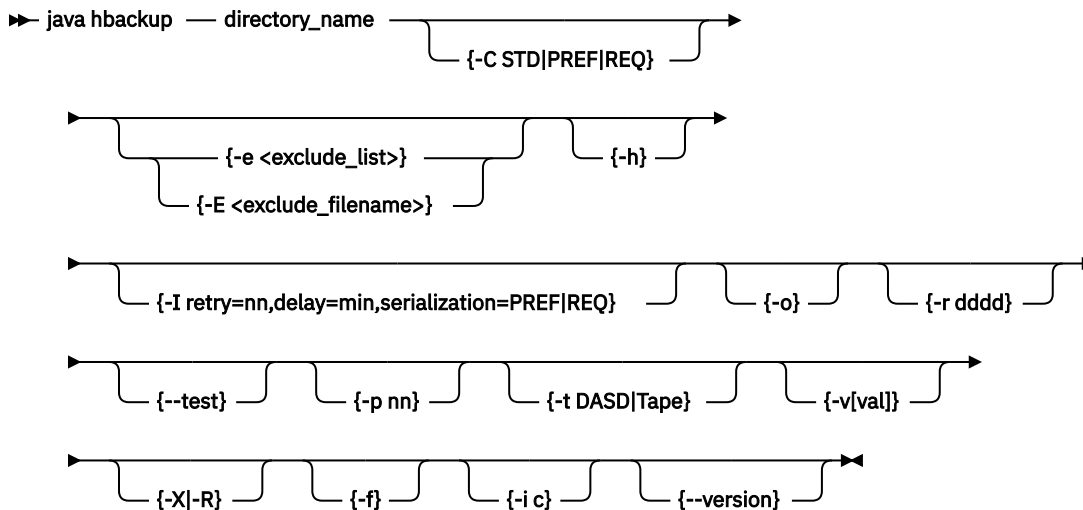

Chapter 72. Storage administrator mode for UNIX commands

The UNIX commands, **hbackup**, **hbdelete**, and **hrecover** can be run as storage administrator commands by specifying the **-o** option on the command. When the **-o** option is specified, the command performed is equivalent to the BACKDS, BDELETE, or RECOVER commands. Authorization to the appropriate RACF Facility class is checked, and if allowed, the command bypasses further permission checking on the UNIX file that is being processed.

Chapter 73. Java *hbackup* command for Incremental UNIX file backup

The Java™ *hbackup* program examines the requested directory subtree for files that are changed since their last backup. The files and directories that are examined can be modified by exclude criteria, either on the command or in a file. Only files that DFSMSHsm supports for backup are examined. The program runs under the authority of the user and you should permit the user ID READ access to SUPERUSER.FILESYS in the UNIXPRIV class to avoid permission errors during the examination.

Syntax of the Java *hbackup* command

Note: Requires CLASSPATH and LIBPATH to be set correctly.

Required parameters of the Java *hbackup* command

This topic describes the required parameter of the *hbackup* command.

directory_name: Specifying the name of the directory

Explanation

directory_name is a required parameter that specifies the starting directory for the *hbackup* program to start examining for files. Only one directory name can be specified.

Optional parameters of the Java *hbackup* command

This topic describes the optional parameters of the Java *hbackup* command.

-X

Specifies that subdirectories should be examined for files in need of backup. However, if a subdirectory is the mount point for a different file system, then that subdirectory should not be entered. (Equivalent to RECURSE(NOCROSSMOUNTS) on the BACKDS Storage Administrator command.) Default processing is not to examine subdirectories. This option cannot be specified along with the -R option.

-R

Specifies that subdirectories should be examined for files in need of backup. All subdirectories are entered until no more are found. (Equivalent to RECURSE(CROSSMOUNTS) on the BACKDS Storage Administrator command.) Default processing is not to examine subdirectories. This option cannot be specified along with the -X option.

-C STD|PREF|REQ

Specifies what form of zFS File Snapshot processing to use for the z/OS UNIX files. Options are:

STD

Do not use zFS File Snapshot to process the UNIX files. Serialization is held on the z/OS UNIX file during the backup.

PREF

Use the zFS File Snapshot processing if possible. When the zFS File Snapshot is initiated, serialization on the file is released, and other processes can write to the file without changing the contents that are being backed up. When the backup is complete, the zFS File Snapshot resources are released.

REQ

zFS File Snapshot processing must be used. If the feature is unavailable, the backup is failed.

-e

Specifies exclude criteria *<exclude_list>* for file names and directories to be excluded from backup processing. Comma separated exclude criteria patterns can be any of the following:

- Patterns to match files in the exclude list can contain any valid file name characters and might contain the wildcard characters: question mark (?) and asterisk (*). Directory names cannot be specified in a file name pattern.
- An asterisk (*) can be used to match any number of characters within a file name. An asterisk may be used at any position in the pattern.
- A question mark (?) can be used to represent any single character in the file name. Multiple question mark characters are allowed.
- A backslash character (\) must be used to escape any question mark, asterisk, open curly brace, open square bracket, and backslash characters to indicate it is not a special character. (for example \?, *, \{, \[, or \\\). Other CCSIDs might have a different character for hex value x'5C' (CCSID 037 backslash) that need to be specified. For example, CCSID 1141 x'5C' would be the umlaut O (Ö).
- If the requested file name pattern does not include any wildcard characters, then that exact name is used to compare with files that are found in the subdirectories processed.
- Directory names that are specified in the exclude list must end in a forward slash character. If the directory name begins with a forward slash character, then it is considered as an absolute path. If the directory name does not begin with a forward slash character, it is considered as a relative path that begins at the directory that is requested on the command. Wildcard characters cannot be used in directory names.
- The comma (,) character cannot be used in file name patterns or directory names.
- The syntax */.../* can be used to indicate any number of directories matched. (Equivalent to */**/* in glob format.)
- A combination of directory names and file name pattern.
- Trailing white space in a criteria is trimmed off.

-E

Specifies a file name, *exclude_filename*, that contains the exclude criteria to be used during processing. The exclude criteria must be specified one per line. A line starting with a blank character is considered a comment and is ignored. Valid criteria must conform to the types of patterns described in -e description. The user must have read permission to the file.

-f

Force a new backup. Send all supported, matching files to DFSMSHsm for backup.

-h

Write out this explanation of options.

-I

UNIX files that are in use at the time of backup will have their backup retried up to a specified maximum number of times, delaying a specified number of minutes in between each retry. On retry, an attempt to obtain exclusive serialization to the UNIX file will be made. If on retry exclusive serialization is obtained then a normal backup of the UNIX file will be made. If exclusive serialization cannot be obtained, then additional retries of the backup will be made until the maximum number of retries has been made. If after the maximum number of retries exclusive serialization cannot be obtained, the backup request will either fail or a backup of the file will be taken anyway, depending on if the command specified serialization was required or preferred.

The -I option has suboptions *retry*, *delay*, and *serialization* that enable the user to specify the maximum number of retries, the time to delay in between retries, and whether exclusive serialization is required or preferred. The -I option and its associated suboptions has the following syntax.

```
-I retry=nn,delay=min,serialization=PREF|REQ
```

retry

Specifies the maximum number of retries. DFSMShsm will retry a maximum of *nn* times to back up a UNIX file after the first attempt fails because of the UNIX file is in use. For *nn*, specify a value 0 to 99. The default value is 0.

delay

Specifies the number of minutes to delay in between retries. DFSMShsm delays for *min* minutes before retrying a backup attempt which failed because the UNIX file is in use. For *min*, specify a value from 0 to 999. The default value is 15.

serialization

Specifies whether exclusive serialization of the UNIX file is required or preferred to make the backup. The default is serialization is required. The following are the possible values for the serialization suboption:

PREF

Serialization is preferred. If the UNIX file is still in use after the max number of retries for the backup have been made, the UNIX file will be backed up anyway. A message indicating a fuzzy backup was made will be issued. If the UNIX file is not in use at that time, a normal backup will be made. If *retry=0* is in effect and exclusive serialization could not be obtained on the first attempt then a fuzzy backup will be made.

REQ

Serialization is required. If the UNIX file is still in use after the max number of retries for the backup have been made, the backup request will fail.

The -I suboptions can be specified in any order and any omitted suboption will have their default values used. However, at least one suboption must be specified.

All supported UNIX file types can be backed up with the -I option, however only Regular Files will be checked to be in use. Symbolic links, FIFOs, and directories will not be checked to be in use and will not have their backup retried.

zFS File Snapshot is not supported for in use UNIX files. If *serialization=PREF* and *-C PREF* or *-C REQ* are specified on the command and the UNIX file is in use at the time of backup, the backup request will still fail.

-o

Storage Administrator mode. Any files that are sent to DFSMShsm for backup are processed as if they are sent by using a BACKDS Storage Administrator command. If using this option, you should also switch to UID(0) by using the *su UNIX* command first so that all files are accessible to the program.

-p

Specifies the maximum number of outstanding requests that are sent to the DFSMSShsm host at any one time. Default value is 100.

-r

Specifies the number of days to keep this backup past when it would normally be expired or rolled off. (RETAININDAYS) Default: None

-t

Specifies the target of the backup. It can be either DASD, tape, or not specified in where DFSMSShsm chooses the backup target. Default: None

-test

Requests only the matched file names are displayed, but not sent to the DFSMSShsm host for backup.

-i

Specifies the host ID of the DFSMSShsm host that the backup request will be directed to. Host ID must be 1 character A-Z, 0-9, @, #, or \$.

The host ID must correlate to a DFSMSShsm host that is active on the system from which the java hbackup command was issued. If the DFSMSShsm host on the system with the specified host ID is inactive or does not exist, message ARC0055A will be issued to the operator console and processing will not continue until the message is responded to. If a filemode host is active on the system, then the backup request will be directed to the filemode host that has the specified host ID. Using this option will not direct backup requests to DFSMSShsm hosts on other systems within the PLEX.

This option, on its own, does not provide functionality to divide and distribute UNIX file backups to multiple DFSMSShsm hosts on a system. The user must decide how to divide and distribute UNIX file backups and which specific DFSMSShsm hosts to direct those backup requests to.

-version

Display the current version of the *hbackup* program.

-v{val}

Issue verbose messages during processing. An optional value might be specified for a level of verbosity. For example, -vDTL . If -v is specified without a value, it defaults to -vSTAT.

val might be:

- STAT - Display statistics.
- DTL - Display detailed information about file selection.
- TIMES - Display timestamps on messages.
- ALL - Display all message types.

Note: The *hbackup* program examines the following types of files:

- Regular files.
- Empty directories.
- Symbolic links.
- FIFO files

UNIX hard links are always sent to DFSMSShsm because only the DFSMSShsm host knows whether the backup version in the DFSMSShsm inventory is the most recent for that file name.

Specifying the environment configuration

Ensure that the environment variables are configured correctly for the Java *hbackup* program to run. They are:

CLASSPATH

Include the */usr/lpp/dfsms/bin/hbackup.jar* path in the CLASSPATH environment variable.

```
CLASSPATH="$CLASSPATH":/usr/lpp/dfsms/bin/hbackup.jar; export CLASSPATH="$CLASSPATH"
```

LIBPATH

Include the `/usr/lpp/dfsms/bin` path in the LIBPATH environment variable.

```
LIBPATH="$LIBPATH":/usr/lpp/dfsms/bin; export LIBPATH="$LIBPATH"
```

Example of how to code the Java *hbackup* command

The following is an example of the Java *hbackup* command.

```
//BPXBAKJ1 JOB (XXXX), 'BACKUP JOB', NOTIFY=&SYSUID, MSGLEVEL=(1,1),
// MSGCLASS=H
//*****
/* Search directory sub-tree for files in need of Incremental backup
/* using Java hbackup program.
//*****
//STEP1 EXEC PGM=BPXBATCH, REGION=0M
//SYSPRINT DD SYSOUT=*
//STDOUT DD SYSOUT=*
//STDERR DD SYSOUT=*
//STDENV DD DUMMY
//STDPARM DD *
SH /bin/sh -c '
set -x;
CLASSPATH="$CLASSPATH":/usr/lpp/dfsms/bin/hbackup.jar ;
export CLASSPATH="$CLASSPATH" ;
LIBPATH="$LIBPATH":/usr/lpp/dfsms/bin ;
export LIBPATH="$LIBPATH" ;
su ;
java hbackup -v -o --test /test/ ;
'
/*
```

Chapter 74. UPDTCDS Command: Updating the control data sets

The UPDTCDS command allows you to update specific fields within the control data sets. Specifically, it enables you to update the expiration date of copy pool dump copies. When the UPDTCDS command is issued, DFSMSHsm updates all of the corresponding control data set records with the specified value.

Syntax of the UPDTCDS command

```

➤ UPDTCDS — COPYPOOL — (cpname) — VERSION( version) —➤
      |
      +— CP —

```

```

➤ DUMPEXPIRATION(DUMPCCLASS( class) NEWDATE( newdate)) —➤

```

Required parameters of the UPDTCDS command

This topic describes the required parameter of the UPDTCDS command.

COPYPOOL: Specifying the name of the copy pool

Explanation

COPYPOOL(*cpname*) is a required parameter that identifies the name of the copy pool that is to be modified.

VERSION: Specifying the version

Explanation

VERSION(*version*) is a required parameter that identifies the version of the specified copy pool.

DUMPEXPIRATION: Indicating that the copy pool dump expiration is to be modified

Explanation

DUMPEXPIRATION is a required parameter that indicates that the expiration date for the specified dump class is to be modified to the specified new date, as follows:

DUMPCCLASS(*class*)

Specifies the dump class that is to be modified. It is required.

NEWDATE(*newdate*)

Specifies the new expiration date. The date must be equal to or later than the date on which the command is issued. The new date format is *yyyy/mm/dd*, where

yyyy

Is the year

mm

Is the month

dd

Is the day of the month.

A leading zero is not required for a one-digit month or day.

Example of how to code the UPDTCDS command

The following example shows how to code the UPDTCDS command.

Note: Any values specified here are only examples and should not be interpreted as the values to be used for your system.

Updating the copy pool dump expiration date

In this example, the UPDTCDS command updates the expiration date for copy pool COPYPOOL1, version 124, class ONSITE to 2050/12/31.

```
UPDTCDS COPYPOOL(COPYPOOL1) VERSION(124) DUMPEXPIRATION(DUMPCCLASS(ONSITE) NEWDATE(2050/12/31))
```

You can use the LIST COPYPOOL(*cpname*) command to display the current versions, dump classes and expiration dates for existing dump copies associated with a copy pool.

Chapter 75. Using the AUDIT command

This topic contains diagnosis, modification, and tuning information.

For control data sets, the AUDIT command detects, reports, diagnoses, and (in many cases) provides repairs for discrepancies within and between the migration control data set (MCDS); the backup control data set (BCDS); the offline control data set (OCDS); VTOCs of DASD volumes; TTOCs for DFSMSHsm tape volumes; and the computer system catalogs, including the master catalog and user catalogs.

For common queues, the AUDIT command enables DFSMSHsm to dynamically correct inconsistencies with minimal impact on processing. Common queues have interrelated entries that may become corrupted due to abends and unexpected losses of connectivity. A corrupted common queue may cause certain requests to not be processed. DFSMSHsm automatically corrects some inconsistencies, but for others, it is necessary to issue the AUDIT COMMONQUEUE command.

These topics can help you make the best use of the AUDIT command for your application. In topics one and two, for each of the AUDIT options, we describe the checking done, and which error conditions can be detected by using that option. For each reported condition, AUDIT may be able to determine a repair action. The actual form of the repair commands, if any, depends on the control information involved.

The options described in [“Using the enhanced audit command to audit DFSMSHsm control information” on page 1256](#) are enhancements to the original AUDIT command described in [“Using the original AUDIT command to audit DFSMSHsm data set information” on page 1280](#). [Table 70 on page 1255](#) compares the information driving the AUDIT options.

Table 70. Comparison of AUDIT Options		
Driving Information	Enhanced AUDIT Option	Original AUDIT Option
Aggregate backup records	ABARSCONTROLS	None
Copy pool records	COPYPOOLCONTROLS(<i>cpname</i>)	None
Specific data set names	None	DATASET NAMES LEVELS
Catalog entries	None	MASTERCATALOG USERCATALOG
Backup Control Data Set	DATASETCONTROLS(BACKUP)	BCDS
Migration Control Data Set	DATASETCONTROLS(MIGRATION)	MCDS
Tape table of contents (ML2 volume)	DIRECTORYCONTROLS	VOLUMES OCDS(ML2) OCDS(ALL)
Tape table of contents (backup volume)	DIRECTORYCONTROLS	BACKUPVOLUMES BACKUPTYPE OCDS(DAILY) OCDS(SPILL) OCDS(ALL)
Volume table of contents (DASD VTOC)	DIRECTORYCONTROLS	VOLUMES
DFSMSHsm images of user data sets	MEDIACONTROLS MEDIACONTROLS(SDSP)	None
Backup-volume records	VOLUMECONTROLS(BACKUP)	None
Common queues	COMMONQUEUE	None

Table 70. Comparison of AUDIT Options (continued)

Driving Information	Enhanced AUDIT Option	Original AUDIT Option
Migration-volume records	VOLUMECONTROLS(MIGRATION)	None
Eligible-volume records	VOLUMECONTROLS(RECOVERABLE)	None

“Error codes (*ERR) and diagnosis” on page 1295 describes all the conditions reported by AUDIT, as well as repair actions taken and diagnostic suggestions for those cases where AUDIT cannot resolve a discrepancy.

“Unexpected errors during an audit” on page 1337 identifies errors that may occur to prevent AUDIT from completing its checking.

“Other considerations when using the AUDIT command” on page 1340 presents considerations for using AUDIT in a multiple-DFSMSHsm-host environment and suggestions for printing output.

Note: If AUDIT is executing and backup of the DFSMSHsm control data sets has been started (by the BACKVOL CDS command or AUTOBACKUP), all DFSMSHsm functions on the host that started this backup are halted until the AUDIT function and the backup of the DFSMSHsm CDS’s have completed.

Using the enhanced audit command to audit DFSMSHsm control information

Table 71 on page 1256 lists the AUDIT commands audit and report errors within DFSMSHsm controls and where to find more information.

Table 71. AUDIT Commands that Audit and Report Errors	
If the command you are interested in is. . .	Then see. . .
AUDIT ABARSCONTROLS (agname)	“Using the AUDIT ABARSCONTROLS command” on page 1257
AUDIT COMMONQUEUE	“Using the AUDIT COMMONQUEUE command” on page 1258
AUDIT COPYPOOLCONTROLS	“Using the AUDIT COPYPOOLCONTROLS command” on page 1259
AUDIT DATASETCONTROLS (BACKUP)	“Using the AUDIT DATASETCONTROLS (BACKUP) command” on page 1260
AUDIT DATASETCONTROLS (MIGRATION)	“Using the AUDIT DATASETCONTROLS (MIGRATION) command” on page 1261
AUDIT DIRECTORYCONTROLS VOLUMES	“Using the AUDIT DIRECTORYCONTROLS command” on page 1263
AUDIT MEDIACONTROLS (CLOUD)	“Using the AUDIT MEDIACONTROLS (CLOUD) command” on page 1267
AUDIT MEDIACONTROLS (SDSP) VOLUMES	“Using the AUDIT MEDIACONTROLS (SDSP) VOLUMES command” on page 1268
AUDIT MEDIACONTROLS (VOLUMES)	“Using the AUDIT MEDIACONTROLS VOLUMES command” on page 1269
AUDIT VOLUMECONTROLS (BACKUP)	“Using the AUDIT VOLUMECONTROLS (BACKUP) command” on page 1272
AUDIT VOLUMECONTROLS (MIGRATION)	“Using the AUDIT VOLUMECONTROLS (MIGRATION) command” on page 1273

Table 71. AUDIT Commands that Audit and Report Errors (continued)

If the command you are interested in is. . .	Then see. . .
AUDIT VOLUMECONTROLS (RECOVERABLE)	“Using the AUDIT VOLUMECONTROLS (RECOVERABLE) command” on page 1274

When the FIX parameter is specified, AUDIT often completes repairs. There may be times, however, when you want to audit without fixing errors. During an audit, the AUDIT function serializes control records, which allows it to compare several sources of information. While the control records are serialized, they are static and the comparisons are valid. Once the audit has completed, the system returns to its normal dynamic mode, and these comparisons may no longer be valid.

Your decision concerning the use of the FIX parameter to repair errors depends mostly upon two factors:

- First, how busy is DFSMSHsm? The higher the activity, the faster your audit report becomes obsolete.
- Second, what is the scope of your audit? If you just want to check the status of one DASD volume, then running AUDIT without the FIX parameter will be helpful. If you audit many controls, your report becomes obsolete quickly.

When auditing a common queue, FIX does not create the same concerns as when auditing other controls. In general, FIX should always be specified when auditing a common queue.

When using the AUDIT functions listed in topic One, you receive important information in the report header and the report body:

- The header of your audit report confirms the performed audit and shows the time, the date, and the system identification. The second line of the report header reflects the AUDIT command and parameters that you have entered.
- The body of your audit report normally consists of two lines printed for each detected error. The first line gives you the error code and a brief description of the error. The lines immediately following the error code list the appropriate repair commands whenever the AUDIT function is able to identify them.

AUDIT COMMONQUEUE does not generate a report. The only output of AUDIT COMMONQUEUE is message ARC1544I.

During an audit, AUDIT executes the following sequence:

1. DETECTION: AUDIT checks for inconsistent sources of information that might prevent DFSMSHsm from retrieving a data set (or group of data sets), or accessing a DFSMSHsm-owned volume.
2. DIAGNOSIS: AUDIT attempts to refer to one or more additional sources of information (a reality outside of the conflicting sources), when it detects an inconsistency. In many instances, AUDIT is able to list either a repair action (FIX) or a recommendation for further diagnosis of the detected error.
3. FIX: AUDIT initiates repair action, when you specify the FIX parameter and when AUDIT determines the appropriate FIX.

You can determine whether repair action has been initiated by examining two items on the audit report. When FIX is specified for a common queue, all detected errors will be fixed. No specific information is given concerning each error.

1. Was the FIX parameter specified?
2. Did AUDIT list the appropriate repair action?

Using the AUDIT ABARSCONTROLS command

When you specify AUDIT ABARSCONTROLS (*agname*), AUDIT makes the following checks for each ABR (Q) record in the BCDS (or for only those ABR records associated with the specified aggregate group name):

- If no ABR records are found for a specified aggregate group, AUDIT reports ***ERR 166**.
- If no ABR record is found at all, AUDIT reports ***ERR 167**.

- If the control file indicated in an ABR record is not cataloged, AUDIT reports ***ERR 168**.
- If at least one type of data file (DFSMSdss or internal) is present for an ABR record,
 - If a DFSMSdss data file is indicated, but the file is not cataloged, and it was created by DFSMSHsm, AUDIT reports ***ERR 168**;
 - If an internal data file is indicated, but the file is not cataloged, and it was created by DFSMSHsm, AUDIT reports ***ERR 168**.
- If no data file is present for an ABR record, AUDIT reports ***ERR 165**.
- If an instruction/activity log file is indicated, but the file is not cataloged, and it was created by DFSMSHsm, AUDIT reports ***ERR 168**.

The FIX or NOFIX option is ignored for ABARSCONTROLS since only diagnosis messages are issued.

Diagnosis and repair action for AUDIT ABARSCONTROLS

When you request AUDIT ABARSCONTROLS, AUDIT does not fix any of the errors detected. See “Error codes (*ERR) and diagnosis” on page 1295 for some troubleshooting hints for any reported conditions.

Using the AUDIT COMMONQUEUE command

When you specify the AUDIT COMMONQUEUE parameter, AUDIT scans the entries in the common queue. When you specify AUDIT COMMONQUEUE(RECALL), AUDIT scans the entries in the Common Recall Queue (CRQ) for logical inconsistencies within the structure.

Diagnosis and repair action for AUDIT COMMONQUEUE(RECALL)

The following indicate that the CRQ may be corrupted:

- Message ARC1506E was issued.
- Message ARC1187E was issued.
- Recall requests are unexpectedly not being selected for processing.

Note: If recall requests are unexpectedly not being selected for processing, issue the QUERY ACTIVE command and examine message ARC1541I. This message displays the factors that affect the selection of requests from the CRQ. A status of anything other than CONNECTED or a hold level of anything other than NONE are probable reasons why certain recall requests are not being selected.

Note: An unexpected loss of connectivity to the CRQ may also introduce errors, but in most cases DFSMSHsm automatically corrects those errors. When this occurs, you may see the multiple issuance of message ARC1102I. Message ARC1102I is issued when DFSMSHsm attempts to recall a data set that has already been recalled. It is normal for this message to occur at the time of a loss of connectivity and it does not indicate a problem with the CRQ list structure.

If you believe that the CRQ has been corrupted, issue the AUDIT COMMONQUEUE(RECALL) FIX command. When this command is issued, DFSMSHsm scans the entries in the CRQ and attempts to correct logical inconsistencies within the structure. AUDIT cannot correct all types of errors and may report that zero errors were detected even though there are errors in the CRQ structure.

Note: The following parameters are not used with AUDIT COMMONQUEUE:

- ALL
- OUTDASE | SYSOUT | TERMINAL
- REPORT(ALL | ERRORS)
- SERIALIZATION(DYNAMIC | CONTINUOUS)

If after issuing the AUDIT command, message ARC1506E or message ARC1187E occurs repeatedly, or certain data sets are unexpectedly not being selected for recall processing, refer to [Chapter 4, “Other space management considerations,”](#) on page 127 for more information about correcting errors within the CRQ.

Using the AUDIT COPYPOOLCONTROLS command

When you specify AUDIT COPYPOOLCONTROLS (*cpname*), AUDIT reads the fast replication control data set records to confirm the existence and accuracy of all DFSMSHsm records associated with the copy pool. No orphaned records are identified.

You can use the AUDIT COPYPOOLCONTROLS command to verify that if a Fast Replication copy pool version indicates that there is an associated catalog information data set, then that corresponding catalog information data set exists on an ML1 volume.

When you specify AUDIT COPYPOOLCONTROLS without a specific copy pool name, AUDIT reads sequentially through all existing fast replication records and confirms the existence and accuracy of all DFSMSHsm records associated with copy pools. The AUDIT function detects and reports orphaned records and other discrepancies. When AUDIT can determine the appropriate solution for a discrepancy, the solution is included in the AUDIT output. All errors detected by AUDIT are identified with an error number.

The following checks are reported:

- If no copy pool 'F' (FRB) record exists, AUDIT reports ***ERR 106**.
- If the specified copy pool does not exist, AUDIT reports ***ERR 170**.
- If the number of dump version does not match the number of version found, AUDIT reports ***ERR 171** and ***ERR 172**.
- If the number of 'H' (FRVP) records indicated does not match the number of records found, AUDIT reports ***ERR 173**.
- If no 'F' (FRB) records for a copy pool are found and an orphaned 'H' (FRVP) record exists, AUDIT reports ***ERR 174**.
- If the 'H' (FRVP) record indicates 'Prepare' and the corresponding 'F' (FRB) record does not, AUDIT reports ***ERR 175**.
- If a 'H' (FRVP) record exists for a version and the corresponding 'F' (FRB) record is not found, AUDIT reports ***ERR 176**.
- If no 'I' (FRTV) record exists for the specified VOLUME *volser*, AUDIT reports ***ERR 177**.
- If the associated FRSV (J) record, as indicated in the FRTV(I) record, is not found, ***ERR 178** is issued.
- If wrong target volume or source volume is indicated in the 'H' (FRVP) and 'I' (FRTV) records, AUDIT reports ***ERR 179**.
- If no 'J' (FRSV) record exists for specified VOLUME *volser*, Copy pool *cpname*, and VERSION *vsr*, AUDIT reports ***ERR 180**.
- If no 'F' (FRB) record exists for *cpname*, AUDIT reports ***ERR 181**.
- If no 'P' (MCP) record exists for VOLUME *volser*, AUDIT reports ***ERR 182**.
- If no VOLUME *volser* from the 'J' (FRSV) record L0 field exists in corresponding 'H' (FRVP) record, AUDIT reports ***ERR 183**.
- If an orphaned 'J' (FRSV) record is detected, AUDIT reports ***ERR 184**.
- If copy pool *cpname* not found in 'J' (FRSV) record copy pool array for VOLUME *volser*, AUDIT reports ***ERR 185**.
- If an orphaned 'K' (FRD) record is detected and copy pool *cpname* no longer exists, AUDIT reports ***ERR 186**.
- If a 'K' (FRD) record exists and a 'F' (FRB) record indicates no dump copy, AUDIT reports ***ERR 187**.
- If no 'K' (FRD) record exists and a 'F' (FRB) record for copy pool *cpname* indicates that it does exist, AUDIT reports ***ERR 188**.
- If no 'H' (FRVP) record exists for the specified copy pool name, AUDIT reports ***ERR 189**.
- If the specified volume is not found in any associated 'H' (FRVP) record for the specified copy pool name, AUDIT reports ***ERR 190**.

- If an associated P (MCP) record for a volume *volser* that is in a storage group that is defined in a copy pool does not indicate the volume is part of a copy pool, ***ERR 191** is reported.
- If an FRSV record is found DFSMSHsm attempts to read associated FRBs records, if any. For each FRB record found , AUDIT reports ***ERR 192**.
- If the DFSMSHsm records indicate that volume *volser* is a copy pool volume but no FRSV (J) record exists, ***ERR 193** is issued.
- If the copy pool record indicates that the catalog information was captured but a data set containing this information was not found, AUDIT reports ***ERR 194**.
- If the copy pool record indicates that the catalog information was captured but the corresponding catalog information data set indicates that it contains catalog information for a different copy pool backup version, AUDIT reports ***ERR 195**.
- ***ERR 200** indicates that there was an unexpected error while trying to process the catalog information data set. This message should be preceded by an ARC1812I.
- ***ERR 202** is issued for each FRTV record that is not associated with any of the copy pool records that were found during the audit.
- ***ERR 204** is issued if auditing determines that a single FRTV (target volume) record is associated with more than one source volume. This error is issued for each copy pool version in which the error was detected.
- ***ERR 215** is issued if a CLOUD DGN record has any inconsistent entries as CLOUD dump.
- ***ERR 217** is issued if the object number in a cloud DGN record does not match the object number of the cloud object prefix.
- ***ERR 218** is issued if any dump copy in a TAPE DGN record is CLOUD type.
- ***ERR 219** is issued if the corresponding cloud dump object of a CLOUD DGN record can not be found.

Diagnosis and repair action for AUDIT COPYPOOLCONTROLS

See “Error codes (*ERR) and diagnosis” on page 1295 for troubleshooting hints for reported conditions and to help determine if corrective action is taken by audit processing.

Using the AUDIT DATASETCONTROLS (BACKUP) command

When you specify the AUDIT DATASETCONTROLS (BACKUP) command, the following checks are performed for each valid data set (B) record in the BCDS (or for only those specified by the DS NAMES or LEVELS parameter):

- If a backup version (C) record indicates the version is on a given tape backup volume, but the TTOC (T) base record for that volume does not exist, AUDIT reports ***ERR 17**.
- If the latest backup version (C) record indicates a version number that is higher than the version number in the MCBGEN field of the associated data set backup (B) record, AUDIT reports ***ERR 35**.
- If there is a discrepancy between the MCBVER and MCCGEN fields of a backup version entry, AUDIT reports ***ERR 36**.
- If a backup version (C) record has a sequence number that is not the same as the sequence number of the associated retained version (Z) record, AUDIT reports ***ERR 37**.
- If a retained version (Z) record exists and the associated backup version (C) record's sequence number field indicates no retained version (Z) records exist, AUDIT reports ***ERR 38**.
- If a retained version (Z) record exists and the associated data set (B) record does not contain a value greater than zero in the sequence number field, AUDIT reports ***ERR 38**.
- If a data set record (or retained backup record) refers to a backup version for which there is no version record, AUDIT reports ***ERR 39**.
- If a data set record refers to a backup version record (or retained backup record) that does not refer back to the data set record, AUDIT reports ***ERR 39**.

- If the entry in a data set record's (or retained backup record's) version index and the backup version record itself indicate that version is on a certain backup volume, but there is no backup volume (**X**) record for that volume serial number, AUDIT reports ***ERR 41**. (The error can apply to any of the tape volumes spanned by a multivolume backup version.)
- If the entry in a data set record's version index and the backup version record itself indicate that version is on a certain migration volume, but there is no migration volume (**V**) record for that volume serial number, AUDIT reports ***ERR 42**.
- If a backup version is found on its indicated migration volume, but no move (**M**) record exists for that version, AUDIT reports ***ERR 43**.
- If the entry in a data set record's (or retained backup record's) version index and the backup version record itself indicate that version is on a certain DASD backup volume, but the backup volume record indicates the volume is a tape (or vice versa), AUDIT reports ***ERR 44**.
- If the entry in a data set record's version index and the backup version record itself indicate that version is on a certain migration volume, but the volume is not mounted or (according to its VTOC) does not contain the backup version, AUDIT reports ***ERR 47**.
- If a specified data set name has no data set record, AUDIT reports ***ERR 48**.
- If the backup version record (B) indicates retained backup version records exist, but they are not found, AUDIT will report MSG 912.

When the scope of the audit is *not* limited by either DSNAMES() or LEVELS(), AUDIT makes additional checks:

- If an invalid record type is found in the BCDS, AUDIT reports ***ERR 30**.
- If a (**L**) record calls for backing up a migrated data set, but no MCDS record exists for that data set, AUDIT reports ***ERR 46**.

When you specify the AUDIT DATASETCONTROLS(BACKUP) parameter, AUDIT also checks to ensure version (C) records have an associated entry in a data set (B) record (or in a retained backup version (Z) record). The check is made for each version (C) record or for only those specified by the LEVELS parameter. A fully qualified backup version name can be used with the LEVELS parameter to process a single MCC record. If the backup version record refers to a BCDS data set (B) record that does not exist, or the (B) record exists but does not refer to the version (C) record, AUDIT reports ***ERR 40**.

If the backup version record refers to a retained version (Z) record that does not exist, or the (Z) record exists but does not refer to the backup version (C) record, AUDIT reports ***ERR 40**.

Important: Each FIXCDS command generated with this error is dependent on previous FIXCDS commands. If NOFIX is used, the offsets in the output data set are invalid.

Diagnosis and repair action for AUDIT DATASETCONTROLS (BACKUP)

When you request AUDIT DATASETCONTROLS (BACKUP):

- AUDIT usually identifies a repair (and takes repair action when FIX is specified) for error messages (*ERR) 30, 35, 36, 40, 41, 42, 43, 44, and 46.
- AUDIT recommends an additional diagnostic step for error messages (*ERR) 17 if the backup tape involved is a volume written in single file format. If you want AUDIT to continue its attempt to identify a repair action, you must specify an additional AUDIT command using the recommended parameter.
- For other reported conditions, see [“Error codes \(*ERR\) and diagnosis” on page 1295](#) for some troubleshooting hints.

Using the AUDIT DATASETCONTROLS (MIGRATION) command

When you specify the AUDIT DATASETCONTROLS (MIGRATION) parameter, AUDIT makes the following checks for each valid data set (**D**) record in the MCDS (or for only those specified by the DSNAMES or LEVELS parameter):

- If a data set record indicates a valid migrated copy, but the data set is uncataloged, AUDIT reports ***ERR 03**.
- If a data set record indicates a valid migrated copy, but the data set's catalog entry does not refer to volume serial MIGRAT, AUDIT reports ***ERR 09**.
- If a data set record indicates the migration copy is on a given tape volume, but the TTOC base record (or indicated extension) does not exist, AUDIT reports ***ERR 17**.
- If a specified data set name has no data set record, AUDIT reports ***ERR 19**.
- If a data set record indicates that a migration copy is on a certain volume, but there is no migration volume record for that volume serial number, AUDIT reports ***ERR 20**. (The error could apply to any of the tape volumes spanned by a multivolume migration copy.)
- If a data set record indicates the migration copy is on a given DASD (or tape) migration volume, but the migration volume record indicates the volume is a tape (or DASD) volume, AUDIT reports ***ERR 21**.
- If a data set record created by HSM Release 3 or later indicating that a migration copy is *not* in an SDSP data set, but no alias (**A**) record exists for the migration copy, AUDIT reports ***ERR 22**.
- If a data set record indicates the existence of a VSAM-associations (**O**) record, but no such record exists, AUDIT reports ***ERR 23**.
- If a VSAM-associations record refers to a migrated VSAM component, but there is no catalog entry for the component, or the catalog entry is something other than a non-VSAM entry referring to single volume serial MIGRAT, AUDIT reports ***ERR 24**.
- If a VSAM-associations record refers to a migrated VSAM component, and its catalog entry properly indicates a migration copy, but no alias record exists for the VSAM component, AUDIT reports ***ERR 25**.
- If a data set record indicates the existence of a back up migrated data set (**L**) record, but no such record exists, AUDIT reports ***ERR 26**.
- If a migration volume's TTOC has no valid entry for a migration copy supposedly starting on that tape, or continuing from another tape, AUDIT reports ***ERR 29**. This error may occur if AUDIT DATASETCONTROLS is executed while migration is currently updating a given TTOC record. If this should occur, run AUDIT DATASETCONTROLS while migration is inactive.
- If a MCD record (D) indicates that a user data set has been encrypted but there is no MCDX record (3), AUDIT reports ***ERR 31**.
- If a MCD record (D) indicates that a user data set has associated 'Retained' MCA records, but there is a mismatch between the number of 'Retained' MCA records the MCD reports and the number of actual copies, AUDIT reports ***ERR 33**.

When the scope of the audit is *not* limited by either DSNAMES() or LEVELS(), AUDIT makes additional checks:

- If a VSAM-associations record refers to a data set record that does not exist, or that does not refer back to the VSAM-associations record, AUDIT reports ***ERR 27**.
- If an alias record refers to a data set record that does not exist, AUDIT reports ***ERR 28**.
- If an invalid record type is found in the MCDS, AUDIT reports ***ERR 30**.
- If a MCDX record (3) refers to a MCD record (D) that does not exist, AUDIT reports ***ERR 32**.

Diagnosis and repair action for AUDIT DATASETCONTROLS (MIGRATION)

When you request AUDIT DATASETCONTROLS (MIGRATION):

- AUDIT usually identifies a repair (and takes repair action when FIX is specified) for error messages (*ERR) 20, 21, 22, 24, 25, 26, 27, 28, 30, and 32.
- AUDIT recommends an additional diagnostic step for error messages (*ERR) 17 and 29 if the migration tape involved is a volume written in single file format. If you want AUDIT to continue its attempt to identify a repair action, you must specify an additional AUDIT command using the recommended parameter.

- For other reported conditions and troubleshooting hints, see [“Error codes \(*ERR\) and diagnosis” on page 1295.](#)

Using the AUDIT DIRECTORYCONTROLS command

When you specify the DIRECTORYCONTROLS VOLUMES(*volser*...) parameter, for each volume serial number specified AUDIT cross-checks information in the volume's directory (a VTOC or TTOC) with control records in the MCDS or BCDS, whichever applies in a given situation. AUDIT then reports any discrepancies found.

To determine the type of directory for each volume serial specified, AUDIT first checks for a volume record. If no migration volume record or backup volume record exists for a specified volume serial number, AUDIT reports ***ERR 110**. When AUDIT finds a volume record, its content determines what further checking is done.

When AUDIT can determine the appropriate fix for an error, the fix is included in the list report.

You can also use the AUDIT DIRECTORYCONTROLS command to verify that the catalog information data sets found on ML1 volumes correspond to a valid copy pool version.

Errors detected when using AUDIT DIRECTORYCONTROLS for a DASD migration volume

For each volume record indicating a DASD migration volume, AUDIT makes the following checks for each DSCB having the attributes DFSMSHsm assigns to its data sets (other DSCBs are ignored):

- If the first qualifier of a data set name indicates a migration copy, but there is no alias record in the MCDS, AUDIT reports ***ERR 140**.
- If the DSCB for a migration copy or backup version indicates an empty data set (TTR of 0), AUDIT reports ***ERR 141**.
- If the first qualifier of a data set name indicates a backup version, but there is no backup version record in the BCDS, AUDIT reports ***ERR 142**.
- If the backup version record corresponding to a DSCB does not indicate a version scheduled for deletion, and there is no move record for that version, AUDIT reports ***ERR 43**.
- If the first qualifier of a data set name indicates a VTOC copy for a certain volume, but there is no eligible volume (**P**) record for that volume in the BCDS, AUDIT reports ***ERR 143**.
- If the eligible volume record corresponding to a VTOC copy DSCB indicates
 - The volume has not been backed up; or
 - Its related VTOC copy data sets are on other volumes; or
 - Its VTOC copy data set is not (determined by the qualifiers in its name) the one we started from
 AUDIT reports ***ERR 144**.
- If the first qualifier of a data set name indicates a Dump VTOC copy for a certain volume, but there is no eligible volume record for that volume in the BCDS, AUDIT reports ***ERR 145**.
- If the eligible volume record corresponding to a Dump VTOC copy DSCB indicates there are no valid dump generations for that volume, AUDIT reports ***ERR 146**.
- If the eligible volume record indicates there is at least one dump generation, but no dump generation record refers to the Dump VTOC copy we started from, AUDIT reports ***ERR 146**.
- When there is a catalog entry for the dsname indicating it is migrated, but the dsname's first qualifiers are not recognized as DFSMSHsm generated,
 - If there is no valid data set record in the MCDS, AUDIT reports ***ERR 147**.
 - If there is a valid data set record in the MCDS referring to the volume we started from, but indicating the migration copy is in an SDSP data set, AUDIT reports ***ERR 148**.
 - When there is a valid data set record in the MCDS, but it indicates a migration copy on some other DASD volume (not in an SDSP data set),

- If the other volume is mounted, but the dsname cannot be found in its VTOC, AUDIT reports ***ERR 147**.
- If the other volume is mounted and the dsname is found in its VTOC, AUDIT reports ***ERR 149**.
- If the other volume is not mounted, AUDIT reports ***ERR 148**.
- When there is a valid data set record in the MCDS, but it indicates a migration copy on a tape volume,
 - If a valid TTOC entry can be found for that tape volume, AUDIT reports ***ERR 149**.
 - If no valid TTOC entry can be found, AUDIT reports ***ERR 147**.
- If the catalog information data set was found on an ML1 volume but the data set is not cataloged, AUDIT reports ***ERR 196**.
- If there is no corresponding Fast Replication backup version for the catalog information data set, AUDIT reports ***ERR 197**.
- ***ERR 198** indicates that the copy pool backup version specified by the catalog information data set indicates that the catalog information was not captured. This catalog information data set does not correspond to a valid existing copy pool backup version.
- If the copy pool version that the catalog information data set indicates that it is associated to is not the catalog information data set that the copy pool version record indicates, AUDIT reports ***ERR 199**.
- ***ERR 200** indicates that there was an unexpected error while trying to process the catalog information data set. This message should be preceded by an ARC1812I message.
- If the catalog locate for the catalog information data set indicates that this data set is cataloged on a different volume, AUDIT reports ***ERR 201**.

Diagnosis and repair action for AUDIT DIRECTORYCONTROLS for DASD

When you request AUDIT DIRECTORYCONTROLS VOLUMES(*volser...*) for a DASD:

- AUDIT usually identifies a repair (and takes repair action when FIX is specified) for error messages (*ERR) 43, 141, 142, 143, 144, 145, 146, 147, and 149.
- AUDIT may recommend an additional diagnostic step for error messages (*ERR) 140 and 148. If you want AUDIT to continue its attempt to identify a repair action, you must specify an additional AUDIT command using the recommended parameter.
- For other reported conditions and troubleshooting hints, see [“Error codes \(*ERR\) and diagnosis” on page 1295](#).

Errors detected when using AUDIT DIRECTORYCONTROLS for a tape volume

For each volume record indicating a *tape migration* volume, AUDIT makes the following checks:

- If no TTOC base record exists, AUDIT reports ***ERR 17**.
- When the TTOC exists, AUDIT makes the following checks for each valid data set entry in that TTOC:
 - If there is a catalog entry indicating a migrated data set, but no data set record in the MCDS, AUDIT reports ***ERR 113**.
 - If there is a catalog entry indicating a migrated data set, and a data set record indicating a valid migration copy on *some other* volume:
 - If the data set record indicates that other volume is a tape, but there is no TTOC base record for that other volume; or
 - If the data set record indicates that other volume is a DASD volume, but its VTOC has no DSCB for the migration copy

AUDIT reports ***ERR 115**.

- If a TTOC entry is not flagged as valid, but has an alias record in the MCDS, AUDIT reports ***ERR 114**.

For each volume record indicating a *tape backup* volume, AUDIT makes the following checks:

- If no TTOC base record exists, AUDIT reports ***ERR 17**.

- When the TTOC exists, AUDIT makes the following checks for each valid data set entry in that TTOC:
 - If, in the BCDS, a backup version record exists, but
 - No data set record exists; or
 - The existing data set record does not refer to the backup version record
 AUDIT reports ***ERR 116**.
 - If the TTOC entry indicates either a VTOC or VCAT copy data set for a given volume:
 - If there is no eligible volume record for that volume, AUDIT reports ***ERR 117**
 - If the existing eligible volume record does not refer to the VTOC or VCAT copy we started from, AUDIT reports ***ERR 118**.
- If a TTOC entry is not flagged as valid, but has a backup version record in the BCDS, AUDIT reports ***ERR 116**.

For either a migration or backup volume, AUDIT makes the following checks, after finding the base TTOC record:

- If the alternate volume serials for duplex volumes do not match between the TTOC and either the MCT or MCV, AUDIT reports ***ERR 58**.
- If one or more TTOC extension records are missing from the TTOC set, AUDIT reports ***ERR 111**.
- If there is an extraneous TTOC extension record, AUDIT reports ***ERR 112**.
- When the TTOC base record indicates the first entry, either a migrated data set or a backup version continues (spans) from another tape volume, referred to as the predecessor volume
 - If the data set entry is INVALID, AUDIT reports ***ERR 125**.
 - If there is no TTOC for the predecessor volume and the data set entry is VALID, AUDIT reports ***ERR 119**.
 - If the TTOC for the predecessor volume is found, but does not indicate the volume being audited as a successor, and the data set entry is VALID, AUDIT reports ***ERR 120**.
 - If the last data set in the predecessor's TTOC is not the same dsname as the first data set in the TTOC of the volume being audited, AUDIT reports ***ERR 121**.
- When the TTOC base record indicates the last entry, either a migrated data set or a backup version continues (spans) to another tape volume, referred to as the successor volume
 - If the data set entry is INVALID, AUDIT reports ***ERR 125**.
 - If there is no TTOC for the successor volume and the data set entry is VALID, AUDIT reports ***ERR 122**.
 - If the TTOC for the successor volume is found, but does not indicate the volume being audited as a predecessor, and the data set entry is VALID, AUDIT reports ***ERR 123**.
 - If the first data set in the successor's TTOC is not the same dsname as the last data set in the TTOC of the volume being audited, AUDIT reports ***ERR 124**.
- If the total valid block count, as determined by the AUDIT function, differs from the value currently reflected in the in the base TTOC record, the AUDIT function corrects the total valid block count in the base TTOC record. This correction can also occur in predecessor or successor TTOC base records.

Diagnosis and repair action for AUDIT DIRECTORYCONTROLS for tape

When you request AUDIT DIRECTORYCONTROLS VOLUMES(*volser*...) for a tape volume:

- AUDIT usually identifies a repair (and takes repair action when FIX is specified) for error messages (*ERR) 111, 112, 113, 114, 115, 116, 118, and 125.
- AUDIT may recommend an additional diagnostic step for error message (*ERR) 17, 119, 120, 121, 122, 123, and 124. If you want AUDIT to continue its attempt to identify a repair action, you must specify an additional AUDIT command using the recommended parameter.

- For other reported conditions and troubleshooting hints, see [“Error codes \(*ERR\) and diagnosis”](#) on page 1295.

