About this document.....	li
Who should read this document.....	li
Major divisions of this document.....	li
Required product knowledge.....	liv
z/OS information.....	liv
How to read syntax diagrams.....	liv
Symbols.....	liv
Syntax items.....	lv
Syntax examples.....	lv
How to provide feedback to IBM.....	lvii
Summary of changes.....	lix
Summary of changes for z/OS 3.2.....	lix
Summary of changes for z/OS 3.1.....	lx
Part 1. DFSMSHsm Storage Administration Guide.....	1
Chapter 1. Welcome to DFSMSHsm.....	7
Purpose of space management.....	7
Purpose of availability management.....	7
What you are expected to do.....	8
Tasks for managing storage with DFSMSHsm.....	8
Overview of DFSMSHsm functions.....	9
DFSMSHsm functions for SMS-managed volumes.....	10
DFSMSHsm functions for non-SMS-managed volumes.....	14
Devices supported by DFSMSHsm.....	16
How to use the example system.....	17
Multiple z/OS images in the example system.....	18
DASD storage in the example system.....	18
Tape devices in the example system.....	19
Other assumptions in the example system.....	20
Chapter 2. Space management of SMS-managed storage.....	23
Space management functions.....	23
Automatic primary space management.....	23
Automatic secondary space management.....	24
Event-driven migration.....	24
Automatic recall.....	32
Automatic dynamic volume expansion space management.....	32
Command space management.....	32
Tasks for automatic space management.....	32
Specifying the storage to be managed and the space requirements.....	32
Specifying how groups of data sets are managed.....	35
Specifying when automatic primary space management can process.....	46

Specifying when automatic secondary space management can process.....	46
Specifying migration of data sets to overflow volumes.....	47
Specifying how to migrate data sets to migration level 2.....	47
Specifying how to do extent reduction.....	49
Specifying how to scratch expired data sets.....	49
Specifying the maximum automatic volume space management tasks and subtasks.....	49
Specifying the maximum automatic secondary space management tasks.....	50
Specifying the maximum interval migration or on-demand migration tasks.....	51
Specifying an on-demand migration number of concurrently queued volumes notification limit.....	52
Specifying recall tasks.....	52
Specifying small data set packing.....	52
Specifying the first qualifier for names of migrated data sets.....	53
Specifying if class transitions should be performed during event-driven migration.....	53
Configuring migration cleanup.....	54
Identifying migration level 2 volumes to DFSMSHsm.....	55
Specifying duplexing for migration level 2 tapes.....	55
Specifying the allowed target tiers.....	55
Integrity age for space management.....	56
Automatic space management operation examples.....	56
Automatic space management.....	56
Integrating cloud storage into a DFSMSHsm automatic space management environment.....	58
Starting automatic secondary space management.....	59
Starting automatic primary space management.....	64
Automatic primary space management.....	65
Event-driven migration example scenario.....	81
Class transitions for Db2 objects example scenario.....	82
Automatic recall.....	83
Additional space management during migration and recall when DFSMSHsm is the data mover.....	87
Command space management tasks.....	88
Deleting migrated data sets.....	88
Migrating an individual data set.....	89
Transitioning an individual data set.....	90
Migrating and transitioning an SMS-managed volume.....	91
Migrating and transitioning a storage group.....	92
Recalling SMS-managed data sets.....	92
Recalling direct access data sets.....	93
Moving data sets.....	93
Reconnecting data sets using fast subsequent migration.....	94
Chapter 3. Space management of non-SMS-managed storage.....	99
Differences in what the example system shows.....	99
Tasks for space management of non-SMS-managed storage.....	99
Specifying the age for deleting list and utility data sets.....	100
Specifying the minimum age for migrating data sets.....	101
Specifying when data sets become eligible for level 1 to level 2 migration.....	101
Specifying recall characteristics for the type of volume.....	101
Defining primary volumes to DFSMSHsm.....	102
Attributes of primary volumes.....	103
Defining pools of volumes.....	105
Pools in systems running under JES2.....	105
Pools in systems running under JES3.....	106
Automatic space management processing for non-SMS-managed storage.....	109
Automatic secondary space management.....	110
Automatic primary space management.....	111
Automatic interval migration.....	119
Recall.....	119

Command space management.....	123
Command volume space management.....	124
Command volume space management (primary).....	124
Controlling migration of data sets and volumes.....	124
Recalling a data set to a specific volume.....	124
Recalling an SMS-managed data set to a non-SMS-managed volume.....	125
Recalling an SMS-managed BDAM data set to a non-SMS-managed volume.....	125
Recalling an SMS-managed sequential extended-format data set to a non-SMS-managed volume.....	125
Chapter 4. Other space management considerations.....	127
Space management of extended address volumes (EAVs).....	127
Track management for SMS-managed volumes.....	128
Track management for non-SMS-managed volumes.....	128
Controlling allocations to extended address volumes (EAVs).....	129
Recommendations for using extended address volumes (EAVs).....	129
Common recall queue.....	129
Connecting to a common recall queue list structure.....	131
Populating the common recall queue.....	131
Selecting requests from the common recall queue.....	132
Processing recall requests on the common recall queue.....	132
Disconnecting from the common recall queue.....	132
Processing of common recall queue requests during shutdown.....	133
Deleting the common recall queue structure.....	133
Processing failures in a common recall queue environment.....	133
Processing priority of recalls and deletions.....	135
Specifying the order in which data sets from a single tape are processed.....	136
Migration volume contention priorities.....	136
Tape migration level 2 volume contention.....	136
Specifying the desired number of ML2 partial tapes.....	141
SDSP data set contention.....	142
Multitasking considerations for SDSP data sets.....	147
Preventing the processing of data sets during space management.....	149
Deferred generation data sets.....	149
Security considerations for automatic space management.....	149
Space management of data sets with discrete data set profiles.....	150
Password protection of data sets on DASD.....	151
Access method services considerations.....	152
GUARANTEED SPACE attribute considerations.....	152
Results of recalling GUARANTEED SPACE VSAM data sets.....	152
Possible problems.....	153
DFSMSHsm retrieval of management classes and storage groups.....	154
Deletion of dynamic I/O device considerations.....	155
Space management considerations for sequential extended-format data sets.....	155
Volume space management processing.....	155
Automatic primary space management processing.....	155
Recall processing.....	155
Object storage in the cloud.....	156
System set up to use the cloud.....	156
DASD volumes.....	156
SETSYS.....	156
Cloud password.....	156
Using the Cloud.....	157
Workload distribution with TCT.....	157
Migration.....	157
Recall.....	158
Delete.....	158
Listing information.....	158