Using the AUDIT FILECONTROLS(BACKUP) command

When you specify the AUDIT FILECONTROLS(BACKUP) command, the following checks are performed for each valid UNIX file (B) record in the BCDS (or for only those specified by the FILE or FILELEVEL parameter):

The following checks are performed for UNIX file records in BCDS:

If the latest backup version MCC record indicates a version number that is higher than the version number in the MCBGEN field of the associated MCB record, AUDIT reports ***ERR 35**.

If there is a discrepancy between the MCBVER and MCCGEN fields of a backup version entry, AUDIT reports ***ERR 36**.

If a backup version MCC record has a sequence number that is not the same as the sequence number of the associated retained version record, AUDIT reports ***ERR 37**.

If a retained version record exists and the associated backup version record's sequence number field indicates no retained version records exist, AUDIT reports ***ERR 38**.

If MCB record (or retained backup record) refers to a backup version for which there is no version record, AUDIT reports ***ERR 39**.

If MCB record refers to a backup version record (or retained backup record) that does not refer to the MCC record, AUDIT reports ***ERR 39**.

If the entry in a data set record's version index and the backup version record itself indicate that version is on a certain migration volume, but there is no migration volume record for that volume serial number, AUDIT reports ***ERR 42**.

If a backup version is found on its indicated migration volume, but no move record exists for that version, AUDIT reports ***ERR 43**.

If the entry in MCC's index and the backup version record itself indicate that version is on a certain migration volume, but the volume is not mounted or (according to its VTOC) does not contain the backup version, AUDIT reports ***ERR 47**.

If a specified file path has no MCB, AUDIT reports ***ERR 48**.

If UFN record is found in BCDS but has no associated MCB record, AUDIT reports ***ERR 212**.

If UFN record is not found, AUDIT reports ***ERR 213**.

If UFN record contains valid hash value for parent, child, sibling or last child but UFN record is missing for it, AUDIT reports ***ERR 214**.

The FIX option in AUDIT FILECONTROLS has no effect with FILE and FILELEVEL keywords.

Note: When AUDIT FILECONTROLS runs, it is normal to see the messages such as *ERR 223, *ERR 224, *ERR 225, *ERR 228, and *ERR 229. Read the action needed for each of these messages below and take the actions accordingly. Also it is unusual to see the messages *ERR 226 and *ERR 227. If found, take the right action as suggested.

When AUDIT FILECONTROLS is not running with FIX option (default is NOFIX) and it is found that a UFN record does not have the previous sibling key, then the audit issues ***ERR 223** that contains a PATCH command to fix such nodes. The recommended way to fix such records is by running an AUDIT FILECONTROLS with FIX option. When the count of these error messages reaches a limit of 1000, then audit stops abruptly and issues *ERR 224. This is an indication that there are many UFN nodes without previous sibling reference and user may choose to re-run the AUDIT FILECONTROLS with FIX option.

When AUDIT FILECONTROLS or AUDITFILECONTROL FILELEVEL, is not running with FIX option (default is NOFIX) and a UFN record is found in soft deleted state (UFN_INVALID = ON), the same is reported by the error message ***ERR 225**. When the count of these error messages reaches a limit of 1000, then audit

stops abruptly and issues *ERR 224. In that case, it is recommended to run AUDIT FILECONTROLS with FIX option to clean-up such records from BCDS.

When the count of *ERR 223, or *ERR 225 messages reaches a limit of 1000, the audit stops abruptly and issues ***ERR 224** message recommending AUDIT FILECONTROLS run with FIX option.

If there was a CDS update failure while deleting a UFN record, such a node is identified during the AUDIT process and reported in the form of ***ERR 226** error messages. The further Delete or Add (backup) requests for the Unix files associated to those UFN nodes are handled appropriately. No immediate action required by the user unless there are many such messages.

The *ERR 226 error messages are not usually expected as they indicate CDS update failures. If there are more than 50 such messages, then the audit reports ***ERR 227** error messages. Once this condition is detected, Audit stops issuing *ERR 226 messages but instead, it continues to issue *ERR 227 messages. The count of *ERR 227 messages will be useful to know the number of such failures. Contact IBM support when *ERR 227 is detected.

When AUDIT FILECONTROLS runs with FIX option and updates a UFN record with its previous sibling reference, then the audit issues an informational message ***ERR 228** to report the same to the user. The message text contains the key of UFN record that is updated.

When AUDIT FILECONTROLS runs with FIX option and removes a UFN record that was marked soft delete, the audit issues an informational message ***ERR 229** to report the same to the user. The message text contains a 60-character UFN file / directory name (shortened if original name was more than 60 characters) associated to the UFN node that is now removed from BCDS.

Using the AUDIT MEDIACONTROLS (CLOUD) command

When you specify the AUDIT MEDIACONTROLS (CLOUD(*cloud_network_connection_name*)) parameter, AUDIT checks the control information located in each APPMETA object for each possible DFSMSHsm image of a user data set in each of the HSMplex containers in the specified cloud. AUDIT then produces a list of errors.

Errors detected when using AUDIT MEDIACONTROLS for cloud storage

DFSMSHsm checks each container that matches the name SYSZARC.<plexname>.MIG.<yyyyddd> for migrated data set images and the name SYSZARC.<plexname>.DMP.<yyyyddd> for dump data set images. For each pseudo-directory that is an object name with a forward-slash init, DFSMSHsm checks that group of objects for validity as a migrated data set image or a dump data set image.

For migrated data set images:

- If no object ending with APPMETA (which contains the CDD record) can be found,
 - Using the object prefix the MCDS is checked
 - If there is no alias record in the MCDS then AUDIT reports ***ERR 210** with the container and prefix names
 - If there is no data set record in the MCDS then AUDIT reports **ERR 210** with the container and prefix names
 - If there is a data set record in the MCDS:
 - If there is no catalog entry for the data set, AUDIT reports ***ERR 207**.
 - If a catalog entry indicates the data set is not migrated, AUDIT reports ***ERR 208**.
 - If a catalog entry indicates the data set is migrated, then AUDIT reports ***ERR 230** with the container and the user data set name
- Using the CDD information, the MCDS is checked.
 - If there is no record in the MCDs,
 - If there is no data set record in the MCDS:
 - If a catalog entry indicates the data set is migrated, AUDIT reports ***ERR 133**.

- If a catalog entry indicates the data set is *not* migrated, AUDIT reports ***ERR 208**.
- If a catalog entry indicates the data set is *not* migrated, AUDIT reports ***ERR 207**.
- If there *is* a data set record in the MCDS:
 - If there is no catalog entry for the data set, AUDIT reports ***ERR 207**.
 - If a catalog entry indicates the data set is not migrated, AUDIT reports ***ERR 208**.
 - If a catalog entry indicates the data set is migrated, but the data set record in the MCDS indicates the data set has been recalled, AUDIT reports ***ERR 133**.
 - If a catalog entry indicates the data set is migrated, but the data set record in the MCDS indicates the data set is migrated to ML1 or ML2, or is a different migration copy, AUDIT reports ***ERR 211**.
 - If both MCDF_CLD_CDA_TCT and MCDF_CLD_DIRECT flags are ON, AUDIT reports ***ERR 231** with the data set name.

For dump data set images:

Build the DGN record key based on the object prefix name, if no DGN record can be found using the key, AUDIT reports ***ERR 216**.

If the DGN record is found:

- If the object number in DGN record does not match the object number of the cloud object prefix, AUDIT reports ***ERR 217**.
- If the DGN record has any inconsistent entries as CLOUD dump, AUDIT reports ***ERR 215**.
- If the dump class record is not found based on the dump class name in the DGN record, AUDIT reports ***ERR 220**.
- If it is a copy pool DGN record:
 - If the FRSV record is not found, AUDIT reports ***ERR 193**.
 - If the FRSV record is found but dump copy number is 0, AUDIT reports ***ERR 180**.
 - If the FRB record is not found, AUDIT reports ***ERR 221**.
- If it is not a copy pool DGN record, read the MCP record using the volser:
 - If the MCP record is not found, or the DGN record prefix is not in the MCP record, AUDIT reports ***ERR 222**.

Diagnosis and repair action for AUDIT MEDIACONTROLS for CLOUD

When you request AUDIT MEDIACONTROLS FOR CLOUD:

- AUDIT usually identifies a repair (and takes repair action when FIX is specified) for error messages (***ERR 133, 207, 208, 210, 211, 216**)
- For other reported conditions and troubleshooting hints, see "ERROR codes (*ERR) and diagnosis".

Using the AUDIT MEDIACONTROLS (SDSP) VOLUMES command

When you specify AUDIT MEDIACONTROLS (SDSP) VOLUMES(*volser...*), for each specified volume AUDIT cross-checks its SDSP data set (if any) for consistency with the other DFSMSHsm control records to which it refers. (Note that VOLUMES is a required parameter.) AUDIT then produces a list of errors.

For each specified volume serial number, AUDIT makes the following checks:

- If there is no migration volume record or the record does not indicate a DASD ML1 volume, AUDIT reports ***ERR 50**.
- If the volume is mounted, but its VTOC does not contain a DSCB for an SDSP data set, AUDIT reports ***ERR 160**.
- For an existing SDSP data set, AUDIT makes the following checks for each migration copy's set of records:

- When the catalog entry indicates that the data set is migrated:
 - If there is no data set record in the MCDS or the data set record indicates an invalid copy, AUDIT reports ***ERR 147**.
 - If the data set record indicates a valid migration copy on some other mounted DASD volume, but that migration copy cannot be found or cannot be opened or does not have valid control information, AUDIT reports ***ERR 147**.
 - If the data set record indicates a valid migration copy elsewhere on this volume or on some other mounted volume, and that migration copy exists and can be opened,
 - If the time stamp for that migration copy is *earlier* than that for the copy in the SDSP we started from, AUDIT reports ***ERR 147**.
 - If the time stamp for that migration copy is *later* than that for the copy in the SDSP we started from, AUDIT reports ***ERR 149**.
 - If the data set record indicates a valid migration copy on a tape volume or on a DASD volume that is not mounted, AUDIT reports ***ERR 148**.
- If there is no catalog entry for the data set, AUDIT reports ***ERR 161**.
- If the catalog entry indicates the data set is *not* migrated, AUDIT reports ***ERR 162**.
- If the migration copy has one or more *gaps* in the sequence of data records, AUDIT reports ***ERR 163**.

Diagnosis and repair action for AUDIT MEDIACONTROLS (SDSP) VOLUMES

When you request AUDIT MEDIACONTROLS (SDSP):

- AUDIT usually identifies a repair (and takes repair action when FIX is specified) for error messages (*ERR) 147, 149, 161, and 162.
- AUDIT may recommend an additional diagnostic step for error message (*ERR) 148. If you want AUDIT to continue its attempt to identify a repair action, you must specify an additional AUDIT command using the recommended parameter.
- For other reported conditions and troubleshooting hints, see [“Error codes \(*ERR\) and diagnosis” on page 1295](#).

Using the AUDIT MEDIACONTROLS VOLUMES command

When you specify the AUDIT MEDIACONTROLS VOLUMES(*volser...*) parameter without the SDSP qualifier, AUDIT checks control information in the common dataset descriptor (CDD, required at the start of every DFSMSHsm-generated copy) in each possible DFSMSHsm image of a user data set on the specified volumes. AUDIT then produces a list of errors.

To determine the type of media for each volume serial number specified, AUDIT first checks for a volume record.

- If no migration volume record and no backup volume record exists for a specified volume serial number, AUDIT reports ***ERR 110**.
- If the volume record indicates a level 0 (not DFSMSHsm-owned) volume, AUDIT reports ***ERR 110**.
- If a backup volume record exists, indicating a DASD volume, AUDIT reports ***ERR 50**.

When AUDIT finds a proper volume record, its content drives further checking.

Errors detected when using AUDIT MEDIACONTROLS for a DASD migration volume

For each specified volume serial number that identifies a mounted DASD migration volume, AUDIT makes the following checks for each data set with a DSCB having the attributes DFSMSHsm assigns to its data sets (other DSCBs are ignored):

- For a dsname with leading qualifiers indicating a *migration copy*:

- If AUDIT cannot identify the first record as a CDD, it reports ***ERR 150**.
- When the first record is a CDD:
 - If there is no data set record in the MCDS:
 - If a catalog entry indicates the data set is migrated, AUDIT reports ***ERR 133** (see also [Diagnosing Error 133](#)).
 - If a catalog entry indicates a nonmigrated data set, AUDIT reports ***ERR 149**.
 - If the data set record exists, but is not flagged as valid:
 - If a catalog entry indicates the data set is migrated, AUDIT reports ***ERR 133** (see also [Diagnosing Error 133](#)).
 - If there is no catalog entry, AUDIT reports ***ERR 149**.
 - If a catalog entry indicates a nonmigrated data set, AUDIT reports ***ERR 149**.
 - If there is a valid data set record in the MCDS:
 - If a catalog entry indicates the data set is migrated, but there is no alias record, AUDIT reports ***ERR 140**.
 - If a catalog entry indicates the data set is migrated, but the data set record in the MCDS refers to a different copy, AUDIT reports ***ERR 149**.
 - If there is no catalog entry, AUDIT reports ***ERR 151**.
 - If a catalog entry indicates a nonmigrated data set, AUDIT reports ***ERR 152**.
- For a dsname with leading qualifiers indicating a *backup version*:
 - If AUDIT cannot identify the first record as a CDD, it reports ***ERR 150**.
 - If the first record is a CDD, but the corresponding data set record in the BCDS has no reference to a backup version with this name, AUDIT reports ***ERR 142**.
- For a dataset with
 - A dsname *not* generated by DFSMSHsm, and
 - A CDD as a first record, and
 - A catalog entry indicating the data set is migrated, but
 - No data set record in the MCDS,AUDIT reports ***ERR 133** (see also [Diagnosing Error 133](#)).

Diagnosis and repair action for AUDIT MEDIACONTROLS for DASD

When you request AUDIT MEDIACONTROLS for DASD:

- AUDIT usually identifies a repair (and takes repair action when FIX is specified) for error messages (*ERR) 133, 140, 142, 149, 151, and 152.

Diagnosing Error 133: If AUDIT reports ***ERR 133** for a migrated VSAM data set, but cannot determine the name of its base cluster to recreate a data set record, AUDIT reports also condition **169**.

- For other reported conditions and troubleshooting hints. see [“Error codes \(*ERR\) and diagnosis” on page 1295](#).

Errors detected when using AUDIT MEDIACONTROLS for a tape volume

For each specified volume serial number identifying a DFSMSHsm-owned backup or migration tape volume, AUDIT next verifies the type and format of tape. If the volume record indicates a tape *other than* one in single file format, AUDIT reports ***ERR 130**.

For a tape volume in single file format, AUDIT mounts the tape and reads blocks sequentially, searching for CDD control information marking the start of one or more blocks constituting a data set copy. (A given tape may contain the start or continuation of a copy spanning volumes.) When a CDD is found, AUDIT

uses the data there—and the number of blocks read since the *last* CDD found—to check other control information, and to verify or reconstruct an entry in the TTOC records for the volume.

If AUDIT cannot allocate or mount a tape volume, it reports ***ERR 131**. If AUDIT *can* allocate and mount the volume, it continues.

- If it finds no corresponding TTOC base record, AUDIT first reports ***ERR 51** (for a migration volume) or ***ERR 71** (for a backup volume).
- If AUDIT finds the TTOC base record and that record indicates that there were in-storage records that may not have been written to the OCDS, AUDIT reports ***ERR 164**.

No TTOC record exists for a migration volume

If the TTOC base is missing, AUDIT makes the following checks:

- For a CDD with a corresponding data set record, flagged as *valid*, in the MCDS:
 - If the catalog entry indicates the data set is migrated, but the data set record indicates a migration copy on some other volume or elsewhere on this volume, AUDIT reports ***ERR 149**.
 - If there is no catalog entry, or the catalog entry indicates a nonmigrated data set, AUDIT reports ***ERR 132**.
- For a CDD with a corresponding data set record, flagged as *invalid*, in the MCDS, if the catalog entry indicates the data set is migrated, AUDIT reports ***ERR 133** (see also [Diagnosing Error 133](#)).
- For a CDD with a corresponding catalog entry indicating a migrated data set, but with no data set record in the MCDS, AUDIT reports ***ERR 133** (see also [Diagnosing Error 133](#)).
- For a CDD with a corresponding data set record, flagged as *valid*, in the MCDS:
 - If the catalog entry indicates the data set is migrated, but the data set record indicates a migration copy on some other volume, but the file block id points to this position and the time and date are same as CDD time and date, AUDIT reports ***ERR 203** and patch the MCDVSN field with the volser of the tape being audited.

If no CDD record is found on the tape, AUDIT reports condition **134**.

Checking TTOC entries for a migration volume

If AUDIT finds the TTOC base record, it checks the sequence of CDDs against the sequence of TTOC entries found in the base record and zero or more TTOC extensions. If a TTOC extension is missing, AUDIT reports ***ERR 111**.

- For a CDD with a corresponding data set record in the MCDS:
 - If the block count in the *previous* TTOC entry does not agree with the number of blocks read since the *previous* CDD found, AUDIT reports ***ERR 135**.
 - If there is no catalog entry or the catalog entry indicates a nonmigrated data set, AUDIT reports ***ERR 132**.
 - If the catalog indicates the data set is migrated, but the data set record is flagged invalid, AUDIT reports ***ERR 133** (see also [Diagnosing Error 133](#)).
 - If the catalog indicates the data set is migrated, but the corresponding TTOC entry is flagged invalid, AUDIT reports ***ERR 136**.
- For a CDD with a corresponding catalog entry:
 - If the catalog entry indicates a nonmigrated data set, AUDIT reports ***ERR 132**.
 - If the catalog entry indicates a migrated data set, but there is no data set or alias record in the MCDS, AUDIT reports ***ERR 133** (see also [Diagnosing Error 133](#)).

At the end of the volume:

- If the valid block count in the TTOC does not agree with the number of valid blocks read, AUDIT reports ***ERR 137**.

- If the total block count in the TTOC does not agree with the total number of blocks read, AUDIT reports ***ERR 138**.

No TTOC record exists for a backup volume

If the TTOC base is missing, AUDIT generates for each CDD found:

- A TTOC entry flagged *valid* if the BCDS contains a data set record referring to a backup version record for the current position on the tape;
- A TTOC entry flagged *invalid* if the BCDS contains a data set record for the CDD, but none of the backup version records refers to the current position on the tape.

If no CDD record is found on the tape, AUDIT reports condition **134**.

Checking TTOC entries for a backup volume

If AUDIT finds the TTOC base record, it checks the sequence of CDDs against the sequence of TTOC entries found in the base record and zero or more TTOC extensions. If a TTOC extension is missing, AUDIT reports ***ERR 111**.

For a CDD with a corresponding data set record in the BCDS:

- If the block count in the *previous* TTOC entry does not agree with the number of blocks read since the *previous* CDD has been found, AUDIT reports ***ERR 135**.
- If the data set record refers to a backup version record for the current position on the tape, but the corresponding TTOC entry is flagged invalid, AUDIT reports ***ERR 136**.

At the end of the volume:

- If the valid block count in the TTOC does not agree with the number of valid blocks read, AUDIT reports ***ERR 137**.
- If the total block count in the TTOC does not agree with the total number of blocks read, AUDIT reports ***ERR 138**.

Diagnosis and repair action for AUDIT MEDIACONTROLS for tape

When you request AUDIT MEDIACONTROLS for a tape volume:

- AUDIT usually identifies a repair (and takes repair action when FIX is specified) for error messages (*ERR) 51, 71, 111, 132, 133, 134, 135, 136, 137, 138, 164, and 203.

Diagnosing Error 133: If AUDIT reports ***ERR 133** for a migrated VSAM data set, but cannot determine the name of its base cluster to recreate a data set record, AUDIT also reports ***ERR 169**.

- For other reported conditions and troubleshooting hints, see [“Error codes \(*ERR\) and diagnosis” on page 1295](#).

Using the AUDIT VOLUMECONTROLS (BACKUP) command

When you specify the AUDIT VOLUMECONTROLS (BACKUP) parameter, AUDIT first cross-checks BCDS backup volume records for consistency with other related DFSMSHsm control records.

If there is no backup volume record for a specified volume serial number, AUDIT reports ***ERR 70**.

For an existing backup volume record (for a specified volume serial, or for each backup volume of a specified type), AUDIT makes the following checks:

- If the alternate volume serials for duplex volumes do not match between the TTOC and either the MCT or MCV, AUDIT reports ***ERR 58**.
- If the backup volume record indicates a tape volume, but there is no TTOC record, AUDIT reports ***ERR 71**.
- If the backup volume record indicates a RACF protected volume, but the TTOC record does not, or vice versa, AUDIT reports ***ERR 52**.

- If the backup volume and TTOC records indicate RACF protection, but there is no entry in RACF TAPEVOL for the volume, AUDIT reports ***ERR 53**.
- If there *is* a RACF TAPEVOL entry for the volume, but the backup volume and TTOC records do *not* indicate RACF protection, AUDIT reports ***ERR 53**.
- If there is no entry in the appropriate backup volume cycle (R) record, AUDIT reports ***ERR 77**.
- If the backup volume record indicates a tape, and the existing backup volume cycle entry indicates a DASD volume, or vice versa, AUDIT reports ***ERR 74**.
- If the backup volume record indicates a volume that's full, but the backup volume cycle entry does not, or vice versa, AUDIT reports ***ERR 75**.
- If the backup volume record indicates a single file format tape, but the backup volume cycle entry does not, or vice versa, AUDIT reports ***ERR 76**.

Checking backup volume cycle records

Next, AUDIT checks each entry in the backup volume cycle records:

- If an entry has no corresponding backup volume record, AUDIT reports ***ERR 77**.
- If the backup volume record exists, but indicates a different usage from that of the entry, AUDIT reports ***ERR 72**.

For each backup volume cycle record set:

- If the last extension of a backup volume cycle set indicates there should be another extension, or there is a gap in the extension numbers for a record set, AUDIT reports ***ERR 78**.
- If some extension, other than the last, indicates that there is no additional extension, AUDIT reports ***ERR 79**.

Checking TTOC records for backup volumes

Finally, checking is driven by TTOC records (if any) in the OCDS:

- If the AUDIT is limited to a specific BACKUPTYPE, or to specific volume serial numbers, AUDIT checks only the corresponding TTOC records.
- If the scope of the AUDIT is *not* limited to specific volume serial numbers or to a specified BACKUPTYPE, or if BACKUPTYPE(ALL) is specified, AUDIT checks *all* TTOC records for backup volumes.

For each TTOC record:

- If there is no backup volume record, AUDIT reports ***ERR 71**.
- If the backup volume record exists, but indicates a different usage from that of the TTOC record, AUDIT reports ***ERR 73**.

Diagnosis and repair action for AUDIT VOLUMECONTROLS (BACKUP)

When you request AUDIT VOLUMECONTROLS (BACKUP):

- AUDIT usually identifies a repair (and takes repair action when FIX is specified) for error messages (*ERR) 52, 53, 71, 72, 74, 75, 76, 77, 78, and 79.
- For other reported conditions and troubleshooting hints, see [“Error codes \(*ERR\) and diagnosis” on page 1295](#).

Using the AUDIT VOLUMECONTROLS (MIGRATION) command

When you specify the AUDIT VOLUMECONTROLS (MIGRATION) parameter, AUDIT first cross-checks MCDS migration volume records for consistency with other related DFSMSHsm control records.

For a specified volume serial number: if there is no migration volume record or if the record indicates a level 0 volume, AUDIT reports ***ERR 50**.

For an existing migration volume record (for a specified volume serial, or for each migration volume), AUDIT makes the following checks:

- If the migration volume record indicates a tape volume, but there is no TTOC record, AUDIT reports ***ERR 51**.
- If the migration volume record indicates a RACF protected volume, but the TTOC record does not, or vice versa, AUDIT reports ***ERR 52**.
- If the migration volume and TTOC records indicate RACF protection, but there is no entry in RACF TAPEVOL for the volume, AUDIT reports ***ERR 53**.
- If there is a RACF TAPEVOL entry for the volume, but the migration volume and TTOC records do *not* indicate RACF protection, AUDIT reports ***ERR 53**.
- If the alternate volume serials for duplex volumes do not match between the TTOC and either the MCT or MCV, AUDIT reports ***ERR 58**.

Checking the level 2 control record

If the level 2 control (**S**) record exists, AUDIT checks each entry:

- If there is no migration volume record for a given entry (key range), AUDIT reports ***ERR 54**.
- If the corresponding migration volume record indicates usage *other than* a DASD level 2 volume, AUDIT reports ***ERR 55**.

Checking migration level 1 free space records

- If the last extension of the free space (**1**) record set indicates there should be another extension, AUDIT reports ***ERR 56**.
- If some extension, other than the last, indicates that there is no additional extension, AUDIT reports ***ERR 57**.

Diagnosis and repair action for AUDIT VOLUMECONTROLS (MIGRATION)

When you request AUDIT VOLUMECONTROLS (MIGRATION):

- AUDIT usually identifies a repair (and takes repair action when FIX is specified) for error messages (*ERR) 52, 53, 56, and 57.
- AUDIT may recommend an additional diagnostic step for error message (*ERR) 51. If you want AUDIT to continue its attempt to identify a repair action, you must specify an additional AUDIT command using the recommended parameter.
- For other reported conditions and troubleshooting hints, see [“Error codes \(*ERR\) and diagnosis” on page 1295](#).

Using the AUDIT VOLUMECONTROLS (RECOVERABLE) command

When you specify the AUDIT VOLUMECONTROLS (RECOVERABLE) parameter, AUDIT cross-checks BCDS control records that concern recoverable (“eligible”) volumes, that is, volumes that have been backed up or dumped. These control records are checked against other DFSMSHsm controls to which they refer. AUDIT then produces a list of errors.

If a specified volume serial has not been backed up or dumped, AUDIT reports ***ERR 105**.

If an existing eligible volume (**P**) record indicates that the volume is owned by DFSMSHsm, but there is no migration volume record in the MCDS or backup volume record in the BCDS for that volume, AUDIT reports ***ERR 90**.

AUDIT detects “errors” for FRBACKUP volumes that are recoverable (***ERR 192**). When the FIX option is used and an FRBACKUP COPYPOOL volume is found to be recoverable, the only action that needs to be taken is to confirm with AUDIT COPYPOOLCONTROLS(*copypoolname*) that this volume is indeed recoverable.

Checking backup related controls

For an eligible volume record (for a specified volume serial, or for each eligible volume) indicating the volume has been *backed up* at least once, AUDIT makes the following checks for each indicated VTOC copy data set:

- If the data set is stored on a migration volume for which there is no migration volume record in the MCDS, AUDIT reports ***ERR 91**.
- If the data set is stored on a DASD backup volume for which there is no backup volume record in the BCDS, AUDIT reports ***ERR 92**.
- If the data set is stored on backup tape:
 - If there is no backup volume record for the tape volume, AUDIT reports ***ERR 92**.
 - If the data set spans tape volumes, and there is no backup volume record for the second tape, AUDIT reports ***ERR 93**.

Checking dump related controls

For an eligible volume record (for a specified volume serial, or for each eligible volume) indicating the volume has been *dumped* at least once, AUDIT makes the following checks:

- If the eligible volume refers to a dump generation for which there is no dump generation (**G**) record, AUDIT reports ***ERR 94**.
- For a dump generation record with a dump copy referring to a dump volume:
 - If there is no dump volume (**Y**) record, AUDIT reports ***ERR 95**.
 - If the dump volume record exists, but is not flagged as belonging to a dump copy, AUDIT reports ***ERR 96**.
 - If the generation referred to from a valid entry in a dump volume record is not the same as the generation referring to that dump volume, or the generation indicates a dump copy starts on a dump volume but the file sequence number is not the same as the entry number of the copy in the dump volume record, or the generation indicates a dump copy spans to a dump volume but the entry referring to the generation is not the first in the dump volume record, AUDIT reports ***ERR 97**.
 - If the dump class name in the dump volume record is not the same as the class name in the generation referring to that dump volume, AUDIT reports ***ERR 99**.
 - If the volume sequence number in the dump volume record is not the same as the sequence of that volume in the dump copy within the dump generation referring to that volume, AUDIT reports ***ERR 100**.
 - If there is no migration volume record for the volume containing the dump copy's VTOC copy data set, AUDIT reports ***ERR 101**.

If the scope of the AUDIT is *not* limited to specific volumes, the next check is driven by dump generation records and their dump device categories. For TAPE dump generation records:

- If a dump generation record refers to a volume for which there is no eligible volume record, AUDIT reports ***ERR 102**.
- If a dump generation record refers to a volume with an eligible volume record that does *not* refer back to that generation, AUDIT reports ***ERR 103**.
- If any dump copy in a dump generation record is CLOUD type, AUDIT reports ***ERR 218**.

For CLOUD dump generation records:

- If a dump generation record has any inconsistent entries as CLOUD dump, AUDIT reports ***ERR 215**.
- If the object number in a dump generation record does not match the object number of the cloud object prefix, AUDIT reports ***ERR 217**.
- If the corresponding cloud dump object can not be found, AUDIT reports ***ERR 219**.

If the scope of the AUDIT is *not* limited to specific volumes, or a generation record for a dumped volume cannot be found, or a dump volume record referred to by a generation does not refer back to that generation, the last check is driven by dump volume records flagged as valid:

- If the dump volume refers to a generation for which there is no dump generation record, AUDIT reports ***ERR 104**.
- When the dump generation record exists:
 - If the dump volume is not part of any dump copy in the generation, AUDIT reports ***ERR 98**.
 - If the dump class name in the dump volume record is not the same as the class name in the generation referring to that dump volume, AUDIT reports ***ERR 99**.
 - If the volume sequence number in the dump volume record is not the same as the sequence of that volume in the dump copy within the dump generation referring to that volume, AUDIT reports ***ERR 100**.

Diagnosis and repair action for AUDIT VOLUMECONTROLS (RECOVERABLE)

When you request AUDIT VOLUMECONTROLS (RECOVERABLE):

- AUDIT usually identifies a repair (and takes repair action when FIX is specified) for error messages (*ERR) 91 and 101.
- For other reported conditions and troubleshooting hints, see [“Error codes \(*ERR\) and diagnosis” on page 1295](#).

Summary of errors detected by the enhanced AUDIT commands

Table 72 on page 1276 summarizes the errors detected and corrected by the audits listed in [“Using the enhanced audit command to audit DFSMSHsm control information” on page 1256](#). In this table, a D signifies that the error is detected, and a C signifies that the error is corrected when you specify the FIX parameter.

Using the original AUDIT command to audit DFSMSHsm data set information

This topic describes the AUDIT parameters used to detect and to report discrepancies in data set information recorded in DFSMSHsm control data sets, the VTOCs identifying data sets, and catalogs.

When the FIX parameter is specified, AUDIT can correct certain errors.

In general, the primary options listed in this topic perform less extensive diagnosis than those listed in topic One. There is some overlap between the parameters in the two topics. You may want to refer

to “Using the enhanced audit command to audit DFSMSHsm control information” on page 1256 as you choose the AUDIT parameters that will best serve your needs.

Table 73 on page 1281 lists the original AUDIT commands audit and report errors within DFSMSHsm controls and where to find more information.

<i>Table 73. Original AUDIT Commands that Audit and Report Errors</i>	
If the command you are interested in is . . .	Then see. . .
AUDIT DATASETNAMES and AUDIT LEVELS	“Using the AUDIT DATASETNAMES and AUDIT LEVELS commands” on page 1282
AUDIT VOLUMES	“Using the AUDIT VOLUMES command” on page 1284
AUDIT BACKUPVOLUMES and AUDIT BACKUPTYPE	“Using the AUDIT BACKUPVOLUMES and AUDIT BACKUPTYPE commands” on page 1286
AUDIT MASTERCATALOG and AUDIT USERCATALOG	“Using the AUDIT MASTERCATALOG and AUDIT USERCATALOG commands” on page 1288
AUDIT MIGRATIONCONTROLDATASET	“Using the AUDIT MIGRATIONCONTROLDATASET command” on page 1290
AUDIT BACKUPCONTROLDATASET	“Using the AUDIT BACKUPCONTROLDATASET command” on page 1291
AUDIT OFFLINECONTROLDATASET	“Using the AUDIT OFFLINECONTROLDATASET command” on page 1292
AUDIT ALL	Equivalent to AUDIT MCDS, then AUDIT BCDS, then AUDIT OCDS(ALL).

The parameters specified in the AUDIT command determine which data sets are audited. SMS-managed data sets are processed similarly to the audit of non-SMS-managed data sets. You can audit:

- Specific data sets
- All cataloged data sets that have the same set of initial characters of the data set name
- All data sets that reside on a specified non-SMS-managed volume
- All data sets that reside on backup volumes of a specified backup type
- All data sets cataloged in a specified catalog
- All data sets that have a data set record in the MCDS
- All data sets that have a data set record in the BCDS
- All data sets that have an entry in an OCDS TTOC record of a specified type

Audit information is written to a SYSOUT or user specified data set, in tabular form, with each row representing the result for one data set. In most cases, you can request that the audit output, in a different format, be sent to the terminal from which the AUDIT command has been issued. However, large reports, such as AUDIT ALL, cannot be sent to the terminal.

Table 74 on page 1281 explains the information that can be reported for a data set.

<i>Table 74. Headings of Output When You Audit Data Set Information</i>		
Printer Output Heading	Terminal Label	Description
ERROR TYPE	ERROR TYPE	**NONE under this heading specifies that no error has been found for the specified data set. *ERR nn specifies the error number detected for the data set.
DATA SET NAME	DSN	The entry under this heading is the name of the data set being audited.

Table 74. Headings of Output When You Audit Data Set Information (continued)		
Printer Output Heading	Terminal Label	Description
AUDITED VOLUME	AUDITED VOL	This is the serial number of the primary, migration, or backup volume being audited.
DATA SET ON VOLUME	DSN ON VOL	A serial number under this heading is the serial number of the primary, migration, or backup volume that contains the data set being audited. In addition, a volume serial number indicates that the data set is cataloged. ????? indicates that the existence of the data set on the volume indicated by the catalog could not be verified. If *ERR 16 or *ERR 17 occurs, this field can contain additional diagnostic information. See “Error codes (*ERR) and diagnosis” on page 1295.
CATALOGED TO VOLUME	CTLG VOL	A serial number under this heading is the serial number of the volume where the data set resides as recorded in the catalog. MIGRAT indicates that the data set is on a migration volume. -NONE-indicates that no record of the data set exists in the catalog. OFFLNE indicates that the catalog could not be opened.
MIGRATED TO VOLUME	MIG VOL	A serial number under this heading is the serial number of the migration volume that contains the data set as recorded in the MCDS. RECALLED indicates that the data set is on a mounted primary volume as indicated in the MCDS. DELETED indicates that the data set has been deleted as indicated in the MCDS. -NONE-specifies that no record of the data set exists in the MCDS.
BACKED UP TO VOLUME	BACK VOL	A serial number under this heading is the serial number of the backup volume that contains the most recent backup version of the data set as recorded in the BCDS. -NONE-indicates that no BCDS backup version record has been found for the data set. (This is not an error if the data set is a VTOC copy data set or a VCAT copy data set, or if the data set resides on a DASD backup volume.)
DUPLICATE DSN ON VOLUME	DUP DSN ON VOL	If the catalog indicates that a data set of the same name resides on a volume other than the one being audited and that fact is verified, the serial number of the other volume is listed under this heading.

Note: All errors listed in AUDIT reports are described in [“Error codes \(*ERR\) and diagnosis”](#) on page 1295.

Using the AUDIT DATASET NAMES and AUDIT LEVELS commands

To get an audit of specific data sets, specify the AUDIT DATASET NAMES parameter. To get an audit of all data sets having the same set of initial characters of their data set names, specify the AUDIT LEVELS parameter.

When you specify either of these options, AUDIT tries to read MCDS data set (**D**) records, if any, and catalog entries, if any, corresponding to the data sets or range of data sets you specify.

If there is no data set record in the MCDS for a specified data set:

- If there is also no catalog entry, the data set (according to its name) is a backup version, but no move (**M**) record exists for that version, AUDIT reports ***ERR 01**.
- If there is no catalog entry, and the data set is *not* (according to its name)
 - A generation data set (GDS)
 - SYSCTLG
 - SYS1.VTOCIX
 - A VTOC copy data set

- A dump VTOC copy data set

AUDIT reports ***ERR 01**.

- If a catalog entry exists, and indicates the data set is not migrated, AUDIT reports condition **04** (not necessarily an error).
- If a catalog entry exists, but indicates the data set *is* migrated, AUDIT reports ***ERR 10**.

When there *is* an MCDS data set record:

1. If the data set record indicates a migration copy on tape, but the TTOC (**T**) records for the indicated migration volume do not contain an entry for the data set, AUDIT reports ***ERR 16**.
 2. If the data set record indicates a migration copy on tape, but the positioning information in the data set record does not agree with the information in the TTOC, or the indicated TTOC extension cannot be found, AUDIT reports ***ERR 17**.
- When neither condition “1” on page 1283 nor condition “2” on page 1283 holds:
 - If there is no catalog entry, but the data set record indicates a migrated copy, AUDIT reports ***ERR 03**.
 - If both the catalog entry and the data set record indicate the data set is not migrated, but AUDIT cannot (using the OBTAIN function) verify the data set is on the volume indicated in the catalog, AUDIT reports ***ERR 06**.
 - If a catalog entry exists, indicating the data set is not migrated, but the data set record indicates the data set *is* migrated:
 - If AUDIT cannot verify the data set is on the volume indicated in the catalog, AUDIT reports ***ERR 09**.
 - If the data is on the volume indicated in the catalog, AUDIT reports ***ERR 18**.
 - If a catalog entry exists, indicating the data set is migrated, but the data set record indicates the data set is now on a primary volume, AUDIT reports ***ERR 11**.

If the specified data set is not supported by DFSMSshm (that is, not a VSAM base cluster and not a non-VSAM data set), AUDIT reports ***ERR 15**.

Information reported when using AUDIT DATASET NAMES and AUDIT LEVELS

When you specify the DATASET NAMES parameter, the audit information is reported for each specified data set, even if there is no audit error. With the LEVELS parameter, to request that audit information be reported for all the data sets audited or for only those data sets for which audit errors are detected, specify the REPORT parameter.

Figure 96 on page 1283 is a sample of the printer output when you audit data sets.

```
-- DFSMSshm AUDIT -          DATASET -- LISTING - AT 18:09:53 ON 91/01/24

ERROR          DATA SET NAME          DATA SET ON   CATALOGED     MIGRATED       BACKED UP
TYPE           TYPE                     VOLUME        TO VOLUME     TO VOLUME     TO VOLUME

**NONE         H952762.PSFB.F40AU001.DSET01          PRIM01        PRIM01        -NONE-        BATP01
*ERR 10        H952762.PSFB.F40AU001.DSET02          ??????       MIGRAT        -NONE-        BATP01
- END OF -     DATASET - LISTING -
```

Figure 96. Sample List of Output for AUDIT DATASET NAMES

Figure 97 on page 1283 is a sample of the terminal output when you audit data sets.

```

Figure 97. Sample Terminal Output for AUDIT DATASET NAMES

Table 74 on page 1281 explains the headings and labels used.

Diagnosis and repair action for AUDIT DATASET NAMES and AUDIT LEVELS

When you request AUDIT DATASET NAMES or AUDIT LEVELS, AUDIT does not fix any of the detected errors. For other reported conditions and troubleshooting hints, see [“Error codes \(*ERR\) and diagnosis” on page 1295](#).

Using the AUDIT VOLUMES command

To request an audit of the data sets on one or more non-SMS-managed primary volumes or migration volumes, specify the AUDIT VOLUMES parameter.

For a specified volume serial, AUDIT first reads the volume record from the MCDS. If you do not include a volume serial number with the VOLUMES parameter, all the non-SMS-managed primary volumes and migration volumes that have volume records in the MCDS are audited.

In the following discussions, the master catalog and any associated user catalogs are called simply “the catalog”.

[“Errors encountered during AUDIT VOLUMES, AUDIT BACKUPVOLUMES, or AUDIT BACKUPTYPE” on page 1339](#) describes conditions which can cause AUDIT to fail its checking.

Errors detected when using AUDIT VOLUMES for a primary or migration DASD

Given a volume record indicating a DASD, the volume table of contents (VTOC) for the volume drives the audit. AUDIT handles each Format 1 DSCB in the VTOC as follows:

If the DSCB indicates any of the following, AUDIT does not check the data set further:

- SYSCTLG
- SYS1.VTOCIX
- SYS1.VVDS
- Model DSCB
- Multivolume data set

If the DSCB indicates a utility data set, AUDIT does not check it further. If FIX is specified, AUDIT scratches and uncatalogs the data set, overriding any expiration date, and issuing a message to identify the data set.

For each remaining DSCB, AUDIT tries to read a corresponding data set record from the MCDS.

When there is no data set record for the data set:

- If the data set (according to its name) is a backup version, but no move record exists for that version, AUDIT reports ***ERR 01**.
- If there is no catalog entry, AUDIT reports condition **01**.
- If a catalog entry exists, but indicates the data set is on a primary volume *other than* the volume being audited, AUDIT reports ***ERR 05**.
- If a catalog entry exists, but indicates the data set is migrated, AUDIT reports ***ERR 10**.
- If the data set is not supported by DFSMSHsm (that is, not a VSAM base cluster and not a non-VSAM data set), AUDIT reports condition **15**.

When there is an MCDS data set record for the data set:

- If the data set record indicates the data set has been migrated, then recalled:
 - If the recall volume is the same as the primary volume being audited, but there is (now) no catalog entry, AUDIT reports ***ERR 02**.
 - If a catalog entry exists, but indicates the data set is on a primary volume different from the recall volume, AUDIT reports ***ERR 07**.
 - If a catalog entry exists, but indicates the data set is on a primary volume different from the one being audited, AUDIT reports ***ERR 08**.

- If a catalog entry exists, but indicates the data set is now migrated, AUDIT reports ***ERR 11**.
- If the data set record indicates the data set is now migrated:
 1. If the data set record indicates a migration copy on tape, but the TTOC records for the indicated migration volume do not contain an entry for the data set, AUDIT reports ***ERR 16**.
 2. If the data set record indicates a migration copy on tape, but the positioning information in the data set record does not agree with the information in the TTOC, or the indicated TTOC extension cannot be found, AUDIT reports ***ERR 17**.

When neither condition “1” on page 1285 nor condition “2” on page 1285 holds:

- If there is (now) no catalog entry, AUDIT reports ***ERR 03**.
- If a catalog entry exists, indicating the data set is on the volume being audited, AUDIT reports ***ERR 18**.

When you specify the AUDIT VOLUMES command to audit a migration level 1 volume, be aware of the following:

- Data sets in a small-data-set-packing data set are not audited.
- Data sets that have been backed up with the BACKDS command and temporarily reside on migration level 1 volumes are audited.

Errors detected when using AUDIT VOLUMES for a tape migration volume

Given a volume record indicating a tape migration volume, the tape table of contents (TTOC) records for the volume drive the audit. For each valid data set entry in the TTOC, AUDIT makes the following checks:

When there is no data set record in the MCDS for the data set:

- If there is (now) no catalog entry, AUDIT reports condition **01**.
- If a catalog entry exists, but indicates the data set *is* migrated, AUDIT reports ***ERR 10**.

When there *is* a data set record in the MCDS, indicating the data set is now migrated:

- If the data set record indicates a migration copy on tape, but the positioning information in the data set record does not agree with the information in the TTOC, AUDIT reports ***ERR 17**.
- If there is (now) no catalog entry, AUDIT reports ***ERR 03**.
- If a catalog entry exists, indicating the data set is on a primary volume, AUDIT reports ***ERR 18**.

Information reported when using AUDIT VOLUMES

Figure 98 on page 1285 is a sample of the printer output when you audit primary or migration volume information.

```
-- DFSMSshm AUDIT -          VOLUME          -- LISTING - AT 10:21:20 ON 91/02/02

```

Figure 99. Sample Terminal Output for AUDIT VOLUMES

Table 74 on page 1281 explains the headings and labels used.

Diagnosis and repair action for AUDIT VOLUMES

When you request AUDIT VOLUMES:

- AUDIT attempts repair action when FIX is specified, for error messages (*ERR) 01 and 02 for a primary volume, and 03 for a migration volume. In each case, AUDIT issues a message that describes the type of correction attempted and whether or not the fix has been successful. When a fix is unsuccessful, the message contains the return code from the routine attempting the fix.
- For other reported conditions and troubleshooting hints, see [“Error codes \(*ERR\) and diagnosis” on page 1295](#).

Using the AUDIT BACKUPVOLUMES and AUDIT BACKUPTYPE commands

When you specify AUDIT BACKUPVOLUMES to request an audit of the data sets with copies on one or more backup volumes, AUDIT first tries to read from the BCDS the backup volume record for each specified volume, or for every backup volume. The device type in each *volume record* determines further checking.

When you specify AUDIT BACKUPTYPE, AUDIT first tries to read from the BCDS the backup cycle volume (BVR) records for

- A specified day, or
- All days in the backup cycle, or
- All spill volumes, or
- All daily and spill backup volumes.

For each entry in a backup cycle volume record, AUDIT then tries to read the corresponding backup volume record. The device type in each *entry* determines further checking.

[“Errors encountered during AUDIT VOLUMES, AUDIT BACKUPVOLUMES, or AUDIT BACKUPTYPE” on page 1339](#) describes conditions which can cause AUDIT to fail its checking.

Error detected when using AUDIT BACKUPVOLUMES or AUDIT BACKUPTYPE for a backup DASD

Given an indication of a backup DASD, the volume table of contents (VTOC) for the volume drives the audit. AUDIT handles each Format 1 DSCB in the VTOC as follows:

If the DSCB indicates a utility data set, AUDIT does not check it further. If FIX is specified, AUDIT scratches and uncatalogs the data set, overriding any expiration date, and issuing a message to identify the data set. (The utility data set names detected on primary and migration volumes should not occur on a backup volume.)

If the DSCB indicates any of the following, AUDIT does not check the data set further:

- A VSAM data set
- An unmovable data set

For each remaining DSCB, AUDIT tries to read a corresponding backup version record from the BCDS. If such a record exists, but the volume indicated in that record is not the same as the volume being audited, AUDIT reports ***ERR 14**.

Error detected when using AUDIT BACKUPVOLUMES or AUDIT BACKUPTYPE for a tape backup volume

Given an indication of a tape backup volume, AUDIT uses the backup category in the backup volume record to read the tape table of contents (TTOC) records for the volume. Those TTOC records drive the audit for that volume.

For each valid data set entry in the TTOC, AUDIT tries to read a backup version record from the BCDS. If such a record exists, but none of the volumes (including any spanned volumes) indicated in that record is the same as the volume being audited, AUDIT reports ***ERR 14**.

Information reported when using AUDIT BACKUPVOLUMES and AUDIT BACKUPTYPE

When you specify AUDIT BACKUPVOLUMES or AUDIT BACKUPTYPE, the order of the output for the different requests is as follows:

- AUDIT BACKUPVOLUMES

The output is ordered according to the sequence of the volume serial numbers in the BCDS.

- AUDIT BACKUPVOLUMES(*volser...*)

The order is the order you specify.

- AUDIT BACKUPTYPE(SPILL)

The order is that of the entries in the spill backup cycle volume record.

- AUDIT BACKUPTYPE(DAILY(*day*))

The order is that of the entries in the daily BVR for the specified day.

- AUDIT BACKUPTYPE(DAILY)

The order is for all volumes for day 1, then all for day 2, and so forth, until all daily backup volumes have been audited. In addition, for each day, the order of the output is that of the entries in the BVR for that particular day.

- AUDIT BACKUPTYPE(ALL)

The order is all daily backup volumes, then all spill backup volumes.

[Figure 100 on page 1287](#) is a sample list of printer output you can request when you audit a backup volume.