Auditing information.....	158
Chapter 5. Space management procedures.....	161
Interrupting and restarting primary space management, secondary space management, or event-driven migration.....	161
When primary space management, secondary space management, or event-driven migration needs to be restarted.....	161
Automatic restart of primary space management or secondary space management.....	162
Automatic restart of event-driven migration.....	162
Manual restart of primary space management or secondary space management.....	163
Defining a new primary space management or secondary space management processing window.....	164
Allowing another host to take over secondary space management functions.....	164
Chapter 6. Availability management of SMS-managed storage.....	165
What the example system shows.....	165
Automatic incremental backup.....	165
Automatic full-volume dump.....	165
Command availability management.....	165
Tasks for automatic availability management.....	166
Dump tasks.....	166
Specifying which volumes to dump and the dump classes to use.....	166
Specifying when automatic dump processing starts.....	168
Specifying the DFSMSdss DASD I/O buffering technique to use for dump.....	168
Specifying concurrent copy for volume dumps.....	169
Specifying the maximum number of dump tasks.....	169
Specifying the day on which a dump occurs.....	170
Specifying the characteristics of dump classes.....	171
Defining dump volumes to DFSMSShsm.....	177
Backup tasks.....	177
Specifying which storage group has automatic backup performed.....	178
Specifying how to manage groups of data sets.....	178
Specifying a storage group priority for autobackup processing.....	179
Specifying whether to use concurrent copy.....	179
Specifying frequency of backup.....	180
Guaranteeing frequency of backup.....	180
Specifying the maximum number of backup versions to keep.....	181
Specifying how long to keep backup versions.....	181
Specifying who can back up data sets by command.....	185
Specifying whether to perform automatic backup.....	186
Example management classes.....	186
Specifying the start time for automatic backup.....	188
Specifying whether to perform volume backup and the kind of device to use.....	189
Specifying the first qualifier for names of backup versions.....	189
Specifying the maximum number of volume backup tasks in each host.....	190
Specifying the data set backup by command environment.....	190
Specifying whether to back up RACF discrete data set profiles.....	190
Specifying whether DFSMSShsm performs spill processing.....	190
Specifying whether to back up only changed data sets.....	190
Specifying how DFSMSShsm should respond to a data set in use.....	191
Specifying the days on which automatic backup occurs.....	192
Defining backup volumes to DFSMSShsm.....	192
Specifying duplexing for backup tapes.....	193
Automatic availability management operation.....	193
Dump processing.....	193
Deleting expired dump copies.....	195
Deleting empty dump containers.....	195
Defining what to do with tapes marked unavailable during DUMP processing.....	195

Dumping DFSMSHsm-managed volumes.....	196
Deleting and uncataloging excess dump VTOC copy data sets.....	198
Automatic backup processing.....	199
Phase 1: Backing up the control data sets.....	199
Phase 2: Moving backup versions.....	200
Phase 3: Backing up migrated data sets.....	200
Phase 4: Backing up SMS-managed volumes from storage groups with the automatic backup attribute.....	201
Selecting daily backup volumes.....	207
Backup volume spill process.....	215
Selecting spill backup volumes.....	216
Initial spill backup volume selection (DASD and tape).....	217
Subsequent spill backup volume selection (DASD and tape).....	218
Cleanup processing.....	218
Backup volume cleanup process.....	219
Releasing a backup volume.....	220
Automatic backup example.....	220
Command availability management.....	221
Dumping a volume.....	222
Dumping the volumes in one or more storage groups.....	222
Backing up an individual data set or UNIX file.....	222
Using the data set or UNIX file backup by command capabilities.....	224
Backing up all data sets on one or more volumes.....	230
Backing up all data sets in one or more storage groups.....	230
Backing up all UNIX files in a directory.....	230
UNIX file wildcard processing.....	231
Backing up all eligible changed data sets on one or more volumes.....	232
Backing up all eligible changed data sets in one or more storage groups.....	232
Backing up all eligible changed UNIX files in a directory.....	232
Deleting expired backup versions from the backup volumes.....	233
Deleting backup versions of specific data sets or UNIX files.....	239
Command recovery and restore.....	240
Data set recovery and restore.....	241
UNIX file recovery.....	250
Restoring a data set from a DFSMSHsm dump copy.....	251
Restoring VSAM data sets.....	253
Managing volume backups with fast replication.....	254
Combining fast replication options in DFSMSHsm.....	256
Combining copy services operations in DFSMS.....	257
Using the copy pool construct for fast replication setup.....	257
Using the copy pool backup storage group type for fast replication setup.....	259
Using the extend and overflow storage group types with fast replication.....	260
Preparing for the fast replication backup.....	260
Creating a fast replication backup.....	261
Recovering a fast replication backup.....	270
Withdrawing DFSMSHsm background copies.....	282
Holding and releasing the fast replication functions.....	283
Deleting unneeded DFSMSHsm fast replication backup versions.....	283
Obtaining DFSMSHsm fast replication backup information.....	284
Preventing DFSMSHsm functions from processing target volumes.....	288
Other copy pool considerations.....	288
Collecting fast replication messages in message data sets	291
Volume recovery and restore.....	294
Specifying the maximum number of data set recovery tasks in each host.....	294
Specifying the maximum number of volume recovery from dump tasks.....	294
Full-volume restore with update.....	295
Full-volume restore from a dump copy.....	298
Volume recovery from incremental backup versions.....	300