```

Figure 101. Sample Terminal List for AUDIT BACKUPVOLUMES

Table 74 on page 1281 explains the headings and labels used.

Diagnosis and repair action for AUDIT BACKUPVOLUMES and AUDIT BACKUPTYPE

When you request AUDIT BACKUPVOLUMES or BACKUPTYPE, AUDIT attempts repair action when FIX is specified, for error message (*ERR) 14 for a tape backup volume. In each case, AUDIT issues a message that describes the type of correction attempted and whether or not the fix has been successful. When a fix is unsuccessful, the message contains the return code from the routine attempting the fix. (See [“Error codes \(*ERR\) and diagnosis”](#) on page 1295.)

Using the AUDIT MASTERCATALOG and AUDIT USERCATALOG commands

You can request the following catalog audits with the AUDIT command:

- An audit of the master catalog by specifying the MASTERCATALOG parameter
- An audit of a user catalog by specifying the USERCATALOG parameter

When you specify the FIX parameter, the AUDIT function enqueues continually on the DFSMSHsm control data sets during the entire audit, to minimize the possibility of other DFSMSHsm functions making changes to them. Because auditing a complete catalog can take considerable time, AUDIT issues the following message:

```

ARC0803A  WARNING:  AUDIT OF CATALOG MAY DEGRADE PERFORMANCE,
REPLY 'Y' TO START AUDIT OR 'N' TO CANCEL AUDIT COMMAND.

```

If the system operator does not reply with a Y, a message is sent to the system console stating that the operator canceled the audit of the catalog.

Assuming the audit is not canceled, the data sets driving the audit are those that are supported for migration and have a cluster (VSAM) or alien (non-VSAM) entry in the specified catalog. For each such entry, AUDIT makes the following checks:

If the catalog entry indicates a data set on a primary volume of a device type managed by DFSMSHsm:

- If AUDIT cannot verify (using the OBTAIN function) that the non-VSAM data set is indeed on the indicated volume (the volume may not be mounted):
 - If there is no MCDS data set record, AUDIT reports ***ERR 04**.
 - If there is an MCDS data set record indicating the data set has been recalled, AUDIT reports ***ERR 06**.
 - If there is an MCDS data set record, indicating the data set is migrated:
 1. If the data set record indicates a migration copy on tape, but the TTOC records for the indicated migration volume do not contain an entry for the data set, AUDIT reports ***ERR 16**.

2. If the data set record indicates a migration copy on tape, but the positioning information in the data set record does not agree with the information in the TTOC, or the indicated TTOC extension cannot be found, AUDIT reports ***ERR 17**.

When neither condition “1” on page 1288 nor condition “2” on page 1289 holds, AUDIT reports ***ERR 09**.

- If the data set is on the indicated volume, but the MCDS data set record indicates the data set is migrated, AUDIT reports ***ERR 18**.

If the catalog entry indicates a migrated data set:

- If there is no MCDS data set record, AUDIT reports ***ERR 10**.
- If there is an MCDS data set record indicating the data set has been recalled, AUDIT reports ***ERR 11**.

```

Figure 103. Sample List of Output for AUDIT USERCATALOG

Table 74 on page 1281 explains the headings and labels used.

Diagnosis and repair action for AUDIT MASTERCATALOG and AUDIT USERCATALOG

When you request AUDIT MASTERCATALOG or AUDIT USERCATALOG, AUDIT does not fix any of the detected errors. You may, however, be able to use the FIXCDS command to add or change a record of a data set in the MCDS, to make the catalog and the MCDS agree. To find out how to use the FIXCDS command, refer to the [z/OS DFSMSHsm Diagnosis](#).

For any reported condition and troubleshooting hints, see [“Error codes \(*ERR\) and diagnosis”](#) on page 1295.

Using the AUDIT MIGRATIONCONTROLDATASET command

When you specify `AUDIT MIGRATIONCONTROLDATASET`, the data set records in the MCDS drive the audit. For each such record (data set), `AUDIT` makes the following checks:

1. If the data set record indicates a migration copy on tape, but the TTOC records for the indicated migration volume do not contain an entry for the data set, AUDIT reports ***ERR 16**.
2. If the data set record indicates a migration copy on tape, but the positioning information in the data set record does not agree with the information in the TTOC, or the indicated TTOC extension cannot be found, AUDIT reports ***ERR 17**.

When neither condition “1” on page 1290 nor condition “2” on page 1290 holds:

- If there is no catalog entry, but the data set record indicates a migrated copy, AUDIT reports ***ERR 03**.
- If both the catalog entry and the data set record indicate the data set is not migrated, but AUDIT cannot (using the OBTAIN function) verify the data set is on the volume indicated in the catalog, AUDIT reports ***ERR 06**.
- If a catalog entry exists, indicating the data set is not migrated, but the data set record indicates the data set *is* migrated:
 - If AUDIT cannot verify the data set is on the volume indicated in the catalog, AUDIT reports ***ERR 09**.
 - If the data set is on the volume indicated in the catalog, AUDIT reports ***ERR 18**.
- If a catalog entry exists, indicating the data set is migrated, but the data set record indicates the data set is now on a primary volume, AUDIT reports ***ERR 11**.

Information reported when using AUDIT MIGRATIONCONTROLDATASET

Figure 104 on page 1290 is a sample list of printer output that you can request when you audit the MCDS.

Figure 105. Sample Terminal List for AUDIT MCDS

Table 74 on page 1281 explains the headings and labels used.

Diagnosis and repair action for AUDIT MIGRATIONCONTROLDATASET

When you request AUDIT MIGRATIONCONTROLDATASET, AUDIT attempts repair action when FIX is specified, for error message (*ERR) 03. In each instance, AUDIT issues a message that describes the type of correction attempted and whether or not the fix has been successful. When a fix is unsuccessful, the message contains the return code from the routine attempting the fix.

For other reported conditions and troubleshooting hints, see “Error codes (*ERR) and diagnosis” on page 1295.

Using the AUDIT BACKUPCONTROLDATASET command

When you specify AUDIT BACKUPCONTROLDATASET, the data set records in the BCDS drive the audit. A backed up data set is audited if either:

- At least one backup version was made when the data set was cataloged, or
- An MCDS data set record exists (the data set was migrated at some time).

For each such record (data set), AUDIT makes the following checks:

1. If the MCDS data set record indicates a migration copy on tape, but the TTOC records for the indicated migration volume do not contain an entry for the data set, AUDIT reports ***ERR 16**.
2. If the MCDS data set record indicates a migration copy on tape, but the positioning information in the data set record does not agree with the information in the TTOC, or the indicated TTOC extension cannot be found, AUDIT reports ***ERR 17**.

When neither condition “1” on page 1291 nor condition “2” on page 1291 holds:

- If there is no catalog entry, but the data set record indicates a migrated copy, AUDIT reports ***ERR 03**.
- If a catalog entry exists, indicating a data set on a primary volume:
 - If AUDIT cannot (using the OBTAIN function) verify the data set is on the volume indicated in the catalog:
 - If there is no MCDS data set record, AUDIT reports ***ERR 04**.
 - If the MCDS data set record indicates the data set was migrated, then recalled, AUDIT reports ***ERR 06**.

- If the MCDS data set record indicates the data set is now migrated, AUDIT reports ***ERR 09**.
- If the data set is on the indicated volume, but the MCDS data set record indicates the data set is migrated, AUDIT reports ***ERR 18**.
- If a catalog entry exists, indicating a migrated data set:
 - If there is no MCDS data set record, AUDIT reports ***ERR 10**.
 - If the MCDS data set record indicates the data set was migrated, then recalled, AUDIT reports ***ERR 11**.

Diagnosis and repair action for AUDIT BACKUPCONTROLDATASET

When you request AUDIT BACKUPCONTROLDATASET, AUDIT attempts repair action when FIX is specified, for error message (*ERR) 03. In each instance, AUDIT issues a message that describes the type of correction attempted and whether or not the fix has been successful. When a fix is unsuccessful, the message contains the return code from the routine attempting the fix.

For other reported conditions and troubleshooting hints, see [“Error codes \(*ERR\) and diagnosis” on page 1295](#).

Using the AUDIT OFFLINECONTROLDATASET command

When you specify AUDIT OFFLINECONTROLDATASET, you must also specify which tape table of contents (TTOC) records you wish to drive the audit. You can choose records for:

- A specific day in the backup cycle (DAILY(*day*)), or
- All days in the backup cycle (DAILY), or
- All spill volumes (SPILL), or
- All level 2 migration tape volumes (ML2), or
- All backup and migration tape volumes (ALL).

Errors detected when using AUDIT OFFLINECONTROLDATASET for backup

If you request any category of backup volume, AUDIT reads from the OCDS the TTOC records for all backup tapes in the categories specified.

For each valid data set entry in each TTOC, AUDIT tries to read a backup version record from the BCDS. If a backup version record exists, but none of the volumes (including any spanned volumes) indicated in that record is the same as the volume whose TTOC is driving the audit, AUDIT reports ***ERR 14**.

Errors detected when using AUDIT OFFLINECONTROLDATASET for migration

If you request the ML2 category, AUDIT reads from the OCDS the TTOC records for all migration level 2 tape volumes.

For each valid data set entry in each TTOC, AUDIT uses the data set name in that entry to find a corresponding data set record from the MCDS:

- If that name was apparently generated by DFSMSHsm for a migration copy (the second qualifier is .HMIG.), AUDIT tries to read the corresponding alias (**A**) record from the MCDS. If this record can be read, AUDIT uses it to try to read the data set record.
- If the name in the TTOC entry is not recognized as generated by DFSMSHsm, or if no alias record can be found, AUDIT uses the name in the TTOC entry to read the data set record.

For each data set, AUDIT then makes the following checks:

- If there is no catalog entry, but the data set record indicates a migrated copy, AUDIT reports ***ERR 03**.
- If a catalog entry exists, indicating the data set is on a primary volume:
 - If there is no MCDS data set record, AUDIT reports ***ERR 04**.
 - If there is an MCDS data set record, indicating the data set has been recalled, but to a volume different from the one recorded in the catalog, AUDIT reports ***ERR 08**.
 - If the data set record indicates a migration copy on tape, but the positioning information in the data set record does not agree with the information in the TTOC, or the indicated TTOC extension cannot be found, AUDIT reports ***ERR 17**.
 - If the data set record indicates the data set is now migrated to a DASD, AUDIT reports ***ERR 18**.
- If the catalog entry indicates a migrated data set:
 - If there is no MCDS data set record, AUDIT reports ***ERR 10**.
 - If there is an MCDS data set record, indicating the data set has been recalled, AUDIT reports ***ERR 11**.

Information reported when using AUDIT OFFLINECONTROLDATASET

The order of output for the different requests for auditing the OCDS is as follows:

- AUDIT OFFLINECONTROLDATASET(DAILY(*day*)):

The output is in ascending volume serial number order for tape daily backup volumes assigned to the day you specify.

- AUDIT OFFLINECONTROLDATASET(DAILY):

The output is ordered by all volumes assigned to day 1, then all volumes assigned to day 2, and so forth, until DFSMSHsm has audited all tape daily backup volumes in the OCDS.

- AUDIT OFFLINECONTROLDATASET(SPILL):

The output is in ascending volume serial number order for tape spill volumes in the OCDS.

- AUDIT OFFLINECONTROLDATASET(ML2):

The output is in ascending volume serial number order for tape migration level 2 volumes in the OCDS.

- AUDIT OFFLINECONTROLDATASET(ALL):

Using the AUDIT command

1. All tape daily backup volumes. These are ordered by day, with the volumes for each day in ascending volume serial number order.
2. All tape spill backup volumes. These are in ascending volume serial number order.
3. Unassigned tape backup volumes. These are in ascending volume serial number order.
4. Migration level 2 volumes. These are in ascending volume serial number order.

Figure 108 on page 1294 is a sample list of printer output you can request when you audit OCDS information for all tape volumes.

Diagnosis and repair action for AUDIT OFFLINECONTROLDATASET

When you request AUDIT OFFLINECONTROLDATASET, AUDIT attempts repair action when FIX is specified, for error messages (*ERR) 03 and 14. In each instance, AUDIT issues a message that describes the type of correction attempted and whether or not the fix has been successful. When a fix is unsuccessful, the message contains the return code from the routine attempting the fix.

For other reported conditions and troubleshooting hints, see “Error codes (*ERR) and diagnosis” on page 1295.

Summary of errors detected by the original AUDIT commands

Table 75 on page 1294 summarizes the errors detected and corrected by the audits listed in “Using the original AUDIT command to audit DFSMSHsm data set information” on page 1280. In this table, a D signifies that the error is detected, and a C signifies that the error is corrected when you specify the FIX parameter.

Table 75. Summary of errors detected or corrected by the listed AUDIT options

Error codes (*ERR) and diagnosis

This topic lists the error conditions that AUDIT can detect.

For certain reported conditions involving control information (see topics One and Two), the AUDIT command can determine an Audit Repair Action. If the FIX option is specified, the AUDIT function takes the specified action. Where the verbs "patch," "create," or "delete" appear in the table, the AUDIT function generates a FIXCDS command (or series of commands) to make the specified changes. The following column also contains additional diagnostic information for some errors.

It is recommended that you direct AUDIT output to a specific data set, and that you review that output for errors that may have occurred when AUDIT tried to repair a problem.

For those cases where AUDIT cannot repair the problem, some Troubleshooting Hints have been provided.

Note: The error messages are listed sequentially, but not every number in the sequence has been used.

Table 76. Error codes used in AUDIT reports

Description	Audit Repair Action	Troubleshooting Hints
*ERR 01		
Neither the catalog nor the MCDS has a record of the data set being audited. This condition can also be caused by the user catalog being offline. This condition may not be an error.	For AUDIT VOLUMES (primary): AUDIT tries to catalog the data set.	If you are auditing a specific data set or level: <ul style="list-style-type: none">A dsname or qualifier may have been misspelled; if so, correct the misspelling and reissue the command.The data set may be uncataloged, in which case DFSMSHsm would not have a migration copy. If there is no misspelling, the catalog in which the data set is cataloged may be offline; if so, the catalog must be brought online before reissuing the command.

Table 76. Error codes used in AUDIT reports (continued)

Description	Audit Repair Action	Troubleshooting Hints
*ERR 02		
The catalog has no record of the data set being audited, but the MCDS record indicates that the data set is on a primary volume.	For AUDIT VOLUMES (primary): If the primary volume being audited is the same as the volume serial indicated in the MCDS record, AUDIT tries to catalog the data set.	
*ERR 03		
The catalog has no entry for the data set that is being audited, but the MCDS record indicates that the data set is on a migration volume.		<p>For AUDIT DSNAMEs:</p> <p>Because there is no catalog entry for the data set with the migration copy, that copy is most likely an old one that has not yet been scratched, probably because of a previous error when the data set was being recalled or deleted. There are two methods to correct the problem: (1) issue the HSEND DELETE command for the data set, deleting the D and A records in the MCDS immediately; or (2) have the migration copy and its D record removed during the next migration cleanup by using the FIXCDS D <i>dsname</i> PATCH() command to reset the assigned flag (MCDFASN) bit to 0 (off) and to set the needs scratch flag (MCDFNSCR) bit to 1 (on).</p> <pre>FIXCDS D <i>dsname</i> PATCH(X'06' BITS(0....1.))</pre> <p>This command <i>resets</i> the assigned bit and <i>sets</i> the needs scratch bit.</p> <p>Also possible: the catalog entry was inadvertently deleted, and the migrated copy is still valid. If this is the case, rebuild the catalog entry as a non-VSAM data set with a volume serial of "MIGRAT".</p>
*ERR 03 (continued)		

Table 76. Error codes used in AUDIT reports (continued)		
Description	Audit Repair Action	Troubleshooting Hints
The catalog has no record of the data set being audited, but the MCDS record indicates that the data set is on a migration volume.	<p>For AUDIT VOLUMES, MCDS, BCDS, or OCDS:</p> <p>AUDIT catalogs the data set and (for VSAM) any VSAM intercept object names associated with the data set, with a volume serial of MIGRAT.</p> <p>If the data set in question is a rolled-off generation data set (GDS), no error is reported, and the GDS is not recataloged.</p>	<p>For AUDIT VOLUMES (primary):</p> <p>Although there is no catalog entry for the migrated data set, there is an uncataloged data set with the same name on the primary volume being audited.</p> <p>If you can verify that there is no relationship between these two data sets, the <i>persistence</i> of the migration copy is probably caused by a previous error when the data set was being recalled or deleted. You can have the migration copy and its D record removed during the next migration cleanup by using the FIXCDS D <i>dsname</i> PATCH() command to reset the assigned flag (MCDFASN) and to set the needs scratch flag (MCDFNSCR).</p> <pre>FIXCDS D dsname PATCH(X'06' BITS(0....1.))</pre> <p>This command <i>resets</i> the assigned bit and <i>sets</i> the needs scratch bit.</p>
*ERR 04		
The catalog record of the data set being audited indicates that the data set is on a level 0 volume, but this could not be verified. No MCDS record of the data set exists for this error condition. This may or may not be an error.		If you can verify that the data set in question is on the volume indicated by the catalog entry, there is no problem. Otherwise, you should either delete the catalog entry or alter it to indicate the correct volume serial numbers.
*ERR 05		
The data set is cataloged on a volume other than the volume being audited. No MCDS record exists for the data set.		The volume being audited apparently has an uncataloged data set with the same name as a data set (on another volume) that <i>is</i> cataloged. You may want to rename the uncataloged data set, then catalog it also under its new name.
*ERR 06		
The catalog and the MCDS records for the data set being audited indicate that the data set is on a primary volume. The data set, however, is not on the volume recorded in the catalog, and the volume where the data set does reside cannot be determined.		<p>The volume in question may not be mounted.</p> <p>If you can verify which volume contains the data set in question, alter the catalog entry to indicate the correct volume. Otherwise, if you can verify that the data set is no longer needed, delete the catalog entry.</p> <p>The existence of the MCDS record indicates that migration cleanup has not yet removed that record of a previously recalled data set.</p>
*ERR 07		

Table 76. Error codes used in AUDIT reports (continued)

Description	Audit Repair Action	Troubleshooting Hints
The serial number of the volume containing the data set being audited as recorded in the catalog does not agree with the serial number of the primary volume containing the data set as recorded in the MCDS. The two conflicting volume serial numbers are on the lists under the CATALOGED TO VOLUME and MIGRATED TO VOLUME headings, respectively.		This condition can occur when a migrated data set is recalled, moved to another primary volume, and the audit is done before migration cleanup has removed the MCDS record. After migration cleanup has removed the record, the AUDIT function no longer reports the condition.
*ERR 08		
The catalog indicates that a data set of the same name resides on a volume other than the one being audited. The MCDS record indicates a primary volume.		The volume being audited apparently has an uncataloged data set with the same name as a data set (on another volume) that <i>is</i> cataloged. You may want to rename the uncataloged data set, then catalog it also under its new name.
*ERR 09		
The catalog record of the data set being audited indicates that the data set is on a volume not managed by DFSMSHsm, but the MCDS indicates that the data set is on a migration volume.		<p>The catalog may have been offline to DFSMSHsm when the catalog entry for the data set in question was replaced with one for a nonmigrated (or recalled) data set. The condition could have also been caused by a DELETE NOSCRATCH operation. The MCDS record for the data set will have the serial number of the volume from which the data set was migrated.</p> <p>If you can determine that the current catalog entry has the correct status for the data set, use the <code>FIXCDS D dsname PATCH()</code> command to reset the assigned flag (MCDFA SN) and to set the needs scratch flag (MCDFN SCR) in the MCDS record; this causes the next migration cleanup to remove the migration copy.</p> <pre>FIXCDS D dsname PATCH(X'06' BITS(0....1.))</pre> <p>This command <i>resets</i> the assigned bit and <i>sets</i> the needs scratch bit.</p> <p>If, however, you determine that the correct status for the data set is a migrated copy, then alter the data set now referred to by the catalog entry to refer to volume MIGRAT.</p>
*ERR 10		

Table 76. Error codes used in AUDIT reports (continued)

Description	Audit Repair Action	Troubleshooting Hints
<p>The catalog record of the data set being audited indicates that the data set is on a migration volume, but the MCDS has no record of the data set.</p>		<p>To indicate a migrated data set, DFSMSHsm uses the volume serial MIGRAT in the catalog entry for that data set. If someone in your organization catalogs data sets on a primary volume called MIGRAT, change that volume serial number and alter all related catalog entries to avoid confusion with DFSMSHsm's indicator.</p> <p>If no such primary volume MIGRAT exists, then you need to verify whether the data set in question is <i>supposed</i> to be migrated:</p> <ul style="list-style-type: none"> • If it is and you need to recall the data set, you need to locate the migration copy. (If no previous LIST output or activity log identifies the migration volume, do a LIST VTOC [for each DASD migration volume] or LIST TTOC [for each tape migration volume].) Then reconstruct the MCDS record, using the following command: <pre data-bbox="1045 905 1469 982">FIXCDS D <i>dsname</i> ADDMIG(<i>volser</i>)</pre> <p>Another way to rebuild the data set record is to run AUDIT MEDIACONTROLS, once you have determined the volume serial number. This may be required for successful recall of the data set.</p> <ul style="list-style-type: none"> • If the data set is <i>not supposed</i> to be migrated, either delete the catalog entry, or alter it to refer to a different (primary) volume.
*ERR 11		

Table 76. Error codes used in AUDIT reports (continued)

Description	Audit Repair Action	Troubleshooting Hints
The catalog record of the data set being audited indicates that the data set is on a migration volume, but the MCDS record indicates that the data set is on a primary volume.		<p>To indicate a migrated data set, DFSMSHsm uses the volume serial MIGRAT in the catalog entry for that data set. If someone in your organization catalogs data sets on a primary volume called MIGRAT, change that volume serial number and alter all related catalog entries to avoid confusion with the DFSMSHsm indicator.</p> <p>If no such primary volume MIGRAT exists, then an error has apparently occurred during an attempted recall of the data set in question. You need to verify whether the data set is <i>supposed</i> to be migrated:</p> <ul style="list-style-type: none"> • If it is and you need to be able to recall the data set, use the <code>FIXCDS D dsname DISPLAY</code> command to determine from the MCDS record what migration volume has held the migration copy, verify (with the <code>LIST</code> or <code>AUDIT</code> command) that the migration copy is still on that migration volume, and set the assigned flag (MCDFASN) in the MCDS record by using a <code>FIXCDS D dsname PATCH()</code> command. <p>This command sets the assigned bit.</p> <pre>FIXCDS D dsname PATCH(X'06' BITS(1.....))</pre>
*ERR 12		
The catalog and MCDS records of the data set being audited indicate that the data set is on a migration volume, but the mounted volume table entry indicates that the volume is not a migration volume. (The data set is apparently a very old migration copy, made before HSM Release 3.)		<p>Most likely an uncataloged data set on the volume has the same name as a (very old) cataloged migrated data set. This is not an error, but you should catalog all your data sets.</p> <p>Otherwise, if you can determine (from lists of migration volumes, and so forth) that DFSMSHsm <i>should</i> have considered the volume as a migration volume, then use the <code>FIXCDS V volser PATCH()</code> command to set the flag in the volume record that identifies the volume as a migration volume rather than a level-0 volume.</p>
*ERR 14		
The BCDS backup version record of the data set being audited specifies a serial number that does not match the serial number of the backup volume being audited. If the data set resides on a tape volume, this error is detected only if the volume is also not spanned by the data set being audited.	For a tape backup volume, AUDIT sets the invalid flag in the TTOC entry, and in the TTOC for any spanned volume.	

Table 76. Error codes used in AUDIT reports (continued)		
Description	Audit Repair Action	Troubleshooting Hints
*ERR 15		
Either the catalog entry for this data set indicates that the type of data set is not supported by DFSMSHsm migration, or the entry did not indicate a volume for the data set.		<p>For AUDIT DSNAMEs: Most likely this error is a typing error in specifying a particular data set to be audited; the object cataloged by that name is not one that is supported by DFSMSHsm. Correct the spelling of the <i>dsname</i> and reissue the AUDIT command.</p> <p>For AUDIT VOLUMES: Since the catalog indicates the data set is something not supported by migration (for instance, a VSAM page space), this may not be an error. Even so, it is probably best to move the data set to another volume.</p>
*ERR 16		
<p>The TTOC records do not coincide with the catalog and the MCDS data set record. One of the following conditions may have occurred:</p> <ul style="list-style-type: none"> • The catalog and the MCDS data set record say the data set is migrated. The volume serial number of the TTOC, however, does not match the volume serial number in the MCDS data set record, or (according to that record) of any volumes the data set might span. • The catalog and the MCDS data set record indicate that the data set is on a specific primary volume. The TTOC, however, contains a valid data set entry for the data set, which means the data set has been migrated (and may have been recalled). • If the DATA SET ON VOLUME field contains “INVALID”, the TTOC indicates that the data set copy is invalid. • If the DATA SET ON VOLUME field contains “NO ENT”, one of the following conditions is true: <ul style="list-style-type: none"> – If the tape being audited is in single-file format, the data set cannot be found in the TTOC extension identified by the MCD record. – If the tape being audited is a multifile tape, the file block identifiers (FBID) in the TTOC do not coincide with the FBID in the MCD record. This situation may be resolved by recalling and again migrating the data set in error. 		<p>The TTOC entry may identify a previous migration copy. A system failure most likely occurred before DFSMSHsm was able to invalidate it. You can use the FIXCDS T command to invalidate the entry for the data set in question:</p> <pre>FIXCDS T key ENTRY(dsname) PATCH(X'34' BITS(.0.....))</pre> <p>Verify that the migration volume referred to in the data set record actually contains a migration copy of the data set. (If the volume is a tape volume, you can issue a LIST TTOC command.)</p>
*ERR 17		

Table 76. Error codes used in AUDIT reports (continued)

Description	Audit Repair Action	Troubleshooting Hints
<p>Here are the possible error conditions AUDIT reports and their meanings:</p> <p>OFFLINE The catalog cannot be opened, and is probably offline.</p> <p>NO TTC The TTOC record of the migration volume or backup volume as indicated in the data set record does not exist. The missing TTOC record can be either the base TTOC record or an extension TTOC record.</p> <p>-SEQ1- The first data set file sequence number in the base TTOC record is greater than the data set file sequence number indicated in the MCDS data set record.</p> <p>-SEQ1- The last data set file sequence number in the base TTOC record is less than the data set file sequence number indicated in the MCDS data set record for a non-VSAM data set.</p> <p>-SEQ1- The last data set file sequence number in the base TTOC record plus one is less than the data set file sequence number indicated in the MCDS record for a VSAM data set.</p> <p>-SEQ2- The TTOC record shows a data set name based on the data set file sequence number found in the MCDS data set record. This data set name in the TTOC does not match the data set name in the MCDS data set record.</p>		<p>Check that the catalog is online to DFSMSHsm while the AUDIT command is running; an offline catalog can cause this error indication.</p> <p>If the catalog is <i>not</i> offline, then diagnosis depends on the tape format involved:</p> <ul style="list-style-type: none"> • If the tape is in single-file format, run the AUDIT MEDCTL command against the tape volume to determine, by checking the tape volume, whether the MCDS data set record or the TTOC record set is in error. (The FIX option will regenerate a TTOC set.) • If the tape is in multifile format, the TTOC entry most likely represents an out of date copy and can be invalidated by using the FIXCDS T command: <pre>FIXCDS T key ENTRY(dsname) PATCH(X'34' BITS(.0.....))</pre>
*ERR 18		

Table 76. Error codes used in AUDIT reports (continued)		
Description	Audit Repair Action	Troubleshooting Hints
The catalog record of the data set being audited indicates that the data set is on a primary volume, but the MCDS indicates that the data set is on a migration volume.		<p>The catalog may have been offline to DFSMSHsm when the catalog entry for the data set in question was replaced with one for a nonmigrated (or recalled) data set. The MCDS record for the data set will have the serial number of the volume from which the data set was migrated.</p> <p>If you can determine that the current catalog entry has the correct status for the data set, then use the FIXCDS D <i>dsname</i> PATCH() command to reset the assigned flag (MCDFASN) and to set the needs scratch flag (MCDFNSCR) in the MCDS record; this causes the next migration cleanup to remove the migration copy.</p> <pre>FIXCDS D <i>dsname</i> PATCH(X'06' BITS(0.....1.))</pre> <p>This command <i>resets</i> the assigned bit and <i>sets</i> the needs scratch bit.</p> <p>If, however, you determine that the correct status for the data set is a migrated copy, then rename and recatalog the data set now referred to by the catalog and alter the original catalog entry to refer to volume MIGRAT.</p>
*ERR 19 userdsn HAS NO D RECORD		
Data set <i>userdsn</i> is not migrated. No data set (D) record can be found.		The data set name may be spelled incorrectly.
*ERR 20 userdsn ON migvol, BUT NO V RECORD		
The catalog indicates that data set <i>userdsn</i> has been migrated and the MCDS indicates that the migration copy is on a specific migration volume (<i>migvol</i>); but there is no migration volume (V) record for that volume.	<p>If the D record is flagged to indicate the copy is in an SDSP data set, and</p> <ul style="list-style-type: none"> • If an SDSP data set can be found on the volume, an ADDVOL command is generated for the L1 volume. • If no SDSP data set can be found on the volume, but the migration copy can be found there, the D record is patched to reset the SDSP flag, and an ADDVOL command is generated for the L1 volume. <p>If the D record is not flagged for a copy in an SDSP data set, and the migration copy can be found on the volume, an ADDVOL command is generated for the L1 volume.</p>	
*ERR 21 userdsn INDICATES DEVICE TYPE X'...', V RECORD INDICATES X'!..'		

Table 76. Error codes used in AUDIT reports (continued)

Description	Audit Repair Action	Troubleshooting Hints
For user data set <i>userdsn</i> , a data set (D) record exists, indicating that the migration copy is on a migration volume of device type X'...', but the volume (V) record for that volume indicates a different device type X'...'.	If the volume record indicates tape, and a TTOC record exists, the data set (D) record is patched to replace the device type. If the volume record indicates DASD and the migration copy can be found on the volume, the data set (D) record is patched to replace the device type.	
*ERR 22 <i>userdsn</i> HAS NO ALIAS RECORD		
The data set (D) record for user data set <i>userdsn</i> indicates that the migration copy is not in an SDSP data set. Therefore, there should be a MCDS alias record identifying the migration copy; but the MCDS alias record does not exist.	If the migration copy can be found on the volume, an alias (A) record is created.	
*ERR 23 <i>userdsn</i>—VSAM ASSOCIATIONS RECORD MISSING		
The MCDS data set (D) record for user data set <i>userdsn</i> indicates the existence of a MCDS VSAM association (O) record, but no such record exists.		If the VSAM data set has already been recalled, then the D record is extraneous; you can use the FIXCDS command to delete it.
*ERR 24 <i>userdsn</i>—MISSING VSAM INTERCEPT OBJECT		
The MCDS VSAM associations (O) record for the migration copy of data set <i>userdsn</i> indicates the existence of an intercept object representing one of the components of the VSAM data set. The catalog entry for this object is <i>not</i> a non-VSAM entry indicating MIGRAT as its only volume serial.	The VSAM Association (O) record is patched, to correspond to the actual components found.	
*ERR 25 <i>userdsn</i>—component MIGRATED, BUT NO ALIAS RECORD		
The VSAM associations (O) record for the migration copy of data set <i>userdsn</i> indicates the existence of an intercept object representing a <i>component</i> of the VSAM data set. This <i>component</i> has a non-ICF catalog entry with a volume serial of MIGRAT, but the MCDS alias (A) record does not exist.	The alias (A) record for the component is created.	
*ERR 26 <i>userdsn</i>—L RECORD MISSING		
The MCDS data set record for data set <i>userdsn</i> indicates that a BCDS backup migrated data set (L) record has been created, but no such L record exists.	If a BCDS data set (B) record is found that indicates a backup was made after the migration date, the MCDS data set (D) record is patched to reset the L-record flag. If no such B record is found and the D record indicates the migration copy is on L1, a BACKDS command is generated for the data set.	
*ERR 27 <i>userdsn</i>—EXTRANEIOUS VSAM ASSOCIATIONS RECORD		

Table 76. Error codes used in AUDIT reports (continued)		
Description	Audit Repair Action	Troubleshooting Hints
A VSAM-associations (O) record refers to an MCDS data set (D) record for data set <i>userdsn</i> . Either the data set record does not exist, or (if present) does not indicate the existence of a VSAM-associations record.	The VSAM Association (O) record is deleted.	
*ERR 28 <i>userdsn</i>—EXTRANEOUS ALIAS RECORD		
An extraneous MCDS alias (A) record is referring to an MCDS data set (D) record for data set <i>userdsn</i> , but the MCDS data set (D) record does not exist.	If there is no data set (D) record, <ul style="list-style-type: none"> • The alias (A) record is deleted; • If the A record indicates a VSAM component, and the catalog entry for that component indicates that it is migrated, the catalog entry is deleted. 	
*ERR 29 <i>userdsn</i>—NO TTOC RECORD		
An MCDS data set (D) record for a migration copy of data set <i>userdsn</i> indicates the migration copy is on a migration tape volume. Either no TTOC record exists for the migration volume, or no TTOC extension contains a valid entry for the migration copy.		You can run AUDIT MEDCTL against the migration tape in the D record, and (if FIX is specified) AUDIT will rebuild the TTOC. This error may occur if AUDIT DATASETCONTROLS is executed while migration is currently updating a given TTOC record. If this occurs, run AUDIT DATASETCONTROLS while migration is inactive.
*ERR 30 INVALID CDS RECORD TYPE		
An invalid record type has been detected in the control data set (MCDS or BCDS) being audited.	The unknown record is deleted (internally).	
*ERR 31 <i>userdsn</i> HAS NO MIGRATED DATA SET RECORD EXTENSION		
The MCD record (D) indicates that a user data set has been encrypted, but there is no MCDX record (3).	No audit repair can be made.	If the data set has already been recalled, then the D record is extraneous; you can use the FIXCDS command to delete it. If the key label is known the FIXCDS command can be used to add the MCDX record (3).
*ERR 32 <i>userdsn</i>—EXTRANEOUS MIGRATED DATA SET RECORD EXTENSION		
An extraneous MCDX record (3) is referring to a MCD record (D) that does not exist or an extraneous MCDX record (3) exists where the MCDX indicator is not enabled in the associated MCD record (D).	If there is no MCD record (D) or the MCD record (D) exists but the MCDX indicator is not enabled, the MCDX record (3) is deleted.	
*ERR 33 <i>userdsn</i>— MISMATCH NUMBER OF RETAINED MCA RECORDS, FOUND <i>num1</i>, EXPECTED <i>num2</i>		
The MCD record (D) reports <i>num1</i> 'Retained' MCA records, but found <i>num2</i>	No audit repair can be made.	Use the DFSMSHsm LIST command to validate 'Retained' MCA records. Delete invalid records, and update the 'Retained' MCA list to reflect the deletion.
*ERR 35 MCB VERSION FIELD FOR <i>dsn</i> NEEDS VERSION NUMBER <i>vernum</i>		

Table 76. Error codes used in AUDIT reports (continued)

Description	Audit Repair Action	Troubleshooting Hints
<p>All MCC (backup version) records that are associated with the specified MCB (data set backup) record have been audited. During the audit of these records, the most current version found based on the MCC record timestamp has been tracked. The MCBGEN field should contain the version number of the most current MCC record, but it does not.</p> <p>If the suggested version number is 1, then in most cases this indicates that the actual version number could not be determined, so versioning is restarted. This situation occurs only if an existing version number cannot be established.</p>	A FIXCDS PATCH is issued to update the MCBGEN field to the highest version number.	None.
*ERR 36 BACKUP VERSION ENTRY <i>backupdsn</i> CONTAINS (<i>mcbver</i>), SHOULD CONTAIN (<i>mccgen</i>)		
The MCC record and associated MCB record have a discrepancy between the MCBVER and MCCGEN fields for the specified version entry. The MCBVER field needs to be modified to be the same as the MCCGEN field for the version entry.	A FIXCDS PATCH is issued to update the MCBVER field to the proper value, which is the value contained in the MCCGEN field of the associated MCC record.	None.
*ERR 37 <MCBR key> BAD SEQUENCE NUMBER		
The sequence number in the MCBR (Z) record and MCC (C) record should be identical, but they are not. Either the data set backup retained copy (Z) record or the data set backup version (C) record are in error.		<p>You can display the MCBR (Z) record using the following command:</p> <pre>FIXCDS Z <MCBR key> INDEX(n) DISPLAY</pre> <p>The default for INDEX(n) is INDEX(1), which will display the most current MCBR record for that data set. See <i>z/OS DFSMSHsm Diagnosis</i> for more information on using the FIXCDS command.</p> <p>You can display the MCC (C) records using the following command:</p> <pre>FIXCDS C <MCC key> DISPLAY</pre> <p>You can find the MCBR key in the ERR37 message text. You can find the MCC keys in the output of the FIXCDS Z DISPLAY command. All MCC records listed in the MCBR version array should contain the same sequence number. Each MCC record needs to be FIXCDS displayed to find its sequence number. You need to consider all of the sequence number information when determining which record contains the incorrect sequence number. You can use the FIXCDS PATCH command to correct the record with the correct sequence number.</p>

Table 76. Error codes used in AUDIT reports (continued)		
Description	Audit Repair Action	Troubleshooting Hints
*ERR 38 <MCC OR MCB key> HAS INVALID SEQUENCE NUMBER		
The dataset backup record contains an indication of the number of dataset backup retained copy records that exist. The number is incorrect.		
*ERR 39 <i>userdsn</i> IS MISSING <i>version</i>		
The BCDS data set (B) record for <i>userdsn</i> refers to a backup <i>version</i> of that data set. However, the corresponding backup version (C) record no longer exists or exists but does not refer back to this (B) record.		<p>The time and date stamp incorporated in the version name may indicate a version old enough that it is no longer useful, and the copy referred to by that version name may no longer exist.</p> <p>If a LIST BCDS LEVEL(<i>userdsn</i>) indicates there are other available versions of <i>userdsn</i>, you may not need the missing version.</p> <p>If there is no other available version, you need to determine (for example, from a previous LIST output) what backup volume contains the version, so that you can use the "FIXCDS C <i>version</i> ..." command to regenerate the C record.</p> <p>You should discover what caused the deletion of the C record and correct that problem to avoid future occurrences.</p>
*ERR 40 <i>userdsn</i> - backup version name MISSING B RECORD		

Table 76. Error codes used in AUDIT reports (continued)

Description	Audit Repair Action	Troubleshooting Hints
<p>The backup version (C) record refers to a BCDS data set record that does not exist, or the (B) record exists but does not refer to the backup version (C) record.</p> <p>In the message, <i>userdsn</i> is the original data set name in the (B) record and version is the generated backup name in the (C) record.</p> <p>Note: Each FIXCDS command generated with this error is dependent on previous FIXCDS commands. If NOFIX is used, the offsets in the output data set are invalid.</p>	<p>If the backup version (C) record indicates the version is invalid, then a BDELETE command is issued to delete the backup version (C) record.</p> <p>If the backup version (C) record indicates the backup version is for an uncataloged data set or a data set with the RACF erase on scratch option, then no action is taken – regardless of whether there is a valid data set (B) record or not.</p> <p>If the backup version (C) record references a data set (B) record that does not exist, then a new (B) record is created and the version added.</p> <p>If the data set (B) record referenced by the backup version (C) record exists but does not correspond to the specified backup version, then one of the following actions will be performed:</p> <ul style="list-style-type: none"> • If the maximum number of backup versions has been reached and the specified backup version is older than any of those described in the data set record, the backup version is deleted. • If the maximum number of backup versions has not been reached, then the data set (B) record is extended. <ul style="list-style-type: none"> – If the version is older than any of those described in the (B) record, then it is added at the end. – If the version is not the oldest, then it is inserted in date order. 	<p>The number of versions specified by SETSYS VERSIONS or in the management class is ignored and new versions might be added until the system maximum has been reached. Subsequent BACKUP, EXPIREBV, or BDELETE commands can be used to cleanup unwanted backup versions. The RECYCLE command must be issued to delete the versions from the backup volumes.</p> <p>GENERATION and VERSION numbers are not updated in the data set (B) record as backup versions are added. Different backup versions can have duplicate numbers.</p> <p>Backup versions are added to the (B) record in date order. If multiple backup versions exist for the same date, they are not specifically ordered by time.</p> <p>Cataloged backup versions take precedence over uncataloged backup versions with newer dates.</p>
*ERR 41 version INDICATED ON <i>backvol</i>, BUT NO X RECORD		
<p>The backup version (C) record for <i>version</i> indicates the version is on backup volume <i>backvol</i>, but no BCDS backup volume (X) record exists for <i>backvol</i>.</p>	<p>If the volume is found to be an L1 volume, the data set (B) record is patched to indicate L1 residence of this version.</p> <p>If the volume is the second or later of a multivolume version, an ADDVOL command is generated for volume serial <i>backvol</i>.</p>	
*ERR 42 version INDICATED ON <i>migvol</i>, BUT NO V RECORD		

Table 76. Error codes used in AUDIT reports (continued)		
Description	Audit Repair Action	Troubleshooting Hints
A backup version (C) record indicates <i>version</i> is on migration volume <i>migvol</i> (that is, it has been created by the (H)BACKDS command), but no MCDS volume record (V) exists for <i>migvol</i> .	If the volume is found to be a backup volume, the data set (B) record is patched to indicate the version is not on L1. Otherwise, an ADDVOL command is generated for the L1 volume.	
*ERR 43 <i>version</i> RESIDES ON <i>migvol</i>, BUT NO M RECORD		
*ERR 43 <i>migvol</i> - CONTAINS <i>version</i>, BUT NO M RECORD		
Backup version <i>version</i> exists on migration volume <i>migvol</i> , but no BCDS move backup version (M) record exists for moving the version to a backup volume.	<p>If a backup version (C) record exists for the version, and</p> <ul style="list-style-type: none"> • If a BCDS data set (B) record referring to the version exists, an M record is created. • If no such B record exists, the C record is patched for subsequent deletion and scratching of the backup version. 	
*ERR 44 <i>version</i> INDICATES DEVICE TYPE X'...', X RECORD INDICATES X'...'		
The BCDS backup version (C) record for <i>version</i> indicates the version is on a backup volume of device type X'...', but the volume (X) record for that volume indicates a different device type X'...'.	<p>If the volume record indicates tape, and a TTOC record exists, the backup version record is patched to replace the device type.</p> <p>If the volume record indicates DASD, and the backup version can be found on the volume, the backup version record is patched to replace the device type.</p>	
*ERR 45 <i>version</i> - NO TTOC ENTRY		
A BCDS backup version (C) record for <i>version</i> indicates the version is on a backup tape volume. Either no TTOC record exists for the backup volume, or no TTOC extension contains a valid entry for the backup version.		
*ERR 46 <i>userdsn</i> - BAD L RECORD		
A backup migrated data set (L) record refers to a migration copy of data set <i>userdsn</i> , but no MCDS data set (D) record exists.	The L record is deleted.	
*ERR 47 <i>version</i> INDICATED ON <i>migvol</i>, BUT CANNOT BE FOUND		

Table 76. Error codes used in AUDIT reports (continued)

Description	Audit Repair Action	Troubleshooting Hints
The BCDS data set (B) record indicates that <i>version</i> is on migration volume <i>migvol</i> and a backup version (C) record exists, but either <i>migvol</i> is not mounted or it does not contain the backup version.		<p>If the version is no longer needed, no action need be taken.</p> <p>If the migration volume is mounted, but you know the version is on a different volume, you can use the FIXCDS command to update volume serial numbers in the C record for the version.</p> <p>If the migration volume is not mounted, it should be mounted to provide access to the version.</p>
*ERR 48 <i>userdsn</i> HAS NO B RECORD		
Data set <i>userdsn</i> , specified as a parameter for auditing backup controls, is not backed up (does not have a BCDS data set (B) record).		The data set name may be spelled incorrectly.
During AUDIT MEDIACONTROLS VOLUMES processing, a data set backup version for <i>userdsn</i> was found on the tape volume specified. There is no BCDS data set (B) record for <i>userdsn</i> .		If a backup version is required for data set <i>userdsn</i> , use the BACKDS command to create a current backup version.
*ERR 50 <i>volser</i> NOT A MIGRATION VOLUME [(DUMP BACKUP LEVEL-0)]		
<p>Specified volume <i>volser</i> is not a migration volume as there is no MCDS migration volume record.</p> <ul style="list-style-type: none"> If volume <i>volser</i> is a BCDS dump volume record, it will be reported as (DUMP). If volume <i>volser</i> is a BCDS backup volume record, it will be reported as (BACKUP). If volume <i>volser</i> is a level-0 volume, it will be reported as (LEVEL-0). 		<p>The volume serial specified in the command may be spelled incorrectly.</p> <p>If not, and the volume is identified as a different type of DFSMSHsm-owned or DFSMSHsm-managed volume, you cannot use this AUDIT option on the volume.</p> <p>If the volume serial is not misspelled and you have evidence that the volume was once managed by DFSMSHsm, you need to check DFSMSHsm logs to determine why the volume was deleted.</p>
*ERR 51 <i>volser</i> - V RECORD INDICATES TAPE, NO TTOC EXISTS		
A migration (V) record for volume <i>volser</i> exists, but no TTOC base record is found.	<p>If the volume record indicates</p> <ul style="list-style-type: none"> A tape <i>other than</i> one in single-file format, and An empty volume <p>an ADDVOL command is generated for <i>volser</i>.</p> <p>If the volume record indicates a tape in single-file format, the base TTOC is created, and individual data set TTOC entries are created as the tape is read.</p>	
*ERR 52 <i>volser</i> - V RECORD INDICATES NO RACF, TTOC INDICATES RACF		
*ERR 52 <i>volser</i> - X RECORD INDICATES NO RACF, TTOC INDICATES RACF		
*ERR 52 <i>volser</i> - X RECORD INDICATES RACF, TTOC INDICATES NO RACF		

Table 76. Error codes used in AUDIT reports (continued)		
Description	Audit Repair Action	Troubleshooting Hints
For volume <i>volser</i> , there is a conflict between either the MCDS volume (V) record or the BCDS backup volume (X) record and the TTOC. The V record or the X record for <i>volser</i> indicates a RACF protected tape, but the TTOC record does not, or vice versa.	If RACF indicates that the volume is RACF protected, either the TTOC or the volume record is patched to indicate that protection.	
*ERR 53 <i>volser</i> - RACF-INDICATED, BUT NOT IN DFSMSHsm'S TAPEVOL		
*ERR 53 <i>volser</i> - IN DFSMSHsm'S TAPEVOL, BUT NOT RACF INDICATED		
For volume <i>volser</i> , there is a conflict between either the MCDS volume (V) record or the BCDS backup volume (X) record and DFSMSHsm's TAPEVOL volume set. The V record or the X record for <i>volser</i> indicate a RACF protected tape, but DFSMSHsm's TAPEVOL volume set does not, or vice versa.	If RACF indicates that the volume is not in DFSMSHsm's tape volume set, RACF is invoked to add the volume to the set; otherwise, the volume record is patched to indicate RACF protection.	
*ERR 54 <i>volser</i> IN L2CR RECORD, NO V RECORD		
Volume <i>volser</i> , which is in the L2CR record, does not have a MCDS volume (V) record.		If the volume is not intended to be (or is no longer) a DASD level-2 migration volume, you can use the FIXCDS command to remove the entry for the volume from the L2CR record or use the DEFINE ML2 to redefine the list of volumes to be associated with the key range involved. Otherwise, issue an ADDVOL command for the volume, to reidentify it to DFSMSHsm as a DASD level-2 migration volume.
*ERR 55 <i>volser</i> IN L2CR RECORD NOT DASD L2 VOLUME		
Volume <i>volser</i> in the L2CR record has a corresponding MCDS volume (V) record that indicates a volume type other than DASD (L2).		If the V record for the volume correctly indicates that the volume is not a DASD level-2 migration volume, you can use the FIXCDS command to remove the entry for the volume from the L2CR record or use the DEFINE ML2 to redefine the list of volumes to be associated with the key range involved. Otherwise, use the FIXCDS command to correct the V record so that the volume is identified as a DASD level-2 migration volume.
*ERR 56 MC1 EXTENSION <i>nnnn</i> MISSING		
The last MC1 migration level-1 free space (1) record incorrectly indicates that there is another extension record <i>nnnn</i> .	The last MC1 extension is patched to indicate no continuation.	
*ERR 57 MC1 EXTENSION <i>nnnn</i> EXTRANEIOUS		
There is an extraneous extension record <i>nnnn</i> in the MCDS migration level-1 free space record.	The extraneous MC1 extension is deleted.	
*ERR 58 <i>orig volser</i> ALTERNATE TAPE VOLSERS MISMATCHED: TTOC <i>ttoc volser</i> {MCT <i>mct volser</i> MCV <i>mcv volser</i>}		

Table 76. Error codes used in AUDIT reports (continued)

Description	Audit Repair Action	Troubleshooting Hints
The alternate volume serials for duplex volumes do not match between the TTOC <i>ttoc volser</i> and either the MCT <i>mct volser</i> or the MCV <i>mcv volser</i> .		
*ERR 70 volser NOT A BACKUP VOLUME [(DUMP MIGRATION LEVEL-0)]		
Volume <i>volser</i> is not a backup volume as there is no BCDS backup volume record. <ul style="list-style-type: none"> If volume <i>volser</i> is a BCDS dump volume, it is reported as (DUMP). If volume <i>volser</i> is a MCDS migration volume, it is reported as (MIGRATION). If volume <i>volser</i> is a level-0 volume, it is reported as (LEVEL-0). 		<p>The volume serial specified in the command may be spelled incorrectly.</p> <p>If not, and the volume is identified as a different type of DFSMSHsm-owned or DFSMSHsm-managed volume, you cannot use this AUDIT option on the volume.</p> <p>If the volume serial is not misspelled and you have evidence that the volume was once known to DFSMSHsm, you need to check DFSMSHsm logs to determine why the volume was deleted.</p>
*ERR 71 volser - TTOC EXISTS, NO X RECORD		
The TTOC base record was found for volume <i>volser</i> , but the backup volume (X) record is missing.		
*ERR 71 volser - X RECORD INDICATES TAPE, NO TTOC EXISTS		
A backup volume (X) record for volume <i>volser</i> exists, but no TTOC base record has been found.	<p>For VOLUMECONTROLS(BACKUP) If the X record indicates an empty volume, an internal ADDVOL command is generated for <i>volser</i>.</p> <p>For MEDIACONTROLS:The base TTOC is created, and individual data set TTOC entries are created as the tape is read.</p>	
*ERR 72 volser - X RECORD - {SP UN DAY nn}, BVR - {UN DAY nn SP}		
<p>A BVR is a BCDS backup cycle volume record subdivided into spill and day of backup cycle (daily).</p> <p>A BVR lists a backup volume <i>volser</i>, but there is a mismatch between the BCDS backup volume (X) record type {SP UN DAY nn} and the BVR type {UN DAY nn SP}.</p>	The BVR entry is deleted.	
*ERR 73 volser - X RECORD - {SP UN DAY nn}, TTOC - {UN DAY nn SP}		
The usage for volume <i>volser</i> in the BCDS backup volume (X) record is inconsistent with the {SP UN DAY nn} usage in the TTOC record key.		Depending on your intended backup usage for the volume, use the FIXCDS command to correct either the TTOC record set (the base and any extensions), or the X record.
*ERR 74 volser - X RECORD INDICATES TAPE, BVR ENTRY INDICATES DASD		
*ERR 74 volser - X RECORD INDICATES DASD, BVR ENTRY INDICATES TAPE		

Table 76. Error codes used in AUDIT reports (continued)		
Description	Audit Repair Action	Troubleshooting Hints
<p>A BVR is a BCDS backup cycle volume record subdivided into spill and day of backup cycle (daily).</p> <p>The BVR record entry does not agree with the BCDS backup volume (X) record as to whether volume <i>volser</i> is a DASD or tape volume.</p>	The BVR entry is patched to agree with the volume record.	
*ERR 75 <i>volser</i> - X RECORD INDICATES FULL, BVR ENTRY INDICATES NOT FULL		
*ERR 75 <i>volser</i> - X RECORD INDICATES NOT FULL, BVR ENTRY INDICATES FULL		
<p>A BVR is a BCDS backup cycle volume record subdivided into spill and day of backup cycle (daily).</p> <p>There is a conflict between a BVR entry and a BCDS backup volume (X) record, where the X record indicates <i>full</i> but the BVR record indicates <i>not full</i>, or vice versa.</p>	The BVR entry is patched to agree with the volume record.	
*ERR 76 <i>volser</i> - X RECORD INDICATES SINGLE-FILE TAPE, BVR IS MULTI-FILE		
*ERR 76 <i>volser</i> - X RECORD INDICATES MULTI-FILE TAPE, BVR IS SINGLE-FILE		
<p>A BVR is a BCDS backup cycle volume record subdivided into spill and day of backup cycle (daily).</p> <p>There is a conflict between a BVR entry and a BCDS backup volume (X) record, for volume <i>volser</i>: The X record indicates a multifile format whereas the BVR entry indicates a single-file format, or vice versa.</p>	The BVR entry is patched to agree with the volume record.	
*ERR 77 <i>volser</i> - X RECORD, NO BVR ENTRY		
<p>A BVR is a BCDS backup cycle volume record subdivided into spill and day of backup cycle (daily).</p> <p>A BVR entry exists for volume <i>volser</i>, but there is no BCDS backup volume (X) record for the volume, or vice versa.</p>	<p>If the BVR entry is missing, an ADDVOL command is generated for the volume, to create the missing entry.</p> <p>If the volume record is missing, the BVR entry is deleted.</p>	
*ERR 78 BVRxx EXTENSION <i>nnnn</i> MISSING		
<p>A BVR is a BCDS backup cycle volume record subdivided into spill and day of backup cycle (daily).</p> <p>In the BVR record set, the last entry indicates that there is another extension (<i>nnnn</i>), but the extension does not exist.</p>	The missing BVR extension is created.	
*ERR 79 BVRxx EXTENSION <i>nnnn</i> EXTRANEOUS		
<p>A BVR is a BCDS backup cycle volume record subdivided into spill and day of backup cycle (daily).</p> <p>There is an extraneous extension <i>nnnn</i> in the BVR record set <i>BVRxx</i>.</p>	The previous BVR extension is patched to indicate the continuation.	

Table 76. Error codes used in AUDIT reports (continued)

Description	Audit Repair Action	Troubleshooting Hints
*ERR 90 <i>volser</i> - NO V OR X RECORD		
An eligible volume (P) record indicates that volume <i>volser</i> has been backed up or dumped and is a DFSMSHsm volume, but neither a BCDS backup volume (X) record nor a MCDS migration volume (V) record exists for volume <i>volser</i> .		<p>If the P record represents a DFSMSHsm-owned volume that was backed up at some point and then deleted, the P record can be left as it is, in case you need to recover the volume.</p> <p>If the volume is not a DFSMSHsm-owned volume, you can use the FIXCDS command to reset the DFSMSHsm-owned flag in the P record.</p>
*ERR 91 <i>volser</i> - <i>vtoccopy</i> INDICATED ON <i>migvol</i>, BUT NO V RECORD		
The BCDS eligible volume (P) record for volume <i>volser</i> indicates that VTOC copy data set <i>vtoccopy</i> is on migration volume <i>migvol</i> , but no corresponding MCDS volume (V) record exists for <i>migvol</i> .	If the VTOC copy can be found on the volume, an ADDVOL command is generated for an L1 volume.	
*ERR 92 <i>volser</i> - <i>vtoccopy</i> INDICATED ON <i>backvol</i>, BUT NO X RECORD		
The BCDS eligible volume (P) record for volume <i>volser</i> indicates that VTOC copy data set <i>vtoccopy</i> is on backup volume <i>backvol</i> , but no corresponding BCDS backup volume (X) record exists for <i>backvol</i> .		If you can confirm that the VTOC copy data set still resides on the volume, then you can add the volume as a backup volume, using the ADDVOL command.
*ERR 93 <i>volser</i> - <i>vtoccopy</i> INDICATED SPANNING TO <i>backvol</i>, BUT NO X RECORD		
The BCDS eligible volume (P) record for volume <i>volser</i> indicates that VTOC copy data set <i>vtoccopy</i> spans to a second volume (<i>backvol</i>). No BCDS backup volume (X) record exists, however, for <i>backvol</i> .		The data set is probably an obsolete VTOC copy data set. If the volume indicated by qualifier “.Vvolser” has not been backed up (or dumped) since the date indicated in qualifier “.Dyyddd”, issue the BACKVOL command for the volume.
*ERR 94 <i>volser</i> - NO DGN RECORD FOR <i>generation</i>		
The BCDS eligible volume record for volume <i>volser</i> refers to dump generation <i>generation</i> , but no corresponding dump generation (G) record exists.		<p>If *ERR 103 occurs for the volume in *ERR 94, use the FIXCDS command to correct either the G record or the <i>generation</i> entry in the P record.</p> <p>If you also see an ERR 104 message referring to this generation, it will identify the dump volume that contained the missing generation.</p>
*ERR 95 <i>volser</i> - NO DVL RECORD FOR <i>dumpvol</i> IN COPY <i>n</i> OF <i>generation</i>		

Table 76. Error codes used in AUDIT reports (continued)		
Description	Audit Repair Action	Troubleshooting Hints
The BCDS eligible volume record for volume <i>volser</i> indicates one or more dump generation record keys. Dump generation copy <i>n</i> of dump generation <i>generation</i> describes a dump volume (<i>dumpvol</i>). No BCDS dump volume record exists for <i>dumpvol</i> .		You should use the ADDVOL command to identify the volume as a dump volume. If the generation contains other dump copies or if you have no need to restore data from that generation (for example, there is a later generation), no further action is needed. Otherwise, use the FIXCDS command to update the Y record for the volume, using the dump class and volume sequence data from the dump copy information in the G record.
*ERR 96 <i>volser</i> - INVALID DVL RECORD FOR <i>dumpvol</i> IN COPY <i>n</i> OF <i>generation</i>		
For volume <i>volser</i> , there is an invalid BCDS dump volume record for dump volume <i>dumpvol</i> in copy <i>n</i> . This is described in the dump generation (G) record for <i>generation</i> .		If you know (for example, from DFSMSHsm LIST output) that the volume does contain part of a dump copy for <i>generation</i> , use the FIXCDS command to turn on the valid flag in the Y record for the volume.
*ERR 97 <i>volser</i> - BAD CHAIN FROM <i>generation</i> TO <i>dumpvol</i>		
1) The dump generation (G) record for <i>generation</i> refers to dump volume <i>dumpvol</i> as holding part of a dump copy, but the dump volume (Y) record for <i>dumpvol</i> contains part of a different generation. 2) The position of dump <i>volser dumpvol</i> in the array of volumes for its dump copy in the (G) record is inconsistent with the position of the entry in the (Y) record which refers to that generation.		If you know (for example, from DFSMSHsm LIST output) that the volume does contain part of a dump copy for <i>generation</i> , use the FIXCDS command to update the Y record for the volume to refer to that generation. You may also see an *ERR 98 message for the dump volume.
*ERR 98 <i>volser</i> - BAD CHAIN FROM <i>dumpvol</i> TO <i>generation</i>		
The dump volume (Y) record for <i>dumpvol</i> indicates that the volume contains part of a dump copy in generation <i>generation</i> , but the dump generation (G) record for <i>generation</i> does not refer to volume <i>dumpvol</i> .		If you also see an *ERR 97 message referring to the volume, use the FIXCDS command to update the Y record for the volume to refer to the <i>generation</i> mentioned in the *ERR 97 message.
*ERR 99 <i>volser</i> - CLASS <i>class1</i> OF <i>dumpvol</i>, CLASS <i>class2</i> IN <i>generation</i>		
For dump generation <i>generation</i> of eligible volume <i>volser</i> , dump volume <i>dumpvol</i> is supposed to contain part of a dump copy. However, the CLASS (<i>class1</i>) listed in the BCDS dump volume record and the CLASS (<i>class2</i>) listed in the BCDS dump generation record are not the same.		Based on your knowledge from previous DFSMSHsm output of the intended dump class for the dump volume, use the FIXCDS command to correct the dump class name in either the Y record for the volume or the G record for <i>generation</i> .
*ERR 100 <i>volser</i> - BAD VOL SEQ FOR <i>dumpvol</i> IN COPY <i>n</i> OF <i>generation</i>		

Table 76. Error codes used in AUDIT reports (continued)

Description	Audit Repair Action	Troubleshooting Hints
For eligible volume <i>volser</i> , the volume sequence number for dump volume <i>dumpvol</i> in the dump volume record does not agree with the sequence number for that volume in copy <i>n</i> in the dump generation (G) record for <i>generation</i> .		Based on your knowledge from previous DFSMSHsm output of the sequence of dump volumes in the dump copy, use the FIXCDS command to correct the volume sequence field in the Y record for the volume, or the position of the volume in the dump copy's array of volumes in the G record for the generation.
*ERR 101 <i>volser</i> - <i>dumpvtoccopy</i> INDICATED ON <i>migvol</i>, BUT NO V RECORD		
A BCDS eligible record for volume <i>volser</i> exists, indicating that dump VTOC copy data set <i>dumpvtoccopy</i> should exist on migration volume <i>migvol</i> . No MCDS migration volume (V) record exists for <i>migvol</i> .	If the DUMPVTOC copy can be found on the volume, an ADDVOL command is generated for an L1 volume.	
*ERR 102 <i>volser</i> - NO P RECORD FOR <i>generation</i>		
For volume <i>volser</i> , there is a dump generation record (<i>generation</i>) that does not have a corresponding BCDS eligible volume (P) record.		If you need to restore the dumped volume from this generation, use the FIXCDS command to recreate the P record, such that it refers to the generation.
*ERR 103 <i>volser</i> - NO INDICATION OF <i>generation</i>		
For volume <i>volser</i> there is a BCDS eligible volume (P) record, but that record has no indication of generation <i>generation</i> , even though a dump generation (G) record exists for that generation.		If *ERR 94 occurs for the volume mentioned in *ERR 103, you should use the FIXCDS command to correct either the DGN record or the <i>generation</i> entry in the P record.
*ERR 104 <i>dumpvol</i> - NO DGN RECORD FOR <i>generation</i>		
The dump volume record for <i>dumpvol</i> indicates that the volume is part of a copy in dump generation <i>generation</i> , but no dump generation (G) record exists for the generation.		If you also see an *ERR 97 message referring to the volume, you should use the FIXCDS command to update the Y record for the volume to refer to the <i>generation</i> mentioned in the *ERR 97 message. If you also see an *ERR 94 message referring to this generation, it will contain the volume serial number, which make up the first 6 bytes of the DGN record key.
*ERR 105 <i>volser</i> - NO P RECORD		
For volume <i>volser</i> , there is no BCDS eligible volume (P) record.		The volume serial specified in the command may be spelled incorrectly.
*ERR 106 <i>cpname</i> - NO F (FRB) RECORD FOUND		
There is no copy pool F FRB record for <i>cpname</i> .		If <i>cpname</i> is " *NONE* ", there are no FRB records. This indicates that a fast replication backup was not created or failed. (That is, the FRBACKUP command has not been issued for the indicated copy pool or has failed.)
*ERR 110 <i>volser</i> - NO V OR X RECORD [DUMP]		

Table 76. Error codes used in AUDIT reports (continued)		
Description	Audit Repair Action	Troubleshooting Hints
For volume <i>volser</i> , there is no MCDS volume (V) record or BCDS backup volume (X) record. DUMP indicates that a dump volume (Y) record exists for <i>volser</i> .		<p>The volume serial specified in the command may be spelled incorrectly.</p> <p>If not, and the volume is identified as a different type of DFSMSHsm-owned or DFSMSHsm-managed volume, you cannot use this AUDIT option on the volume.</p> <p>If the volume serial is not misspelled and you have evidence that the volume was once known to DFSMSHsm, you need to check DFSMSHsm logs to determine why the volume was deleted.</p>
*ERR 111 <i>volser</i> - MISSING TTOC EXTENSION <i>nnnn</i>		
Volume <i>volser</i> is missing one or more TTOC extensions (<i>nnnn</i>). (Gaps exist in the sequence of extension numbers.)	The missing TTOC extension is created.	
*ERR 112 <i>volser</i> - EXTRANEIOUS TTOC EXTENSION <i>nnnn</i>		
For volume <i>volser</i> , TTOC extension <i>nnnn</i> is extraneous.	The extraneous TTOC extension is deleted.	
*ERR 113 <i>volser</i> TTOC EXT. <i>nnnn</i> - NO {A D} RECORD FOR <i>ttocdsn</i>		
<p>In TTOC extension <i>nnnn</i> for volume <i>volser</i>, the data set entry for <i>ttocdsn</i> is flagged to indicate a valid copy, but one of the following conditions exists:</p> <ul style="list-style-type: none"> No MCDS data set (D) record or MCDS alias entry (A) record exists for <i>ttocdsn</i>. An MCDS alias entry (A) record exists for <i>ttocdsn</i> but the MCDS data set (D) record referred to does not. 	<p>An MCDS data set (D) record is created for the TTOC entry.</p> <p>Note: If a (D) record was not created for data set <i>ttocdsn</i>, this tape begins with a partial data set. To have a (D) record properly created and built for this data set, you need to run AUDIT MEDIACONTROLS against the tape volume <i>volser</i>.</p>	
*ERR 114 <i>volser</i> - TTOC EXT. <i>nnnn</i> - <i>ttocdsn</i> HAS 'A' REC		
In TTOC extension <i>nnnn</i> for volume <i>volser</i> , the data set entry for <i>ttocdsn</i> does not indicate a valid copy, but an MCDS alias entry (A) record exists for <i>ttocdsn</i> .	<p>If there is no corresponding D record, the alias (A) record for the TTOC entry is deleted.</p> <p>If the corresponding D record is no longer valid and the catalog does <i>not</i> indicate the data set is migrated, the alias (A) record for the TTOC entry is deleted.</p> <p>If the corresponding D record is valid and indicates a migration copy at the current location, the TTOC entry is flagged valid.</p>	
*ERR 115 <i>volser</i> - TTOC EXT. <i>nnnn</i> - <i>ttocdsn</i> IS MIGRATION COPY		

Table 76. Error codes used in AUDIT reports (continued)

Description	Audit Repair Action	Troubleshooting Hints
Volume <i>volser</i> with TTOC extension <i>nnnn</i> indicates that <i>ttocdsn</i> is a valid migration copy. The catalog indicates that the data set is migrated. The corresponding MCDS data set (D) record indicates a different migration volume from volume <i>volser</i> , but that volume (according to its TTOC, for a tape volume, or its VTOC, for a DASD volume) does not contain the migration copy.	The MCDS data set (D) record is updated to refer to this TTOC entry.	
*ERR 116 <i>volser</i> - TTOC EXT. <i>nnnn</i> - <i>ttocdsn</i> HAS INVALID C RECORD		
In TTOC extension <i>nnnn</i> for volume <i>volser</i> , the data set entry for <i>ttocdsn</i> does not indicate a valid copy, but a BCDS backup version (C) record exists for <i>ttocdsn</i> .		
*ERR 116 <i>volser</i> - TTOC EXT. <i>nnnn</i> - <i>ttocdsn</i> HAS INVALID C RECORD (continued)		
In TTOC extension <i>nnnn</i> for volume <i>volser</i> , the data set entry for <i>ttocdsn</i> is flagged as a valid copy, and a BCDS backup version (C) record exists for <i>ttocdsn</i> , but a corresponding BCDS data set record does not exist, or does not refer to that version.	All associated backup version records are deleted from DFSMSHsm's control dataset, and the TTOC entry is patched invalid.	
*ERR 117 <i>volser</i> - TTOC EXT. <i>nnnn</i> - NO P RECORD FOR <i>vtoccopy</i>		
*ERR 117 <i>volser</i> - TTOC EXT. <i>nnnn</i> - NO P RECORD FOR <i>vcatcopy</i>		
For volume <i>volser</i> with TTOC extension <i>nnnn</i> , no BCDS eligible volume (P) record exists for VTOC copy data set <i>vtoccopy</i> or <i>vcatcopy</i> .		The data set is probably an obsolete VTOC (or VCAT) copy data set created when the volume indicated in the qualifier ".Vvolser" was backed up. Because no P record now exists for that volume, or if you need the backup, you should issue the BACKVOL command for the volume to create a backup and to regenerate the P record.
*ERR 118 <i>volser</i> - TTOC EXT. <i>nnnn</i> - <i>vtoccopy</i> NOT IN P RECORD FOR <i>srcvol</i>		
*ERR 118 <i>volser</i> - TTOC EXT. <i>nnnn</i> - <i>vcatcopy</i> NOT IN P RECORD FOR <i>srcvol</i>		
For volume <i>volser</i> , TTOC extension <i>nnnn</i> indicates a VTOC copy (<i>vtoccopy</i>) or a VCAT copy (<i>vcatcopy</i>), but <i>vtoccopy</i> or <i>vcatcopy</i> is not referred to in the corresponding BCDS eligible volume (P) record for <i>srcvol</i> .	The current TTOC entry is patched invalid.	
*ERR 119 <i>volser</i> - NO PREDECESSOR TTOC FOR <i>prevol</i>		
The TTOC for volume <i>volser</i> indicates that the first data set (migration copy or backup version) on the tape volume is continued (spans) from volume <i>prevol</i> . However, no corresponding (migration or backup) TTOC base record exists for tape volume <i>prevol</i> .		
*ERR 120 <i>volser</i> - NOT A SUCCESSOR FROM TTOC FOR <i>prevol</i>		

Table 76. Error codes used in AUDIT reports (continued)		
Description	Audit Repair Action	Troubleshooting Hints
The TTOC for volume <i>volser</i> indicates that the first data set (migration copy or backup version) on the tape volume is continued (spans) from volume <i>prevol</i> . The TTOC, however, for <i>prevol</i> does not indicate volume <i>volser</i> as a successor.		
*ERR 121 <i>volser</i> - <i>ttocdsn</i> NOT SPANNED FROM TTOC FOR <i>prevol</i>		
The TTOC for volume <i>volser</i> indicates that the first data set (<i>ttocdsn</i>) on the tape volume is continued (spans) from the volume <i>prevol</i> , and the TTOC for <i>prevol</i> indicates <i>volser</i> as a successor volume; but the last TTOC entry for volume <i>prevol</i> has a different data set name from the first TTOC entry for the current volume <i>volser</i> .		
*ERR 122 <i>volser</i> - NO SUCCESSOR TTOC FOR <i>sucvol</i>		
The TTOC for volume <i>volser</i> indicates that the last data set on the tape volume continues on (spans to) volume <i>sucvol</i> . There is, however, no corresponding (migration or backup) TTOC base record for tape volume <i>sucvol</i> .		
*ERR 123 <i>volser</i> - NOT A PREDECESSOR TO TTOC FOR <i>sucvol</i>		
The TTOC for volume <i>volser</i> indicates that the last data set (migration copy or backup version) on the tape volume continues on (spans to) volume <i>sucvol</i> . The TTOC, however, for <i>sucvol</i> does not indicate volume <i>volser</i> as a predecessor.		
*ERR 124 <i>volser</i> - <i>ttocdsn</i> NOT SPANNED TO TTOC FOR <i>sucvol</i>		
The TTOC for volume <i>volser</i> indicates that the last data set (<i>ttocdsn</i>) on the tape volume continues on (spans to) volume <i>sucvol</i> . A TTOC record set exists for volume <i>sucvol</i> , and it indicates <i>volser</i> as a predecessor volume; but the first TTOC entry for volume <i>sucvol</i> has a different data set name from the last TTOC entry for the current volume <i>volser</i> .		
*ERR 125 <i>volser1</i> SPANS {TO FROM} <i>volser2</i>, BUT <i>ttcdsn</i> THAT SPANNED IS NO LONGER VALID		
<i>volser1</i> is the volume being audited. If TO is the insert, <i>volser2</i> is the successor volume and the last data set (<i>ttcdsn</i>) on <i>volser1</i> continues on (spans to) <i>volser2</i> . If FROM is the insert, <i>volser2</i> is the predecessor volume and the first data set on <i>volser1</i> spans from <i>volser2</i> . The TTOC for <i>volser1</i> indicates that <i>volser2</i> is also needed for <i>ttcdsn</i> , but this is incorrect since <i>ttcdsn</i> is no longer valid.	If a TTOC exists for <i>volser2</i> and it indicates a data set spans to or from <i>volser1</i> and the spanning data set names are the same on both TTOCs, the TTOC for <i>volser2</i> is corrected by patching the appropriate field, TTCSUCVL or TTCPREVL, to blanks. The TTOC for <i>volser1</i> is corrected by patching the appropriate field, TTCSUCVL or TTCPREVL, to blanks.	
*ERR 130 <i>volser</i> - NOT SINGLE-FILE-FORMAT 3480 TAPE VOLUME		

Table 76. Error codes used in AUDIT reports (continued)

Description	Audit Repair Action	Troubleshooting Hints
For volume <i>volser</i> , either a MCDS volume record or a BCDS backup volume record exists, but does not indicate a cartridge type tape written in single-file format.		The MEDIACONTROLS option cannot be used with this volume, because the volume is not written in single-file format.
*ERR 131 <i>volser</i> - CANNOT BE MOUNTED.		
For volume <i>volser</i> , either a MCDS volume record or a BCDS backup volume record exists, but the volume cannot be allocated or mounted.		The volume cannot be mounted, or the operator has chosen not to mount the tape volume. Determine that the volume is accessible to your operator before reissuing this AUDIT command for this volume.
*ERR 132 <i>volser</i> - <i>userdsn</i> NO LONGER MIGRATED		
A migration copy of <i>userdsn</i> exists on migration volume <i>volser</i> , but no catalog entry exists for <i>userdsn</i> , or the catalog indicates that <i>userdsn</i> is on a level-0 volume.	<p>If there is no MCDS data set (D) record and the current TTOC entry is flagged valid, the TTOC entry is patched invalid, and an existing alias (A) record is deleted;</p> <p>If a data set (D) record refers to the current copy on this tape, the TTOC entry is patched valid until the problem can be resolved;</p> <p>If the D record refers to another copy and the current TTOC entry is flagged valid, the TTOC entry is patched invalid.</p>	
*ERR 133 <i>volser</i> - <i>userdsn</i> (MIGRATED) NEEDS VALID D RECORD		
For volume <i>volser</i> , the catalog indicates that user data set name <i>userdsn</i> is migrated (<i>volser</i> is MIGRAT), but the MCDS data set (D) record either does not exist or is not flagged as valid.	The current TTOC entry is patched valid. A valid MCDS data set (D) record and (if needed) an alias (A) record are created.	If the data set in question is a VSAM component, see ERR 169 for additional diagnostic data and handling. If Audit rebuilt the MCD record for a VSAM data set and used the data component name for the key, further action is required to change the key to the cluster name. See ERR 169 for details and instructions.
*ERR 134 <i>volser</i> - CANNOT IDENTIFY ANY DFSMSHsm DATA SET		
The MCDS volume (V) record indicates that volume <i>volser</i> is a migration volume, but there is no common data set descriptor (CDD) record found on the tape, thus no DFSMSHsm migration copy or backup version can be identified.	The first data set TTOC entry is patched invalid.	
*ERR 135 <i>volser</i> - TTOC ENTRY FOR <i>ttocdsn</i> - BLOCK COUNT SHOULD BE <i>nnnn</i>		
In volume <i>volser</i> , the block count indicated for TTOC entry <i>ttocdsn</i> does not agree with the actual block count. The TTOC block count should be <i>nnnn</i> .	The TTOC entry is patched with the correct block count.	
*ERR 136 <i>volser</i> - TTOC ENTRY FOR <i>ttocdsn</i> - SHOULD BE VALID		

Table 76. Error codes used in AUDIT reports (continued)		
Description	Audit Repair Action	Troubleshooting Hints
For volume <i>volser</i> , both the MCDS data set (D) record and the catalog indicate that the TTOC entry for <i>ttocdsn</i> should be flagged as valid, but it is flagged as invalid.	The TTOC entry is patched valid, and (if needed) an alias (A) record is created.	
*ERR 137 <i>volser</i> - TTOC BASE NEEDS VALID-BLOCK COUNT <i>nnnn</i>		
For volume <i>volser</i> , a block count discrepancy exists between the number of blocks of valid data and the count of valid blocks in the TTOC base record. The TTOC base record needs to be updated with the valid block count of <i>nnnn</i> .	The base TTOC is patched with the valid block count.	
*ERR 138 <i>volser</i> - TTOC BASE NEEDS TOTAL-BLOCK COUNT <i>nnnn</i>		
For volume <i>volser</i> , a block count discrepancy exists between the number of blocks of data and the count of blocks in the TTOC base record. The TTOC base record needs to be updated with the block count of <i>nnnn</i> .	The base TTOC is patched with the total block count.	
*ERR 140 <i>migvol</i> - <i>userdsn</i> HAS NO ALIAS RECORD		
*ERR 140 <i>migvol</i> - <i>cdddsn</i> HAS NO ALIAS RECORD		
For migration volume <i>migvol</i> , no MCDS alias entry (A) record exists for one of the following conditions: <ul style="list-style-type: none"> • Data set name <i>userdsn</i> in the VTOC has the form of a DFSMSHsm-generated migration copy name. • Data set name <i>cdddsn</i>, in what appears to be a common data set descriptor (CDD) record, indicates a migration copy. (The catalog entry for <i>cdddsn</i> indicates volume serial MIGRAT; an MCDS data set (D) record for <i>cdddsn</i> refers to an alias (A) record for the migration copy.) 	An alias (A) record is created, referring to this migration copy.	
*ERR 141 <i>migvol</i> - SCRATCHED EMPTY DATA SET {<i>migdsn</i> <i>version</i>}		
For migration volume <i>migvol</i> , migration copy <i>migdsn</i> or backup version <i>version</i> is empty.	The empty data set is scratched and uncataloged.	
*ERR 142 <i>migvol</i> - <i>version</i> HAS NO C RECORD		

Table 76. Error codes used in AUDIT reports (continued)

Description	Audit Repair Action	Troubleshooting Hints
<p>For migration volume <i>migvol</i>, one of the following conditions exists for the data set named <i>version</i> in the VTOC:</p> <ul style="list-style-type: none"> The name has the form of a DFSMSHsm-generated backup version name, but no corresponding BCDS backup version (C) record exists. The first record of data set <i>version</i> appears to be a common data set descriptor (CDD) record, but the index of versions in the B record does not refer to <i>version</i>. 	The data set is scratched.	
*ERR 143 <i>migvol</i> - NO P RECORD FOR <i>srcvol</i> OF <i>vtoccopy</i>		
*ERR 143 <i>migvol</i> - NO P RECORD FOR <i>srcvol</i> OF <i>vcacopy</i>		
Migration volume <i>migvol</i> contains either the VTOC copy <i>vtoccopy</i> or the VCAT copy <i>vcacopy</i> made during a backup of volume <i>srcvol</i> . However, no BCDS eligible volume (P) record exists for source volume <i>srcvol</i> .	The copy data set is scratched and uncataloged.	
*ERR 144 <i>migvol</i> - <i>vtoccopy</i> NOT IN P RECORD FOR <i>srcvol</i>		
*ERR 144 <i>migvol</i> - <i>vcacopy</i> NOT IN P RECORD FOR <i>srcvol</i>		
Migration volume <i>migvol</i> contains either the VTOC copy <i>vtoccopy</i> or the VCAT copy <i>vcacopy</i> made during a backup of volume <i>srcvol</i> . The BCDS eligible volume (P) record does not refer to either <i>vtoccopy</i> or <i>vcacopy</i> .	The copy data set is scratched and uncataloged.	
*ERR 145 <i>migvol</i> - NO P RECORD FOR <i>srcvol</i> OF <i>dumpvtoccopy</i>		
Migration volume <i>migvol</i> contains the dump VTOC copy <i>dumpvtoccopy</i> made during a volume dump of <i>srcvol</i> . However, no BCDS eligible volume (P) record exists for source volume <i>srcvol</i> .	The copy data set is scratched and uncataloged.	
*ERR 146 <i>migvol</i> - <i>dumpvtoccopy</i> NOT IN ANY DGN RECORD FOR <i>srcvol</i>		
Migration volume <i>migvol</i> contains the dump VTOC copy <i>dumpvtoccopy</i> made during a volume dump of <i>srcvol</i> . However, no dump generation record (DGN) exists that refers to <i>dumpvtoccopy</i> .	The copy data set is scratched and uncataloged.	
*ERR 147 <i>migvol</i> - <i>userdsn</i> NEEDS D RECORD		
<p>User data set <i>userdsn</i> is on migration volume <i>migvol</i>. The catalog indicates that this data set is migrated. The MCDS data set (D) record for <i>userdsn</i> is either missing or indicates some other migration volume, but the VTOC or TTOC for that other migration volume does not refer to <i>userdsn</i>.</p> <p>The <i>userdsn</i> is not recognized as a DFSMSHsm-generated name.</p>	The D record is created, or patched, to refer to the copy on the migration volume being audited.	

Table 76. Error codes used in AUDIT reports (continued)

Description	Audit Repair Action	Troubleshooting Hints
*ERR 148 migvol - userdsn MAY BE OLD MIGRATION COPY		
An MCD record was found for the migrated data set on the volume, or in the SDSP data set being processed. The catalog indicates that this data set is migrated. A discrepancy was found between the MCD record and the volume being audited.		<p>For AUDIT MEDIACONTROLS(SDSP) VOLUME(volser):</p> <p>If the MCD record indicates this data set is on tape, the AUDIT output will recommend AUDIT MEDIACONTROLS VOLUME(<i>tapevolser</i>).</p> <p>If the data set is determined to be properly migrated to tape and you want the SDSP entry removed to prevent further ERR148s, then</p> <ol style="list-style-type: none"> 1. Recall the migrated copy from the tape volume. 2. Create an MCD record for the data set in the SDSP as follows: <pre>FIXCDS D userdsn ADDMIG(sdspvol)</pre> <p>Note: If the MCD create fails due to an already existing MCD record, delete the existing MCD record and create a new MCD record for the SDSP data set as suggested. The command to delete the MCD record is:</p> <pre>FIXCDS D userdsn DELETE</pre> <ol style="list-style-type: none"> 3. Delete the MCD entry from the MCDS and remove the entry from the SDSP by issuing the following command: <pre>HSEND DELETE userdsn</pre> <p>The MCD record indicates it is not in an SDSP data set, and the issuance of an OBTAIN for the data set on the volume indicated in the MCD record resulted in "volume not mounted".</p> <p>The MCD record indicates an SDSP data set, but the volume indicated in the MCD record does not match the volume being audited. The volume indicated in the MCD record cannot be checked because we could not allocate the SDSP data set on that volume, or the volume was not mounted.</p>
*ERR 148 migvol - userdsn MAY BE OLD MIGRATION COPY (continued)		

Table 76. Error codes used in AUDIT reports (continued)

Description	Audit Repair Action	Troubleshooting Hints
An MCD record was found for the migrated data set on the volume, or in the SDSP data set being processed. The catalog indicates that this data set is migrated. A discrepancy was found between the MCD record and the volume being audited.		<p>For AUDIT DIRECTORYCONTROLS VOLUMES(<i>dasdvol</i>), the MCD record indicates the migration copy was created before HSM Release 3, and</p> <ul style="list-style-type: none"> The MCD record indicates the data set is in an SDSP data set. However, AUDIT found the migrated data set on the DASD volume being audited. AUDIT will recommend running AUDIT MEDIACONTROLS(SDSP) VOLUMES(<i>sdspvol</i>) to assist in diagnosing the error. The MCD record says it is on a DASD volume other than the one currently being audited. AUDIT tried to OBTAIN the data set from that other volume, but the volume was not mounted. AUDIT will recommend AUDIT MEDIACONTROLS VOLUMES(<i>volser</i>) of the volume indicated in the MCD record.
*ERR 149 <i>migvol</i> - <i>migdsn</i> IS OLD MIGRATION COPY		
<p>User data set <i>migdsn</i> is on migration volume <i>migvol</i>. The catalog indicates that <i>migdsn</i> is migrated. The MCDS data set (D) record for <i>migdsn</i> refers to a migration copy on a different volume. The VTOC or TTOC for that other migration volume indicates that a migration copy of <i>migdsn</i> does exist on that volume.</p> <p>The <i>migdsn</i> is not recognized as a DFSMSHsm-generated name.</p>	The data set is scratched. If an alias (A) record exists, it is deleted.	
*ERR 150 <i>migvol</i> - <i>version</i> HAS NO CDD RECORD		
On migration volume <i>migvol</i> , the first record in (what appears to be, by its name) migration copy <i>migdsn</i> or in (what appears to be, by its name) backup version <i>version</i> , cannot be identified as a common data set descriptor (CDD) record.		<p>The data set, if named like a DFSMSHsm backup version, may nevertheless not be a DFSMSHsm data set. If it is not, and because the data set is on a migration volume, not a backup volume, there should be no problem.</p> <p>If the data set is a backup version, it is not possible to recover it without a CDD as the first record, and there is no point in having DFSMSHsm move the version to a backup volume.</p> <ul style="list-style-type: none"> If no C record exists, the version can be scratched from the volume. If a C record exists for the version, issue the BDELETE command to delete the version.
*ERR 151 <i>migvol</i> - <i>cdddsn</i> NOT CATALOGED, HAS COPY <i>migdsn</i>		

Table 76. Error codes used in AUDIT reports (continued)		
Description	Audit Repair Action	Troubleshooting Hints
On migration volume <i>migvol</i> , the first record in (what appears to be, by its name) migration copy <i>migdsn</i> appears to be a common data set descriptor (CDD) record created from data set <i>cdddsn</i> . There is, however, no catalog entry for <i>cdddsn</i> .	The MCDS data set (D) record is patched as invalid, and patched to indicate that the migration copy is to be scratched. The record will automatically be cleaned up the next time DFSMSHsm migration runs (secondary space management processing).	
*ERR 152 <i>migvol</i> - <i>cdddsn</i> NOT MIGRATED, HAS COPY <i>migdsn</i>		
On migration volume <i>migvol</i> , the first record in (what appears to be, by its name) migration copy <i>migdsn</i> appears to be a Common Data set Descriptor (CDD) record created from data set <i>cdddsn</i> . The catalog entry, however, for <i>cdddsn</i> indicates that the data set is not migrated.	The MCDS data set (D) record is patched as invalid, and patched to indicate that the migration copy is to be scratched. The record will automatically be cleaned up the next time DFSMSHsm migration runs (secondary space management processing).	
*ERR 160 <i>migvol</i> - DOES NOT HAVE SDSP DATA SET		
For migration volume <i>migvol</i> , no SDSP data set listed in the VTOC exists. The name of such a data set must be <i>uid.SMALLDS.Vmigvol</i> , where <i>uid</i> is the authorized userid for the current startup of DFSMSHsm.		The volume serial specified in the command may be spelled incorrectly. If not, your installation may have changed the UID value in the DFSMSHsm startup procedure since the SDSP data set on the volume was created. You may need to rename the data set, changing the first qualifier to the current UID value.
*ERR 161 <i>migvol</i> - <i>userdsn</i> NOT CATALOGED, HAS {VALID INVALID} COPY IN SDSP		
The small data set packing (SDSP) data set on migration volume <i>migvol</i> contains a migration copy of <i>userdsn</i> , but that data set is not cataloged. The message text indicates whether the data set appears to be valid or invalid.	<p>If there is no data set (D) record, and no catalog entry, the migration copy is deleted (internally) from the SDSP.</p> <p>If there is a D record, but no catalog entry, and the copy has gaps in its records, the migration copy is deleted (internally) from the SDSP, and the D record is patched invalid.</p> <p>If the D record identifies the migration copy as valid (that is, recalled) and the data set is not cataloged, and the D record does not indicate that the migration copy needs to be scratched, a FIXCDS PATCH command is generated by AUDIT to turn on the “needs scratch” indicator.</p>	<p>If there is a D record, but no catalog entry, and the D record appears to represent a valid migration copy, you should determine one of the following:</p> <ul style="list-style-type: none"> • If the data set is invalid and you want it deleted, you should issue an HSEND DELETE command, to have associated records deleted and have the data set removed from the SDSP. Following is an example of the HSEND DELETE command: <div style="background-color: #f0f0f0; padding: 10px; margin: 10px 0;"> <pre>HSEND DELETE userdsn</pre> </div> • If the data set is valid, you should catalog it to a volume serial of ‘MIGRAT’.
*ERR 162 <i>migvol</i> - <i>userdsn</i> NOT MIGRATED, HAS COPY IN SDSP		

Table 76. Error codes used in AUDIT reports (continued)

Description	Audit Repair Action	Troubleshooting Hints
The small data set packing (SDSP) data set on migration volume <i>migvol</i> contains a migration copy of <i>userdsn</i> , but the catalog entry for that data set indicates that the data set is not migrated.	<p>If there is no data set (D) record, the migration copy is deleted (internally) from the SDSP.</p> <p>If there is a D record, but the catalog does not indicate MIGRAT, and the copy has gaps in its records, the migration copy is deleted (internally) from the SDSP, and the D record is patched invalid.</p> <p>If there is a D record, but the catalog does not indicate MIGRAT, and there are no record gaps in the copy, and the D record is flagged other than “invalid, needs scratch,” the D record is patched as invalid, and patched to indicate that the migration copy be scratched.</p>	
*ERR 163 migvol - userdsn MISSING ONE OR MORE RECORDS IN SDSP		
The small data set packing (SDSP) data set on migration volume <i>migvol</i> contains a migration copy of <i>userdsn</i> , but the migration copy is missing one or more records.		<p>If the data set is no longer needed, you can issue a DELETE command for the data set.</p> <p>If you can recall the data set successfully, then the record gap is not significant.</p> <p>If the data set cannot be recalled successfully, but a backup copy exists, then delete the data set (to remove the catalog entry and D record), and issue the RECOVER command for the data set.</p>
*ERR 164 TTOC FOR VOLUME <i>volser</i> INDICATES IN-STORAGE RECORDS EXIST		
The TTOC for the tape volume indicates that in storage records existed that may not have been written to the OCDS on DASD. After this AUDIT has completed, all data sets on the tape will have entries in the existing TTOC record for this volume.	The TTCFAIST bit in the base TTOC is patched off.	
*ERR 165 NO DATA FILES ARE INDICATED FOR ABR RECORD KEY = <i>abrrecordkey</i>		
The ABR record with key <i>abrrecordkey</i> indicates that neither a DFSMSdss data file nor an internal data file is included with the aggregate backup.		The ABR record specified is invalid and should be deleted.
*ERR 166 ABARSCONTROLS SPECIFIED USING AGGREGATE GROUP = <i>aggrouppname</i>. A MATCHING AGGREGATE GROUP NAME COULD NOT BE FOUND IN THE BCDS.		
The aggregate group name specified with the AUDIT command has no ABR records (has not been backed up).		Aggregate group name <i>agname</i> was probably spelled incorrectly.
*ERR 167 ABARSCONTROLS SPECIFIED, BUT NO ABR RECORDS WERE FOUND IN THE BCDS.		
The BCDS has no record of aggregate backup activity.		No ABR records exist, therefore no aggregate backups have successfully completed.
*ERR 168 [CONTROL DFSMSdss DATA INTERNAL DATA INSTRUCTION/ACTIVITY LOG] FILE NAME = <i>filename</i>, INDICATED IN THE ABR RECORD, BUT IS NOT CATALOGED. ABR RECORD KEY = <i>abrrecordkey</i>		

Table 76. Error codes used in AUDIT reports (continued)		
Description	Audit Repair Action	Troubleshooting Hints
The aggregate group backup refers to a particular file, but the file cannot be found in the catalog.		You should catalog the file indicated by <i>filename</i> .
*ERR 169 MCD RECORD CREATED FOR VSAM DATA SET <i>dsname</i> NEEDS NEW KEY		
In diagnosing error 133 for a migrated VSAM data set, AUDIT cannot determine its base cluster name and has used data component name <i>dsname</i> to recreate the MCDS data set record.		<p>You need to determine the base cluster name of the VSAM data set, and issue a FIXCDS command to change the key of the MCD record:</p> <pre>FIXCDS D <i>dsname</i> NEWKEY(<i>base cluster_name</i>)</pre> <p>Then, if AUDIT re-created an alias (A) record, you can either</p> <ul style="list-style-type: none"> recall and remigrate the VSAM data set; or issue a FIXCDS command to patch the alias record: <p>where <i>generated_name</i> can be found in the AUDIT output that created the alias record, or at offset X'9C' (field MCDMCANM) in the MCD record.</p> <pre>FIXCDS A <i>generated_name</i> PATCH(X'4'<i>base cluster_name</i>)</pre>
*ERR 170 SPECIFIED COPY POOL <i>cpname</i> DOES NOT EXIST		
*ERR 171 F RECORD INDICATES <i>x</i> {DUMP TOTAL DASD SMS SPECIFIED} VERSIONS, ONLY <i>y</i> VERSIONS WERE FOUND		
Number of (FRD) Dump Version records found is not equal to the number of dumped versions indicated in the (FRB) copy pool record.		<ul style="list-style-type: none"> If DUMP, the number of (FRD) Dump Version records found is not equal to the number of dumped versions indicated in the (FRB) copy pool record. If TOTAL, the number of versions found is not equal to the number of versions indicated in the FRB record. If DASD, the number of all DASD versions found is not equal to the number indicated in the FRB record. If SMS SPECIFIED, the number of non-rolloff versions found is not equal to the number indicated in the FRB record.
*ERR 172 H RECORD INDICATES <i>x</i> DASD VERSIONS, ONLY <i>y</i> VERSIONS WERE FOUND		
*ERR 173 COPY POOL <i>cpname</i> F RECORD INDICATES <i>x</i> H RECORDS FOR VERSION <i>z</i>, ONLY <i>y</i> RECORDS WERE FOUND		
(FRB) Copy pool record field and the number of (FRVP) volume pair records found do not match.		This error may be resolved by other audit discoveries. Some audit actions delete FRVP records which may result in these counts be correct.
*ERR 174 COPY POOL <i>cpname</i> F RECORD WAS NOT FOUND, ORPHANED H RECORDS EXIST		

Table 76. Error codes used in AUDIT reports (continued)		
Description	Audit Repair Action	Troubleshooting Hints
A volume pair record has been found, but the copy pool record to which it belongs does not exist.	The volume pair record is deleted. Note: Repair actions are only performed when FIX is specified on the audit command.	Error only found when no <i>cpname</i> was specified on the AUDIT COPYPOOLCONTROLS command.
*ERR 175 H (FRVP) RECORD INDICATES IT IS A 'PREPARE' RECORD, THE CORRESPONDING F (FRB) RECORD DOES NOT		
		<ul style="list-style-type: none"> You need to determine which indicator is correct. Use the FIXCDS PATCH command to correct the problem. You can use the LIST COPYPOOL command to help you determine which indicator is correct. Either the 'Prepare' flag should be on in the F (FRB) record or the FRVP records are orphan entries and should be deleted using the FIXCDS DELETE command.
*ERR 176 H RECORD FOR VERSION <i>x</i> EXISTS, BUT VERSION CANNOT BE FOUND IN CORRESPONDING F RECORD FOR COPY POOL <i>cpname</i>		
The copy pool record for this volume pair record does not contain a corresponding version entry.	The volume pair record is deleted. Note: Repair actions are only performed when FIX is specified on the audit command.	This volume pair record is not needed. This error is only detected when no <i>cpname</i> is specified on the AUDIT COPYPOOLCONTROLS command.
*ERR 177 I (FRTV) RECORD WAS EXPECTED FOR VOLUME <i>volser</i> AND WAS NOT FOUND		
A F (FRB) record indicates this is a valid version. The volume represented by this FRTV record needs to be made available and an FRTV record should be created to represent it or the fast replication backup of this copy pool will fail.		The FIXCDS CREATE command can be used to recreate the FRTV record.
*ERR 178 I (FRTV) RECORD FOR TARGET VOLUME <i>targetvolser</i>, EXPECTS FRSV (J) RECORD FOR SOURCE VOLUME <i>sourcevolser</i>, WHICH WAS NOT FOUND		
		<p>AUDIT has detected that the FRSV (J) record for source volume <i>sourcevolser</i> does not exist. This record should exist unless this version is a PREPARED version.</p> <p>Note: The ERR178 may be incorrectly issued when the copy pool name is not specified on the AUDIT command. Use the LIST COPYPOOL(<i>cpname</i>) ALLVOLS(ALLVERS) command to identify which copy pool these target volumes belong to. Then reissue the AUDIT COPYPOOLCONTROLS(<i>cpname</i>) command, specifying the copy pool name the <i>sourcevolser</i> and <i>targetvolser</i> belong to.</p> <p>If the ERR178 message is persistent, record errors exist.</p>

Table 76. Error codes used in AUDIT reports (continued)		
Description	Audit Repair Action	Troubleshooting Hints
*ERR 179 <i>cpname</i> VERSION <i>versionnumber</i>, H RECORD HAS WRONG TARGET VOLUME <i>targetvolser</i>, OR I RECORD HAS WRONG SOURCE VOLUME <i>sourcevolser</i>		
		<p>Determine which record is incorrect and correct the record using the FIXCDS PATCH command.</p> <p>Then use the FRDELETE command to delete the copy pool version (<i>cpname</i>) identified in the message.</p> <p>Example: FRDELETE COPYPOOL(<i>cpname</i>) ALL BOTH</p>
*ERR 180 J RECORD NOT FOUND FOR VOLUME <i>volser</i>, IT BELONGS TO COPY POOL <i>cpname</i>, VER= <i>vernum</i>		
A volume pairs record was found indicating source volume <i>volser</i> , but the source volume record does not exist.		This error will be issued if the source volume has been removed from the copy pool, and a successful FRBACKUP has taken place since its removal.
*ERR 181 F (FRB) RECORD FOR <i>cpname</i> NOT FOUND, POSSIBLY ORPHANED J (FRSV) RECORD FOR VOLUME <i>volser</i>		
		<ul style="list-style-type: none"> Remove <i>cpname</i> from the FRSV <i>cpname</i> array. If there are no <i>cpnames</i> left in the array, delete the FRSV record for VOLUME <i>volser</i>.
*ERR 182 NO P (MCP) RECORD FOUND FOR VOLUME <i>volser</i>, IS THIS AN ERROR?		
*ERR 183 VOLUME <i>volser</i> FROM THE J (FRSV) RECORD L0 FIELD COULD NOT BE FOUND IN A CORRESPONDING H (FRVP) RECORD		
		H (FRVP) record was not found or <i>volser</i> was not found in the corresponding H (FRVP) records.
*ERR 184 ORPHANED J RECORD DETECTED FOR VOLUME <i>srcvol</i>		
No <i>cpname</i> copy pool record (FRB) was found for any cypool this source volume belongs to. A source volume can belong to many copy pools.	<p>The FRSV source volume record is deleted.</p> <p>Note: Repair actions are only performed when FIX is specified on the audit command.</p>	Previously issued ERR181 message(s) may be help to identify the copy pool name this record was known to have belonged to. This error is only detected when no <i>cpname</i> is specified on the AUDIT COPYPOOLCONTROLS command.
*ERR 185 COPY POOL <i>cpname</i> COULD NOT BE FOUND IN THE J (FRSV) RECORD COPY POOL ARRAY FOR VOLUME <i>volser</i>		
		You need to use the FIXCDS PATCH command to patch the FRSV record with the <i>cpname</i> , or if the FRSV record contains no other copy pool names, deleted it with the FIXCDS DELETE command.
*ERR 186 ORPHANED K RECORD FOUND, COPY POOL <i>cpname</i> NO LONGER EXISTS		
The copy pool record for this copy pool dump record does not exist. This record is no longer needed.	<p>The FRD copy pool dump record is deleted.</p> <p>Note: Repair actions are only performed when FIX is specified on the audit command.</p>	This error is only detected when no <i>cpname</i> is specified on the AUDIT COPYPOOLCONTROLS command.

Table 76. Error codes used in AUDIT reports (continued)

Description	Audit Repair Action	Troubleshooting Hints
*ERR 187 K RECORD EXISTS, COPY POOL <i>cpname</i> F RECORD INDICATES NO DUMP COPY		
The FRB copy pool record indicates there is no dump copy for this copy pool version. An FRD copy pool dump version record exists for this version.	The corresponding version entry in the FRB copy pool record is patched to indicate the dump version exists. Note: Repair actions are only performed when FIX is specified on the audit command.	This error is only detected when no <i>cpname</i> is specified on the AUDIT COPYPOOLCONTROLS command.
*ERR 188 K (FRD) RECORD NOT FOUND, F (FRB) RECORD FOR COPY POOL <i>cpname</i> INDICATES THAT IT DOES EXIST		
The FRB record indicates a dump for this copy pool exists, but the record representing the dump cannot be found.		
*ERR 189 H (FRVP) RECORD NOT FOUND COPY POOL <i>cpname</i>		
During the AUDIT VOLUMECONTROLS (RECOVERABLE), an error was detected.		You should consider running AUDIT COPYPOOLCONTROLS (<i>cpname</i>) to learn more regarding this discrepancy.
*ERR 190 VOLUME <i>volser</i> COULD NOT BE FOUND IN ANY ASSOCIATED H (FRVP) RECORD FOR COPY POOL <i>cpname</i>		
		You should consider running AUDIT COPYPOOLCONTROLS (<i>cpname</i>) to learn more regarding this discrepancy.
*ERR 191 P RECORD FOUND FOR VOLUME <i>volser</i>, IS NOT INDICATED AS A COPY POOL VOLUME		
*ERR 192 F RECORD FOUND FOR COPYPOOL <i>cpname</i>, WHICH VOLUME <i>volser</i> BELONGS TO		
If detected during AUDIT VOLCTL(RECOVERABLE), this is detected and flagged so that you can confirm that the source volume described is recoverable.	If detected during AUDIT VOLCTL(RECOVERABLE) FIX, the fix is to build the proper AUDIT COPYPOOLCONTROLS command and execute to confirm that the volume referenced is in a recoverable state. AUDIT does not issue any patch commands to correct any records. Its intent is to allow you the opportunity to confirm that this volume is a valid recoverable volume.	Audit the specified copy pool to determine the recoverability of this volume.
*ERR 193 J RECORD NOT FOUND FOR VOLUME <i>volser</i>		
		<ul style="list-style-type: none"> The MCP or DGN record for volume <i>volser</i> indicates that an FRSV record should exist for this volume. Expect this error to be issued for each dumped version of this volume. The MCPF_COPYPOOL bit should be patched off if it is determined that this is no longer a cpool volume, as is indicated by the missing FRSV record. FIXCDS P <i>volser</i> PATCH('9' BITS(.....0))
*ERR 194 CATALOG INFORMATION DATA SET <i>dsname</i> FOR COPY POOL <i>cpname</i>, VERSION <i>version</i> WAS NOT FOUND		

Table 76. Error codes used in AUDIT reports (continued)		
Description	Audit Repair Action	Troubleshooting Hints
The copy pool record indicates that the catalog information was captured but a data set containing this information was not found by AUDIT.		Remove the indication of catalog information from the FRB and reset the number sequence field to zero.
*ERR 195 COPY POOL <i>cpname</i>, VERSION <i>version</i>, INDICATES CATALOG INFORMATION DATA SET <i>dsname</i> BUT THE DATA SET CORRESPONDS TO A DIFFERENT COPY POOL VERSION		
The copy pool record indicates that the catalog information was captured but the corresponding catalog information data set indicates that it contains catalog information for a different copy pool backup version.		Run AUDIT DIRECTORYCONTROLS against the ML1 volume where the catalog information data set resides. If necessary, remove the indication of catalog information from the FRB and reset the number sequence field.
*ERR 196 CATALOG INFORMATION DATA SET <i>dsname</i>, IS NOT CATALOGED		
The catalog information data set was found on an ML1 volume but the data set is not cataloged.		Catalog the data set.
*ERR 197 CATALOG INFORMATION DATA SET <i>dsn</i> INDICATES COPY POOL <i>cpname</i> BUT A CORRESPONDING BACKUP WAS NOT FOUND		
There is no corresponding Fast Replication backup version for the catalog information data set.		Determine if the catalog information data set corresponds to a valid fast replication backup version. If it does, patch the FRB record for the fast replication backup version to indicate that the catalog information data set exists. If it does not, delete the catalog information data set.
*ERR 198 CATALOG INFORMATION DATA SET <i>dsname</i>, CORRESPONDS TO COPY POOL <i>cpname</i> , VERSION <i>version</i> BUT THE COPY POOL BACKUP VERSION DOES NOT INDICATE CATALOG INFORMATION WAS CAPTURED		
The copy pool backup version specified by the catalog information data set indicates that the catalog information was not captured. This catalog information data set does not correspond to a valid existing copy pool backup version.		Delete the catalog information data set.
*ERR 199 CATALOG INFORMATION DATA SET <i>dsname</i>, CORRESPONDS TO COPY POOL <i>cpname</i> , VERSION <i>version</i> BUT THE COPY POOL BACKUP VERSION INDICATES A DIFFERENT CATALOG INFORMATION DATA SET		
The copy pool version that the catalog information data set indicates that it is associated to is not the catalog information data set that the copy pool version record indicates.		Update the entry within the FRB record which corresponds to this copy pool backup version to indicate that the catalog information is available and to reflect the correct number sequence of the data set.
*ERR 200 ERROR ENCOUNTERED WHEN PROCESSING CATALOG INFORMATION DATA SET <i>dsn</i> , FOR COPY POOL <i>cpname</i> VERSION <i>vers</i>		
There was an unexpected error while trying to process the catalog information data set. This message should be preceded by an ARC1812I message.		Refer to the ARC1812I message.
*ERR 201 CATALOG INFORMATION DATA SET <i>dsn</i>, IS CATALOGED TO A DIFFERENT VOLUME		

Table 76. Error codes used in AUDIT reports (continued)

Description	Audit Repair Action	Troubleshooting Hints
The catalog locate for the catalog information data set indicates that this data set is cataloged on a different volume.		Determine if the catalog is inaccurate or if this is a duplicate uncataloged version of the catalog information data set. Scratch the uncataloged copy if appropriate. If the uncataloged copy is valid, determine if the cataloged copy should be deleted and the uncataloged copy should be cataloged.
*ERR 202 ORPHAN I (FRTV) RECORD FOUND FOR TARGET VOLUME <i>tgtvol</i>, SOURCE VOLUME <i>srcvol</i>		
The source volume record was not found for this target volume record and the target volume record was not validated by the volume pair record validation process. This record is no longer needed.	The target volume record is deleted. Note: Repair actions are only performed when FIX is specified on the audit command.	This error is only detected when no <i>cpname</i> is specified on the AUDIT COPYPOOLCONTROLS command.
*ERR 203 VALID MCD FOR DATA SET <i>dsn</i> HAS INCORRECT VOLSER, SHOULD BE VOL= <i>volser</i>		
During AUDIT MEDIACONTROLS, both a valid CDD record and corresponding valid MCD record have been identified. The MCD record does not indicate that it is for the tape volume being audited. Since the file block id and the timestamp in these two records are identical, this MCD record must belong to this migrated data set.	The migrated data set record (D) is patched with the volsr of the tape that is being audited.	
*ERR 204 I (FRTV) RECORD FOR VOLUME <i>targetvolser</i> HAS MULTIPLE H (FRVP) RECORD ENTRY REFERENCES		
Multiple FRVP record entry references were found for the target volume <i>tgtvolser</i> . A target volume can have a single valid FRVP record entry reference only. The target volume is "overused."		*ERR 179 messages are issue to assist determining the copy pools and versions that are using the target volume. The existing copy pool backups identified during auditing are not reliable backups and should be deleted using the FRDELETE command. You should then issue the FRBACKUP command to create a valid backup of each copy pool.
*ERR 205 K RECORD EXISTS, COPY POOL <i>cpname</i> F RECORD DOES NOT HAVE THIS VERSION		
A dump version record was found that has no version entry in the associated FRB record for the copy pool.	The copy pool dump version record is deleted. Note: Repair actions are only performed when FIX is specified on the audit command.	This error is only detected when no <i>cpname</i> is specified on the AUDIT COPYPOOLCONTROLS command.
*ERR 206 MCD INDICATES <i>dsn</i> IS IN CLOUD <i>cloud_network_connection_name</i> BUT NO CONTAINER <i>conname</i> OR OBJECTS WITH THE PREFIX <i>prefix</i> EXISTS		
MCD indicates that the data set is migrated to cloud but no container or no objects with the prefix that is stored in MCD exists.		If the data set is invalid and you want it deleted, you should issue an HSEND DELETE command, to have associated records deleted.
*ERR 207 <i>dsn</i> NOT CATALOGED, HAS {VALID INVALID} COPY IN CLOUD IN CONTAINER <i>container</i>		

Table 76. Error codes used in AUDIT reports (continued)

Description	Audit Repair Action	Troubleshooting Hints
The data set has a migration copy of user <i>dsn</i> in cloud, but that data set is not cataloged. The message text indicates whether the data set appears to be valid or invalid.	<p>If there is no data set D record, and no catalog entry, the migration copy(object) is deleted from cloud.</p> <p>If the D record identifies the data set is recalled and the data set is not cataloged, and the D record does not indicate that the migration copy needs to be scratched, a FIXCDS PATCH command is generated by AUDIT to turn on the "needs scratch" indicator.</p>	<p>If there is a D record, but no catalog entry, and the D record appears to represent a valid migration copy, then determine one of the following:</p> <p>If data set is invalid and you want to delete it, you can issue FIXCDS D <i>dsn</i> DELETE to delete MCD record and run AUDIT MEDIACONTROLS(CLOUD(<i>cloud_network_connection_name</i>)) command with FIX option to remove migration copy from cloud.</p> <p>DFSMSdss can be used to restore the data set directly.</p>
*ERR 208 <i>dsn</i> NOT MIGRATED, HAS COPY IN CLOUD IN CONTAINER container		
The data set has a migration copy of user <i>dsn</i> in cloud, but catalog indicates that the data set is not migrated.	<p>If there is no data set D record and data set not cataloged as MIGRAT (recalled), the migration copy is deleted from cloud.</p> <p>If there is a D record, but the catalog does not indicate MIGRAT, and the D record is flagged other than "needs scratch," the D record is patched to indicate that the migration copy be scratched</p>	DFSMSdss can be used to restore the data set directly.
*ERR 209 NUMBER OF OBJECTS FOR <i>dsn</i> IN CLOUD IS NOT EQUAL TO THE VALUE THAT IS STORED IN MCD		
Real number of objects for data set <i>dsn</i> migrated to cloud is not equal to the number of objects value that is stored in MCD. Migration copy can be invalid.		Contact IBM support.
*ERR 210 CDD IS NOT FOUND FOR PREFIX <i>prefix</i> IN CONTAINER container		
Objects were found for pseudo-directory <i>prefix</i> but an APPMETA object could not be found to further examine the migration copy.		<p>Use the LIST CLOUD command to list what objects exist for that prefix. It may be possible to use the DFSMSdss RESTORE command to recover the data set. If FIX specified, the orphan objects are deleted and MCDS may retained. To delete the MCDS records follow the below steps.</p> <p>a. If Catalog entry indicates it is migrated, issue HSEND DELETE <i>usrdsn</i> to have associated records deleted.</p> <p>b. If no catalog entry or cataloged to LO, issue an AUDIT DATASETCONTROLS(MIGRATION) command to have associated records deleted.</p> <p>Following is an example of the HSEND AUDIT command: HSEND AUDIT DATASET CONTROLS(MIGRATION)</p> <p>HSEND DELETE <i>usrdsn</i></p>

Table 76. Error codes used in AUDIT reports (continued)

Description	Audit Repair Action	Troubleshooting Hints
*ERR 211 prefix IS OLD MIGRATION COPY OF dsname IN CONTAINER containername		
A migration copy for <i>dsname</i> was found in CONTAINER container, but it is not the most recent version.	The migration copy is deleted.	You can use the DFSMSdss RESTORE command to recover the old migration copy.
*ERR 212 file HAS UFN RECORD BUT DOES NOT HAVE B RECORD		
A UFN record was found for file <i>file</i> , but MCB record does not exist.		
*ERR 213 file MISSING UFN RECORD		
UFN record is not found for file <i>file</i> or file path is incorrect. <i>file</i> contains the file path or hash value. If file contains hexadecimal hash value then this is the only information that is available for the file.		
*ERR 214 file – MISSING UFN RECORD FOR [(PARENT CHILD SIBLING LAST CHILD)]		
UFN record contains valid hash value for parent, child, sibling or last child but MCB record is missing.		Maybe not all requested MCB's were processed if AUDIT FILCONTROLS(BACKUP) FILELEVEL() is issued. Use AUDIT FILCONTROLS(BACKUP) for full processing.
*ERR 215 THE DGN RECORD DGNkey IS FOR A CLOUD DUMP BUT CONTAINS INVALID VALUES		
Invalid values might include: <ol style="list-style-type: none"> 1. Cloud dump flag, DGNF_CLOUD is 0. 2. DGNCOPY# is greater than maximum number of allowed in a dump generation. 3. DGNNVSN is not 0. 4. DGN_CLOUD_NAME_LEN and DGN_CLOUD_NAME are inconsistent. 5. DGN TCT compression ratio is invalid. 6. Dump class name in DGNDCL is incorrect. 7. Container name in DGN record is incorrect. 8. More than one DGN cloud provider type indicators are set to 1. For example, both DGNF_CLD_CDA_TCT and DGNF_CLD_CDA_DIRECT flags are set to 1 		Use the FIXCDS G <i>dgnkey</i> DISPLAY <i>offset</i> command to identify invalid values, and then use FIXCDS G <i>dgnkey</i> PATCH <i>offset</i> command to change the fields with expected values. Or, contact IBM support.
*ERR 216 DGN IS NOT FOUND FOR PREFIX prefix IN CONTAINER container		
The corresponding DGN record is not found for the cloud dump prefix.	The orphaned cloud dump copy is deleted. Note: Repair actions are only performed when FIX is specified on the AUDIT command.	Determine if the orphaned dump copy is a result of an error during automatic dump expiration or deletion. Specify FIX on the AUDIT command to delete the orphaned cloud dump copy. Or, contact IBM support.
*ERR 217 THE NUMBER OF OBJECTS WITH PREFIX prefix IN THE CONTAINER container IS NOT CORRECT		

Table 76. Error codes used in AUDIT reports (continued)		
Description	Audit Repair Action	Troubleshooting Hints
The number of objects for dump copy prefix offloaded to cloud object store does not match the number of objects stored in the DGN record.		Contact IBM support.
*ERR 218 THE DUMP DEVICE CATEGORY OF DUMP CLASS <i>dumpclass</i> IS CLOUD AND NOT CONSISTENT AS OTHER COPIES IN DGN RECORD		
Mixed CLOUD and TAPE dump classes (copies) are not allowed in a dump generation.		For more information, use LIST VOLUME ALLDUMPS BCDS.
*ERR 219 DGN INDICATES <i>volser</i> IS IN CLOUD <i>cloud_network_connection</i> BUT NO CONTAINER <i>container</i> OR OBJECTS WITH THE PREFIX <i>prefix</i> EXIST		
DGN indicates that the volume is dumped to cloud object store but no container or objects with the prefix stored in the DGN exists.		Contact IBM support.
*ERR 220 MISSING DCL RECORD FOR DUMP CLASS <i>dumpclass</i>		
The DGN record contains information for dump class <i>dumpclass</i> , but the DCL record for <i>dumpclass</i> does not exist.		Use DEFINE DUMPCLASS command to redefine the dump class, if needed.
*ERR 221 F (FRB) RECORD FOR <i>cpname</i> NOT FOUND, POSSIBLY ORPHANED G (DGN) RECORD FOR VOLUME <i>volser</i>		
DGN record is found for copy pool <i>cpname</i> , but FRB record does not exist.		Consider running AUDIT COPYPOOLCONTROLS (<i>cpname</i>) to learn more about this discrepancy.
*ERR 222 P (MCP) RECORD FOR VOLUME <i>volser</i> WITH DUMP DATE <i>dump_date</i> AND DUMP TIME <i>dump_time</i> NOT FOUND, POSSIBLY ORPHANED G (DGN) RECORD		
DGN record exists with primary volume <i>volser</i> , but either MCP record for <i>volser</i> does not exist or the volume no longer has a valid dump generation associated with the DGN record.		For more information, use LIST PRIMARYVOLUME(<i>srcvol</i>) ALLDUMPS BCDS.
*ERR 223 FIXCDS 2 x'[UFN KEY]' PATCH(X'FC' x'[PREVIOUS SIBLING KEY]') PREVIOUS SIBLING KEY MISSING		
Previous sibling key is not updated on the UFN record being audited.	<p>If there are a very few such records, the above FIXCDS command can be a quick fix. If the count is too many to fix using FIXCDS commands, run the AUDIT FILECONTROLS function with FIX option.</p> <p>The recommended option is running AUDIT FILECONTROLS with FIX option.</p>	<p>User is running the AUDIT with NOFIX option. A limit of 1000 terminates the Audit and issues the message *ERR 224. The recommended way to fix then is to run AUDIT FILECONTROLS with FIX option.</p> <p>If these messages are recurring, this may indicate that the Unix file backups were done by turning off the PATCH bit MCVTF_CTL_FIXUFN.</p>
*ERR 224 ERROR LIMIT HAS STOPPED THE AUDIT, RERUN THE AUDIT WITH FIX OPTION		
ERR 223 or ERR 225 have reached the preset limit of 1000.	Run the AUDIT FILECONTROLS with FIX option.	User is running the AUDIT with NOFIX option. Check if the PATCH bit MCVTF_CTL_FIXUFN is turned OFF which is recommended to be ON.
*ERR 225 x'[UFN KEY]' UFN NODE MARKED SOFT DELETE FOUND		

Table 76. Error codes used in AUDIT reports (continued)

Description	Audit Repair Action	Troubleshooting Hints
Indicates this UFN node on BCDS is soft deleted (UFN_INVALID=ON).	Run the AUDIT FILECONTROLS with FIX option.	User is running the AUDIT with NOFIX option. A limit of 1000 terminates the Audit and issues the message *ERR 224. The recommended way to fix then is to run AUDIT FILECONTROLS with FIX option. If user wants to retain the UFN node, then back-up the associated file once again. That is going to turn OFF the soft delete flag (UFN_INVALID) and the new node will be added appropriately.
*ERR226 x'[UFN KEY]' PREVIOUS SIBLING KEY UPDATED IN THE UFN RECORD IS INCORRECTLY REFERENCING A DIFFERENT NODE.		
The previous sibling of the record being audited is not referencing back to the node being audited.	If the number of messages exceeds 50, audit starts printing ERR 227 indicating exceeding the allowed limit for ERR 226. Audit continues. Contact IBM support when ERR 226 message is seen.	Contact IBM support for further investigation.
*ERR 227 MAX LIMIT OF ERR 226 MESSAGES REACHED		
The number of ERR 226 messages have reached a maximum limit of 50.	User has run the AUDIT FILECONTROLS with NOFIX option. It is an unusual case of too many logical errors. Contact IBM support for further investigation.	Contact IBM support for further investigation.
*ERR 228 INFO: PREVIOUS SIBLING REFERENCE FIXED FOR THE UFN RECORD [64-character UFN Key]		
When AUDIT FILECONTROLS is run with FIX option, it has updates the previous sibling reference (UFN_PSIB) for the UFN record mentioned in the message text.	Not required. This message is informational.	Not required. This message is informational.
*ERR 229 INFO: PREVIOUS SIBLING REFERENCE FIXED FOR THE UFN RECORD [64-character UFN Key]		
When AUDIT FILECONTROLS is run with FIX option, it has updated the previous sibling reference (UFN_PSIB) for the UFN record mentioned in the message text.	Not required. This message is informational.	Not required. This message is informational.
*ERR 230 CDD IS NOT FOUND FOR MIGRATED <i>dsn</i> IN CONTAINER <i>container</i>		
A migration copy for <i>dsname</i> was found in CONTAINER container without a valid CDD		Issue a HSEND DELETE command to have associated records deleted Following is an example of the HSEND DELETE command: HSEND DELETE <i>userdsn</i>
*ERR 231 THE MCD RECORD <i>MCDkey</i> IS FOR A CLOUD MIGRATION COPY BUT CONTAINS INVALID VALUES		
More than one MCD cloud provider type indicators are set to 1. For example, both MCDF_CLD_CDA_TCT and MCDF_CLD_DIRECT are both ON.		Use the FIXCDS D <i>mckey</i> DISPLAY offset command to identify invalid values and then use FIXCDS D <i>mckey</i> PATCH <i>offset</i> command to change the field with expected values. Or contact IBM support.

Unexpected errors during an audit

Unexpected errors during an audit are errors that do not relate directly to the purpose of the audit, which is to find and repair problems with DFSMSHsm data sets and controls. For example, if the AUDIT function attempts to fix a problem and the command used to complete the fix fails, the AUDIT function provides you with an error message.

If such an error occurs, the AUDIT function writes a brief message to an output data set in the form of MSG 9xx. The AUDIT function will also write an informational message (MSG 998 or 999) to describe the AUDIT function running when the error occurs.

In addition, the DFSMSHsm command activity log contains any associated ARCxxxxx messages that describe the actual problem.

Unexpected error messages

The unexpected error messages that might be issued during an audit are explained in this topic.

MSG 900 ERROR ON ADDVOL OF VOLUME(*volser*)

Explanation

An error has been encountered in performing the ADDVOL command for the VOLUME indicated.

MSG 901 ERROR ON FIXCDS COMMAND

Explanation

An error has been encountered in performing the FIXCDS command.

MSG 902 GENCB ERROR

Explanation

An error has been encountered in performing the GENCB macro.

MSG 903 ERROR LOCKING CDS

Explanation

An error has been encountered while RESERVING/ENQUEUEING or RELEASING/DEQUEUEING the DFSMSHsm CDSs.

MSG 904 ERROR BUILDING MVT FOR VOLUME(*volser*)

Explanation

An error has been encountered during the building of a volume table entry for the VOLUME indicated.

MSG 905 [ALLOCATION | DEALLOCATION] ERROR FOR [(*dsname*) | VOLUME(*volser*)]

Explanation

An error has been encountered during ALLOCATION DEALLOCATION processing for the DATASET indicated or the VOLUME indicated.

MSG 906 LOCATE ERROR ON VOLUME(*volume*)

Explanation

An error has been encountered in the performing of the LOCATE macro for the VOLUME indicated.

MSG 907 [GETMAIN | FREEMAIN] ERROR FOR SUBPOOL(*subpool*)

Explanation

An error has been encountered in the performing of either the GETMAIN or the FREEMAIN macro.

MSG 908 ERROR CLOSING DSN(*dsname*) [VOLUME(*volser*) | SDSP FOR VOLUME(*volser*)].

Explanation

An error has been encountered during the closing of the data set *dsname*. The data set is on the volume *volser*.

MSG 909 ERROR OPENING DSN(*dsname*) [VOLUME(*volser*) | SDSP FOR VOLUME(*volser*)]

Explanation

An error has been encountered during the opening of the data set *dsname*. The data set is on the volume *volser*.

MSG 910 ERROR READING [DSN | VTOC] FOR VOLSER(*volser*)

Explanation

An error has been encountered during the reading of the data set indicated. The data set is on either the SDSP VOLUME indicated or the VOLUME indicated.

MSG 911 **ERROR DELETING CATALOG ENTRY FOR {record_key}**

Explanation

An error has been encountered during the DELETING of the indicated CATALOG entry.

MSG 912 **ERROR [DELETING | READING | WRITING] CDS RECORD, KEY = {record_key}**

Explanation

An error has been encountered during either DELETING, READING, or WRITING a record in DFSMSHsm's CDS records.

MSG 913 **ERROR CONVERTING MCP RECORD, KEY = {record_key}**

Explanation

An error has been encountered that prevented the indicated MCP record from being converted to the release 3 format.

MSG 914 **ERROR ON BDELETE COMMAND**

Explanation

An error has been encountered in performing the BDELETE command.

MSG 915 **VOLUME *volser* HAS A DISASTER ALTERNATE VOLUME**

Explanation

The volume *volser* has a disaster alternate volume that is currently being used. AUDIT MEDIACONTROLS of volumes with disaster alternate volumes is not permitted.

MSG 916 **I/O ERROR ON VOLUME *volser***

Explanation

An I/O error has been encountered reading the tape during AUDIT processing.

MSG 917 **AUDIT SKIPPING EXISTING TTOC RECORDS FOR VOLUME *volser***

Explanation

AUDIT has detected in-storage TTOC records for this volume that were not written to the OCDS. This allows AUDIT to fast forward to an indicated point on this tape volume, reducing the time required to audit this tape and restore the OCDS records.

MSG 919 **AUDIT MEDCTL CANNOT RESUME ON VOLUME *volser*.**

Explanation

AUDIT has detected an invalid parameter or the tape is in FAILEDCREATE status. ARC0876I was issued to the user and the command activity log explaining why audit could not resume.

MSG 920 **ORIGINAL AUDIT COMMANDS WILL NOT PROVIDE COMPLETE RESULTS. IBM RECOMMENDS USE OF THE PREFERRED ENHANCED AUDIT COMMANDS.**

Explanation

You have issued an ORIGINAL DFSMSHsm AUDIT command option. DFSMSHsm's Original AUDIT commands are no longer being updated. It is recommended that you identify an equivalent ENHANCED DFSMSHsm AUDIT command option to audit your DFSMSHsm Control Data Set Information. To assist you in determining which ENHANCED AUDIT command would serve you best, refer to the table 'Comparison of AUDIT options'

MSG 922 **COPY POOL=*cpname* VERSION=*version* IS NOT SUPPORTED ON THIS RELEASE OF DFSMSHSM. IBM RECOMMENDS RE-RUNNING THE AUDIT ON A HOST WHICH SUPPORTS THIS COPY POOL BACKUP VERSION**

Explanation

The audited copy pool backup version has attributes which are not supported by the release of the DFSMSHsm host on which the audit was performed. Issue the AUDIT command again on a DFSMSHsm host running on a higher release of z/OS to ensure that the copy pool version is properly audited.

For example, DFSMSHsm running on z/OS V1R12 supports auditing a copy pool backup version with an incomplete fast reverse restore. If the audit command is issued on a DFSMSHsm host running on z/OS V1R11, the incomplete fast reverse restore attribute is not supported and cannot be audited. This message is issued.

**MSG 924 UNEXPECTED ERROR OCCURRED
 DURING CALLS TO THE CLOUD**

Explanation

AUDIT has encountered an unexpected error when attempting to access CLOUD. See preceding error messages for more information about the cloud services error.

MSG 925 SHA 256 HASH IS NOT AVAILABLE

Explanation

AUDIT has encountered a HASH error during FILECONTROL processing.

**MSG 926 ERROR IN DETERMINING DGN
 KEY FROM CLOUD DUMP PREFIX
 prefix_name.**

Explanation

AUDIT has encountered an error when attempting to determine the dump generation record (DGN) key from the cloud dump copy name *prefix_name*.

**MSG 998 AUDIT CONTINUING, COMMAND
 ACTIVITY LOG MAY CONTAIN
 ADDITIONAL INFORMATION**

Explanation

AUDIT has encountered an unexpected error. This message is preceded by a 9xx message that indicates the type of error and related information. Additional information may be found in the DFSMSHsm command activity log. The AUDIT command continues with either the next data set or volume.

**MSG 999 AUDIT ENDING EARLY, SEE
 COMMAND ACTIVITY LOG**

Explanation

The AUDIT function has encountered an unexpected error. This message is preceded by a 9xx message that indicates the type of error and related information. Additional information can be found in the DFSMSHsm command activity log. The AUDIT command is ENDING because of the error encountered.

Errors encountered during AUDIT VOLUMES, AUDIT BACKUPVOLUMES, or AUDIT BACKUPTYPE

AUDIT can encounter certain conditions, as follows, when requested to audit data set information on a primary, migration, or backup volume. The conditions are listed in the order in which they might be encountered.

Also, if an error occurs when AUDIT tries to read the job file control block (JFCB) when opening the VTOC, the AUDIT command sends the identification of the module with the error to the DFSMSHsm log and to the operator and abnormally ends auditing with a dump.

**ARC0500I CANNOT ALLOCATE VOLUME
 volser, DARC=*reascode***

Explanation

The volume cannot be allocated. The error message contains the volume serial number and the return code from dynamic allocation.

**ARC0525I *dsname* SCRATCH FAILED ON
 VOLUME=*volser*,RC=*retcode***

Explanation

In attempting to scratch (or scratch and uncatalog) a utility data set, either the scratch or uncatalog operation failed.

**ARC0805I I/O ERROR OCCURRED DURING
 READING OF VTOC ON VOLUME
 *volser***

Explanation

When reading data set control blocks, AUDIT encountered an I/O error.

**ARC0806I OPEN OF VTOC FOR VOLUME *volser*
 FAILED**

Explanation

AUDIT was not able to open the volume table of contents (VTOC) to read the data set control blocks.

**ARC0807I INSUFFICIENT SPACE FOR
 READING VTOC OF VOLUME *volser***

Explanation

AUDIT could not get buffer space to read the data set control blocks.

ARC0808I UNABLE TO AUDIT VOLUME *volser*

Explanation

The volume has not been previously identified with the ADDVOL command, or is not mounted.

Other considerations when using the AUDIT command

There might be other considerations when you use the AUDIT command, such as with using multiple DFSMSHsm hosts, printing audit information, and encountering errors.

Multiple DFSMSHsm host considerations when using the AUDIT command

For the greatest accuracy in a multiple-host HSMplex, with any AUDIT command other than AUDIT COMMONQUEUE, issue the command from one host after you have stopped DFSMSHsm in the other hosts. For most users, this is unrealistic even though AUDIT may report discrepancies due to the concurrent operation of multiple hosts. If you cannot stop DFSMSHsm in the other hosts, use one of the following approaches when you issue the AUDIT command:

- Run the AUDIT NOFIX command once, and then run it again several days later. Those errors common to both executions are likely to be true discrepancies in the CDSs.
- Execute the AUDIT command from one host immediately after restoring a CDS from backups, before other hosts are started.
- For AUDIT COMMONQUEUE, it is best to issue the command when all hosts are active and connected.

Note: If AUDIT is running and backup of the DFSMSHsm control data sets has started (using BACKVOL CDS command or AUTOBACKUP), all DFSMSHsm functions on the host that started this backup are halted until the AUDIT function and the backup of the DFSMSHsm CDSs have completed.

Printing information from the AUDIT command

When you have decided what to audit, you can specify whether you want to audit information only for data sets with error conditions or all data sets. You can also specify if you want the AUDIT command to try to fix the error condition automatically.

When you issue the AUDIT command, printer output is always produced and sent to the SYSOUT data set or to an alternative output data set. When you issue AUDIT &ellip; TERMINAL, output is printed at the terminal from which the command is issued in addition to the printer output.

If you have the output sent to an alternative output data set, you identify the data set name with the OUTDATASET parameter. It is recommended that you always direct your AUDIT output to an alternative data set, and that you thoroughly review this output for content, accuracy, and understanding of corrections. At times, the output will contain further diagnostic and troubleshooting recommendations for errors that were encountered. Always investigate any reported MSGxxx error, and you should understand and accept any failures, and not ignore them.

Note: This is not applicable for AUDIT COMMONQUEUE.

Chapter 76. Using the LIST command

You use the LIST command to determine the status of DFSMSShsm and SMS-managed volumes and data sets. When you list primary volume, migration volume, or data set information, you can decide whether DFSMSShsm lists the information from the MCDS, the BCDS, or both. You can also decide to let DFSMSShsm print the output from the LIST command at your terminal, send it to a SYSOUT data set, or send it to an alternative output data set. This topic describes the categories of information you can list, explains the output of the LIST command, and contains sample printer output and sample terminal output for all categories of information.

All references to primary volumes in this topic include the SMS-managed volumes that have been internally ADDVOLED to DFSMSShsm, thereby becoming eligible for DFSMSShsm automatic processing.

You can list the following categories of information:

- [Aggregate backup and recovery activity](#)
- [Backup volumes](#)
- [Cloud storage](#)
- [Copy pools](#)
- [Copy pool backup storage groups](#)
- [Data sets](#)
- [Dump class](#)
- [Dump volumes](#)
- [Migration or primary volume from MCDS or BCDS](#)
- [DFSMSShsm host serialization \(HOSTID\)](#)
- [Tape volume from TTOC](#)
- [User authorization](#)

Requesting information for aggregate backup and recovery activity information

To get a list of aggregate backup and recovery information for all the aggregate groups that DFSMSShsm manages, specify LIST AGGREGATE(*). This command orders the output in alphanumeric sequence by aggregate group name. To get a list of the information for all the active versions of a specific aggregate group that DFSMSShsm manages, specify LIST AGGREGATE(*agname*).

Table 77 on page 1341 explains the output labels for any aggregate volume.

Table 77. Output labels when you request information for aggregate backup and recovery		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
ABR RECORD KEY	ABRKEY	This field contains the key of the ABR record.
AGGREGATE GROUP NAME	AGNAME	This field contains the name of the aggregate group processed.
DFSMSShsm VERSION	HSMVERS	This field contains the DFSMSShsm version and release number.
AGGREGATE ACCOUNT CODE	AGGREGATE ACCOUNT CODE	This field contains an installation-defined accounting code for the aggregate.
ABACKUP DATE	ABKDATE	This field contains the date when ABACK was performed.

Table 77. Output labels when you request information for aggregate backup and recovery (continued)

Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
ABACKUP TIME	ABKTIME	This field contains the time when ABACK was performed.
VERSION	VERSION	This field contains the version number for this ABACKUP.
COPY NUMBER	COPYNUM	This field contains the copy number to which this ABR record pertains.
UNITNAME	UNIT	This field contains the unitname.
NUMBER OF COPIES	NUMCOPIES	This field contains the number of copies created for this version of the ABACKUP output.
SOURCE SYSTEM	SRCSYS	This field contains the source system name.
MANAGEMENT CLASS	MGMTCLS	This field contains the name of the management class that is associated with the aggregate group that was backed up.
REMOTE DESTINATIONS	REM-DEST	This field is reserved for future function.
CONTROL FILE NAME	CF	This field contains the data set name of the control file.
DFSMSdss DATA FILE NAME	DFLO	This field contains the data set name of the DFSMSdss data file.
INTERNAL I/O DATA FILE NAME	DFINT	This field contains the data set name of the Internal/IO data file.
ACTIVITY LOG/ INSTRUCTION FILE NAME	INS/LOGF	This field contains the data set name of the instruction/activity log file. ** ERROR ** at the end of the data set name field indicates an error occurred during the ABACKUP. The file is not recoverable.
ABACKUP ACTIVITY LOG DATA SET NAME	ABKLOGDSN	This field contains the data set name of the ABACKUP activity log.
INSTRUCTION DATA SET NAME	INSTDSN	This field contains the data set name of the instruction data set.
FILTER OUTPUT DATA SET NAME	FODSN	This field contains the data set name of the FILTER OUTPUT data set.
CONTROL FILE VOLSERS	CFVOLS	This field contains a list of the volume serial numbers that contain the control file and associated library names.
DFSMSdss DATA FILE VOLSERS	DFLOVOLS	This field contains a list of the volume serial numbers that contain the DFSMSdss data file and associated library names.
INTERNAL I/O DATA FILE VOLSERS	DFINTVOLS	This field contains a list of the volume serial numbers that contain the I/O data file and associated library names.
INSTRUCTION / ACTIVITY LOG FILE VOLSERS	INS/LOGFVOLS	This field contains a list of the volume serial numbers that contain the instruction/activity log file and associated library names.
TAPE EXPIRATION DATE	TPEXPDATE	This field contains the expiration date for the ABARS output files.
NUMBER OF USER TAPES	DSTPCNT	This field contains the number of tapes.
NUMBER OF ACCOMPANY TAPES	ACCTPCNT	This field contains the number of tape volumes containing data sets from the ACCOMPANY list.
STORAGE USED AT ABACKUP SITE LO, ML1, ML2, TOTAL	ABKLOSTO, ABKML1STO, ABKML2STO, ABKTOTSTO	This field contains the amount of data that was backed up from the various hierarchy levels. LO=Level 0 DASD, ML2=ML2 tape/DASD, ML1=ML1 DASD, TOTAL=total amount of data backed up.

Table 77. Output labels when you request information for aggregate backup and recovery (continued)		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
ABACKUP CPU TIME	ABACKUP CPU TIME	This field contains the CPU time that was used for the ABACKUP of this aggregate group.
TAPE STACKING	TAPE STACKING	This field indicates if the ABACKUP output files have been stacked or not stacked.
DATE	ARVDATE-TIME	This field contains the date when the last ARECOVER was performed.
RETCODE	ARVRC	This field contains the return code of the most recent ARECOVER.
OPTION	ARVOPT	This field contains the performed ARECOVER option: EXECUTE/VERIFY/PREPARE
XMIT=Y/N	XMIT	This field indicates if the XMIT option was requested.
STORAGE REQUIREMENTS LO, ML1, ML2, TOTAL	ABKLOSTO, ABKML1STO, ABKML2STO, ABKTOTSTO	This field contains the storage required to complete recovery.
ARECOVER ACTIVITY LOG DATA SET NAME	ARVLOGDSN	This field contains the data set name of the ARECOVER activity log that is associated with the latest ARECOVER.
CONFLICT RESOLUTION DATA SET NAME	CONDSN	This field contains the data set name of the CONFLICT RESOLUTION data set that is associated with the latest ARECOVER.
RESTART DATA SET NAME	RSTDSN	This field contains the data set name of the RESTART data set that is associated with the latest ARECOVER.
ARECOVER CPU TIME	ARECOVER CPU TIME	This field contains the CPU time used for the ARECOVER of this aggregate group.
TAPE STACKING	TAPE STACKING	This field indicates if the ABACKUP output files have been stacked or not stacked.
TOTAL BACKUP VERSIONS	TOTAL BACKUP VERSIONS	This field contains the total number of backup versions for each data set. This total includes all active and retained backup versions.

Figure 110 on page 1344 is a sample of a terminal list when you have specified AGGREGATE(PAY1) VERSION(0002), and TERMINAL parameters.

Figure 111. Sample Printer List when You Specify AGGREGATE(PAY1), VERSION(001) and ODS.

Requesting information for backup volumes

You specify the LIST command with the BACKUPVOLUME parameter to get a list of the information for all the backup volumes that DFSMSHsm manages. The command lists the volumes in alphanumeric sequence by volume serial number. You specify LIST BACKUPVOLUME(volser) to get a list of the information for a specific backup volume that DFSMSHsm manages. [Table 78 on page 1345](#) explains the output labels for any backup volume.

Table 78. Output labels when you request information for backup volumes		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
VOLSER	VOL	This field contains the volume serial number of the backup volume.
DEVICE TYPE	DEVTYPE	This field contains the name of the unit where this volume can be allocated.
BACKUP TYPE	BACKTYP	DAILY or SPILL indicates the DFSMSHsm volume category of the backup volume. AVAIL indicates that the backup category has not been assigned and the volume is available as a daily or spill backup volume when DFSMSHsm uses the volume for the first time.
VOL FULL	FULL	For a DASD backup volume, a YES indicates that DFSMSHsm has failed to back up a data set because the backup volume does not have enough space. For a tape backup volume, a YES indicates that while DFSMSHsm is writing to the tape, the end-of-tape marker is reached or a data-movement error has occurred. The volume has been marked full to prevent further use.
TOTAL TRACKS	TOTAL TRKS	This field contains the total track capacity of the DASD volume. This field does not apply to tape.
FREE TRACKS	FREE TRKS	This field contains the number of tracks on the DASD volume available for data sets. This field does not apply to tape.
THRESH	THRESH	This field contains the threshold of occupancy for the DASD backup volume. This field does not apply to tape.
LAST BACKUP DATE	LAST BACKUP DATE	This field contains the date when the volume was most recently used as a target volume for backup, spill, or recycle processing.
PSWD	PSWD	A YES or Y indicates that the tape volume is password protected. This field does not apply to DASD.
EXP	EXP	A YES or Y indicates that the tape volume is protected by an expiration date. This field does not apply to DASD.
RACF	RACF	A YES or Y indicates that the tape volume is RACF protected. This field does not apply to DASD.
EMPTY	EMPTY	A YES or Y indicates that the tape volume is empty. This field does not apply to DASD.
IDRC	IDRC	Y = Volume contains data in the Improved Data Recording Capability format. N = Volume does not contain data in the Improved Data Recording Capability format. ** = Volume is empty—not assigned the Improved Data Recording Capability format.

Table 78. Output labels when you request information for backup volumes (continued)		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
DUPLEX ALT	DUPLEX ALT	<p><i>volser</i> indicates the volume serial number of the duplexed alternate</p> <p>*PEND* indicates that an exception condition and an internal TAPECOPY is pending</p> <p>*NONE* indicates that the volume was not created in a duplexing environment</p> <p>NA indicates that the original volumes are DASD rather than tape</p>
PCT FULL	PCT FULL	This field contains the percentage of the backup volume used for a tape written using 3590 architecture. A value of **** means the percentage is unknown.

Figure 112 on page 1346 is a sample printer list of all the backup volumes when you specify the BACKUPVOLUME parameter. If you requested information for only one volume, the list has only one entry.

Note: If **** appears in the FREE TRACKS field for a DASD backup volume, DFSMSHsm has not yet calculated—and therefore does not know—the amount of free space on this volume.

Figure 112. Sample Printer List of All the Backup Volumes when You Specify BACKUPVOLUME

Requesting information for cloud storage

You specify the LIST CLOUD (*cloud_network_connection_name*) to get a list of the contents of cloud storage at various levels. The first level, LIST CLOUD(*cloud_network_connection_name*), returns a list of the DFSMSHsm containers that are found in the specified cloud. The next level, LIST CLOUD(*cloud_network_connection_name*) CONTAINER(*containername*), returns a list of the pseudo-directories found within the container. The pseudo-directory name is a prefix for all of the objects within a particular migration copy. The last level, LIST CLOUD(*cloud_network_connection_name*) CONTAINER(*containername*) PREFIX(*objectprefixname*), returns a list of all of the objects that make up that migration or full volume dump copy.

Table 79. Output labels for List of Cloud Storage Contents		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
CLOUD NAME	CLOUD NAME	The <i>cloud_network_connection_name</i> from which the listing was retrieved
CONTAINER NAME	CONTAINER NAME	Name of container

Table 79. Output labels for List of Cloud Storage Contents (continued)		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
PREFIX NAME	OBJECT PREFIXES	Pseudo-directory name for the migration copy or the full-volume dump copy residing in cloud. It is a common unique prefix for all objects that make up a migration copy or the full-volume dump copy.
CLOUD INFORMATION FOR DATASET	DATASET NAME	For migration copy residing in cloud, this field contains the name of the original data set that was migrated, when an APPMETA object is found with valid DFSMSHsm information. This field does not apply to full volume dump copies residing in cloud object store. 'CDD NOT FOUND' is displayed.
OBJECT NAME	OBJECT NAMES	The full object name

Figure 113 on page 1347 is a sample printer list of a specific cloud when you specify the CLOUD(*cloud_network_connection_name*) parameter:

Requesting information for copy pools

You specify the LIST command with the COPYPOOL parameter to get a list of information for each version of each copy pool that has at least one fast replication backup version. The command lists the copy pools in alphanumeric sequence by copy pool name. You specify LIST COPYPOOL(*cpname*) to get a list of the detailed information for each version of the specified copy pool. The information includes source volume to target volume pairings. Table 80 on page 1348 explains the output labels for copy pools.

Table 80. Output labels when you request information for copy pools		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
CATINFO	CATINFO	This field indicates whether data set catalog information was captured for this version. CATINFO=Y/N/P (YES/NO/PARTIAL)
COPYPOOL	COPYPOOL	This field contains the copy pool name.
*DATA SET NAME	Not Supported	Data sets backed up in this copy pool version.
DATE	DATE	This field contains the creation date of the copy pool version.
DCLASS	DCLASS	This fields contains the changes to existing output formatting.

Table 80. Output labels when you request information for copy pools (continued)		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
DUMPCCLASS	DUMPCCLASS	This field indicates if the dump class associated with the copy pool is required or optional.
DUMPDEVCAT	DUMPDEVCAT	This field indicates the dump device category as follows: Value Meaning CLOUD Indicates the copy pool dump version resides in the cloud object store. TAPE Indicates the copy pool dump version resides on tapes.
DUMPSTATE	DUMPSTATE	This field indicates the dump state of volumes in the copy pool.
FASTREPLICATIONSTATE	FASTREPLICATIONSTATE	This field indicates the fast replication state of the copy pool.
FCFRR	FCFRR	This field indicates whether the copy is defined allowing fast reverse restore (FCFRR=Y) or not (FCFRR=N).
INCREMENTAL	INCREMENTAL	This field indicates whether the corresponding version is an Incremental version.
RECOVERYINCOMPLETE	RECOVERYINCOMPLETE	This field indicates whether the copy pool version was recovered completely.
*SGNAME	SGNAME	This field contains the storage group name.
*SOURCE	SOURCE	This field lists source volumes in the storage group.
*TARGET	TARGET	This field lists target volumes in the storage group.
TIME	TIME	This field contains the creation time of the copy pool version.
TOKEN (C)	TOKEN (C)	This field contains the token in alphanumeric format.
TOKEN (H)	TOKEN (H)	This field contains the token in hexadecimal format.
TOTAL NUM OF VOLUMES	TOTAL NUM OF VOLUMES	This field lists the total number of volumes backed up for this copy pool version.
VERSION	VERSION	This field contains the copy pool version number.
VALID	VALID	This field indicates whether the copy pool version is valid, as follows: Value Meaning Y Indicates that the copy pool version contains a valid DASD backup copy. N Indicates that the copy pool version does not contain a valid DASD backup copy. * Indicates that the copy pool version is in a state defined in a z/OS V1R8 or later environment, and thus, cannot be used for recovery on this host system.
VTOCENQ	VTOCENQ	This field indicates whether DFSMSshm serialized on the VTOCs of the volumes that were processed.

Note: * Appears only if you specify COPYPOOL(*cpname*).

Figure 116 on page 1350 is a sample printer list of all the copy pools when you specify the COPYPOOL parameter.

Figure 119. Sample printer list of a specific copy pool when you specify the COPYPOOL(cpname) parameter and one of the dump versions resides on cloud object storage

Requesting information for copy pool backup storage groups

You specify the COPYPOOLBACKUPSTORAGEGROUP(*cpbsgname*) parameter on the LIST command to get a list of volumes in the copy pool backup storage group that DFSMSHsm has assigned as a target volume. The corresponding source volumes are also listed. The command lists the specified copy pool storage group's target volumes in alphanumeric sequence by volume serial number.

Figure 120 on page 1352 is a sample printer list of a specific copy pool backup storage group when you specify the COPYPOOLBACKUPSTORAGEGROUP(*cpbsgname*) parameter.