Processing priority of volume recoveries.....	302
Chapter 7. Availability management of non-SMS-managed storage.....	303
Tasks for availability management of non-SMS-managed storage.....	303
Specifying how frequently data sets are backed up.....	303
Specifying how many versions to keep for each backed up data set.....	303
Specifying which volumes are backed up automatically.....	304
Specifying which volumes are dumped automatically.....	305
Automatic availability management of non-SMS-managed volumes.....	306
Backing up cataloged and uncataloged data sets with the same name.....	307
Command availability management for non-SMS-managed storage.....	308
Dumping a volume.....	308
Changing the backup conditions for a data set.....	308
Backing up an individual data set.....	309
Inline backup of an individual data set.....	309
Backing up all primary volumes.....	309
Backing up all changed data sets on volumes.....	309
Deleting expired backup versions of non-SMS-managed data sets.....	310
Deleting backup versions of specific data sets.....	311
Recovering specific data sets.....	311
Recovery of VSAM data sets.....	314
Data set restore from a DFSMSHsm dump copy.....	314
Data set recovery of retired data sets.....	315
Combining full-volume restore with volume recovery.....	316
Volume recovery from incremental backup versions.....	316
Chapter 8. Aggregate backup and recovery support (ABARS).....	319
How aggregate backup works.....	322
Specifying data sets to be backed up.....	322
Backing up applications.....	324
ABACKUP command.....	324
Example of data sets associated with an aggregate group.....	325
Filtering for generation data sets.....	326
Preparing for aggregate backup.....	326
SMS requirements during aggregate backup.....	328
Creating selection data sets.....	329
Creating an instruction data set.....	334
Defining an aggregate group.....	336
Management class considerations.....	338
DFSMSHsm coexistence considerations for aggregate groups and management classes.....	339
Protecting aggregate backup tape volumes.....	340
Checking authorization during aggregate backup.....	340
Authorizing comprehensive ABACKUP command authority.....	341
Authorizing restricted ABACKUP command authority.....	341
Using the aggregate backup installation exits.....	342
Ensuring that the necessary volumes are online.....	343
Defining SETSYS parameters for aggregate backup.....	343
Determining the unit type for the control and data files.....	345
Minimizing data set contention.....	345
Data sets that DFSMSHsm dynamically allocates during aggregate backup processing.....	345
Performing aggregate backup.....	346
ABACKUP command.....	347
Issuing the ABACKUP command with the VERIFY parameter.....	349
Issuing the ABACKUP command with the EXECUTE parameter.....	350
Aggregate backup output.....	351
Data files.....	351
Control file.....	351
Instruction and activity log file.....	352

Activity log.....	352
ABACKUP CPU time and accounting codes.....	353
DFSMSshm coexistence considerations for new ABACKUP output data sets.....	354
Expiring ABR records in the BCDS.....	354
ABACKUP considerations.....	355
ABARS user catalog and catalog alias ABACKUP support.....	356
Aggregate backup assist.....	357
How aggregate backup assist works.....	357
What aggregate backup assist produces.....	357
Special considerations for ABARS.....	357
Authorization and security requirements.....	358
Input requirements.....	358
SMF data.....	358
Aggregate job names.....	358
Storage requirements.....	359
DD statements used by ABA.....	359
Sample JCL.....	360
Sample output.....	360
Aggregate stacking procedure.....	360
Backing up data with ABARS aggregate backup function.....	361
Stacking multiple aggregates on one tape.....	362
Aggregate recovery from the stacked tape.....	364
Preventing aggregate roll off and tape expiration.....	365
Deleting specific versions of aggregates from a stacked tape.....	365
RACF protection of tapes used for stacking.....	366
RACF protection of tapes after EXPIREBV processing of versions.....	366
End of volume during the stacking process.....	367
Cleanup after stacking errors.....	367
Copying ABARS aggregates to another device type.....	368
How aggregate recovery works.....	372
Recovered aggregate data sets.....	373
Example aggregate recovery site.....	374
Preparing for aggregate recovery.....	374
Authorization checking during aggregate recovery.....	376
Authorizing comprehensive ARECOVER command authority.....	377
Authorizing restricted ARECOVER command authority.....	377
Considering storage management subsystem requirements.....	378
Determining aggregate recovery site constraints.....	379
Retrieving the instruction data set.....	379
Creating an ABR record in the BCDS.....	381
Issuing the DEFINE ARPOOL command.....	382
Defining SETSYS parameters for aggregate recovery.....	384
Defining the model entity.....	387
Using the aggregate recovery installation exits.....	387
Processing generation data sets.....	387
GDSs from level 0 DASD in the include list.....	388
Migrated GDSs in the include list.....	388
GDSs in the ALLOCATE list.....	389
GDS processing order.....	389
Processing migrated data sets in the INCLUDE list.....	389
Processing VSAM data sets in the ALLOCATE list.....	389
Catalog considerations during ARECOVER processing.....	390
Performing aggregate recovery.....	391
ARECOVER command.....	392
Issuing the ARECOVER command with the PREPARE parameter.....	398
Issuing the ARECOVER command with the VERIFY parameter.....	398
Issuing the ARECOVER command with the EXECUTE parameter.....	399
Issuing the ARECOVER command with the ONLYDATASET parameter.....	399