```

Figure 120. Sample Printer List for COPYPOOLBACKUPSTORAGEGROUP

Requesting information for data sets

To get a list of the information for all migrated data sets with the same first qualifier, specify the LIST command with the LEVEL(*qualifier*) parameter. The command lists the data sets in alphanumeric sequence by data set name.

To get a list of the information for *all* migrated data sets, specify the LIST command with the DATASETNAME parameter. The command lists the data sets in alphanumeric sequence by data set name followed by a summary list. To get a list of the information for a specific data set, specify the LIST command with a specific DATASETNAME(*dsname*) parameter.

You can specify one or more of the subparameters of the SELECT parameter to restrict the list to data sets that meet certain criteria.

When you request information for data sets, you can also request whether information should be listed from the migration control data set (MCDS), backup control data set (BCDS), or both control data sets.

Requesting data set information from the MCDS

Table 81 on page 1352 explains the output labels for a list of all data sets, all data sets that have the same first qualifier, or a specific data set.

Table 81. Output labels when you request MCDS information for data sets		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
DATASET NAME	DSN	This field contains the name of the user data set.
MIG VOLUME	MIGVOL	This field contains the volume serial number of the migration volume the data set is on if the data set is currently migrated. If the data set is on more than one tape migration level 2 volume, this field contains the volume serial number of the first volume the data set is on. The field contains ONLINE if the data set has been recalled. If the data set has been migrated to cloud storage, this field contains %CLOUD.
LAST REF DATE	LAST REF	This field contains the date of the most recent reference of the data set.

Table 81. Output labels when you request MCDS information for data sets (continued)		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
MIGRATED DATE	MIG	This field contains the date when the data set was last migrated.
TRKS ALLOC	TRKS	If the data set is currently migrated, this field contains the number of tracks allocated for the data set on the primary volume from which the data set migrated. If the data set is recalled, this field is the number of tracks allocated for the recalled data set.
QTY 2K BLKS	2K BLKS	This field contains the size, in 2 KB blocks, of the data set on the migration volume. This field does not apply to tape. If the quantity exceeds 99,999,999, it is represented in units of K (1000 bytes) instead.
TIMES MIG	TIMES MIG	This field contains the number of times DFSMSHsm has migrated the data set. If migration cleanup has deleted the data set record, this is the number of times DFSMSHsm has migrated the data set since the record was deleted.
DS ORG	DSO	This field contains the type of data set organization: PE (partitioned data set extended) PS (physical sequential), PO (partitioned), DA (BDAM), VS (VSAM), PSL (large format sequential) or *** if the data set organization is unknown.
SDSP DS	SDSP	A YES under this heading indicates that the data set resides in a small-data-set-packing data set.
QTY 16K BLOCKS	16K BLOCKS	This field contains the size, in 16 KB blocks, of the data set on the tape migration level 2 volume. If the data set is recalled, but might be eligible for reconnection during a subsequent migration, this value contains the size, in 16 KB blocks, that the data set would be on the tape migration level 2 volume. This field does not apply to DASD migration volumes, or cloud..
LAST MIG VOLUME	LAST MIGVOL	This field contains the volume serial number of the last tape migration level 2 volume if the data set spans more than one tape volume. *NONE* indicates that the data set does not span more than one tape volume. This field does not apply to DASD.
	CLOUD	SMS Cloud construct name or CDA provider file for target cloud storage.
	CONTAINER	Name of container where the migration copy was placed.
	OBJECT PREFIX	Pseudo-directory name for the migration copy. It is a common unique prefix for all objects that make up a migration copy.
ENCRYPTION TYPE	ENCRYPTION TYPE	This data set is encrypted using the type: '0100'X - AES-256 XTS protected key. It will not be displayed if the data set is not encrypted and the field will contain only ****...
KEYLABEL	KEYLABEL	This data is encrypted with the key label displayed. It will not be displayed if the data set is not encrypted and the field will contain only ****...
A field containing only **** is not applicable (see individual field descriptions in the sample lists).		

Figure 121 on page 1354 is a sample of a printer list from the MCDS for all data sets. If you request information for a specific data set, the list contains only the entry for that data set.

Data sets

Figure 123. Sample Printer List when You Specify DATASETNAME and SUMMARY

Requesting data set information from the BCDS

Table 83 on page 1355 explains the output labels for a list of all data sets, all data sets that have the same first qualifier, a specific data set, or list of any copy pools that a volume is a part of.

Table 83. Output labels when you request data set information from the BCDS		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
DSNAME	DSN	This field indicates the data set name of the data set that was backed up.
BACKUP FREQ	BACK FREQ	This field indicates the number of days that must elapse after DFSMSHsm backs up a data set before DFSMSHsm can automatically back up the data set again. "****" indicates that the data set is SMS-managed.
MAX ACTIVE BACKUP VERSIONS	MAX VERS	This field indicates the maximum number of backup versions of the data set that DFSMSHsm is to keep. If more than one data set has backup versions with the same data set name, DFSMSHsm can list more than the maximum number of backup versions. "****" indicates that the data set is SMS-managed.
BACKUP VERSION DATA SET NAME	BDSN	This field indicates the data set name of the backup version.
BACKUP VOLUME	BACKVOL	This field indicates the volume serial number of the volume the backup version is on. The volume can be a backup volume or a migration level 1 volume.
FROM VOLUME	FRVOL	This field indicates the volume serial number of the primary volume where the data set is when DFSMSHsm makes the backup version. If the data set is migrated at the time of backup, this field contains the volume serial number of the primary volume from which the data set migrates.
BACKUP DATE	BACKDATE	This field indicates the date the backup version was created.
BACKUP TIME	BACKTIME	This field indicates the time the backup version was created.
SYS CAT	CAT	This field indicates (YES or NO) that the backup version was made from a cataloged data set.
GEN NMBR	GEN	This field indicates the generation number of the backup version. The most recent backup version is 0, the next most recent is 1, and so forth. "****" indicates that the version is a retained backup copy.
VER NMBR	VER	This field indicates the version number of the backup version. This is an absolute number that uniquely identifies this backup version during its life span. The numbering begins at 1 for the first backup version of the data set. "****" indicates that the version is a retained backup copy.

Table 83. Output labels when you request data set information from the BCDS (continued)		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
UNS/ RET	UNS/RET	<p>This field indicates special or exception conditions.</p> <p>Value Meaning</p> <p>UNS indicates that the data set was unserialized when backed up.</p> <p>RET indicates that the version listed is a retired version.</p> <p>U/R indicates an unserialized, retired version.</p> <p>NO indicates a version that is neither unserialized nor retired.</p>
RET DAYS	RETDAYS	<p>This field indicates the RETAINDAYS keyword was active at the time of the backup. The value represents the minimum number of days that DFSMSHsm maintains the backup copy. "*****" indicates that RETAINDAYS was not specified.</p>
	RACF IND	<p>This field indicates (YES or NO) if the RACF indicator was on at the time of backup.</p> <p>Note: The RACF IND field is displayed only when the output destination is TERMINAL.</p>
BACKUP PROF	BACK PROF	<p>This field indicates (YES or NO) if a RACF discrete backup profile exists.</p>

Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description								
NEW NAME		<p>This field consists of three single-character placeholders. The single-character placeholders are explained:</p> <p>First character indicates (Y or N) if NEWNAME was specified at the time of backup.</p> <p>Second character The values of the second character are:</p> <p>Y indicates the data set is a VSAM data set with an associated AIX/PATH and with SPHERE(NO) specified.</p> <p>N indicates the data set is a VSAM data set with an associated AIX/PATH and without SPHERE(NO) specified.</p> <p>* indicates the data set is a non-VSAM or VSAM data set with no associated AIX/PATH.</p> <p>Third character The values of the second character are:</p> <p>Y indicates the data set is a VSAM data set, is uncataloged or migrated, and the backup was processed with the GVCN(YES) option.</p> <p>N indicates the data set is a VSAM data set, is uncataloged or migrated, and the backup was processed with the GVCN(NO) option.</p> <p>* indicates the data set is a non-VSAM or VSAM data set and is cataloged, but not migrated.</p> <p>Note: The NEWNAME field is displayed only when the output destination is OUTDATASET or SYSOUT.</p>								
	NEWNM	<p>This field indicates (YES or NO) if NEWNAME was specified at the time of backup.</p> <p>Note: The NEWNM field is displayed only when the output destination is TERMINAL.</p>								
	NOSPH	<p>This field indicates:</p> <table><thead><tr><th>Value</th><th>Meaning</th></tr></thead><tbody><tr><td>YES</td><td>if the data set is a VSAM data set with an associated AIX/PATH and with SPHERE(NO) specified.</td></tr><tr><td>NO</td><td>if the data set is a VSAM data set with an associated AIX/PATH and without SPHERE(NO) specified.</td></tr><tr><td>***</td><td>if the data set is a non-VSAM or VSAM data set with no associated AIX/PATH.</td></tr></tbody></table> <p>Note: The NOSPH field is displayed only when the output destination is TERMINAL.</p>	Value	Meaning	YES	if the data set is a VSAM data set with an associated AIX/PATH and with SPHERE(NO) specified.	NO	if the data set is a VSAM data set with an associated AIX/PATH and without SPHERE(NO) specified.	***	if the data set is a non-VSAM or VSAM data set with no associated AIX/PATH.
Value	Meaning									
YES	if the data set is a VSAM data set with an associated AIX/PATH and with SPHERE(NO) specified.									
NO	if the data set is a VSAM data set with an associated AIX/PATH and without SPHERE(NO) specified.									
***	if the data set is a non-VSAM or VSAM data set with no associated AIX/PATH.									

Table 83. Output labels when you request data set information from the BCDS (continued)		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
	GVCN	<p>This field indicates:</p> <p>Value Meaning</p> <p>YES if the data set is a VSAM data set, is uncataloged or migrated, and the backup was processed with the GVCN(YES) option.</p> <p>NO if the data set is a VSAM data set, is uncataloged or migrated, and the backup was processed with the GVCN(NO) option.</p> <p>*** if the data set is a non-VSAM or VSAM data set and is cataloged, but not migrated.</p> <p>Note: The GVCN field is displayed only when the output destination is TERMINAL.</p>
TOTAL BACKUP VERSIONS	TOTAL BACKUP VERSIONS	This field indicates the total number of data set backup versions.
ENCRYPTION TYPE	ENCRYPTION TYPE	This data set is encrypted using the type: '0100'X - AES-256 XTS protected key. It will not be displayed if the data set is not encrypted.
KEYLABEL	KEYLABEL	This data is encrypted with the key label displayed. It will not be displayed if the data set is not encrypted.

Figure 127. Sample Terminal Output for the LIST LEVEL(qualifier) BACKUPCONTROLDATASET Command

Requesting data set information from the MCDS and BCDS

To get a list of data set information from the MCDS and BCDS, specify the LIST command with the DATASETNAME BOTH parameters. To get a list of the information from the MCDS and BCDS for a specific data set specify the LIST command with the DATASETNAME(dsname) BOTH parameters.

The information is provided in separate lists. In each list, the data sets are in alphanumeric sequence by data set name.

Figure 128 on page 1360 is a sample printer list of all data sets when you specify the DATASETNAME, BOTH, and INCLUDEPRIMARY parameters. If you request information for a specific data set, the list contains only the entries for that data set.

Data sets

Figure 128. Sample Printer List of All Data Sets when You Specify DATASETNAME, BOTH, and INCLUDEPRIMARY

Requesting data set information for the latest backup version

Table 84 on page 1360 explains the output labels contained in a list of cataloged data sets whose latest backup version is on the specified backup volume.

Table 84. Output labels when you request data set information for the latest backup version		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
DATA SET NAME	DSN	This field contains the original data set name of the backup version.
FROM VOLUME	FRVOL	This field contains the volume serial number of the primary volume where the data set is when DFSMSHsm makes the backup version. If the data set is migrated at the time of backup, this field contains the volume serial number of the primary volume from which the data set migrates.
BACKUP DATE	BACKDATE	This field contains the date the backup version has been created.
BACKUP TIME	BACKTIME	This field contains the time the backup version has been created.
UNS/ RET	UNS/RET	This field indicates special or exception conditions. UNS indicates that the data set was unserialized when backed up. RET indicates that the version listed is a retired version. U/R indicates an unserialized, retired version. NO indicates a version that is neither unserialized nor retired.

Table 84. Output labels when you request data set information for the latest backup version (continued)		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
RET DAYS	RD	This field contains the RETAINDAYS parameter specified at the time of backup. The value represents the minimum number of days that DFSMSHsm maintains the backup copy. *** indicates that RETAINDAYS was not specified.

Figure 129 on page 1361 is a sample of a printer list having specified the LIST command with the DATASETNAME and SELECT(VOLUME(volser)) parameters.

Requesting information for dump classes

To get a list of the dump class information for a specific type of volume managed by DFSMSHsm, specify the LIST command with the DUMPCLASS(class) parameter. Table 85 on page 1361 explains the output labels when requesting dump class information.

Table 85. Output labels when you request dump class information		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
DUMP CLASS	CLASS	This field indicates the type of dump class for the unit type.
UNIT TYPE	UNIT	This field indicates the type of unit.
AUTO REUSE	REUSE	This field indicates (YES or Y, NO or N) whether the volume for this dump class is automatically available for reuse.
DATASET RESTORE	RESTORE	This field indicates (YES or Y, NO or N) whether to allow a physical data set restore from a full-volume dump copy for this dump class.
RESET CHANGE	RESET	This field indicates (YES or Y, NO or N) whether the change bit for each data set is to be reset by DFSMSDss following a successful full-volume dump.
CLASS DISABLE	DISABLE	This field indicates (YES or Y, NO or N) whether the dump class is disabled.

Table 85. Output labels when you request dump class information (continued)		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
CP REQ	REQD	For a copy pool related dump, this field indicates whether the dump class is required or optional. A value of "***" (or "*" in terminal output) indicates that a value was not specified. This field has no significance for a noncopy pool dump.
FRR AVA	AVAILABLE	For a copy pool recovery, this field indicates (YES or Y, NO or N) whether the tapes related to this dump class are available to be mounted. This field has no significance for noncopy pool recoveries.
DAY	DAY	This field indicates the day in the dump cycle. This can be "***".
FREQ	FREQ	This field indicates the minimum number of days that must elapse between the last volume dump to this class and the next automatic dump.
RETPD	RETPD	This field indicates the number of days dump copies for this dump class must be retained. This can be *NOLIM.
TAPE EXPDT	TAPEEXPDT	This field indicates the expiration date for the dump copies created in this dump class. This can be "*****".
VTOC COPIES	VTOCOPIES	This field indicates the number of VTOC copies.
DISPOSITION	DISP	This field indicates the disposition of the dump volume of this unit type. This can be "*****".
HWCMP	HWCMP	This field indicates (YES or NO) whether the data will be compressed before it is encrypted.
ENCRYPT	ENCRYPT	This field indicates the type of encryption to be performed (NONE, RSA, KEYPASSWORD, or ICOUNT).
ENCTYPE	ENCTYPE	This field indicates the type of encryption to be performed (CLRAES128, CLRTDES, or ENCTDES).
ICOUNT	ICOUNT	This field indicates the number of hash iterations to perform on the password to generate the key.
RSAKEY/KPWD	ENC_KEY	This field indicates either the RSA key label, or the password used to encrypt the dump.
RECOVER RESET	RECRST	<p>This field indicates whether or not DFSMSdss resets (sets to OFF) the data-set-changed indicator (DS1DSCHA) in the VTOC entry for all data sets that are restored during full volume recover processing.</p> <p>Value Meaning</p> <p>YES The indicator is reset.</p> <p>NO The indicator is not reset and retains the value the data sets had when dumped.</p> <p>DUMP If the RESET keyword was specified in the dump class at the time the dump was created, the indicator is reset. If either RESET was not specified, NORESET was specified or the dump copy was created prior to z/OS DFSMSHsm V2R1, the indicator is not reset and retains the value it had when the dumped was created.</p>

Table 85. Output labels when you request dump class information (continued)		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
MINSTACK	MINSTACK	This field indicates the minimum number of dump copies that should be stacked onto a tape before starting another dump task with this dump class. If not specified, the MAXSTACK specified or defaulted value will be used for MINSTACK.
STACK	STACK	This field indicates the maximum number of dump copies to be written to a dump volume in this dump class. The value is set from the STACK or its alias MAXSTACK keyword on the DEFINE DUMPCLASS command.
DUMP DEVCAT	DUDEVCAT	Value Meaning CLOUD Indicates the dumps in the dump class reside in the cloud object storage. TAPE Indicates the dumps in the dump class reside on tapes.
CLOUD	CLOUD	This field contains the name of the SMS cloud network connection construct or the CDA provider file.

Figure 131 on page 1363 is a sample printer list of the dump classes when you specify the DUMPCLASS parameter. If you specify the parameter DUMPCLASS(class), only dump volumes of class are listed.

Requesting information for dump volumes

To get a list of the information for a specific dump volume managed by DFSMSHsm, specify the LIST command with the DUMPVOLUME(*volser*) parameter. To get a list of the information for the dump volumes of the requested status managed by DFSMSHsm, specify the LIST command with the DUMPVOLUME parameter without the volume serial number and with a status parameter (AVAILABLE, UNAVAILABLE, EXPIRED, UNEXPIRED, or NORETENTIONLIMIT). The command lists the volumes in alphanumeric sequence by volume serial number.

Table 86 on page 1364 explains the output labels for any dump volume. These fields are listed for each dump volume and for each dump copy stacked on the volume.

Table 86. Output labels when you request information for dump volumes		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
DUMP VOLSER	DUMPVOL	This field contains the volume serial number of the dump volume.
VOL STATUS	STAT	<p>This field contains the status of the dump volume. Possible values are:</p> <p>Value Meaning</p> <p>AVAIL An available volume is one that has been added to DFSMSHsm's inventory but never used or that has been used but has since been invalidated and remains under DFSMSHsm ownership.</p> <p>UNAVA An unavailable volume is one that has had its contents invalidated, but was not eligible to be automatically reused.</p> <p>EXPIR An expired volume is one that contains parts of one or more valid dump copies, and has reached or passed its expiration date.</p> <p>UNEXP An unexpired volume is one that contains parts of one or more valid dump copies, and has not reached its expiration date.</p> <p>NORET No retention limit.</p>
UNIT TYPE	UNIT	This field contains the unit type of the dump volume.

Table 86. Output labels when you request information for dump volumes (continued)		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
SEQ	FILESEQ	This field contains the number of the file containing the dump copy. If the field contains "****", then the file shown is continued from another dump tape.
SOURCE VOLSER	SOURCEVOL	This field contains the volume serial number of the source for this dump copy.
SMS	SMS	This field indicates whether a volume is SMS-managed. Value Meaning Yes Identifies the volume as SMS-managed No Identifies the volume as non-SMS-managed.
CLASS	CLASS	This field contains the dump class of the dump volume.
DUMPED DATE	DUMPED DATE	This field contains the date of the dump copy.
DUMPED TIME	DUMPED TIME	This field contains the time of the dump copy.
EXP DATE	EXPDATE	This field contains the expiration date of the dump volume.
IDRC	IDRC	Value Meaning Y Volume contains data in the Improved Data Recording Capability format. N Volume does not contain data in the Improved Data Recording Capability format. ** Volume is empty - not assigned the Improved Data Recording Capability format.
LIBRARY	LIBRARY	This field contains the tape library information for the volume. The field can be: Value Meaning library name the library with which the tape volume is associated. *NO LIB* the tape volume is not associated with a tape library. *ERROR** an error occurs when the library information is retrieved. Check the command activity log for additional messages.
PCT FULL	PCT FULL	This field contains the percentage of the dump volume used by all its dump copies. A value of '100' means the last dump copy spans to another volume. A value of '****' means the percentage is unknown.
CP	CP	This field indicates (Y or N) whether the dump volume has at least one source volume that belongs to a Copy Pool.
SET OF DUMP VOLSERS	DUMPVOLS	This field contains a list of volume serial numbers for the tape volumes used to dump the source volume.

Dump volumes

Table 86. Output labels when you request information for dump volumes (continued)		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
HWCOMPRESS	HWCOMP	This field indicates (YES or NO) whether the data was compressed before it was encrypted.
ENCRYPT	ENCRYPT	This field contains the encryption method used (RSA, KEYPASSWORD, or NONE).
ENCRYPTION TYPE	ENCTYPE	This field contains the type of encryption performed (CLRAES128, CLRTDES, or ENCTDES). This field only appears in LIST DUMPVOLUME (volser) output.
RSA KEY LABEL/ RSAKEY/KPWD	KEYPASSWORD	This field contains either the RSA key label, or the password used to encrypt the dump. This field only appears in LIST DUMPVOLUME(volser) output.

Figure 134 on page 1366 is a sample printer list of the specified dump volume when you specify the DUMPVOLUME(volser) parameter.

Figure 136. Sample Printer List of all Dump Volumes when You Specify DUMPVOLUME without (volser)

Requesting dump content information for dump volumes

Table 87 on page 1367 explains the dump content output labels for dump volumes. These fields are listed for each dump volume and for each dump copy that is stacked on the volume.

Table 87. Output labels when you request dump content information for dump volumes

Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
DUMP VOLSER	DUMPVOL	This field contains the volume serial number of the dump volume. If this field contains %CLOUD , it indicates cloud object storage for dump copies.
VOL STATUS	STAT	This field contains the status of the dump volume. Possible values are: Value Meaning AVAIL An available volume is one that has been added to DFSMSHsm's inventory but never used or that has been used but has since been invalidated and remains under DFSMSHsm ownership. UNAVA An unavailable volume is one that has had its contents invalidated, but was not eligible to be automatically reused. EXPIR An expired volume is one that contains parts of one or more valid dump copies, and has reached or passed its expiration date. UNEXP An unexpired volume is one that contains parts of one or more valid dump copies, and has not reached its expiration date. NORET No retention limit.
UNIT TYPE	UNIT	This field contains the unit type of the dump volume.
SEQ	FILESEQ	This field contains the number of the file containing the dump copy. If the field contains '***', then the file shown is continued from another dump tape.
SOURCE VOLSER	SOURCEVOL	This field contains the volume serial number of the only dump copy on the volume, or the dump copy specified with DUMPCONTENTS(srcvol).
SMS	SMS	This field indicates whether a volume is SMS-managed. Value Meaning Yes Identifies the volume as SMS-managed No Identifies the volume as non-SMS-managed.
CLASS	CLASS	This field contains the dump class of the dump volume.
DUMPED DATE	DUMPED DATE	This field contains the date of the dump copy.
DUMPED TIME	DUMPED TIME	This field contains the time of the dump copy.
EXP DATE	EXPDATE	This field contains the expiration date of the dump volume.

Dump volumes

Table 87. Output labels when you request dump content information for dump volumes (continued)		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
IDRC	IDRC	<p>Value</p> <p>Meaning</p> <p>Y Volume contains data in the Improved Data Recording Capability format.</p> <p>N Volume does not contain data in the Improved Data Recording Capability format.</p> <p>** Volume is empty - not assigned the Improved Data Recording Capability format.</p>
LIBRARY	LIB	<p>This field contains the tape library information for the volume. The field can be:</p> <p>Value</p> <p>Meaning</p> <p>library name the library with which the tape volume is associated.</p> <p>*NO LIB* the tape volume is not associated with a tape library.</p> <p>*ERROR** an error occurs when the library information is retrieved. Check the command activity log for additional messages.</p>
PCT FULL	PCT FULL	This field contains the percentage of the dump volume used by all its dump copies. A value of '100' means the last dump copy spans to another volume. A value of '***' means that the percentage is unknown.
SET OF DUMP VOLSER	DUMPVOLS	<p>This field contains a list of volume serial numbers for the tape volumes that are used to dump the source volume.</p> <p>Note: Only one VTOC copy data set is kept for a given dump copy. The above entries are given for a single volume serial number. The following entries are repeated once for each data set that has been dumped to the dump volume. The values shown represent the data set names as they appear in the data set VTOC entry for the data sets.</p>
SOURCE VOLUME	SOURCEVOL	This field contains the volume serial number of the source volume.
DUMP COPY DATA SET	DUMP COPY DATA SET	<p>This field contains the data set name of the dump copy where the contents are listed below.</p> <p>If DUMP VOLSER = %CLOUD, this field contains the object prefix which is the pseudo-directory name for the full-volume dump copy residing in cloud object store. It is a common unique prefix for all objects that make up a full-volume dump copy.</p>
CLOUD	CLOUD	The name that is defined in the SMS cloud network connection construct or the CDA provider file where the full-volume dump copies reside.
CONTAINER	CONTAINER	This field contains the name of the container.
DATASET NAME	DSN	This field contains the list of data sets on the dumped volume.

Table 87. Output labels when you request dump content information for dump volumes (continued)		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
ORG	ORG	<p>This field contains the data set organization on the dumped volume. Possible values are:</p> <p>Value Meaning</p> <p>DA BDAM</p> <p>PE Partitioned data set extended</p> <p>PO Partitioned organization</p> <p>PS Physical sequential</p> <p>VS VSAM</p> <p>** Unknown data set organization</p>
MULTI	MULTI	<p>This field contains the non-VSAM indicator for determining if a data set is a multivolume data set. Possible values are:</p> <p>Value Meaning</p> <p>Yes Data resides on multiple volumes</p> <p>No Data resides on a single volume</p> <p>*** VSAM data sets whether multivolume, single volume, or VTOC index.</p>
CREATED	CREATE	This field contains the creation date of the data set on the dumped volume.
REFERENCED	REF	This field contains the date the data set was last referred to.
EXP DATE	EXP	This field contains the expiration date of the data set. This may be **NONE** .
RACF	RACF	<p>This field indicates whether the data set is RACF protected.</p> <p>Note: If the data set is protected with a generic profile, this field indicates NO. It is only an indication of VTOC information.</p>
PSWD	PSWD	This field indicates whether the data set is password protected.
CHANGED	CHANGED	<p>This field indicates whether the data set has been opened for something other than input since the last backup copy was made.</p> <p>*** Is presented for a VTOC index.</p>
The list data is obtained from the format-1 label. For some data set VTOC entry types, not all of the above fields are maintained.		

Figure 137 on page 1370 is a sample printer list of dump content information for a specific dump volume when you specify the DUMPVOLUME(*volser*) and DUMPCONTENTS(*srcvol*) parameters.

----- END OF - DUMP VOLUME - LISTING -----													

Figure 138. Sample Printer List of cloud dump information for a specific source volume when you specify DUMPVOLUME(%CLOUD) and DUMPCONTENTS(srvol)

Requesting information for primary and migration volumes

To get a list of information for migration or primary volumes, specify the LIST command with the VOLUME, PRIMARYVOLUME, or MIGRATIONVOLUME parameters. Each parameter gives you the following results:

VOLUME

Specific primary or migration volume

VOLUME(volser)

Specific primary or migration volume

PRIMARYVOLUME

All primary volumes

PRIMARYVOLUME(volser)

Specific primary volume

MIGRATIONVOLUME

All migration volumes

MIGRATIONLEVEL1

All migration level 1 volumes

MIGRATIONLEVEL2

All migration level 2 volumes

MIGRATIONLEVEL2(DASD)

All DASD migration level 2 volumes

MIGRATIONLEVEL2(TAPE)

All tape migration level 2 volumes

When you specify LIST VOLUME, DFSMSHsm prints the list in the following order:

1. Primary volumes
2. Migration level 1 volumes
3. Migration level 2 DASD volumes
4. Migration level 2 tape volumes

When you specify LIST MIGRATIONVOLUME, DFSMSHsm prints the list in the following order:

1. Migration level 1 volumes
2. Migration level 2 DASD volumes
3. Migration level 2 tape volumes

When you request information for migration or primary volumes, you can also request that information be listed from the migration control data set (MCDS), backup control data set (BCDS), or both control data sets. When you specify the MIGRATIONCONTROLDATASET parameter, DFSMSHsm lists information about primary and migration volumes. When you specify the BACKUPCONTROLDATASET parameter, DFSMSHsm lists information about primary volumes that have been backed up.

Requesting primary and migration volume information from the MCDS

Table 88 on page 1371 explains output labels when DFSMSHsm lists information from the MCDS for primary and DASD migration volumes.

Table 88. Output labels when you request information from the MCDS for primary and DASD migration volumes		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
VOLSER	VOL	This field indicates the volume serial number of the primary or migration volume.

Table 88. Output labels when you request information from the MCDS for primary and DASD migration volumes (continued)		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
DEVICE TYPE	DEVTYPE	This field indicates the name of the unit where this volume can be allocated.
VOLUME TYPE	VOLTYPE	<p>Value Meaning</p> <p>PRIM The volume has been added as a primary volume.</p> <p>P SMS The volume is known as an SMS-managed volume.</p> <p>LEV 1 The volume has been added as a migration level 1 volume.</p> <p>L 1-OV The OVERFLOW subparameter has been specified on the ADDVOL command for the DASD migration level 1 volume.</p> <p>L2-AV The volume has been added as a DASD migration level 2 volume and is still available to be assigned a key range.</p> <p>L2-UN The volume has been added as a DASD migration level 2 volume and has already been assigned a key range.</p> <p>D The DRAIN attribute has been specified on the ADDVOL command for the DASD migration level 1 or level 2 volume. For example: LEV-1 D, L2-AV D, and L2-UN D.</p>
THRESHOLD HI---LOW	HI-THRESH LO-THRESH	This field indicates the high and low threshold of occupancy defined for this volume. The low threshold of occupancy applies only to primary volumes. Values for SMS-managed volumes are from storage group attributes that DFSMSHsm last retrieved from SMS and are not necessarily the most current values.
FRAG INDEX	FRAG	This field indicates the qualitative measure of the scattered free space on a volume. The values of the index can range from 0 to 1. The higher the value, the more fragmented the free space on the volume.
HOSTID AUTO- MIG	AUTO-HOST MIG	This field indicates the ID of the DFSMSHsm host that assigned the primary volume attribute when making the volume eligible for automatic space management (ADDVOL command AUOTMIGRATION parameter). A value of NONE indicates that the primary volume attribute was not assigned by a DFSMSHsm host. SMS-managed volumes and migration level 1 volumes are excluded and this field indicates "*****" or "***". This field applies to primary volumes only.
HOSTID AUTO- BACK	BACK	This field indicates the ID of the DFSMSHsm host that assigned the primary volume attribute when making the volume eligible for automatic backup (ADDVOL command AUTOBACKUP parameter). A value of NONE indicates that the primary volume attribute was not added by a DFSMSHsm host. SMS-managed volumes and migration level 1 volumes are excluded and this field indicates "*****" or "***". This field applies to primary volumes only.

Table 88. Output labels when you request information from the MCDS for primary and DASD migration volumes (continued)

Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
HOSTID AUTO-DUMP	DUMP	This field indicates the ID of the DFSMSHsm host that assigned the primary volume attribute when making the volume eligible for full-volume automatic dump (ADDVOL command AUTODUMP parameter). A value of NONE indicates that the primary volume attribute was not added by a DFSMSHsm host. SMS-managed volumes are excluded and this field indicates "*****" or "***". This field applies to primary and migration level 1 volumes only.
AUTO RECL	AUTO-RECALL	A YES or Y indicates that the volume is eligible to receive data sets that have the primary volume attribute of automatic recall. This field applies only to DFSMSHsm primary volumes. SMS-managed volumes are excluded with asterisks (*).
SDSP AVAIL	SDSP	YES or Y indicates the following: <ul style="list-style-type: none"> • This volume contains a small-data-set-packing data set and • This volume was ADDVOLed with the SDSP parameter and • The SETSYS SMALLDATASETPACKING command was specified This field applies only to migration level 1 volumes.
MIN AGE	MIN-AGE	This field indicates the inactive age of the data set that most recently migrated from the volume during the last volume space management. SMS-managed volumes are excluded with asterisks (*).
MIGRATED DS--TRKS	MIGDS MIGTRKS	This is the number of data sets that has been migrated or deleted from the volume during the last volume space management. Tracks are not applicable for level 0 volumes and are excluded with asterisks (*). Both fields are only applicable for the last VOLUME request, not for a LEVEL request like secondary space management.
DATE---TIME LAST MIGRATED	MIGDATE-TIME	This is the date and time of the last migration from this volume if primary, or to this volume if Level 2 DASD. This field is invalid for Level 1 volumes.
SPACE-MGMT TYPE/AGE	SPACE-MGMT	This is the space management technique assigned to this volume. MIG indicates migration, DBA indicates data set deletion, and DBU indicates data set retirement. Values for SMS-managed volumes are from storage group attributes that DFSMSHsm last retrieved from SMS and are not necessarily the most current values.
SPACE-MGMT TYPE/AGE	AGE	This field applies only to DFSMSHsm primary volumes. SMS-managed volumes are excluded with asterisks (*). This is the number of days a data set on this volume must be inactive before it is eligible for the type of space management indicated under SPACE-MGMT. DEFAULT or DEF indicates that the age criteria is not specified for the volume in the ADDVOL command. In this case, the age criteria is the larger of SETSYS days value and integrity value, which is based on whether DFSMSHsm is running in a single-DFSMSHsm-host environment or in a multiple-DFSMSHsm-host environment.
BUDEV CATGY	BACKUP-DEVICE-CATEGORY	This field indicates the backup device category, tape or DASD, assigned to this volume. If no category has been assigned, the field contains ANY. This field applies only to DFSMSHsm primary volumes. SMS-managed volumes are excluded with asterisks (*).

Table 88. Output labels when you request information from the MCDS for primary and DASD migration volumes (continued)

Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
DUMP CLASS	DUMPCCLASS	This is the dump class of the primary or migration volume. Values for SMS-managed volumes are from storage group attributes that DFSMSHsm last retrieved from SMS and are not necessarily the most current values.
A field containing only **** is not applicable to this volume (see individual field descriptions in the sample lists).		

Figure 139 on page 1374 is a sample printer list of primary volumes when you specify the PRIMARYVOLUME and MIGRATIONCONTROLDATASET

Figure 140. Sample Printer List of Migration Volumes from the MCDS when You Specify MIGRATIONVOLUME and MIGRATIONCONTROLDATASET

Figure 141 on page 1374 is a sample terminal list for a primary volume when you specify the VOLUME, MIGRATIONCONTROLDATASET, and TERMINAL parameters. The format of the terminal list for a specific primary volume or DASD migration volume or for all primary volumes or all DASD migration volumes has the same format as shown in Figure 141 on page 1374, except that the third line is not produced for migration level 1 volumes. If you request information for only one volume, the list has only one entry.

```

VOL=PRIM13  DEVTYP=3390      VOLTYPE=P SMS  MIGDS=0000  MIGTRKS=****

DUMPCCLASS = DCLASS01 DCLASS02 DCLASS03 DCLASS04 DCLASS05

```

Figure 141. Sample Terminal List of a Volume from the MCDS when You Specify VOLUME, MIGRATIONCONTROLDATASET, and TERMINAL

Table 89 on page 1375 explains the output labels when DFSMSHsm lists information from the MCDS for tape migration level 2 volumes.

Table 89. Output labels when you request information from the MCDS for tape migration level 2 volumes		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
VOLSER	VOL	This field contains the volume serial number of the tape migration level 2 volume.
DEVICE TYPE	DEVTYPE	This field contains the name of the unit where this volume can be allocated.
MIGRATE TYPE	MIGTYPE	L2-TP: The tape volume has been added as a tape migration level 2 volume.
VOL FULL	VOL FULL	A YES or Y indicates that an end-of-tape marker is reached or a data-movement error occurs while DFSMSHsm is writing on the tape volume.
DATE VOL LAST SP MANAGED	SP-MGT-DATE	This is the date that DBA/DBU was last performed on this volume.
VOL EMPTY	VOL EMPTY	A YES or Y indicates that the volume is empty.
DELETED DS	DELDS	This is the number of data sets that were deleted from the volume during the last volume space management.
PSWD	PSWD	A YES or Y indicates that the tape volume is password protected.
EXP	EXP	A YES or Y indicates that this tape volume is protected by an expiration date.
RACF	RACF	A YES or Y indicates that the tape volume is RACF protected.
AVAILABLE	AVAIL	A YES or Y indicates that the tape volume is available. A NO or N normally results from a reply by an operator indicating that the tape will not be mounted.
IN USE	IN USE	Value Meaning NO The tape volume is not being used. MIGD Data set migration is using the tape volume. MIGV Volume migration is using the tape volume. RECL Recall is using the tape volume. RCYS The tape volume is a recycle source volume. RCYT The tape volume is a recycle target volume. DBAU Data set deletion or data set retirement is using the tape volume.
SELECTED	SELD	A YES or Y indicates that this volume is a target migration tape, is not marked full, and was the last tape selected for a migration function. Issue the QUERY MIGRATION command for each host to determine which DFSMSHsm migration function has selected this volume.

Primary and migration volumes from the MCDS

Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
IDRC	IDRC	<p>Value Meaning</p> <p>Y Volume contains data in the Improved Data Recording Capability format.</p> <p>N Volume does not contain data in the Improved Data Recording Capability format.</p> <p>** Volume is empty—not assigned the Improved Data Recording Capability format.</p>
DUPLEX ALT	DUPLEX ALT	<p>Value Meaning</p> <p>volser indicates the volume serial number of the duplexed alternate.</p> <p>*PEND* indicates that an exception condition occurred and an internal TAPECOPY is pending.</p> <p>*NONE* indicates that the volume was not created in a duplexing environment. Although an alternate copy may exist that was created by TAPECOPY, no duplex alternate exists.</p> <p>NA indicates that the original volumes are DASD rather than tape.</p>
PCT FULL	PCT FULL	This field contains the percentage of the migration volume used for a tape written using 3590 architecture. A value of **** means the percentage is unknown.

Figure 142 on page 1376 is a sample printer list of tape migration level 2 volumes when you specify the `MIGRATIONLEVEL2(TAPE)` and `MIGRATIONCONTROLDATASET` parameters.

Requesting primary and migration volume information from the BCDS

[Table 90 on page 1377](#) explains the output labels from the BCDS for the list of migration or primary volumes.

Table 90. Output labels when you request information from the BCDS for primary and migration volumes		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
VOLSER	VOL	This field contains the volume serial number of the volume.
SMS	SMS	This field indicates whether a volume is SMS-managed. Value Meaning Yes Identifies the volume as SMS-managed No Identifies the volume as non-SMS-managed.
OWNED BY catalog	VSAM CTLG	This field contains the data set name of the catalog that currently controls the volume. If the volume is not owned by a VSAM catalog, this field contains NOT OWNED BY catalog. If the controlling catalog is the master catalog, this field contains **MASTER CATALOG**.
CATALOG ON VOLSER	CTLG VOL	This field contains the volume serial number of the volume on which the catalog resides, SYSRES, or blanks.
LAST BACKED UP DATE TIME	LAST BACKED UP ON	This field contains the date and time of the last volume backup for the volume.
DUMPCCLASS	LAST DUMPED TO CLASS	This is the dump class of the primary or migration volume.
DUMPED	ON	This field contains the date of the latest dump in the class.
TIME	AT	This field contains the time of the latest dump in the class.
EXP DATE	EXP DATE	This field contains the expiration date of the latest dump in the class. If RETENTIONPERIOD(NOLIMIT) was specified with the DEFINE DUMPCCLASS or BACKVOL command, the value stored is zero (0) and the value displayed is *NOLIMIT.
A field containing only *** is not applicable to this volume (see individual field descriptions in the sample lists).		

Figure 143 on page 1377 is a sample printer list from the BCDS for a specific primary volume when you specify PRIMARYVOLUME(volser) and BACKUPCONTROLDATASET parameters. The format of the printer list for all primary volumes has the same format as that shown in Figure 143 on page 1377. Similar output is produced for migration level 1 volumes if requested, using the VOLUME, MIGRATIONVOLUME, or MIGRATIONLEVEL1 parameters. If you request information for only one volume, the list has only one entry.

Requesting primary volume dump information from the BCDS

Table 91 on page 1378 explains the output labels when you request dump information from the BCDS for primary volumes.

Table 91. Output labels when you request dump information from the BCDS for primary volumes		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
SOURCE VOLSER	SOURCEVOL	This field contains the volume serial number of the source volume.
GEN	GEN	This field contains relative generation number of the dump for the volume.
SMS	SMS	This field indicates whether a volume is SMS-managed. Value Meaning Yes Identifies the volume as SMS-managed No Identifies the volume as non-SMS-managed.
DUMPED	DATE	This field contains the date of the dump for the volume.
TIME	TIME	This field contains the time of the dump for the volume.
CLASS	DUMPCLASS	This field contains the dump class of the primary volume.
EXP DATE	EXPDATE	This field contains the expiration date of the dump. This might be *NOLIMIT on both the printer listing and on the terminal.
SET OF DUMP VOLSERs / CLOUD INFO	DUMPVOLS	This field indicates the volume serial number of the dump volume. If this field contains %CLOUD, it indicates cloud object storage for dump copies.

Figure 146 on page 1379 is a sample printer list of the tape dump information for a specific primary volume.

Requesting contents of backup VTOC for a primary volume from the BCDS

Table 92 on page 1379 explains the output labels when you request the contents of backup VTOC information for primary volumes from the BCDS.

Table 92. Output labels when you request contents of backup VTOC information from the BCDS for primary volumes		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
VTOC COPY	VTOCCOPY	This field contains the VTOC copy number.
PRIMARY VOLUME	SOURCEVOL	This field contains the volume serial number of the source volume.
DATASET NAME	DSN	This field contains the data set name on the primary volume.

Table 92. Output labels when you request contents of backup VTOC information from the BCDS for primary volumes (continued)

Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
ORG	ORG	<p>This field contains the data set organization on the primary volume. Possible values are:</p> <p>Value Meaning</p> <p>DA BDAM</p> <p>PE Partitioned data set extended</p> <p>PO Partitioned organization</p> <p>PS Physical sequential</p> <p>VS VSAM</p> <p>Unknown data set organization</p>
MULTI	MULTI	<p>This field contains the non-VSAM indicator for determining if a data set is a multivolume data set. Possible values are:</p> <p>Value Meaning</p> <p>Yes Data resides on multiple volumes</p> <p>No Data resides on a single volume.</p> <p>VSAM data sets, whether multivolume, single volume, or VTOC index.</p>
CREATED	CREATE	This field contains the creation date of the data set on the primary volume.
REFERENCED	REF	This field contains the date the data set was last referred to.
EXP DATE	EXP	This field contains the expiration date of the data set. This may be **NONE**.
RACF	RACF	This field contains the indication whether the data set is RACF-protected.
PSWD	PSWD	This field contains the indication whether the data set is password protected.
CHANGED	CHANGED	This field contains the indication whether the data set has been opened for something other than input since the last backup copy was made. *** Is presented for a VTOC index.

Note: The list data is obtained from the Format-1 label. For some data set VTOC entry types, not all of the fields in Table 92 on page 1379 are maintained.

Figure 149 on page 1381 is a sample printer list of the contents of a backup VTOC for a specific primary volume.

Figure 149. Sample Printer List from the BCDS when You Specify PRIMARYVOLUME(volser), BACKUPCONTENTS, and BACKUPCONTROLDATASET

Requesting a list of records serialized by DFSMSHsm host ID

You specify LIST HOST(*hostid*) to get a list of all MCDS, BCDS, and OCDS records currently serialized by the specified DFSMSHsm host ID.

Table 93 on page 1381 explains the output labels when you request a list of records serialized by DFSMSHsm host ID.

Table 93. Output labels when you request information about records serialized by DFSMSHsm host ID		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
HOSTID	HOSTID	This field contains the DFSMSHsm host ID of the DFSMSHsm host that serialized the record.
TYPE	TYPE	This field contains the type of control data set record.
KEY	KEY	This field contains the record key.

Figure 150 on page 1381 is a sample printer list of records serialized by a specific DFSMSHsm host when you specify the HOST(*hostid*) parameter. If you also specify RESET, the HOSTID field in each serialized record is set to X'00'.

```

ARC0817I HOSTID=3 FOUND IN DFSMSHsm CONTROL DATA SET RECORD,
TYPE=V KEY=M2TP01, RESET SUCCESSFUL
ARC0817I HOSTID=3 FOUND IN DFSMSHsm CONTROL DATA SET RECORD,
TYPE=R, KEY=BVR01-0000, RESET SUCCESSFUL
ARC0817I HOSTID=3 FOUND IN DFSMSHsm CONTROL DATA SET RECORD,
TYPE=T, KEY=L2-M2TP01-0000, RESET SUCCESSFUL

```

Figure 150. Sample Printer List when You Specify HOST(*hostid*) and RESET

Requesting information from the tape table of contents (TTOC)

You specify LIST TAPETABLEOFCONTENTS(volser) to get a list of the information contained in the TTOC for a tape backup or migration level 2 volume managed by DFSMSHsm. Preceding the list is an echo of the LIST command issued.