Recovering the ABARS instruction data set.....	400
Backing up and recovering the ABARS activity log.....	401
Conflict avoidance and conflict resolution processing options.....	401
ARECOVER data set name conflict resolution.....	402
Holding and releasing ABARS functions.....	408
Displaying SMS class definitions during ABACKUP and ARECOVER.....	409
ABARS user catalog and catalog alias ARECOVER support.....	410
Data sets that are dynamically allocated during aggregate recovery processing.....	410
Aggregate recovery output.....	411
Activity log.....	411
ARECOVER CPU time and accounting codes.....	413
Using ISMF panels to perform aggregate backup.....	413
Using ISMF panels to perform aggregate recovery.....	418
Using the NetView file transfer program to transmit aggregate Backup files.....	427
Using NetView file transfer program panels.....	427
Issuing the ARECOVER command when using NetView FTP.....	431
ABARS considerations for sequential data striping.....	431
Aggregate backup processing.....	431
Aggregate recovery processing.....	432
Aggregate roll-off processing.....	432
Defining GDGs at the recovery site.....	433
Ensuring backup copies of ARECOVERed SMS-managed data sets exist at the recovery site.....	433
Directing ABARS files to DASD.....	434
 Chapter 9. Making disaster backup copies of DFSMSHsm-owned tape volumes.....	435
Planning disaster recovery.....	435
Disaster backup facilities.....	436
Making copies of DFSMSHsm-owned tape volumes.....	436
Converting tape volumes marked partially full to marked full.....	440
Replacing an original with an alternate tape volume.....	440
Creating duplex tapes off site.....	441
Sending alternate tapes off site.....	441
Managing alternate volumes.....	441
Disaster alternate volumes.....	442
Considerations when using disaster alternate volumes.....	443
 Chapter 10. Other availability management considerations.....	445
Additional considerations for backup.....	445
Backup volume contention resolution.....	445
Implications of redefining the backup cycle.....	446
Inline backup.....	447
Preventing backup processing when using the HOLD BACKUP command.....	449
GUARANTEED SPACE attribute.....	451
Data set or UNIX file backup with concurrent copy.....	453
Data set backup using NEWNAME.....	454
UNIX file backup using NEWNAME.....	455
Additional considerations for dump.....	455
Dumping DFSMSHsm-owned volumes.....	455
Dumping control data sets.....	456
Dumping the journal data set.....	456
Preventing dump processing.....	456
Dumping all allocated space.....	457
Invoking full-volume dump compression.....	457
Bypassing enqueue processing between full-volume dump and DFP functions.....	458
Volume recovery and restore considerations.....	458
Restoring data sets or volumes directly with DFSMSdss.....	458
Requesting a list of dump volumes for a dump copy.....	458
Determining the dump copy data set name.....	458

Invoking the DFSMSdss RESTORE function.....	459
Preventing recovery and restore processing when using the HOLD RECOVER command.....	459
Using the date-last-referenced field for recovery.....	459
Deferred generation data sets.....	460
Security considerations for availability management.....	460
Authorization checking during recovery.....	460
Recovering or restoring RACF-indicated data sets.....	461
Maintaining password protection for recovered data sets.....	463
DFSMSHsm retrieval of management classes.....	464
Availability management considerations for extended SAM and extended and compressed	
VSAM data sets.....	464
Availability management considerations for sequential data striping.....	464
Backup processing.....	464
Recover and restore processing.....	465
Common dump queue.....	466
Types of hosts used in a common dump queue.....	468
Connecting to a common dump queue.....	469
Placing requests on the common dump queue.....	470
Selecting requests from the common dump queue.....	471
Processing requests off of the common dump queue.....	471
Disconnecting from the common dump queue.....	472
Using QUERY, CANCEL and ALTERPRI in the common dump queue.....	472
Processing of failures in the common dump queue.....	474
Common recover queue.....	474
Types of hosts used in a common recover queue.....	476
Connecting to a common recover queue.....	478
Placing requests on the common recover queue.....	479
Selecting requests from the common dump queue.....	480
Processing requests off of the common recover queue.....	480
Using QUERY, CANCEL and ALTERPRI in the common recover queue.....	481
Disconnecting from the common recover queue.....	482
Processing of failures in the common recover queue.....	483
Chapter 11. Availability management procedures.....	485
Backup and recovery procedures.....	485
Interrupting and restarting backup processing.....	485
Defining a new automatic backup start window.....	487
Backing up and recovering a catalog.....	487
Full-volume dump procedures.....	489
Interrupting and restarting automatic dump processing.....	489
Defining a new automatic dump start window.....	490
Chapter 12. Maintaining DFSMSHsm control data sets.....	493
Tasks for maintaining the control data sets.....	493
Specifying how DFSMSHsm backs up the control data sets.....	493
Allocating backup data sets.....	494
Choosing the data mover to be used.....	494
Using non-intrusive journal backup.....	496
Specifying how many backup versions to keep.....	497
Specifying the names of the backup data sets.....	497
Specifying the device type for backup of the control data sets.....	498
Invoking the CDS backup exit (ARCCBEXT).....	499
Backing up to multiple DASD data sets.....	499
Backing up to multiple tape data sets.....	501
Considerations in a multiple DFSMSHsm host environment.....	502
Considerations when using multicluster control data sets.....	502
Nulling the journal.....	503
Changing the names of the backup data sets.....	503

Changing backup device from tape to DASD.....	503
Changing backup device from DASD to tape.....	504
Using the QUERY command to get CDS information.....	505
Backing up the control data sets manually.....	505
Possible failures during CDS and journal backup.....	505
Reasons for recovering the control data sets.....	507
I/O errors.....	507
Recovering control data sets using the enhanced CDS recovery function.....	508
Requirements for using the enhanced CDS recovery function.....	508
Implementing enhanced CDS recovery using JCL.....	508
Recovering multicluster non-key range control data sets.....	513
Control data set recovery procedure using CDSVERSIONBACKUP with UPDATEC.....	513
Updating recovered control data sets using UPDATEC.....	516
VSAM considerations for the control data sets.....	516
Determining if control data sets are accurate.....	517
Repairing errors in the control data sets.....	517
Procedures for handling a journal EOV error.....	517
Recovering from a journal I/O error.....	518
Moving the journal.....	518
Steps to ensure that the control data sets are accurate.....	519
Control data set backup and recovery examples.....	519
Recovery examples using the enhanced CDS recovery function.....	519
Performance considerations in a multiple DFSMSHsm host environment.....	525
MASH configuration considerations.....	526
Chapter 13. Managing DFSMSHsm media.....	527
Moving all data sets from one level 0 volume to other level 0 volumes.....	527
Processing SMS-managed data sets.....	527
Processing non-SMS-managed data sets.....	528
Examples of moving data sets between level 0 volumes.....	528
Moving some data sets from migration level 1 volumes.....	530
Using the FREEVOL command for migration level 1 volumes.....	531
Using the MIGRATE command for migration level 1 volumes.....	532
Deleting non-SMS-managed data sets from migration volumes.....	532
Moving all the data sets from a migration level 1 volume.....	533
Processing for SMS-managed data sets.....	533
Processing for non-SMS-managed data sets.....	534
Moving data sets from a DASD migration level 2 volume to other migration level 2 volumes.....	534
Removing residual dump and backup VTOC copy data sets from migration level 1 volumes.....	535
Preventing further migration to a DASD migration volume.....	535
Moving data sets from DASD backup volumes.....	535
Removing volumes from DFSMSHsm management or control.....	536
Removing dump copies and dump VTOC copy data sets from DFSMSHsm.....	536
JES3 considerations.....	537
Consolidating valid data on tape volumes.....	537
Defining the parameters of the recycle process.....	537
Initiating recycle processing.....	539
PERCENTVALID calculation.....	541
Selecting tape volumes during recycling.....	541
Making cartridge-type, single-file-format tapes from reel-type or multiple-file-format tapes.....	542
Limiting data that is written to a cartridge-type device.....	542
Specifying capacity utilization.....	543
Considerations for using the 3592 Model J tape drive.....	544
Considerations for using the 3592 Model E05 tape drive.....	545
Considerations for using the 3592 Model E06 tape drive.....	546
Considerations for using the 3592 Model E07 tape drive.....	548
Limiting the number of ML2 and backup data sets that span tape volumes.....	549
How to handle inconsistencies between tape media contents and OCDS TTOC records.....	550

Recovering a damaged DFSMSHsm single-file migration level 2 volume.....	551
Making migration level 2 key range volumes available.....	551
Recovering a migrated data set.....	551
Recovering a migration volume.....	552
Procedure 1.....	552
Procedure 2.....	553
Recovering backup versions from a damaged migration level 1 volume.....	554
Returning dump tapes to use.....	555
Managing SDSP data sets.....	555
Reorganizing SDSPs.....	556
SDSP backup and recovery.....	556
Removing SDSPs.....	557
Protecting DFSMSHsm-owned tape volumes.....	558
Converting to a new tape technology.....	558
Requesting DFSMSHsm service from your applications.....	558
 Chapter 14. Obtaining information.....	 559
Obtaining information from the control data sets.....	559
Obtaining backup volume information.....	560
Obtaining data set information.....	560
Obtaining UNIX file information.....	561
Obtaining copy pool information.....	562
Obtaining dump class information.....	564
Obtaining dump volume information.....	564
Obtaining DFSMSHsm host serialization information.....	565
Obtaining lists of backup and dump parameters and backup volume serial numbers.....	566
Running new reports with the DFSMSrmm Report Generator.....	566
Obtaining information about migration and DFSMSHsm-managed volumes.....	567
Obtaining DFSMSHsm-managed volume information.....	568
Obtaining tape volume information.....	569
Obtaining user authorization information.....	570
Determining which tape dump volumes are available for output during dump processing.....	570
Obtaining information about the DFSMSHsm address space.....	570
Determining which tape volumes are available for output.....	573
Determining which tape backup volumes are available for output.....	573
Determining which tape migration level 2 volumes are available for output.....	574
Obtaining statistical information about DFSMSHsm operations.....	574
Running new reports with report generator.....	575
Using the problem determination aid to trace DFSMSHsm processing.....	586
Specifying to DFSMSHsm to use the PDA.....	586
Using the TRAP command to obtain information about conditions in the system when an error occurs.....	586
Using DEBUG to determine the results of DFSMSHsm processing without moving data sets.....	587
 Chapter 15. DFSMSHsm tape libraries.....	 589
Automated tape library.....	589
Manual tape library.....	589
 Chapter 16. Using DFSMSHsm with DFSMSrmm.....	 591
Retaining DFSMSHsm tape volumes by expiration date.....	591
Retaining DFSMSHsm tape volumes by DFSMSrmm vital record processing.....	591
Tape security when using DFSMSHsm and DFSMSrmm.....	592
Recommendations for using DFSMSHsm with DFSMSrmm.....	592
 Chapter 17. Operating procedures for DFSMSHsm.....	 593
Partitioning DFSMSHsm functions.....	593
Starting DFSMSHsm.....	594
Stopping DFSMSHsm.....	595

Shutdown processing on the common recall queue.....	596
Preventing DFSMSHsm functions from running.....	596
Allowing previously prevented DFSMSHsm functions to run.....	600
Canceling DFSMSHsm requests.....	604
Altering the priority of DFSMSHsm queued requests.....	606
Printing DFSMSHsm log information.....	607
Restarting DFSMSHsm after an abnormal end.....	614
Running automatic functions concurrently.....	615
Updating the DFSMSHsm control data sets.....	616
Chapter 18. RACF considerations.....	617
RACF basics.....	617
RACF data set profiles.....	617
RACF indication.....	618
Always-call support.....	618
RACF protect-all environment.....	619
RACF environment for DFSMSHsm.....	619
DFSMSHsm and RACF concepts.....	620
The RACF user ID for DFSMSHsm.....	622
RACF started task table.....	622
Always-call support for migrated data sets and backup copies.....	623
Migration and recall from DASD.....	624
Backup and recovery from DASD.....	624
Aggregate backup and recovery data set security.....	624
Backing up RACF-indicated data sets.....	625
Authorizing the use of concurrent copy for data set backup commands.....	625
Small data set packing data set security.....	625
Uncataloging migrated data sets.....	625
Controlling command access with RACF FACILITY class.....	625
Chapter 19. Health Checker for DFSMSHsm.....	627
Check registration.....	627
Chapter 20. Data recovery scenarios.....	629
Case 1: Damaged CDS, full journal.....	629
Case 2: Damaged journal, undamaged CDS.....	632
Case 3: Full journal, undamaged CDS.....	632
Case 4: Structurally damaged CDS, missing journal records.....	633
Case 5: Time sequence gaps in CDS records, journal records also missing.....	633
Case 6: Overwritten migration tape.....	634
Case 7: Overwritten backup tape.....	637
Case 8: Damaged ML1 volumes.....	641
Case 9: Reestablish access to previously deleted migrated data sets (no backup exists, ML2 only).....	646
Case 10: Correcting errors within the common recall queue.....	647
Case 11: Recovering a deleted ML1 data set without a backup.....	649
Case 12: Recovering from a large-scale cyber event.....	650
Chapter 21. Consolidated commands, storage group definitions, and management classes for the example system.....	653
ADDVOL command.....	653
DEFINE command.....	655
SETSYS command.....	656
Storage groups.....	658
Management classes.....	659
Chapter 22. Preventive methods for avoiding data loss.....	661
Steps for preventing a full journal (damaged CDS).....	661