Table 94 on page 1381 explains the output labels when you request information from the TTOC.

Table 94. Output labels when you request information from the tape table of contents		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
VOLSER	VOLSER	This field contains the volume serial number of the tape volume.
UNIT NAME	UNIT NAME	This field contains the name of the unit where this volume can be allocated.

Table 94. Output labels when you request information from the tape table of contents (continued)		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
VOL TYPE	VOL TYPE	This field contains the DFSMSHsm volume category of the tape volume. SPILL indicates a spill backup volume. D(nn) indicates a backup volume assigned to day nn in the backup cycle. UNASS indicates that the volume has not been assigned as a daily or spill backup volume, or that it has been assigned as a daily backup volume but not to a specific day in the backup cycle. ML2 indicates that the volume is a tape migration level 2 volume.
REUSE CAPACITY	CAPACITY	This field contains the nominal number of blocks that DFSMSHsm could write to this tape if it were emptied and written again. It is the actual average in this HSMplex for all full tapes of its cartridge type, recording technology, and function as calculated by the reporting host when it last started DFSMSHsm. The blocks are 16 384 bytes each. ***** indicates that no ML2 or backup tape volumes marked full exist.
VALID BLKS	VALID BLOCKS	This field contains the number of blocks of data on the tape volume that are still valid.
PCT VALID	PCT VALID	This field contains the percent that this tape's valid blocks are of the reuse capacity. A value of 100 is shown for tapes whose number of valid blocks exceed the reuse capacity.
VOL STATUS	VOL STATUS	Empty under this heading indicates that the tape is empty. Full under this heading indicates that while DFSMSHsm was writing to tape, either an end-of-tape marker was reached or a data-movement error occurred, and the volume was marked full to prevent further use. Partial under this heading indicates that the tape is neither empty nor full. The tape has been written to but may or may not contain valid data.
RACF	RACF	YES or Y indicates that the tape volume is RACF protected.
PREV VOL	PREV VOL	If this field contains a volume serial number, the first data set on this tape volume is valid and does not begin on this volume, but is a continuation of the last data set on the indicated previous volume. If the field contains NONE, either the first data set is not valid or it begins on this volume.
SUCC VOL	SUCC VOL	If this field contains a volume serial number, the last data set on this tape volume is valid and does not end on this volume. The data set is continued on the indicated succeeding volume as the first data set on that volume. If the field contains NONE, either the last data set is not valid or it ends on this volume.
NUM REC	NUM REC	This field contains the number of offline control data set T records, including the base and extension records, used to contain this TTOC.
ONE FILE	ONE FILE	A YES or Y indicates that the tape volume has a single file containing the user data sets. A NO or N indicates that each user data set on the tape volume is in a separate tape data set. An *** indicates the ONE FILE is irrelevant because DFSMSHsm has not written on the volume.

Table 94. Output labels when you request information from the tape table of contents (continued)		
Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
ALT VOL	ALTVOL	Volume serial number of duplicate tape copy created by DFSMSHsm TAPECOPY command; *NONE* if duplicate tape is not so created; ***** indicating that the information is not known. If the optional parameter SELECT (DISASTERALTERNATEVOLUMES) is specified, this field shows the alternate tape volume that has been flagged as disaster alternate volume.
LIB	LIB	<p>This field contains the tape library information for the volume. The field can be:</p> <p>Value Meaning</p> <p><i>library name</i> the library with which the tape volume is associated.</p> <p>*NO LIB* the tape volume is not associated with a tape library.</p> <p>*ERROR** an error occurs when the library information is retrieved. Check the command activity log for additional messages.</p>
STORAGE GROUP	STORAGE GROUP	<p>This field contains the name of the storage group. If there is a library name for the volume, there must be a storage group name. Connected tape volumes must be in the same storage group and library. The storage group field can be:</p> <p>Value Meaning</p> <p><i>storage group name</i> storage group name associated with the tape volume.</p> <p>**NO SG* a storage group is not associated with this volume.</p> <p>*ERROR** an error occurs when the library information is retrieved. Check the command activity log for additional messages.</p>
DATA SET NAME	DATA SET NAME	This field contains the name of the data sets on the volume. If the data set is on a tape backup volume, this name is the DFSMSHsm-generated backup version name. If a data set is on a tape migration level 2 volume, this name is the original data set name, not the migrated data set name that DFSMSHsm generates.
NUM BLOCKS	NUM BLOCKS	This field contains the number of blocks used on this volume for this data set.
RELATIVE FBID	REL FBID	This field contains the file sequence number of this data set or the set of blocks relative to the beginning of the single tape volume. For example, the first data set or data set segment on the tape volume has a relative FBID of 4 independent of any predecessor tapes.
VSAM	VSAM	YES or Y indicates that the data set is a backup version or a migration copy of a VSAM data set.
RACF	RACF	YES or Y indicates that the data set is discretely RACF-protected.
LAST REF DATE	LAST REF DATE	This field contains the last date when the migrated data set was referred to. This field does not apply to backup versions.
EXP DATE	EXP DATE	This field contains the expiration date of the user's data set. This field does not apply to backup versions. For ML2 tapes, asterisks means the date is a never expire date.

Table 94. Output labels when you request information from the tape table of contents (continued)

Printer Output Label (OUTDATASET or SYSOUT)	Terminal Label	Description
A field containing only **** is not applicable to this volume (see individual field descriptions in the sample lists.)		

Note: The LIST TTOC *volser* ODS *dsn* command can take an extensive amount of time to complete processing when trying to write out over 1 million data set entries in the ODS *dsn*. You can only get a million records if you are using extended TTOCs.

Nine reports are possible for the LIST TTOC display output. The report columns are all the same. Only the header and trailer inserts will change to indicate what type of report has been requested on the input command.

- If the input command is issued for a list of tape volumes that have DISASTERALTERNATEVOLUMES, the header and trailer insert will be DISASTER ALTERNATE - LISTING.
- If the input command is issued for a list of tape volumes that have failed recycle, then the header and trailer insert will be FAILED RECYCLE - LISTING.
- If the input command is issued for a list of tape volumes that have failed create, then the header and trailer insert will be FAILED CREATE - LISTING.
- If the input command is issued for tape volumes that contain data sets that span four or more volumes, then the header and trailer insert will be EXCESSIVE VOLUME - LISTING.
- If the input command is issued for a list of tape volumes that have TAPETABLEOFCONTENTS SELECT(CONNECTED), then the trailer insert will be ***END OF CONNECTED TAPE VOLUME SET ***.
- If the input command is issued for a list of ML2 volumes taken away by RECALL or ABACKUP, then the header and trailer insert will be RECALL TAKE AWAY — LISTING.
- If the input command is issued for a list of volumes having alternate tapes in a library, then the header and trailer insert will be LIBRARY(ALTERNATE) — LISTING.
- If the input command is issued for a list of volumes having alternate tapes not in a library, then the header and trailer insert will be NOLIB(ALTERNATE) — LISTING.
- If the input command issued is other than those listed above, the header and trailer insert will be TAPE VOLUME TTOC - LISTING.

Figure 151 on page 1384 is a sample of an ODS output dataset list when you have specified the TAPETABLEOFCONTENTS SELECT(CONNECTED) parameter.

Figure 160. Sample Printer List when You Specify SELECT(NOTASSOCIATED)

Requesting information for all user entries or a specific user entry

To get a list of the information for all user entries, specify the LIST command with the USER parameter. User entries exist only for those users who have been, or are currently, authorized. The output is in alphanumeric sequence by user identification. To get a list of the information for a specific user entry, specify the LIST command with the USER(userid) parameter. The list for all the users or a specific user includes the user identity and authorization.

The last line of this output specifies whether DFSMSHsm commands are protected by RACF FACILITY Class profiles or by the DFSMSHsm AUTH command. Use this information to determine whether the user IDs listed with the LIST USER command are to be used for authorization to storage administrator commands.

Figure 161 on page 1387 is a sample printer list of user entries when you specify USER.

```
- DFSMSHSM CONTROL DATASET - USER-- LISTING ----- AT 08:49:11 ON 02/08/20 FOR SYSTEM 3090

----- END OF - USER - LISTING -----
```

Figure 161. Sample Printer List of User Entries when You Specify USER

Chapter 77. Using the QUERY command

You use the QUERY command to determine what values you specified with the DFSMSHsm commands, to list DFSMSHsm statistics, or to list the status of pending requests.

When you issue the QUERY command, the information you have requested is printed as a message at your terminal and is sent to the DFSMSHsm log. The following list shows the messages, arranged by parameter name, associated with the QUERY command.

Note:

1. Paired braces { } mean that only one of the items within the braces will appear in the actual message text.
2. Paired brackets [] mean that the item within the brackets may or may not appear in the actual message text.
3. A vertical bar (|) separates alternative choices.

For more information about the messages you receive when you use QUERY command, refer to [z/OS MVS System Messages, Vol 2 \(ARC-ASA\)](#).

Chapter 78. Using the REPORT command

You use the REPORT command to generate reports based on the DFSMSHsm statistics records in the MCDS.

When you request a statistics report, you can specify the DELETE parameter to scratch the statistics records used as input to the report after the REPORT command finishes its processing. This parameter is not related to the DELETE subparameter of the FUNCTION parameter. You can also have the output from the REPORT command sent either to the SYSOUT class or to an alternative output data set. For an alternative method of creating customized reports about HSM activities from SMF (FSR and WWFSR) records, see [Chapter 14, “Obtaining information from DFSMSHsm,”](#) on page 559 and the *z/OS DFSMSrmm Reporting*.

Requesting a report of the daily statistics for all functions

Specify REPORT DAILY to get a report of the daily statistics. [Table 95 on page 1401](#) shows the output headings for the daily statistics report.

If you specify selected functions such as REPORT DAILY FUNCTION BACKUP or REPORT DAILY FUNCTION RECOVER, then line 5 is output only if BACKUP is requested and line 6 is output only if RECOVER is requested.

Table 95. Headings of output when you request a daily statistics report		
Line number	Daily statistics output heading	Description
1	DAILY STATISTICS REPORT FOR YY/MM/DD	When you specify REPORT DAILY, this line contains today's date. When you specify REPORT DAILY FROMDATE(yyyy/mm/dd) TODATE(yyyy/mm/dd), this line contains the first date that you specify. DFSMSHsm reports all statistics for the first date. Then it reports the daily statistics for the second day, and so forth.
2	STARTUPS=xxx	This field shows how many times DFSMSHsm was started on the specified day.
2	SHUTDOWNS=xxx	This field shows how many times DFSMSHsm was stopped on the specified day.
2	ABENDS=xxx	This field shows how many times DFSMSHsm abnormally ended for the specified day.
2	WORK ELEMENTS PROCESSED=xxxxxx	This field shows how many management work elements DFSMSHsm processed for the specified day. If DFSMSHsm is reporting daily statistics for all functions, this field means how many management work elements DFSMSHsm processed.
2	BKUP VOL RECYCLED=xxxxx	This field shows how many tape backup volumes DFSMSHsm recycled for the specified day.
2	MIG VOL RECYCLED=xxxxx	This field shows how many tape migration level 2 volumes DFSMSHsm recycled for the specified day.
3	DATA SET MIGRATIONS BY VOLUME REQUEST=xxxxxx	This field shows how many data sets were processed during automatic and command volume migration.
3	DATA SET MIGRATIONS BY DATA SET REQUEST=xxxx	This field shows how many data sets were processed by the DATASETNAME parameter of the MIGRATE command
3	BACKUP REQUESTS=xxxxxx	This field shows how many data sets were backed up during automatic and command backup processing.
4	EXTENT REDUCTIONS=xxxxxx	This field shows the number of extent reductions performed each day.
4	RECALL MOUNTS AVOIDED=xxxxxx	This field shows how many times a recall request was satisfied by a tape already mounted.
4	RECOVER MOUNTS AVOIDED=xxxxxx	This field shows how many times a recover request was satisfied by a tape already mounted.

Table 95. Headings of output when you request a daily statistics report (continued)

Line number	Daily statistics output heading	Description
5	FULL VOLUME DUMPS = xxxxx REQUESTED	This field shows how many full-volume dumps were requested.
5	xxxxx FAILED	This field shows how many of the full-volume dumps failed.
5	DUMP COPIES=xxxxxx REQUESTED	This field shows how many dump copies were requested.
5	xxxxxx FAILED	This field shows how many of the dump copies failed. You get this version of line 5 only when you issue the command REPORT DAILY FUNCTION BACKUP.
6	FULL VOLUME RESTORES = xxxxx REQUESTED	This field shows how many full-volume restores were requested.
6	xxxxx FAILED	This field shows how many of the full-volume restores failed.
6	DATASET RESTORES = xxxxx REQUESTED	This field shows how many data set restores were requested.
6	xxxxx FAILED	This field shows how many of the data set restores failed. You get this version of line 4 only when you issue the command REPORT DAILY FUNCTION RECOVER.
7	ABACKUPS=xxxxx REQUESTED	This field shows how many aggregate backups were requested.
7	xxxxx FAILED	This field shows how many of the aggregate backups failed.
7	EXTRA ABACKUP MOUNTS=xxxxx	This field shows how many times ABACKUP had to remount an ML2 tape taken away by recall.
8	DATA SET MIGRATIONS BY RECONNECTION=xxxxx	This field shows the number of data sets reconnected.
8	NUMBER OF TRACKS RECONNECTED=xxxxx	This field shows the number of tracks on level 0 volumes that were freed by reconnection.
9	FAST REPLICATION VOLUME BACKUP=xxxxxxxx REQUESTED, xxxxxxxx FAILED	This field shows the number of fast replication backup versions that were requested and how many of the fast replication backups failed.
10	FAST REPLICATION VOLUME RECOVER=xxxxxxxx REQUESTED, xxxxxxxx FAILED	This field shows the number of fast replication recoveries that were requested and how many of the fast replication recoveries failed.
11	DATA SET CLASS TRANSITION=xxxxxxxx REQUESTED, xxxxxxxx FAILED	This field shows the number of class transitions that were requested and how many of the class transitions failed.

Table 95. Headings of output when you request a daily statistics report (continued)

Line number	Daily statistics output heading	Description
12 and 13	HSM FUNCTION	<p>This field contains the names of the functions DFSMSHsm processed. When you specify REPORT DAILY FUNCTION, DFSMSHsm reports the daily statistics in the following order:</p> <ol style="list-style-type: none"> 1. MIGRATION <p>The category SUBSEQUENT MIGS reflects all movements of data sets from ML1 to ML1, ML1 to ML2, and ML2 to ML2. This includes FREEVOL moves but does not include RECYCLE moves. The PRIMARY to LEVEL2 category includes data set migrations by reconnection. The PRIMARY to CLOUD category includes data set migrations by reconnection.</p> 2. RECALL 3. DELETE <p>Deletion of migrated data sets include only those deleted by the DELETEBYAGE (DBA) or DELETEBACKEDUP (DBU) functions from migration volumes, generation data sets that have been rolled-off from migration volumes, and migrated data sets that have expired by date or MCLASS attributes.</p> <p>Deletion of primary data sets include only those deleted by the DELETEBYAGE (DBA) or DELETEBACKEDUP (DBU) functions, generation data sets that have been rolled-off from primary volumes, and primary data sets that have expired by date or MCLASS attributes.</p> <p>The DBA and DBU functions apply only to non-SMS data sets.</p> 4. BACKUP <p>SUBSEQUENT BACKUP results from command backup, daily backup, FREEVOL processing and is the combined total of the following:</p> <ul style="list-style-type: none"> • Data sets moved from backup volumes to spill volumes. • Data sets moved from ML1 volumes to backup volumes. <p>DELETE BACKUP results from command backup, daily backup, BDELETE and EXPIREBV processing and is the combined total of the following:</p> <ul style="list-style-type: none"> • Backup volumes deleted after DFSMSHsm processes the EXPIREBV command • Deletion of excessive incremental backups • Data sets deleted after DFSMSHsm processes the BDELETE command 5. RECOVER 6. RECYCLE 7. CLASS TRANSITION <p>You can also choose to ask DFSMSHsm to report statistics for specific DFSMSHsm functions. For example, when you specify REPORT DAILY FUNCTION RECYCLE(ALL), DFSMSHsm prints a daily statistics report of the number of tape backup and ML2 volumes DFSMSHsm recycled during the time period you specified.</p> <p>MIGRATION and RECALL statistics do not include amounts for extent reductions.</p>
12 and 13	NUMBER DATASETS	This field shows how many data sets DFSMSHsm processed for each function.
12 and 13	-----READ----- TRK/BLK BYTES	This field shows how many tracks or blocks DFSMSHsm read when processing the specific function. For data movement involving DASD, the first part of the field contains the number of tracks. For recycle, the first part of the field contains the number of 16K tape blocks. The last part of the field contains the number of kilobytes DFSMSHsm read when processing the specific function.

Table 95. Headings of output when you request a daily statistics report (continued)		
Line number	Daily statistics output heading	Description
12 and 13	-----WRITTEN----- TRK/BLK BYTES	This field shows how many tracks or blocks DFSMShsm wrote when processing the specific DFSMShsm function. For data movement involving DASD, the first part of the field contains the number of tracks. TRK/BLK represents the number of tracks of compressed data written and BYTES represents the number of bytes written (uncompressed). For recycle, the first part of the field contains the number of 16K tape blocks. The last part of the field contains the number of kilobytes DFSMShsm wrote when processing the specific function.
12 and 13	-----REQUESTS----- SYSTEM USER FAILED	This field shows how many requests came from DFSMShsm during its automatic processing, how many came from the user, and how many of the total requests failed.
12 and 13	AVERAGE AGE	This field contains the average age of the data sets that each function processed. For the MIGRATION and DELETE functions, this is the age of the average data set since it was last referred to. It is calculated by subtracting the date last referred to from the age of migration and dividing the result by the total number of data sets processed. For the RECALL function, this age is how long the average data set has been migrated. For the BACKUP, SPILL, and RECOVER functions, this age is the last time DFSMShsm made a backup version of the data set. The average age does not apply to the RECYCLE function.
12 and 13	-----AVERAGE TIME----- QUEUED WAIT PROCESS TOTAL	This field shows the average time in seconds that the request for each data set was waiting to be processed, the time spent allocating and opening each data set, and the time spent processing each data set. TOTAL shows the average time it took DFSMShsm to process each data set request. For the SUMMARY, the time for each day is accumulated prior to calculating the daily average. The AVERAGE TIME field is the total time for all days divided by the total number of data sets, giving the average time per data set.

If you specify the FROMDATE and TODATE parameters, DFSMShsm prints a summary of all the daily statistics after it prints the daily statistics for each day you specified. If you have requested statistics for specific functions, the report contains statistics for only those functions.

Note: If the letter K, M, G, or T follows any field, then the reported number is represented to the nearest kilobyte (kilotrack), megabyte, gigabyte, or terabyte, respectively. All output will be reported to the smallest possible unit measure. For example:

```
1 KILOBYTE = 1024 bytes
1 KILOTRACK = 1024 tracks
1 MEGABYTE = 1,048,576 bytes
1 GIGABYTE = 1,073,741,824 bytes
1 TERABYTE = 1,099,511,627,776 bytes.
```

```
999,945,993,123 will be represented as 976509759K.
103,999,945,993,123 will be represented as 99182077M.
112,103,999,945,993,123 will be represented as 104404986G.
4,112,103,999,945,993,123 will be represented as 3739937T.
```

The maximum reportable number is 4 611 686 018 427 387 904 or 4194304T. After this value is exceeded, the output reported resets and begins at zero. If it is suspected that this condition exists, rerun the report with a closer specified FROMDATE/TODATE.

Figure 162 on page 1405 is a sample of a daily statistics report that you get when you specify REPORT DAILY FUNCTION FROMDATE(2002/08/19) TODATE(2002/08/20). Therefore, you have the daily statistics for each day and then you have a summary report for the two days.

```
--DFSMShM STATISTICS REPORT ----- AT 15:07:26 ON 2002/08/20 FOR SYSTEM=MVS4
```

Figure 162. Sample report of daily statistics by function

Requesting a report of the volume statistics for all functions

You specify REPORT VOLUMES to get a report of the volume statistics for all volumes managed by DFSMSHsm. You specify VOLUMES with a volume serial number to get a statistics report for a specific volume.

Note: REPORT VOLUMES shows only the last full-volume dump and full-volume restore of each source volume for each day. It will not show multiple dumps or restores of a given source volume on a given day. To find out the total number of full-volume dumps and full-volume restores on a given day, issue the REPORT DAILY command.

Table 96 on page 1406 contains the volume statistics report for all the functions.

Table 96. Headings of output when you request a volume statistics report		
Line Number	Volume Statistics Output Heading	Description
1	VOLUME STATISTICS REPORT FOR VOLUME <i>volser</i> FOR YY/MM/DD	When you specify REPORT VOLUMES, this line contains today's date. When you specify REPORT VOLUMES FROMDATE(<i>yyyy/mm./dd</i>) TODATE(<i>yyyy/mm./dd</i>), this line contains the first date you specify. DFSMSShsm reports all volume statistics for the first date, then reports the volume statistics for the second day, and so forth. This line also shows the volume serial number of the volume whose statistics are being reported.
2	UNIT TYPE= <i>unittype</i>	This field shows the type of unit where the volume is mounted. These fields will have U to represent an L0 non-DFSMSShsm volume.
2	HSM VOLUME TYPE= <i>voltype</i>	This field shows the type of volume whose statistics are being reported. The types of volumes are: PRIMARY, ML1, ML2, DAILY, SPILL and BACKUP.
3	MIGRATED DATA SETS BY VOLUME REQUEST= <i>xxxx</i>	This field shows how many data sets were processed during automatic and command volume migration.
3	DATA SET MIGRATIONS BY DATA SET REQUEST= <i>xxxx</i>	This field shows how many data sets were processed by the DATASETNAME PARAMETER of the MIGRATE command.
3	DATA SETS ON VOLUME= <i>xxxxxx</i>	This field contains the number of non-VSAM data sets that DFSMSShsm has processed. When DFSMSShsm generates a report for primary volumes, this field contains N/A. This field also contains N/A for the summary reports.
4	MINIMUM AGE= <i>xxx</i>	This field contains the age of the youngest data set that migrated from the volume the last time DFSMSShsm did volume migration.
4	TOTAL TRACKS= <i>xxxxxxxx</i>	This field shows the total number of allocated tracks on the volume as of the last free space check prior to the creation of this VSR.
4	FREE TRACKS= <i>xxxxxxxx</i>	This field shows the total number of free tracks available for allocation for new data sets other than suballocated VSAM data sets. This value is accurate as of the last free space check prior to the creation of this VSR.
4	FRAGMENT INDEX= <i>xxx</i>	This field shows the fragmentation index for the volume.
5	VOLUME DUMP= <i>xxxxxxxx</i> ;	This field shows the status of the volume dump. The status <i>xxxxxxxx</i> may be one of the following: <ul style="list-style-type: none"> • DONE • NOT DONE • FAILED
5	DUMP COPIES= <i>xxx</i> REQUESTED	This field shows the number of dump copies requested.
5	FAILED= <i>xxx</i>	This field shows the number of dump copies that failed. You get this version of line 3 only when you issue the command REPORT VOLUMES FUNCTION BACKUP.
6	VOLUME RESTORE= <i>xxxxxxxx</i> ;	This field shows the status of the volume restore. The status <i>xxxxxxxx</i> may be one of the following: <ul style="list-style-type: none"> • DONE • NOT DONE • FAILED
6	DATASET RESTORES = <i>xxxxxx</i> REQUESTED	This field shows the number of data sets requested to be restored.
6	FAILED= <i>xxxxxx</i>	This field shows the number of data sets that failed restoration. You get this version of line 6 only when you issue the command REPORT VOLUMES FUNCTION RECOVER.

Table 96. Headings of output when you request a volume statistics report (continued)

Line Number	Volume Statistics Output Heading	Description
7	DATA SET MIGRATIONS BY RECONNECTION=xxxxx	This field shows the number of data sets reconnected.
7	NUMBER OF TRACKS RECONNECTED=xxxxx	This field shows the number of tracks on level 0 volumes that were freed by reconnection.
7	NUMBER OF TRACKS RECONNECTED TO CLOUD=xxxxx	This field shows the number of tracks on level 0 volumes that were freed by reconnection.
8	FAST REPLICATION BACKUP=xxxxx REQUESTED, xxxxx FAILED	This field shows the number of times that a fast replication backup was attempted for the volume and the number of failed attempts for that volume.
9	FAST REPLICATION RECOVER=xxxxx REQUESTED, xxxxx FAILED	This field shows the number of times that a fast replication recovery was attempted for the volume and the number of failed attempts for that volume.
10	DATA SET CLASS TRANSITION=xxxxx REQUESTED, xxxxx FAILED	This field shows the number of class transitions that were requested and how many of the class transitions failed.

Table 96. Headings of output when you request a volume statistics report (continued)		
Line Number	Volume Statistics Output Heading	Description
11 and 12	HSM FUNCTION	<p>This field contains the names of the functions DFSMSHsm processed. When you specify REPORT VOLUMES FUNCTION, DFSMSHsm reports the volume statistics in the following order:</p> <ol style="list-style-type: none"> 1. MIGRATION <p>The category SUBSEQUENT MIGS reflects all movement of data sets from ML1 to ML1, ML1 to ML2, and ML2 to ML2. This includes FREEVOL moves but does not include RECYCLE moves. The PRIMARY to LEVEL2 category includes data set migrations by reconnection. The PRIMARY to CLOUD category includes data set migrations by reconnection.</p> 2. RECALL 3. DELETE <p>Deletion of migrated data sets include only those deleted by the DELETEBYAGE (DBA) or DELETEBACKEDUP (DBU) functions from migration volumes, generation data sets that have been rolled-off from migration volumes, and migrated data sets that have expired by date or MCLASS attributes.</p> <p>Deletion of primary data sets include only those deleted by the DELETEBYAGE (DBA) or DELETEBACKEDUP (DBU) functions, generation data sets that have been rolled-off from primary volumes, and primary data sets that have expired by date or MCLASS attributes.</p> <p>The DBA and DBU functions apply only to non-SMS data sets.</p> 4. BACKUP <p>SUBSEQUENT BACKUP results from command backup, daily backup, FREEVOL processing and is the combined total of the following:</p> <ul style="list-style-type: none"> • Data sets moved from backup volumes to spill volumes • Data sets moved from ML1 volumes to backup volumes <p>DELETE BACKUP results from command backup, daily backup, BDELETE and EXPIREBV processing and is the combined total of the following:</p> <ul style="list-style-type: none"> • Backup volumes deleted after DFSMSHsm processes the EXPIREBV command • Deletion of excessive incremental backups • Data sets deleted after DFSMSHsm processes the BDELETE command 5. RECOVER 6. RECYCLE 7. CLASS TRANSITION <p>You can also choose to ask DFSMSHsm to report statistics for specific DFSMSHsm functions. For example, when you specify REPORT VOLUME FUNCTION RECOVER, DFSMSHsm prints a volume statistics report of the number of data sets DFSMSHsm recovered during the time period you specified.</p> <p>MIGRATION and RECALL statistics do not include amounts for extent reductions.</p>
11 and 12	NUMBER DATASETS	This field shows how many data sets DFSMSHsm processed for each function.
11 and 12	-----READ----- TRK/BLK K-BYTES	This field is not applicable.
11 and 12	----WRITTEN---- TRK/BLK K-BYTES	This field is not applicable.

Table 96. Headings of output when you request a volume statistics report (continued)		
Line Number	Volume Statistics Output Heading	Description
11 and 12	----REQUESTS---- SYSTEM USER FAILED	This field shows how many requests came from DFSMSHsm during its automatic processing, how many came from the user, and how many of the total requests failed.
11 and 12	AVERAGE AGE	This field contains the average age of the data sets that each function processed. For the MIGRATION and DELETE functions, this is the age of the average data set since it was last referred to. It is calculated by subtracting the date last referred to from the age of migration and dividing the result by the total amount of data sets processed. For the RECALL function, this age is how long the average data set has been migrated. For the BACKUP, SPILL, and RECOVER functions, this age is the last time DFSMSHsm made a backup version of the data set. The average age does not apply to the RECYCLE function.
11 and 12	AVERAGE TIME QUEUED WAIT PROCESS TOTAL	This field shows the average time in seconds that the request for each data set was waiting to be processed, the time spent allocating and opening each data set, and the time spent processing each data set. TOTAL shows the average time it took DFSMSHsm to process each data set request.

If you specify the FROMDATE and TODATE parameters, DFSMSHsm prints a summary of all the volume statistics after it prints the volume statistics for each day you specified. If you have requested statistics for specified functions, the report contains statistics for only those functions.

Figure 163 on page 1410 is a sample of a volume statistics report you get when you specify REPORT VOLUMES FUNCTION FROMDATE(2002/08/16) TODATE(2002/08/175). Therefore, you have the volume statistics for all volumes for each day and then you have a summary report for two days.