Preventing a full journal (undamaged CDS).....	661
Preventing structural damage to CDS and missing journal records.....	662
Preventing time sequence gaps in CDS records (journal records also missing).....	662
Preventing overwritten migration tape or overwritten backup tape.....	663
Prepare for recovery of a head crash on an ML1 volume.....	663
Reestablishing access to previously deleted, migrated data sets (no backup exists, ML2 only)....	663
 Chapter 23. Linux-z/OS DFSMSHsm dump or restore how-to.....	665
How DFSMSHsm supports linux.....	665
Using DFSMSHsm with Linux requirements.....	665
Hardware environment.....	665
DASD background.....	665
Linux requirements.....	666
Linux disk utilities.....	666
Authorization requirements.....	667
Setting up your dump environment for Linux volumes.....	667
Performing only dumps.....	667
When do you want your dumps performed?.....	667
How long do you want to keep your dumps?.....	668
How many dumps are stacked on each dump tape?.....	668
How many tape drives do you have?.....	668
Recovering your data.....	668
Recovering a volume with DFSMSHsm.....	668
Recovering a volume with DFSMSdss.....	669
Recovering a partition with DFSMSHsm.....	669
Recovering a partition with DFSMSdss.....	670
Example dump environment.....	670
How to define your dump cycle.....	671
How to define your dump classes.....	671
How to ADDVOL your volumes.....	672
How to start automatic dumping.....	672
Recovering from a dump.....	673
Submitting DFSMSHsm commands using JCL and FTP.....	674
The DFSMSHsm LIST command.....	675
Naming conventions.....	675
Data set and partition naming conventions.....	675
Volume serial number naming conventions.....	676

Part 2. DFSMSHsm Storage Administration Reference.....677

Chapter 24. DFSMSHsm commands.....	681
User commands.....	681
Operator commands.....	681
Storage administrator commands.....	682
System programmer commands.....	683
Using RACF FACILITY class to control authorization of commands.....	684
Using DFSMSHsm commands.....	684
Positional parameters.....	684
Keyword parameters.....	685
Abbreviating commands and parameters.....	685
Delimiters.....	686
Line continuations.....	686
Data set naming conventions.....	686
Comments.....	686
TSO attention key.....	686
How to read syntax diagrams.....	687
Considering the command sequence.....	687

Submitting DFSMSHsm commands.....	687
Commands in a system without RACF: Method 1.....	688
Commands in a system without RACF: Method 2.....	689
Chapter 25. ABACKUP command: Backing up aggregated data sets.....	691
Syntax of the ABACKUP command.....	692
Required parameters of the ABACKUP command.....	692
agname: Specifying the aggregate group name.....	692
EXECUTE and VERIFY: Specifying whether data movement processing or data verification occurs.....	692
Optional parameters of the ABACKUP command.....	693
FILTEROUTPUTDATASET: Specifying the output data set.....	693
LIST: Listing data sets not backed up due to the SKIP parameter.....	693
MOVE: Removing the data sets.....	693
OPTIMIZE: Overriding the SETSYS ABARSOPTIMIZE command.....	694
PROCESSIONLY: Designating the categories to process.....	694
SKIP: Skipping data sets on volumes protected by PPRC or XRC.....	694
STACK and NOSTACK: Overriding the SETSYS ABARSTAPES setting.....	695
UNIT: Designating the output device.....	695
Examples of how to code the ABACKUP command.....	695
Chapter 26. ADDVOL command: Adding or changing DFSMSHsm volumes.....	697
Syntax of the ADDVOL command.....	698
Required parameters of the ADDVOL command.....	700
volser: Specifying the volume to be added or changed.....	700
BACKUP, DUMP, MIGRATION, and PRIMARY: Identifying the type of volume.....	700
UNIT: Specifying the type of device.....	700
Optional parameters of the ADDVOL command.....	701
AUTOBACKUP and NOAUTOBACKUP: Specifying whether the primary volume is eligible for automatic backup.....	701
AUTODUMP and NOAUTODUMP: Specifying whether a volume is eligible for automatic dumping to tape or cloud.....	702
AUTOMIGRATION and NOAUTOMIGRATION: Specifying whether the primary volume is eligible for automatic volume space management.....	702
AUTORECALL and NOAUTORECALL: Specifying whether the primary volume is eligible for automatic recall.....	703
BACKUPDEVICECATEGORY: Specifying where backup versions reside.....	703
DAILY and SPILL: Identifying the type of backup volume.....	704
DELETEBYAGE, DELETEIFBACKEDUP, and MIGRATE: Specifying the type of space management on a primary volume.....	704
DENSITY: Specifying the tape density.....	705
DRAIN and NODRAIN: Specifying whether a volume should be selected for migration output.....	706
DUMPClass: Restricting the specified volume to use a specific dump class.....	706
MIGRATIONLEVEL1 and MIGRATIONLEVEL2: Specifying the migration level.....	707
OVERFLOW and NOOVERFLOW: Specifying the usage of a level 1 volume for data set migration and backup versions.....	707
SMALLDATASETPACKING and NOSMALLDATASETPACKING: Specifying small data set packing on the level 1 volume.....	708
THRESHOLD: Specifying thresholds of occupancy.....	708
TRACKMANAGEDTHRESHOLD: Specifying the high and low threshold for the track-managed space of a non-SMS level 0 extended address volume.....	710
Selecting thresholds for volumes.....	710
Examples of how to code the ADDVOL command.....	711
Chapter 27. ALTERDS command: Changing the back-ups for a non-SMS-managed data set.....	715
Syntax of the ALTERDS command.....	715
Required parameters of the ALTERDS command.....	716
name: Specifying the name of the data set or UNIX file being altered.....	716

Optional parameters of the ALTERDS command.....	716
FREQUENCY and SYSFREQUENCY: Specifying the frequency of backup versions.....	716
VERSIONS and SYSVERSIONS: Specifying the number of backup versions to maintain.....	717
Examples of how to code the ALTERDS command.....	717
Chapter 28. ALTERPRI command: Altering the priority of queued requests.....	719
Syntax of the ALTERPRI command.....	720
Required parameters of the ALTERPRI command.....	720
REQUEST, USERID, and DATASETNAME, and FILENAME: Specifying the requests to be reprioritized.....	720
Optional parameters of the ALTERPRI command.....	720
HIGH and LOW: Specifying the new priority of a request.....	720
Examples of how to code the ALTERPRI command.....	721
Chapter 29. ARECOVER command: Recovering a specified aggregate group.....	723
Syntax of the ARECOVER command.....	724
Required parameters of the ARECOVER command.....	725
AGGREGATE: Specifying the aggregate group to be recovered.....	725
DATASETNAME: Specifying the control file.....	725
VOLUMES and XMIT: Specifying the volume type.....	725
EXECUTE, VERIFY, and PREPARE: Specifying whether data movement or verification should occur or whether an ABR record should be created.....	726
Optional parameters of the ARECOVER command.....	726
ACTIVITY: Recovering the activity log.....	727
DATASETCONFLICT: Resolving data set naming conflicts.....	727
DATE and VERSION: Specifying the specific aggregate group to be recovered.....	728
INSTRUCTION: Recovering the instruction data set.....	728
MENTITY: Specifying a model entity.....	728
MIGRATEDDATA: Specifying the migration level for recovering migrated data sets.....	728
NOBACKUPMIGRATED: Specifying that automatic backup does not occur for recovered migrated data sets.....	729
ONLYDATASET: Recover a single data set or a group of data sets from an aggregate group backup.....	729
PERCENTUTILIZED: Specifying the percentage of DASD space used during ARECOVER of data sets to non-SMS volumes.....	730
RECOVERNEWNAMEALL and RECOVERNEWNAMELEVEL: Specifying a high-level qualifier for recovered data sets.....	730
STACK and NOSTACK: Specifying whether or not the ABACKUP output is STACKED.....	731
TARGETUNIT: Specifying unit types to be used for ARECOVER.....	731
TGTGDS: Overriding the SETSYS ARECOVERTGTGDS command.....	732
UNIT: Specifying unit types used for ARECOVER.....	732
VOLCOUNT: Allowing data sets to expand to multivolume as necessary during ARECOVER....	733
How to create the ABR record.....	733
Examples of how to code the ARECOVER command.....	733
Chapter 30. AUDIT command: Auditing DFSMSHsm.....	737
Auditing control data sets.....	737
Auditing common queues.....	738
Using the AUDIT command.....	738
Syntax of the enhanced AUDIT commands.....	738
Syntax of the original AUDIT commands.....	740
Required and optional parameters of the AUDIT command.....	743
ABARSCONTROLS: Requesting an audit of ABR records in the BCDS.....	743
ALL, BACKUPCONTROLDATASET, MIGRATIONCONTROLDATASET, and OFFLINECONTROLDATASET: Requesting an audit of data sets.....	743
BACKUPTYPE, BACKUPVOLUMES, and VOLUMES: Requesting an audit of primary, migration, or backup volumes.....	744
COMMONQUEUE: Requesting an audit of common queues.....	745

COPYPOOLCONTROLS: Requesting an audit of fast replication CDS record relationships.....	746
DATASETCONTROLS: Requesting an audit of data set control records.....	746
DATASETNAMES, LEVELS, and RESUME: Requesting an audit of data sets.....	746
DIRECTORYCONTROLS VOLUMES: Comparing a VTOC or a TTOC to CDS records.....	747
FILECONTROLS: Requesting an audit of UNIX file control records.....	747
FILE, FILELEVEL, and RESUME: Requesting an audit of UNIX files.....	748
MASTERCATALOG and USERCATALOG: Requesting an audit of a catalog.....	748
MEDIACONTROLS VOLUMES, MEDIACONTROLS(SDSP) VOLUMES and MEDIACONTROLS(CLOUD): Requesting an audit of control information.....	748
VOLUMECONTROLS (BACKUP, MIGRATION, and RECOVERABLE): Requesting an audit of control information.....	749
Optional parameters of the AUDIT command.....	750
FIX and NOFIX: Specifying whether auditing repairs errors.....	750
OUTDATASET, SYSOUT, and TERMINAL: Specifying the output location for the report.....	751
REPORT: Specifying how much audit information to print.....	752
SERIALIZATION: Stabilizing control information.....	752
Using the AUDIT command.....	753
Chapter 31. AUTH command: Identifying authorized users.....	755
Syntax of the AUTH command.....	755
Required parameters of the AUTH command.....	755
userid: Specifying the user whose authorization is to be changed.....	756
DATABASEAUTHORITY and REVOKE: Giving authority to or revoking authority of a user.....	756
Examples of how to code the AUTH command.....	757
Chapter 32. BACKDS command: Backing up a specific data set.....	759
Syntax of the BACKDS command for a UNIX file.....	760
Required parameters of the BACKDS command.....	761
dsname: Specifying the name of the data set to be backed up.....	761
filepath: Specifying the name of the UNIX file to be backed up.....	761
Optional parameters for the BACKDS command.....	762
CC: Specifying concurrent copy for data set backup.....	762
CHANGEDONLY/TOTAL: Specifying whether to back up UNIX files that have a last backup date in their metadata	764
DELETE: Specifying whether to delete the UNIX file after a successful backup.....	764
EXCLUDE and EXCLUDEF: Specifying files or directories to be excluded from processing.....	764
INUSE: Tailoring backup processing of UNIX files in use at the time of backup.....	766
NEWNAME: Specifying a name to assign to the backup version.....	767
RECURSE: Examine subdirectories of the specified UNIX file path.....	769
RETAIN DAYS: Specifying the number of days to retain a backup copy.....	769
TARGET: Specifying a required target output device.....	770
UNIT: Specifying the type of device.....	770
VOLUME: Specifying the volume where the data set resides.....	770
Delete expired backup versions of UNIX files.....	770
Examples of how to code the BACKDS command.....	771
Chapter 33. BACKFILE command: Backing up a specific UNIX file.....	773
Chapter 34. BACKDS command: Backing up a specific data set.....	775
Chapter 35. BACKFILE command: Backing up a specific UNIX file.....	777
Chapter 36. BACKVOL command: Backing up data sets from volumes or dumping volumes.....	779
Backing up data sets from one or more SMS-managed volumes or dumping SMS-managed volumes.....	779
Syntax of the BACKVOL command with SMS-managed volumes.....	780
Required parameters for SMS-managed volumes.....	781
CONTROLDATASETS: Specifying the control data sets to be backed up.....	781