Using the REPORT command

```
--DFSMSHSM STATISTICS REPORT ----- AT 15:10:12 ON 2002/08/20 FOR SYSTEM=MVS4  
  
VOLUME STATISTICS REPORT FOR VOLUME MIG410 FOR 02/08/16

Figure 163. Sample report of volume statistics by function

Requesting a summary of the daily or volume statistics

You specify REPORT DAILY FUNCTION SUMMARY to get the summary totals of the daily statistics for all functions. You specify REPORT VOLUME FUNCTION SUMMARY to get the summary totals of the volume statistics for all volumes and all functions. You specify the VOLUMES parameter with a volume serial number to get summary statistics for only one volume. If you request a summary of specified functions, the summary contains the statistics totals for only the specified functions.

When you specify SUMMARY, you get only the summary report. If you do not specify SUMMARY, you get the statistics report you requested and a summary at the end of the report if DFSMSHsm reports the statistics for more than one day. A sample of the summary statistics report is not shown because the

information is in the same format as the summary information shown in [Figure 162 on page 1405](#) and [Figure 163 on page 1410](#).

Note: For an equivalent time period, it is possible that the number of data sets reported by the REPORT VOLUME command and the number of data sets reported by the REPORT DAILY command will not be the same on the summary page, under the heading "Number Datasets". Some functions (such as MIGRATION, RECALL, BACKUP, RECOVER, and SPILL) involve two volumes, while other functions do not. As each volume counts each data set action, some data set actions will be counted more than once.

Appendix A. Accessibility

Accessible publications for this product are offered through [IBM Documentation for z/OS \(www.ibm.com/docs/en/zos\)](http://www.ibm.com/docs/en/zos).

If you experience difficulty with the accessibility of any z/OS documentation see [How to Send Feedback to IBM](#) to leave documentation feedback.

Notices

This information was developed for products and services that are offered in the USA or elsewhere.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not grant you any license to these patents. You can send license inquiries, in writing, to:

IBM Online Privacy Statement

IBM Software products, including software as a service solutions, ("Software Offerings") may use cookies or other technologies to collect product usage information, to help improve the end user experience, to tailor interactions with the end user, or for other purposes. In many cases no personally identifiable information is collected by the Software Offerings. Some of our Software Offerings can help enable you to collect personally identifiable information. If this Software Offering uses cookies to collect personally identifiable information, specific information about this offering's use of cookies is set forth below.

Depending upon the configurations deployed, this Software Offering may use session cookies that collect each user's name, email address, phone number, or other personally identifiable information for purposes of enhanced user usability and single sign-on configuration. These cookies can be disabled, but disabling them will also eliminate the functionality they enable.

If the configurations deployed for this Software Offering provide you as customer the ability to collect personally identifiable information from end users via cookies and other technologies, you should seek your own legal advice about any laws applicable to such data collection, including any requirements for notice and consent.

For more information about the use of various technologies, including cookies, for these purposes, see IBM's Privacy Policy at ibm.com/privacy and IBM's Online Privacy Statement at ibm.com/privacy/details in the section entitled "Cookies, Web Beacons and Other Technologies," and the "IBM Software Products and Software-as-a-Service Privacy Statement" at ibm.com/software/info/product-privacy.

Policy for unsupported hardware

Various z/OS elements, such as DFSMSdfp, JES2, and MVS, contain code that supports specific hardware servers or devices. In some cases, this device-related element support remains in the product even after the hardware devices pass their announced End of Service date. z/OS may continue to service element code; however, it will not provide service related to unsupported hardware devices. Software problems related to these devices will not be accepted for service, and current service activity will cease if a problem is determined to be associated with out-of-support devices. In such cases, fixes will not be issued.

Minimum supported hardware

The minimum supported hardware for z/OS releases identified in z/OS announcements can subsequently change when service for particular servers or devices is withdrawn. Likewise, the levels of other software products supported on a particular release of z/OS are subject to the service support lifecycle of those

products. Therefore, z/OS and its product publications (for example, panels, samples, messages, and product documentation) can include references to hardware and software that is no longer supported.

- For information about software support lifecycle, see: [IBM Lifecycle Support for z/OS \(www.ibm.com/software/support/systemsz/lifecycle\)](http://www.ibm.com/software/support/systemsz/lifecycle)
- For information about currently-supported IBM hardware, contact your IBM representative.

Programming interface information

This information primarily contains information that is NOT intended to be used as Programming Interfaces of DFSMSHsm.

This information also contains intended Programming Interfaces that allow the customer to write programs to obtain the services of DFSMSHsm. This information is identified where it occurs, either by an introductory statement to a topic or by the following marking:

Programming Interface Information

Trademarks

IBM, the IBM logo, and [ibm.com](http://www.ibm.com) are trademarks or registered trademarks of International Business Machines Corp., registered in many jurisdictions worldwide. Other product and service names might be trademarks of IBM or other companies. A current list of IBM trademarks is available on the Web at [Copyright and Trademark information \(www.ibm.com/legal/copytrade.shtml\)](http://www.ibm.com/legal/copytrade.shtml).

Microsoft, Windows, Windows NT, and the Windows logo are trademarks of Microsoft Corporation in the United States, other countries, or both.

Java and all Java-based trademarks and logos are trademarks or registered trademarks of Oracle and/or its affiliates.

The registered trademark Linux® is used pursuant to a sublicense from the Linux Foundation, the exclusive licensee of Linus Torvalds, owner of the mark on a worldwide basis.

UNIX is a registered trademark of The Open Group in the United States and other countries.

Glossary

The terms in this glossary are defined as they pertain to technical terms and abbreviations used in support of DFSMSHsm.

This glossary includes terms and definitions from:

- The *American National Standard Dictionary for Information Systems*, ANSI X3.172-1990, copyright 1990 by the American National Standards Institute (ANSI). Copies may be purchased from the American National Standards Institute, 11 West 42nd Street, New York, New York 10036. Definitions are identified by the symbol (A) after the definition.
- The *Information Technology Vocabulary* developed by Subcommittee 1, Joint Technical Committee 1, of the International Organization for Standardization and the International Electrotechnical Commission (ISO/IEC JTC1/SC1). Definitions of published parts of this vocabulary are identified by the symbol (I) after the definition; definitions taken from draft international standards, committee drafts, and working papers being developed by ISO/IEC JTC1/SC1 are identified by the symbol (T) after the definition, indicating that final agreement has not yet been reached among the participating National Bodies of SC1.
- *IBM Dictionary of Computing*, New York: McGraw-Hill, 1994.

3480

An IBM 3480 Magnetic Tape Subsystem device.

3480X

A 3480 XF device or an IBM 3490 Magnetic Tape Subsystem device.

3490

An IBM 3490 Magnetic Tape Subsystem device.

3490E

See 3490.

3590

An IBM TotalStorage Enterprise Tape Drive 3590. See 3590-B1x, 3590-E1x and 3590-H1x.

3590B1x

An IBM TotalStorage Enterprise Tape Drive 3590 Model B1x.

3590E1x

An IBM TotalStorage Enterprise Tape Drive 3590 Model E1x.

3590H1x

An IBM TotalStorage Enterprise Tape Drive 3590 Model H1x.

3592E05

An IBM TotalStorage Enterprise Tape Drive 3592.

3592E06

IBM System Storage Tape System 3592 Model E06.

3592E07

An IBM Enterprise Tape Drive 3592 Model E07.

3592J1A

An IBM TotalStorage Enterprise Tape Drive 3592.

ABARS

Aggregate backup and recovery support. See *aggregate backup* and *aggregate recovery*.

ABEND

Abnormal end.

ACB

Access method control block.

accompany data set

In aggregate backup and recovery processing, a data set that is physically transported from the backup site to the recovery site instead of being copied to the aggregate data tape. It is cataloged during recovery.

ACCOMPANY keyword

The keyword used in the selection data set to create an accompany list.

accompany list

An optional list in the selection data set that identifies the accompany data sets.

ACEE

Access control environment element.

ACS

See *automatic class selection (ACS) routine*.

active copies

A set of backup copies created that have not yet rolled off. The number of active copies is determined by the SMS management class or SETSYS value. The maximum number of active copies will remain one hundred.

active data

Data that is frequently accessed by users and that resides on level 0 volumes.

activity log

In DFSMSHsm, a SYSOUT or DASD-type data set used to record activity and errors that occurred during DFSMSHsm processing.

AG

See *aggregate group (AG)*.

aggregate backup

The process of copying the data sets and control information of a user-defined group of data sets so that they may be recovered later as an entity by an aggregate recovery process.

aggregate data sets

In aggregate backup and recovery processing, data sets that have been defined in an aggregate group as being related.

aggregate group (AG)

A Storage Management Subsystem class that defines control information and identifies the data sets to be backed up by a specific aggregate backup.

aggregate recovery

The process of recovering a user-defined group of data sets that were backed up by aggregate backup.

AIX

See *alternate index (AIX)*.

allocate data set

In aggregate backup and recovery processing, a data set name that is listed in the selection data set. The space for this data set is allocated and the data set is cataloged at the recovery location, but the actual data is not restored.

ALLOCATE keyword

The keyword used in the selection data set to create an allocate list.

allocate list

An optional list in the selection data set that identifies the allocate data sets.

alternate index (AIX)

In systems with VSAM, a collection of index entries related to a given base cluster and organized by an alternate key, that is, a key other than the prime key of the associated base cluster data records. Its function is to provide an alternate directory for locating records in the data component of a base cluster. See *path*.

alternate index cluster

In VSAM, the data and index components of an alternate index.

alternate tape volumes

In DFSMSHsm, copies of original tape volumes created during tape copy processing. The volumes can either be stored on-site or off-site for use later in the event of a disaster. During the tape replace processing, these volumes can replace the original volumes that may be lost.

APAR

Authorized program analysis report.

APF

Authorized program facility.

ASID

Address space identifier.

ATL

See *automated tape library (ATL)*.

audit

A DFSMSHsm process that detects discrepancies between data set information in the VTOCs, the computing system catalog, the MCDS, BCDS, and OCDS.

AUTH

The DFSMSHsm command used to identify an authorized user who can issue DFSMSHsm system programmer and storage administrator commands.

authorized user

In DFSMSHsm, the person or persons who are authorized through the DFSMSHsm AUTH command to issue DFSMSHsm system programmer, storage administrator, and operator commands.

automated tape library (ATL)

A device consisting of robotic components, cartridge storage frames, tape subsystems, and controlling hardware and software, together with the set of volumes which reside in the library and may be mounted on the library tape drives. See *manual tape library (MTL)*.

automatic backup

In DFSMSHsm, the process of automatically copying eligible data sets from DFSMSHsm-managed volumes or migration volumes to backup volumes during a specified backup cycle.

automatic cartridge loader feature

A feature of the 3480 Magnetic Tape Subsystem providing the operator with the capability of preloading multiple tapes to be used as migration, backup, or dump tapes.

automatic class selection (ACS) routine

A procedural set of ACS language statements. Based on a set of input variables, the ACS language statements generate the name of a predefined SMS class, or a list of names of predefined storage groups, for a data set.

automatic dump

In DFSMSHsm, the process of using DFSMSdss to automatically do a full volume dump of all allocated space on DFSMSHsm-managed volumes to designated tape dump volumes.

automatic primary space management

In DFSMSHsm, the process of automatically deleting expired data sets, deleting temporary data sets, releasing unused overallocated space, and migrating data sets from DFSMSHsm-managed volumes.

automatic secondary space management

In DFSMSHsm, the process of automatically deleting expired migrated data sets from the migration volumes, deleting expired records from the migration control data set, and migrating eligible data sets from level 1 volumes to level 2 volumes.

automatic space management

In DFSMSHsm, includes automatic volume space management, automatic secondary space management, and automatic recall.

automatic volume space management

In DFSMSHsm, includes automatic primary space management and automatic interval migration.

availability management

In DFSMSHsm, the process of ensuring that a current version (backup copy) of the installation's data sets resides on tape or DASD.

backup

In DFSMSHsm, the process of copying a data set residing on a level 0 volume, a level 1 volume, or a volume not managed by DFSMSHsm to a backup volume. See *automatic backup* and *incremental backup*.

backup control data set (BCDS)

A VSAM, key-sequenced data set that contains information about backup versions of data sets, backup volumes, dump volumes, and volumes under control of the backup and dump functions of DFSMSHsm.

backup copy

In DFSMSHsm, a copy of a data set that is kept for reference in case the original data set is destroyed.

backup cycle

In DFSMSHsm, a period of days for which a pattern is used to specify the days in the cycle on which automatic backup is scheduled to take place.

backup frequency

In DFSMSHsm, the number of days that must elapse since the last backup version of a data set was made until a changed data set is again eligible for backup.

backup profile

In DFSMSHsm, a RACF discrete data set profile associated with the backup version of a cataloged data set that is protected by a RACF discrete data set profile.

backup version

Synonym for backup copy.

backup volume

A volume managed by DFSMSHsm to which backup versions of data sets are written.

backup volume cleanup process

A DFSMSHsm process that scratches data set backup versions that are no longer needed on DASD.

backup VTOC copy data set

In DFSMSHsm, a copy of the VTOC of a volume that was backed up by DFSMSHsm. This VTOC data set contains only part of the data set VTOC entry for each data set from the original data set. This data set is written on a migration level 1 volume.

base cluster

In systems with VSAM, a key-sequenced or entry-sequenced file over which one or more alternate indexes are built. See *cluster*.

base data component

In VSAM, a component of the base cluster containing data of a data set.

base sysplex

A base (or basic) sysplex is the set of one or more z/OS systems that are given a cross-system coupling facility (XCF) name and in which the authorized programs can then use XCF coupling services. A base system does not include a coupling facility. See *parallel sysplex* and *sysplex*.

basic format

The format of a data set that has a data set name type (DSNTYPE) of BASIC. A basic format data set is a sequential data set that is specified to be neither large format nor extended format. The size of a basic format data set cannot exceed 65 535 tracks on each volume.

BCDS

Backup control data set.

BCR

Backup control record.

BDAM

Basic direct access method.

BSAM

Basic sequential access method.

cartridge system tape

The base tape cartridge media used with 3480 or 3490 magnetic tape subsystems. See also *Enterprise Tape Cartridge*.

catalog

(1) A data set that contains extensive information required to locate other data sets, to allocate and deallocate storage space, to verify the access authority of a program or operator, and to accumulate data set usage statistics. A catalog has a basic catalog structure (BCS) and its related volume tables of contents (VTOCs) and VSAM volume data sets (VVDSs). (A) (ISO) (2) To enter information about a file or a library into a catalog. (A) (ISO) (3) The collection of all data set indexes that are used by the control program to locate a volume containing a specific data set. (4) To include the volume identification of a data set in the catalog.

CDS

Control data set.

CDSQ serialization

A technique that serializes DFSMSHsm CDSs with a global enqueue product (such as GRS).

CDSR serialization

A technique that serializes DFSMSHsm CDSs with volume reserves.

CDT

Class descriptor table.

CF

Coupling facility.

changed data set

In DFSMSHsm, a data set that has been opened for other than read-only access.

CLIST

Command list.

cluster

In systems with VSAM, a named structure consisting of a group of related components, for example, a data component with its index component. See also *base cluster*.

command list

A command procedure containing executable sequences of TSO commands, subcommands, and command procedure statements.

command procedure

In TSO, a data set or a member of a partitioned data set containing TSO commands to be performed sequentially by the EXEC command. See also *command list*.

common data set descriptor record

The record that precedes a user's data set on a DFSMSHsm-owned volume and that is used to return the data set to the user's format.

common filter services

A subcomponent of DFP common services. Common filter services compares data items with filter keys and indicates which data items match the keys and how many matches have been found.

common recall queue (CRQ)

A single recall queue shared by multiple DFSMSHsm hosts that enables the recall workload to be balanced across each of those hosts.

common service area (CSA)

One of the data areas in the system that is addressable by all address spaces, in which any address space can request a space that is protected during use by the requestor's storage protection key.

compaction

In DFSMSHsm, a method of compressing and encoding data that is migrated or backed up.

comprehensive command authority

In DFSMSHsm, allowing a user to issue the ABACKUP command for all aggregate groups.

compress

In DFSMSHsm, to release unused space in a partitioned data set during the migrate/recall and backup/recovery processes.

computing system catalog

In DFSMSHsm, the master catalog and any associated user catalogs used as sources during the audit process.

concurrent copy

A function to increase the accessibility of data by enabling you to make a consistent backup or copy of data concurrent with the typical application program processing.

connected set

A group of tapes volumes that are related to each other because one or more data sets span the physical tape volumes. Or, a single tape volume with a data set or data sets that do not span to any other volumes.

contiguous space

An unbroken consecutive series of storage locations.

control data set

In DFSMSHsm, one of three data sets (BCDS, MCDS, and OCDS) that contain records used in DFSMSHsm processing.

control file

In aggregate backup and recovery processing, one of three aggregate files generated by the aggregate backup process. It contains the catalog, allocation, volume, and related information necessary to perform aggregate recovery.

converter/interpreter processing

The job segment that converts and interprets JCL for the operating system.

copy pool

A named set of storage groups that contains data to be copied and recovered collectively.

copy pool backup storage group

A type of SMS storage group that contains all of the volumes that DFSMSHsm might select as the target of a fast replication.

coupling facility

A special logical partition that provides high-speed caching, list processing, and locking functions in a sysplex.

cross-system coupling facility (XCF)

A component of z/OS that provides functions to support cooperation between authorized programs running within a sysplex.

CRQ

Common recall queue.

CRQplex

One or more DFSMSHsm hosts that are connected to the same CRQ. There may be multiple CRQplexes within a single HSMplex.

CSA

Common service area.

CSECT

Control section.

CTC

Channel-to-channel.

current backup version

In DFSMSHsm, a backup copy of the data set that was created on a date after the data set was last updated.

CVT

Communications vector table.

cycle start date

In DFSMSHsm, the date a backup cycle, dump cycle, or migration cleanup cycle is started.

DADSM

Direct Access Device Space Management.

DAE

Dump analysis elimination.

daily backup volume

In DFSMSHsm, a volume associated with a given day in the backup cycle and assigned to contain backup versions created on that cycle day.

DAIR

Dynamic allocation interface return code.

DASD

Direct access storage device. See *direct access storage device (DASD)*.

DASD calculation services (DCS)

A subcomponent of DFP common services. DCS retrieves and calculates data set information for both VSAM and non-VSAM data sets based on the user's input request.

DASD volume

A DASD space identified by a common label and accessed by a set of related addresses. Also referred to generically as "volume" in some instances.

data class

A collection of allocation and space attributes, defined by the storage administrator, that is used to create a data set.

data control block (DCB)

A control block used by access method routines in storing and retrieving data.

Data Facility Sort (DFSORT)

An IBM-licensed program that is a high-speed data processing utility. DFSORT provides an efficient and flexible way to handle sorting, merging, and copying operations, as well as providing versatile data manipulation at the record, field, and bit level.

Data Facility Storage Management Subsystem (DFSMS)

An operating environment that helps automate and centralize the management of storage. To manage storage, SMS provides the storage administrator with control over data class, storage class, management class, storage group, and automatic class selection routine definitions.

data file

In aggregate backup and recovery processing, one of three aggregate files generated by the aggregate backup process. It contains the backup copies of the data sets to be recovered.

data set

The major unit of data storage and retrieval in z/OS DFSMS, consisting of a collection of data in a prescribed arrangement and described by control information to which the system has access.

data migration

See *migration*.

data set change indicator

A bit in the Format 1 data set VTOC entry that indicates whether the data set has been opened for output.

data set deletion

In DFSMSHsm, the space management technique of deleting non-SMS-managed data sets that have not been used for a specified number of days and that do not have expiration date protection.

data set group

Data sets that have the same set of initial characters in their names.

data set organization

The type of arrangement of data in a data set. Examples are sequential organization or partitioned organization.

data set pool

One or more volumes managed by DFSMSHsm to which data sets that have migrated can be recalled, depending on the set of initial characters of the data set name.

data set retirement

In DFSMSHsm, the space management technique of deleting non-SMS-managed data sets that have not been referred to for a specified number of days, and that have a backup version. See *delete-if-backed-up (DBU)*.

date last referred to

In DFSMSHsm, the last date when a data set was opened.

DBA

Delete-by-age.

DBU

Delete-if-backed-up.

DCB

Data control block.

DCR

Dump control record.

DCS

DASD calculation services.

debug mode

In DFSMSHsm, the method of operation that projects the changes that would occur in normal operation but in which no user data moves.

decompaction

In DFSMSHsm, the process of decoding and expanding data that was compacted during daily space management or backup.

delete-by-age (DBA)

In DFSMSHsm, the space management technique of deleting non-SMS-managed data sets that have not been opened for a specified number of days.

delete-if-backed-up (DBU)

In DFSMSHsm, the space management technique of deleting non-SMS-managed data sets that have not been opened for a specified number of days, and that have a current backup version. See *data set retirement*.

demotion

The process of one host losing level functions to another. Both original and promoted hosts can go through the demotion process. See *promotion*.

DFP

Data Facility Product.

DFP common services

A component of DFP that contains three subcomponents: common filter services (CFS), DASD calculation services (DCS), and device information services (DIS).

DFSMS

See *Data Facility Storage Management Subsystem (DFSMS)*.

DFSMSdfp

DFSMS data facility product. A z/OS DFSMS functional component and a base element of z/OS that provides functions for storage management, data management, device management, and distributed data access.

DFSMSdss

DFSMS data set services. A z/OS DFSMS functional component that provides functions for copying, moving, dumping, and restoring data sets and volumes.

DFSMSHsm

DFSMS hierarchical storage manager. A z/OS DFSMS functional component that provides functions for backing up and recovering data, and managing space on volumes in the storage hierarchy.

DFSMSHsm-authorized user

The person or persons who are authorized through the DFSMSHsm AUTH command to issue system programmer and storage administrator commands.

DFSMSHsm log

In DFSMSHsm, a pair of sequential data sets, X and Y, containing a chronological list of transactions and statistics occurring in DFSMSHsm.

DFSMSHsm-managed volume

(1) A primary storage volume, which is defined to DFSMSHsm but which does not belong to a storage group. (2) A volume in a storage group, which is using DFSMSHsm automatic dump, migration, or backup services. See *system-managed volume* and *DFSMSrmm-managed volume*.

DFSMSHsm-owned volumes

A storage volume on which DFSMSHsm stores backup versions, dump copies, or migrated data sets.

DFSMSHsm secondary address space

A separate address space started and controlled by DFSMSHsm to perform aggregate backup or aggregate recovery processing.

DFSMSrmm

DFSMS removable media manager. A z/OS DFSMS functional component that provides functions for managing removable media.

DFSMSrmm-managed volume

A tape volume that is defined to DFSMSrmm. See *system-managed volume* and *DFSMSHsm-managed volume*.

DFSORT

See *Data Facility Sort (DFSORT)*.

direct access storage device (DASD)

A device in which the access time is effectively independent of the location of data.

directed recall

Moving a migrated data set from a level 1 or a level 2 volume to a level 0 volume and specifying the target volume and unit name where the data set can be allocated.

disaster

An unplanned occurrence that keeps a company or organization from conducting its normal business for some time period.

disaster backup

A means to protect a computing system complex against data loss in the event of a disaster.

disaster recovery

A means to replace lost data at another location with sufficient resources in order to resume operation.

discrete backup profile

A RACF profile created when DFSMSHsm backs up a cataloged, RACF-indicated data set.

discrete profile

A RACF profile that contains security information about a specific data set on a particular volume.

disposition processing

In OS/VS, a function performed by the initiator at the end of a job step to keep, delete, catalog, or uncatalog data sets, or to pass them to a subsequent job step, depending on the data set status of the disposition specified in the DISP parameter of the DD statement.

Distributed System License Option (DSLO)

A license option available to IBM customers with a basic license that permits them to copy certain IBM-licensed materials for the purpose of installing multiple systems.

DSLO

Distributed Systems License Option.

DSR

Daily statistics record.

dump

See *full volume dump*.

dump class

A DFSMSHsm-named set of characteristics that describe how volume dumps are managed.

dump copy

In DFSMSHsm, a copy of the volume image produced by the DFSMSdss full volume dump function.

dump cycle

In DFSMSHsm, a period of days for which a pattern is used to specify the days in the cycle on which automatic full volume dump is scheduled to take place.

dump generation

A successful full volume dump of a volume that may contain one to five identical dump copies.

dump VTOC copy data set

In DFSMSHsm, a copy of the VTOC of a volume dumped by DFSMSHsm. This VTOC data set contains only part of the data set VTOC entry for each data set from the original data set. This data set is written on a migration level 1 volume.

DVT

Device vector table.

EA

Extended addressability.

EATTR

Keyword controlling whether the allocation of EAS-eligible data sets can reside in cylinder-managed space. Can be used as follows:

- In the ALLOCATE or DEFINE CLUSTER commands, see [z/OS DFSMS Access Method Services Commands](#).
- As a JCL keyword, see [z/OS MVS JCL Reference](#).
- On the ISMF Data Class Define pane, see [z/OS DFSMSdfp Storage Administration](#).

EBCDIC

Extended Binary Coded Decimal Interchange Code.

ECB

Event control block.

EEMT2

Enterprise encrypted format 2 recording technology.

EEMT3

Enterprise encrypted format 3 recording technology.

EEMT4

Enterprise encrypted format 4 recording technology.

EFMT1

Enterprise format 1 recording technology.

EFMT2

Enterprise format 2 recording technology.

EFMT3

Enterprise format 3 recording technology.

EFMT4

Enterprise format 4 recording technology.

eligibility age

The number of days since a data set met its criteria to be migrated.

emergency mode

In DFSMSHsm, the method of operation that prevents data set movement and deletion in space management, backup, and recovery processes.

encode

(T) To convert data by the use of a code in such a manner that reconversion to the original form is possible.

Enterprise Systems Architecture/390 (ESA/390)

An IBM architecture for mainframe computers and peripherals. Processor systems that follow the ESA/390 architecture include the ES/9000 family. See also *z/Architecture*®.

Enterprise Systems Connection (ESCON)

A peripheral interface for an Enterprise Systems Architecture/390 and zSeries computer. The I/O interface uses ESA/390 logical protocols over a serial interface that configures attached units to a communication fabric.

Enterprise Tape Cartridge

Cartridge system tape with increased capacity that can only be used with 3592 Magnetic Tape Subsystems (MEDIA5, MEDIA6, MEDIA7, MEDIA8, MEDIA9, MEDIA10, MEDIA11, MEDIA12, and MEDIA13). See *cartridge system tape*.

erase-on-scratch

A security function that overwrites the space occupied by a data set when the data set is scratched from a DASD device.

ESA/390

See *Enterprise Systems Architecture/390 (ESA/390)*.

ESCON

See *Enterprise Systems Connection (ESCON)*.

ESDS

Entry-sequenced data set.

esoteric unit names

The names a user assigns to I/O devices that have the same device type. When the user specifies the assigned unit name to DFSMSHsm, DFSMSHsm associates the unit name to its device type.

ESTAE

Extended subtask ABEND exit.

ESTAI

Extended subtask ABEND intercept.

event-driven migration

In DFSMSHsm, a space management function similar to primary space management, except it is event-driven instead of scheduled. Low activity data sets are moved from the volume and occupied space is reduced until the volume low threshold is reached. There are two methods of event-driven migration: hourly (interval migration) and immediate (on-demand migration). See *interval migration* and *on-demand migration*.

exclude data set

In aggregate backup and recovery processing, a data set in the selection data set exclude list. This data set is to be excluded from being processed by aggregate backup.

EXCLUDE keyword

The keyword used in the selection data set to create an exclude list.

exclude list

An optional list in the selection data set that identifies those data sets that are to be excluded from being processed by aggregate backup.

expiration

The removal of a user data set from either a user (non-DFSMSHsm-owned) volume, or from a DFSMSHsm-owned volume when the user data set has been migrated. If there is an explicit expiration date, it is found in the data set VTOC entry for a nonmigrated data set, or in the MCD record for a migrated data set. If there is no explicit expiration date, the management class attributes are checked to determine an implicit expiration date.

extended addressability

A type of extended format VSAM data set that allows greater than 4GB of data storage.

extended format compressed data set

A SAM or VSAM data set whose processing detects errors caused by an incomplete transfer of a physical block of data to a physical record in the data set. Each physical record is ended by a “hidden” suffix. SAM or VSAM processing determines, by examining these suffixes, if a data transfer to a physical record has ended prematurely.

extended remote copy (XRC)

A hardware- and software-based remote copy service option that provides an asynchronous volume copy across storage subsystems for disaster recovery, device migration, and workload migration.

extent reduction

In DFSMSHsm, the releasing of unused space, reducing the number of extents, and compressing partitioned data sets.

extents

A continuous space on a direct access storage volume, occupied by or reserved for a particular data set, data space, or file.

facility class profile

A way that RACF protects all DFSMSHsm command access. An active RACF facility class establishes the security environment.

fallback

Pertaining to returning to use of an earlier release of a program after a later release has been installed and used.

fast replication

The functions that create an instant data copy. The IBM System Storage DS8000 FlashCopy function is an example of fast replication.

fast replication target volume

A DFSMSHsm-owned volume that contains the fast replication backup copy of a DFSMSHsm-managed volume. Fast replication target volumes are contained within SMS copy pool backup storage groups.

fast reverse restore

A FlashCopy option that reverses a FlashCopy relationship without waiting for the completion of the background copy of the previous FlashCopy.

fast subsequent migration

The function that reconnects a data set to the same ML2 tape volume from which it was recalled instead of migrating the data set again. The data set must satisfy a set of requirements when recalled and when a fast subsequent migration reconnect is attempted.

fast subsequent migration reconnect

The action that is attempted when fast subsequent migration is performed on a recalled data set. This is also referred to in context as "reconnect", "reconnecting", and "reconnection."

FBA

Fixed-block architecture.

FIFO

First in, first out.

fixed-block architecture

Data stored in blocks of fixed size; these blocks are addressed by block number relative to the beginning of the particular file.

FlashCopy

An optional feature of the Storage System DS family that can make an instant copy of data, that is, a point-in-time copy of a volume.

FMID

Function modification identifier.

fragmentation index

The qualitative measure of the scattered free space on a volume.

FSR

Functional statistics record.

full volume dump

In DFSMSHsm, the process of using a DFSMSdss function that backs up the entire allocated space on a volume.

full volume restore

In DFSMSHsm, the process of using a DFSMSdss function that restores the entire volume image.

functional statistics record

A record that is created each time a DFSMSHsm function is processed. It contains a log of system activity and is written to the system management facilities (SMF) data set.

functional verification procedure

A procedure distributed with DFSMSHsm that tests to verify that all basic DFSMSHsm functions are working correctly.

GDG

Generation data group.

GDS

Generation data set.

general pool

In a DFSMSHsm environment with JES3, the collection of all DFSMSHsm primary volumes added to that processor that have a mount status of permanently-resident or reserved, that have the automatic recall attribute specified, and that have a mount attribute of storage or private.

generation data group

A collection of data sets with the same base name, such as PAYROLL, that are kept in chronological order. Each data set is called a generation data set.

generic profile

A RACF profile that contains security information about multiple data sets, users, or resources that may have similar characteristics and require a similar level of protection.

global scratch pool

A group of empty tapes that do not have unique serial numbers and are not known individually to DFSMSHsm. The tapes are not associated with a specific device. See *specific scratch pools*.

GRS

Global resource serialization.

GRSplex

One or more z/OS systems using global serialization to serialize access to shared resources.

GTF

Generalized trace facility.

hardware/software compression facility

A function for both SAM and VSAM extended format compressed data sets that has the ability to use either hardware data compression for best performance, or software data compression for DASD space considerations.

high threshold of occupancy

In DFSMSHsm, the upper limit of space to be occupied on a volume managed by DFSMSHsm. See *low threshold of occupancy*.

HMT

HSM Monitor/Tuner.

HSMplex

One or more DFSMSHsm hosts that share a set of control data sets. The hosts may be on single or multiple z/OS images.

IBM System Storage

Follow-on product line to the IBM TotalStorage products.

IBM System Storage and TotalStorage Enterprise Tape Cartridge

A Cartridge system tape with increased capacity that can only be used with 3592 Magnetic Tape Subsystems (MEDIA5, MEDIA6, MEDIA7, MEDIA8, MEDIA9, and MEDIA10).

ICETOOL

DFSORT's multipurpose data processing and reporting utility.

IDRC

Improved data recording capability.

improved data recording capability

An improved data recording mode that, depending on data set characteristics and machine model, may allow a significant increase in effective cartridge data capacity and performance.

inactive age

In DFSMSHsm, the number of days since the data set was last referred to.

inactive data

Copies of active or low-activity data that reside on DFSMSHsm-owned dump and incremental backup volumes. See *low-activity data*.

include data set

In aggregate backup and recovery processing, a data set in the selection data set include list. This data set is processed by aggregate backup.

INCLUDE keyword

The keyword used in the selection data set to create an include list.

include list

In the selection data set, the list of include data sets to be processed by aggregate backup.

incremental backup

In DFSMSHsm, the process of copying a data set that has been opened for other than read-only access since the last backup version was created, and that has met the backup frequency criteria.

incremental recovery

Recovery of the latest backup copy of a data set or data sets made by incremental backup.

inline backup

The process of copying a specific data set to a migration level 1 volume from a batch environment. This process allows you to back up data sets in the middle of a job.

installation verification procedure (IVP)

A procedure distributed with DFSMSHsm that tests to verify that the basic facilities of DFSMSHsm are functioning correctly.

installation exit

A means specified by an IBM software product by which a customer's system programmers may modify or extend the functions of the IBM software product. Such modifications or extensions consist of exit routines written to replace an existing module of an IBM software product, or to add one or more modules or subroutines to an IBM software product for the purpose of modifying the functions of the IBM software product.

instruction data set

In aggregate backup and recovery processing, a data set that contains instructions, commands, or any data the aggregate backup site defines as needed for aggregate recovery at the recovery site.

instruction file

In aggregate backup and recovery processing, one of three aggregate files generated by the aggregate backup process. It contains the instruction data set.

Interactive Storage Management Facility (ISMF)

The interactive panels of DFSMSdftp that allow users and storage administrators access to the storage management functions of DFSMSdss and DFSMSHsm.

Interactive System Productivity Facility (ISPF)

An IBM licensed program used to develop, test, and run application programs interactively. ISPF is the interactive access method for all storage management functions.

interval migration

A space management function that performs hourly space management on eligible SMS-managed and non-SMS-managed volumes that are at or have exceeded a threshold level (such as the midpoint between the high and low threshold or the high threshold). Data sets are migrated from the eligible

volume until the low threshold is reached or there are no more eligible data sets. See [“Using interval migration”](#) on page 25.

IPCS

Interactive problem control system.

ISMF

See *Interactive Storage Management Facility (ISMF)*.

ISPF

See *Interactive System Productivity Facility (ISPF)*.

ISPF/PDF

Interactive System Productivity Facility/Program Development Facility.

IVP

Installation verification procedure.

JCL

Job control language.

JES

Job entry subsystem.

JES2

Job entry subsystem 2.

JES3

Job entry subsystem 3.

JFCB

Job file control block.

journal data set

In DFSMSHsm, a sequential data set used by DFSMSHsm for recovery of the MCDS, BCDS, and OCDS. The journal contains a duplicate of each record in the control data sets that has changed since the MCDS, BCDS, and OCDS were last backed up.

KB

Kilobyte; 1024 bytes.

key-range data set

A key-sequenced data set that is defined with one or more KEYRANGE groups.

KSDS

Key-sequenced data set.

large format

The format of a data set that has a data set name type (DSNTYPE) of LARGE. A large format data set has the same characteristics as a sequential (non-extended format) data set, but its size on each volume can exceed 65 535 tracks. There is no minimum size requirement for a large format data set.

LE

Logical end.

level functions

(1) Functions that must be performed but need be performed by only one processing unit. Level functions include backing up the control data sets, backing up migrated data sets, deleting expired dump copies, moving backup versions from level 1 volumes to backup volumes, migration cleanup and level-1-to-level-2 migration. (2) See *primary-processing-unit functions*.

level 0 volume (L0)

A volume that contains data sets directly accessible by the user. The volume may be either DFSMSHsm-managed or non-DFSMSHsm-managed.

level 1 volume (L1)

A volume owned by DFSMSHsm containing data sets that migrated from a level 0 volume.

level 2 volume (L2)

A volume under control of DFSMSHsm containing data sets that migrated from a level 0 volume, from a level 1 volume, or from a volume not managed by DFSMSHsm.

like device

Pertaining to (DASD) devices with identical geometry: that is, the same number of bytes per track, the same number of tracks per cylinder, and the same number of cylinders per actuator.

linear data set

In VSAM, a named linear string of data, stored in such a way that it can be retrieved or updated in 4096-byte units.

list of names (LON) data set

In ABARS, a data set that contains the fully-qualified names of data sets to be recovered from an aggregate backup version during ARECOVER processing.

logical end (LE)

Signifies that a concurrent copy environment has been successfully initialized. After logical end, the data is again available for unrestricted application access. Actual movement of data begins after logical end. See *physical end*.

low-activity data

Data that is infrequently accessed by users and is eligible to be moved or has been moved to DFSMSHsm-owned migration volumes.

low threshold of occupancy

The lower limit of space to be occupied on a volume managed by DFSMSHsm. See *high threshold of occupancy*.

managed volume

See *DFSMSHsm-managed volume* and *primary volume*.

management class

A list of data set migration, backup, and retention attributes that DFSMSHsm uses to manage storage at the data set level.

management work element (MWE)

A control block containing the necessary information to direct DFSMSHsm functions.

manual tape library (MTL)

A set of tape drives defined as a logical unit by the installation together with the set of system-managed volumes which may be mounted on those drives. See *automated tape library (ATL)*.

master catalog

A key-sequenced data set or file with an index containing extensive data set and volume information that VSAM requires to locate data sets or files, to allocate and deallocate storage space, to verify the authorization of a program or operator to gain access to a data set or file, and to accumulate usage statistics for data sets or files.

MB

Megabyte; 1 048 576 bytes.

MCB

Backed up data set record.

MCBR

Backed up data set record for retained backup copies.

MCC

Backup version record.

MCD

MCDS data set record.

MCDS

See *migration control data set (MCDS)*.

MCR

Management control record.

MCVT

Management communication vector table.

MEDIA5

IBM Enterprise Tape Cartridge.

MEDIA6

IBM Enterprise WORM Tape Cartridge.

MEDIA7

IBM Enterprise Economy Tape Cartridge.

MEDIA8

IBM Enterprise Economy WORM Tape Cartridge.

MEDIA9

IBM Enterprise Extended Tape Cartridge.

MEDIA10

IBM Enterprise Extended WORM Tape Cartridge.

MEDIA11

IBM Enterprise Advanced Tape Cartridge.

MEDIA12

IBM Enterprise Advanced WORM Tape Cartridge.

MEDIA13

IBM Enterprise Advanced Economy Tape Cartridge.

MHCR

Multiple-processing-unit control record.

migration

In DFSMSHsm, the process of moving a cataloged data set from a DFSMSHsm-managed volume to a migration level 1 or migration level 2 volume, from a migration level 1 volume to a migration level 2 volume, or from a volume not managed by DFSMSHsm to a migration level 1 or migration level 2 volume.

migration cleanup

In DFSMSHsm, a process of automatic secondary space management that deletes unnecessary records or migration copies.

migration control data set (MCDS)

A VSAM, key-sequenced data set that contains statistics records, control records, user records, records for data sets that have migrated, and records for volumes under migration control of DFSMSHsm.

migration level 1 (ML1) volume

Level 1 volume used for migration from level 0 or primary volumes. See *level 0 volume*, *level 1 volume*, *level 2 volume*, *migration*, *migration volume*, and *primary volume*.

migration level 2 (ML2) volume

Level 2 volume used for migration from level 1 or directly from primary volumes. See *level 0 volume*, *level 1 volume*, *level 2 volume*, *migration*, *migration volume*, and *primary volume*.

migration volume

A volume, under control of DFSMSHsm, that contains migrated data sets.

minimal discrete profile

A profile with no access list or model profile. The minimal discrete profile is used when recovering a RACF-indicated data set whose original profile or backup profile no longer exists.

minimum migration age

In DFSMSHsm, the number of days a data set must remain unopened before DFSMSHsm can select it to migrate from a volume.

MIPS

Million instructions per second.

ML1

Migration level 1. Synonym for level 1 volume.

ML2

Migration level 2. Synonym for level 2 volume.

model entity

A model data set name that defines a discrete data set profile for RACF protection.

MSS

Mass Storage System.

MTL

See *manual tape library (MTL)*.

multicluster, key-range control data set

A control data set (MCDS or BCDS) that is represented by two or more key-sequenced data set (KSDS) clusters. Each cluster is a single key range. See *single-cluster, key range control data set*.

multiple-file format

In DFSMSHsm, a 3480 tape format, or the equivalent, that requires a unique standard label data set for each user data set written. When DFSMSHsm writes in multiple-file format, it writes one tape data set for every user data set to all 3480 migration and backup volumes.

multiple DFSMSHsm-host environment

Any environment in which two or more DFSMSHsm hosts share a common set of control data sets.

mutually exclusive parameters

A set of parameters of which only one can be used. If more than one parameter is specified, only the last parameter specified is used.

MWE

See *management work element (MWE)*.

non-DFSMSHsm-managed volume

A volume not defined to DFSMSHsm containing data sets that are directly accessible to users.

non-intrusive journal backup

A method of journal backup during which all DFSMSHsm activity is allowed to continue while DFSMSHsm creates a backup of the preexisting journal records. After the initial backup of the journal completes, all DFSMSHsm activity is quiesced and DFSMSHsm completes the backup of the journal. Non-intrusive journal backup can be used to reduce the impact of journal backup on DFSMSHsm availability and performance. See *quiesced journal backup* and [“Using non-intrusive journal backup” on page 496](#).

OCDS

Offline control data set.

O/C/EOV

Open/close/end-of-volume.

OCO

Object code only.

offline control data set (OCDS)

In DFSMSHsm, a VSAM, key-sequenced data set that contains information about tape backup volumes and tape migration level 2 volumes.

on-demand migration

A space management function that performs near immediate space management on eligible SMS-managed volumes that have exceeded the specified volume high threshold, instead of waiting for interval migration to run at the top of each hour. Data sets are migrated from the eligible volume until the low threshold is reached or there are no more eligible data sets. See [“Using on-demand migration” on page 27](#).

online

(1) Pertaining to the operation of a functional unit when under the direct control of a computer. (A) (ISO) (2) Pertaining to a user’s ability to interact with a computer. (A) (3) Pertaining to a user’s access to a computer via a terminal. (A) (4) Controlled by, or communicating with, a computer.

original tape volume

In DFSMSHsm, a 3480 or 3490 single-file tape volume, or the equivalent, used to store data during migration or backup processing, and from which a copy (called the alternate volume) is made for disaster recovery.

owned space

The storage space on a set of volumes to which DFSMSHsm allocates migrated data sets and backup versions, but to which user jobs should not allocate. Included in this set are migration level 1, migration level 2, and backup volumes.

owned volume

A volume on which DFSMSHsm writes dump, migration, or backup data sets.

parallel sysplex

A sysplex with one or more coupling facilities. See *base sysplex* and *sysplex*.

partitioned data set (PDS)

A data set in DASD that is divided into partitions, called members, each of which can contain a program, part of a program, or data.

partitioned data set extended (PDSE)

A DFP library structure that is an enhanced replacement for a partitioned data set.

path

In VSAM, a named logical entity providing access to the records of a base cluster either directly or through an alternate index.

PCDD

Pseudo common data set descriptor (CDD) record.

PDA

Problem Determination Aid.

PDF

Program Development Facility.

PDS

Partitioned data set.

PDSE

Partitioned data set extended.

PE

Physical end.

peer-to-peer remote copy (PPRC)

A hardware-based remote copy option that provides a synchronous volume copy across storage subsystems for disaster recovery, device migration, and workload migration.

performance scaling

Formatting a tape so that less than its full capacity is used. Formatting a tape to its optimal performance capacity decreases the amount of time required to access the data on the tape. A tape that is formatted to its optimal performance capacity can later be reused and formatted to its full capacity.

physical data set restore

In DFSMSHsm, the process of using a DFSMSdss function to restore one data set from a dump copy created by using the DFSMSHsm full volume dump function.

physical end (PE)

Signifies that the concurrent copy process has finished copying the data to the output device. See *logical end*.

physical sequential

See *sequential data set*.

pool of volumes

See *data set pool*, *general pool*, and *volume pool*.

PPRC

Peer-to-peer remote copy.

primary processing unit

In a multiple processing-unit-environment, the processing unit assigned to do level functions for backup and dump. Level functions for backup are: backup of CDS, move backup versions, and backup of migrated data sets. Level functions for dump are: delete expired dump copies, and delete excess dump VTOC copy data sets.

primary-processing-unit functions

(1) The level functions (backing up migrated data sets, deleting expired dump copies, and moving backup versions from level 1 volumes backup volumes) that must be performed by the primary processing unit. (2) See *level functions*.

primary space management

See *automatic primary space management*.

primary volume

A non-SMS volume managed by DFSMSHsm containing data sets that are directly accessible to the user.

problem determination aid trace

This data set is used to gather information about DFHSM processing.

promotion

The process of one host taking over level functions for another. See *demotion*.

PSCB

Protected step control block.

PSP

Preventive service planning.

PSW

Program status word.

PTF

Program temporary fix.

quiesced journal backup

A method of journal backup during which all DFSMSHsm activity is quiesced while DFSMSHsm complete backup of the journal. See *non-intrusive journal backup* and [“Using non-intrusive journal backup” on page 496](#).

quiesce time

A time of day after which an automatic function does not start processing any more volumes.

RACF

See *Resource Access Control Facility (RACF)*.

recall

The process of moving a migrated data set from a level 1 or level 2 volume to a DFSMSHsm-managed volume or to a volume not managed by DFSMSHsm.

reconnection

See *fast subsequent migration reconnect*.

record-level sharing (RLS)

See *VSAM record-level sharing (VSAM RLS)*.

recording format

For a tape volume, the format of the data on the tape; for example, 18, 36, 128, 256, 384 tracks, EFMT1, EFMT2, EEFMT2, EFMT3, EEFMT3, EFMT4, or EEFMT4.

recovery

In DFSMSHsm, the process of copying a backup version of a data set from a backup volume to a specified volume or to the volume from which the backup version was created.

recycle process

A DFSMSHsm process that, based on the percentage of valid data on a tape backup or migration level 2 volume, copies all valid data on the tape to a tape spill backup or migration level 2 volume.

reentrant

The attribute of a program or routine that allows the same copy of that program or routine to be used concurrently by two or more tasks.

Resource Access Control Facility (RACF)

An IBM licensed program that provides access control by identifying and by verifying users to the system. RACF authorizes access to protected resources, logs unauthorized access attempts, and logs accesses to protected data sets.

restart data set

A data set created by DFSMSHsm if aggregate recovery fails. It contains a list of all the data sets successfully restored during the aggregate recovery and allows the user to restart the aggregate recovery after the cause of the failure has been resolved.

restore

In DFSMSHsm, the process of invoking DFSMSdss to perform the program's recover function. In general, it is to return to an original value or image, for example, to restore data in main storage from auxiliary storage.

restricted command authority

In DFSMSHsm, allowing a user having at least read authority to each data set within an aggregate group to process ABACKUP or ARECOVER.

retained copies

Retained copies are the set of backup copies that have rolled off from the active copies and have not yet reached their retention periods. A nearly unlimited number of retained copies for each data set can be maintained.

retired version

In DFSMSHsm, a specially marked backup version that DFSMSHsm created before it deleted the non-SMS-managed original data set during data set retirement.

retirement

See *data set retirement*.

reverse restore

A FlashCopy option that reverses a FlashCopy relationship by copying over modified tracks from the original target volume to the original source volume. The background copy process must complete before you can perform reverse restore.

REXX

Restructured extended executor.

RLS

Record level sharing.

roll off

When a new backup, dump, or generation data set copy is created, the oldest copy becomes a candidate for deletion, to maintain a customer-specified limit.

RPL

Request parameter list. Part of VSAM control block.

RRDS

Relative record data set.

SAF

System authorization facility.

SAQ

Supplement for additional quantities.

SCP

System control programming.

SDSP

Small data set packing.

secondary address space

Synonym for DFSMSHsm secondary address space.

secondary space management

See *automatic secondary space management*.

selection data set

In aggregate backup and recovery processing, a sequential data set or a member of a partitioned data set used to define the data sets that compose the input to the aggregate backup function. It contains any include, exclude, accompany, or allocate lists.

sequential data set

A data set whose records are organized on the basis of their successive physical positions, such as on magnetic tape.

similar device

A (DASD) device with the same number of bytes per track and tracks per cylinder.

single-cluster control data set

A control data set (MCDS or BCDS) that is represented by a single VSAM key-sequenced data set (KSDS) cluster. This can be a key-range or non-key-range cluster.

single-file format

In DFSMSHsm, a 3480 or 3490 format, or the equivalent, consisting of one standard-label data set that spans up to 255 tape volumes.

single DFSMSHsm-host environment

Any environment in which a single DFSMSHsm host has exclusive use of a set of control data sets.

small data set packing (SDSP)

In DFSMSHsm, the process used to migrate data sets that contain equal to or less than a specified amount of actual data. The data sets are written as one or more records into a VSAM data set on a migration level 1 volume.

small-data-set-packing data set

In DFSMSHsm, a VSAM key-sequenced data set allocated on a migration level 1 volume and containing small data sets that have migrated.

SMF

System Management Facilities.

SMP

System Modification Program.

SMP/E

System Modification Program Extended.

SMS

Storage Management Subsystem.

SMS class

A list of attributes that SMS applies to data sets having similar allocation (data class), performance (storage class), or availability (management class) needs.

SMS-managed data set

A data set that has been assigned a storage class.

SnapShot

A function of the IBM RAMAC Virtual Array (RVA) that allows an instantaneous copy to be made of data sets using DFSMS software.

space manager

Synonym for storage administrator.

space management

In DFSMSHsm, the process of managing aged data sets on DFSMSHsm-managed and migration volumes. The three types of space management are: migration, deletion, and retirement.

spanning data sets

Data sets that span one or more tape volumes. The tape volumes that are spanned are part of a connected set. See *connected set*.

specific scratch pool

A group of empty tapes with unique serial numbers that are known to DFSMSHsm as a result of being defined to DFSMSHsm with the ADDVOL command.

spill backup volume

A volume owned by DFSMSHsm to which all but the latest backup version of a data set are moved when more space is needed on a DASD daily backup volume or all valid versions are moved when a tape backup volume is recycled.

spill process

A DFSMSHsm process that moves all but the latest backup version of a data set from a DASD daily backup volume to a spill backup volume.

SSF

Software Support Facility.

SSI

Subsystem interface.

SSM

Secondary space management.

SSSA

Subsystem option block extension for SMS.

storage administrator

In DFSMSHsm, the person who is authorized through the DFSMSHsm AUTH command to enter DFSMSHsm system programmer and storage administrator commands, who can affect the authority of other DFSMSHsm users, and who controls the manner in which DFSMSHsm manages DASD space.

storage class

A named list of data set storage service attributes that identifies performance and availability requirements. SMS uses these attributes to control data placement.

storage group

(1) A named list of DASD volumes used for allocation of new SMS-managed data sets, or a dummy storage group, or a VIO storage group. (2) A list of real DASD volumes, or a list of serial numbers of volumes that no longer reside on a system but that end users continue to refer to in their JCL.

storage hierarchy

An arrangement in which data may be stored in several types of storage devices that have different characteristics such as capacity and speed of access.

Storage Management Subsystem (SMS)

A z/OS DFSMS facility used to automate and centralize the management of storage. Using SMS, a storage administrator describes data allocation characteristics, performance and availability goals, backup and retention requirements, and storage requirements to the system through data class, storage class, management class, storage group, and ACS routine definitions.

suballocated file

A VSAM file that occupies a portion of an already defined data space. The data space may contain other files. See *unique file*.

subsystem interface (SSI)

The means by which system routines request services of the master subsystem, a job entry subsystem, or other subsystems defined to the subsystem interface.

SVC

Supervisor call instruction.

sysplex

A set of z/OS systems communicating and cooperating with each other through certain multisystem hardware components and software services to process customer workloads. This term is derived from *system complex*. See *base sysplex* and *parallel sysplex*.

sysplex timer

An IBM unit that synchronizes the time-of-day (TOD) clocks in multiple processors or processor sides.

system-managed storage

Storage managed by the Storage Management Subsystem. SMS attempts to deliver required services for availability, performance, and space to applications.

take back

Process performed by a demoted host to take back the level functions that have been taken over by a promoted host.

TCB

Task control block.

threshold of occupancy

A limit of occupied space on a volume managed by DFSMSHsm.

time sharing option (TSO)

An option on the operating system for a System/370 that provides interactive time sharing from remote terminals.

TIOT

Task input/output table.

TMP

Terminal monitoring program.

TOD

Time of day.

trace

(1) A record of the execution of a computer program that exhibits the sequence in which the instructions were executed. (2) To record a series of events as they occur.

TSN

Time sharing option.

TSO/E

Time sharing option/extended.

TTOC

Tape table of contents.

TVT

Tape volume table.

TS1120

IBM System Storage TS1120 (3592 Model E05, 3592-2 and 3592-2E).

TS1130

IBM System Storage TS1130 (3592 Model E06, 3592-3E).

TS1140

IBM System Storage TS1140 (3592 Model E07, 3592-4E).

UCB

Unit control block.

UID

The DFSMSHsm authorized-user identification in 1 to 7 characters.

undirected recall

In DFSMSHsm, moving a migrated data set from a level 1 or level 2 volume to a level 0 volume without specifying the target volume or unit where the volume can be allocated. Undirected recall can be automatic or by command.

unique file

A VSAM file that occupies a data space of its own. The data space is defined at the same time as the file and cannot contain any other file. See *suballocated file*.

unlike device

A DASD device with a different number of bytes per track and tracks per cylinder, or both.

user catalog

An optional catalog used in the same way as the master catalog and pointed to by the master catalog. Use of user catalogs lessens the contention for the master catalog and facilitates volume portability.

user exit

A programming service provided by an IBM software product that may be requested during the execution of an application program that transfers control back to the application program upon the later occurrence of a user-specified event.

virtual DASD

In DFSMSHsm, this refers to the 3850 Mass Storage System (MSS).

virtual storage access method (VSAM)

An access method for direct or sequential processing of fixed-length and variable-length records on disk devices. The records in a VSAM data set or file can be organized in logical sequence by a key field (key sequence), in the physical sequence in which they are written on the data set or file (entry sequence), or by relative-record number.

virtual storage constraint relief (VSCR)

A function that increases the amount of storage available for the user's application program.

volume

(1) A certain portion of data, together with its data carrier, that can be handled conveniently as a unit. (ISO) (2) A data carrier that is mounted and demounted as a unit, for example, a reel of magnetic tape, a disk pack. (ISO) (3) That portion of a single unit of storage that is accessible to a single read/write mechanism, for example, a drum, a disk pack, or part of a disk storage module. (4) A storage medium that is mounted and demounted as a unit; for example, magnetic tape or diskette.

volume pool

In DFSMSHsm, a set of related primary volumes. When a data set is recalled, if the original volume that it was on is in a defined volume pool, the data set can be recalled to one of the volumes in the pool.

volume serial number

An identification number in a volume label that is assigned when a volume is prepared for use in the system.

volume table of contents (VTOC)

(1) A table on a direct access volume that describes each data set on the volume. (2) An area on a disk or diskette that describes the location, size, and other characteristics of each file and library on the disk or diskette.

VSA

VSAM data set allocation control block.

VSAM

Virtual storage access method.

VSAM record-level sharing (VSAM RLS)

An extension to VSAM that provides direct record-level sharing of VSAM data sets from multiple address spaces across multiple systems. Record-level sharing uses the z/OS coupling facility to provide cross-system locking, local buffer invalidation, and cross-system data caching.

VSAM RLS

See *VSAM record-level sharing (VSAM RLS)*.

VSAM sphere

(1) The base cluster of a VSAM data set and its associated alternate indexes. (2) A sphere containing the following eight components: base cluster, base data object, base index object, base path, alternate index, alternate index data object, alternate index index object, and alternate index path.

VSCR

Virtual storage constraint relief.

VSR

Volume statistics record.

VTOC

Volume table of contents.

VTOC copy data set

A data set that contains a copy of the VTOC entry for each data set that DFSMSHsm backs up or dumps.

VTs

Virtual tape server.

VVDS

VSAM volume data set.

WWFSR

ABACKUP or ARECOVER backup and recovery record.

XCF

Cross-system coupling facility.

XRC

Extended remote copy.

z/Architecture

An IBM architecture for mainframe computers and peripherals. The IBM Z® family of servers uses the z/Architecture. It is the successor to the S/390®, zSeries, and 9672 family of servers. See *Enterprise Systems Architecture/390 (ESA/390)*.

B

BACKDS command

- deleting expired backup versions of UNIX files [770](#)
- examples [771](#)
- for DFSMSHsm [759](#), [775](#)
- optional parameters
 - CC [762](#)
 - CHANGEDONLY [764](#)
 - DELETE [764](#)
 - EXCLUDE [764](#), [766](#), [1004](#)
 - NEWNAME [767](#)
 - RECURSE [769](#)
 - TARGET [770](#)
 - UNIT [770](#)
 - VOLUME [770](#)
- required parameters
 - dsname [761](#)
 - filepath [761](#)
 - UNIT parameter [309](#)
 - VOLUME parameter [309](#)

BACKFILE command

- for DFSMSHsm [773](#), [777](#)

backing up

- and recovering the ABARS activity log [401](#)
- applications [324](#)

backup

- additional considerations [445](#)
- all changed data sets on a volume, non-SMS-managed [309](#)
- all data sets on a volume, SMS-managed [230](#)
- all eligible changed data sets
 - in one or more storage groups [232](#)
 - on a volume [232](#)
- all eligible changed UNIX files
 - in a directory [232](#)
- all primary volumes, non-SMS-managed [309](#)
- automatic
 - example [220](#)
 - example system [165](#)
 - specifying storage for [178](#)
 - specifying whether to perform [186](#)
 - when to start, specifying time [188](#)
- cleanup process [219](#)
- conditions for a data set, changing [308](#)
- control data set (CDS)
 - examples [519](#)
 - how to [493](#)
 - manual [505](#)
 - processing [199](#)
 - protecting tapes [499](#)
 - recovery and multiple backup data sets, using UPDATEC [513](#)
 - specifying DASD for [498](#)
 - specifying device type [498](#)
 - specifying how many backup versions to keep [497](#)
 - specifying tape for [498](#)

backup (*continued*)

control data set (CDS) (*continued*)

- when accessing in RLS mode [200](#), [494](#), [498](#), [504](#)

copies

- always-call support [623](#)
- of DFSMSHsm-owned tape volumes [435](#)
- of SMS-managed data sets at recovery site [433](#)

current, definition [114](#)

cycle

- defining when to start [192](#)
- specifying [192](#)

daily volume selection

- DASD [209](#)
- DASD and tape [212](#)
- initial DASD [209](#)
- initial DASD or tape [213](#)
- subsequent DASD [211](#)
- subsequent DASD or tape [215](#)

daily, selecting [207](#)

DASD spill volume [218](#)

data sets

- all changed, in one or more storage groups [230](#)
- all changed, on a volume [232](#)
- by command, specifying who can [185](#)

data sets for CDSs

- changing names [503](#)
- specifying names [497](#)

determining candidate data sets, non-SMS-managed volumes [112](#)

DFSMSHsm-managed volumes from storage groups [201](#)

disaster, facilities [436](#)

eligible data sets [203](#)

expired versions of non-SMS-managed data sets, deleting [310](#)

frequency

- non-SMS-managed, specifying [303](#)
- relationship to maximum number of backup versions [181](#)
- SMS-managed, guaranteed backup [180](#)
- SMS-managed, specifying [180](#)

from DASD, RACF considerations [624](#)

ICF catalog, procedure [487](#)

individual data set [222](#)

individual data set, non-SMS-managed [309](#)

initial DASD daily volume selection [209](#)

initial selection, DASD or tape daily [213](#)

inline backup

- about [447](#)
- invoking [447](#)
- non-SMS-managed [309](#)
- SMS-managed [230](#)

interrupting and restarting [485](#)

management classes, example [186](#)

migrated data sets [200](#)

migrated data sets, specifying first qualifier [53](#)

name of

- cartridge-type single-file data sets [206](#)
- dump copy data sets [197](#)
- versions of data sets [204](#)
- VTOC copy data sets [202](#)

obtaining information [560](#)

overview

- backup (*continued*)

syntax [797](#)

VERSIONS parameter [311](#)

bypass enqueue processing between dump and DFP

functions [458](#)

BYPASS subparameter, DATASETCONFLICT parameter, ARECOVER command [394](#), [402](#)

C

CANCEL

- DFSMSshm queued requests [604](#)

CANCEL command

- examples [803](#)

- for DFSMSshm [801](#)

optional parameters

DATASETNAME [802](#)

FILENAME [802](#)

REQUEST [802](#)

SASINDEX [803](#)

TCBADDRESS [803](#)

USERID [802](#)

syntax [801](#)

canceling a TSO request [686](#)

candidate data sets

- extent reduction, migrate, SMS-managed storage [71](#)

- for backup, determining, SMS-managed storage [68](#)

- for both migration and extent reduction, migrate, SMS-managed storage [71](#)

- for extent reduction, determining, SMS-managed storage [69](#)

- for migration, determining, SMS-managed storage [67](#)

capacity utilization

- specifying [543](#)

cartridge-type tape volumes

- making from reel-type or multiple-file-format tapes [542](#)

case 1: damaged CDS, full journal [629](#)

case 10: correcting errors within the common recall queue [647](#)

case 11: recovering a deleted ML1 data set without a backup [649](#)

case 12: recovering from a large-scale cyber event [650](#)

case 2: damaged journal, undamaged CDS [632](#)

case 3: full journal, undamaged CDS [632](#)

case 4: structurally damaged CDS, missing journal records [633](#)

case 5: time sequence gaps in CDS records, journal records also missing [633](#)

case 6: overwritten migration tape [634](#)

case 7: overwritten backup tape [637](#)

case 8: Damaged ML1 volumes [641](#)

case 9: reestablish access to previously deleted migrated data sets (no backup exists, ml2 only) [646](#)

catalog

- considerations

- single-processing-unit environment [137](#)

- tapes [136](#)

- controlling migration, non-SMS-managed [124](#)

- daily backup, selecting [207](#)

- disaster alternate [442](#)

- dump

- defining to DFSMSHsm [177](#)

- specifying concurrent copy with [169](#)

- specifying the kind of tape units to use [174](#)

- specifying what to do with [173](#)

volume (*continued*)

- dumping, non-SMS-managed [308](#)

- initial selection

- DASD daily backup [209](#)

- DASD or tape daily backup [213](#)

- spill backup [217](#)

- tape daily backup [211](#)

- making disaster backup copies [439](#)

- migration

- deleting non-SMS-managed data sets with the MIGRATE command [532](#)

- using the FREEVOL command for [533](#)

- migration level 1

- damaged, recovering backup versions from [554](#)

- moving all data sets [533](#)

- using the MIGRATE command [532](#)

- migration level 2, contention [136](#)

- non-SMS-managed

- automatic availability management of [306](#)

- backing up all primary [309](#)

- online, ensuring [343](#)

- pool

- configuration in JES3 [107](#)

- defining [105](#)

- pooling

- example [19](#)

- JES2 [105](#)

- JES3 [107](#)

- recovery, incremental backup [316](#)

- selecting

- backup [216](#)

- DASD and tape daily backup [212](#)

- DASD daily backup [209](#)

- recall, non-SMS-managed [119](#)

- tape daily backup [211](#)

- serialization, dump [197](#)

- source, backup [307](#)

- space management, preventing processing of data sets [149](#)

- subsequent selection

- DASD daily backup [211](#)

- DASD or tape daily backup [215](#)

- DASD spill [218](#)

- spill backup [218](#)

- tape daily backup [212](#)

- tape spill [218](#)

- tape

- alternate, replacing an original with [440](#)

- consolidating valid data [537](#)

- DFSMSHsm-owned, copying categories [438](#)

- DFSMSHsm-owned, making backup copies [435](#)

- DFSMSHsm-owned, making copies [436](#)

- DFSMSHsm-owned, protecting [558](#)

- dump, selecting [198](#)

- selecting during recycling [541](#)

- to be backed up, specifying [304](#)

- to be dumped, SMS-managed [166](#)

- to be dumped, specifying [305](#)

- with storage groups [11](#)

VOLUME parameter

- BACKDS command [309](#)

- BACKVOL command [222](#)

- MIGRATE command [532](#)

- RECYCLE command [539](#)

- volume, damage on an ML1 [641](#)
- VOLUMEPOOL parameter, DEFINE command [107](#)
- VOLUMES parameter, ARECOVER command [393](#)
- VSAM considerations for control data sets [516](#)
- VSAM data set
 - accessing during backup [204](#)
 - backing up [204](#)
 - GUARANTEED SPACE attribute
 - availability management [451](#)
 - recalling, changes in the storage group [153](#)
 - recalling, changes in the storage-class-to-data set mapping [153](#)
 - recalling, problems [153](#)
 - recalling, problems with conversions of data sets [154](#)
 - recovering [451](#)
 - recovering, changes in the storage group [451](#)
 - recovering, changes in the storage-class-to-data set mapping [452](#)
 - recovering, problems [451](#)
 - recovering, problems with conversions of data sets [452](#)
 - space management [152](#)
 - recovering [314](#)
 - recovering from a DFSMSHsm backup version [246](#)
 - restore [253](#)
 - restoring from a dump copy [247](#)
 - space management [75](#)
- VTOC
 - copy data set
 - backup, names [202](#)
 - create [202](#)
 - volume recovery [316](#)
 - dump copies
 - example [175](#)
 - specifying number to keep [175](#)
- VTOCCOPIES subparameter, DUMPCLASS parameter, DEFINE command [176](#)

W

- wait for a spill backup volume [217](#)
- what our example system shows, space management [23](#)
- who can back up data sets by command, specifying [185](#)
- withdrawing FlashCopy relationship [282](#)
- write dump VTOC copy data set [198](#)
- writing to a cartridge-type, single-file format tape during migration [78](#)

X

- XMIT parameter, ARECOVER command [393](#)
- XRC primary volume
 - FlashCopy operation
 - FRRECOV [887](#)

Z

- z/OS images [593](#)
- ZCOMPRESS [1207](#)
- zEDC [1207](#)
- zEDC compression
 - during migration [75](#)

Product Number: 5655-ZOS

SC23-6871-70