STORAGEGROUP: Specifying the storage group to back up or dump.....	781
VOLUMES: Specifying the volumes to be backed up or dumped.....	782
Optional parameters for SMS-managed control data sets.....	783
BACKUPDEVICECATEGORY: Specifying the backup device for the control data sets and journal.....	783
DATAMOVER: Specifying the type of data movement used when backing up the control data sets.....	783
NULLJOURNALONLY: Specifying that DFSMSHsm null the journal.....	784
Optional parameters for SMS-managed volumes.....	784
BACKUPDEVICECATEGORY: Specifying where the backup versions are to reside.....	784
DUMP, INCREMENTAL, and TOTAL: Specifying which data sets are backed up.....	785
DUMPCLASS: Specifying that each dump copy be targeted to a particular dump class.....	785
RETENTIONPERIOD: Requesting a specific retention period for the dump copy.....	786
STACK/MAXSTACK and MINSTACK: Specifying the maximum and minimum number of dump copies to be stacked for the specified dump classes.....	786
TERMINAL: Requesting that backup or dump messages appear at the terminal.....	788
Examples of how to code the BACKVOL command for SMS-managed volumes.....	788
Backing up data sets from one or more non-SMS-managed volumes or from all primary volumes or dumping non-SMS-managed volumes.....	789
Syntax of the BACKVOL command with non-SMS-managed volumes.....	790
Summary of parameters.....	790
Required parameters for non-SMS-managed volumes or all primary volumes.....	791
CONTROLDATASETS: Specifying the control data sets to be backed up.....	791
PRIMARY and VOLUMES: Specifying the volumes to be backed up or dumped.....	791
Optional parameters for non-SMS-managed control data sets.....	792
BACKUPDEVICECATEGORY: Specifying the backup device for the control data sets and journal.....	792
DATAMOVER: Specifying the type of data movement used when backing up the control data sets.....	792
NULLJOURNALONLY: Specifying that DFSMSHsm null the journal.....	792
Optional parameters for non-SMS-managed volumes or all primary volumes.....	793
BACKUPDEVICECATEGORY: Specifying where the backup versions reside.....	793
DUMP, INCREMENTAL, and TOTAL: Specifying which data sets are backed up.....	793
DUMPCLASS: Specifying that each dump copy be targeted to a particular dump class.....	794
FREQUENCY: Specifying the frequency of backup for data sets.....	794
RETENTIONPERIOD: Requesting a specific retention period for the dump copy.....	794
STACK/MAXSTACK and MINSTACK: Specifying the maximum and minimum number of dump copies to be stacked for the specified dump classes.....	795
TERMINAL: Requesting that backup or dump messages appear at the terminal.....	795
UNIT: Specifying the type of device.....	795
Examples of how to code the BACKVOL command for non-SMS-managed volumes.....	795
Chapter 37. BDELETE command: Deleting backup versions of a data set.....	797
Syntax of the BDELETE command.....	797
Required parameters of the BDELETE command.....	797
dsname: Specifying the name of the data set whose backup versions are to be deleted.....	797
pathname: Specifying the name of the UNIX file whose backup versions are to be deleted ...	798
ALL, DATE and TIME, and VERSIONS: Specifying which backup versions to delete.....	798
ALL: Deleting all backup versions.....	798
DATE and TIME: Specifying the date and time of the backup version to delete.....	798
VERSIONS: Specifying the backup versions to delete.....	799
Optional parameters of the BDELETE command.....	799
FROMVOLUME: Specifying the volume where the data set resided when the backup versions were created.....	799
Examples of how to code the BDELETE command.....	799
Chapter 38. CANCEL command: Canceling a queued or active DFSMSHsm request.....	801
Syntax of the CANCEL command.....	801

Optional parameters of the CANCEL command.....	801
DATASETNAME: Canceling a queued request by data set name.....	802
FILENAME: Canceling a queued request by UNIX file name.....	802
REQUEST: Canceling a queued request by request number.....	802
USERID: Canceling a queued request by user ID.....	802
SASINDEX: Canceling an active request by ABARS secondary address space.....	803
TCBADDRESS: Canceling an active request by TCB address.....	803
Examples of how to code the CANCEL command.....	803
Chapter 39. DDELETE Command – Deleting cloud dump copies.....	805
Syntax of the DDELETE command.....	805
Required parameters of the DDELETE command.....	805
STORAGEGROUP: Specifying the storage group whose dump copies are to be deleted.....	805
VOLUMES: Specifying the volumes whose dump copies are to be deleted.....	806
DATE and TIME: Specifying the particular cloud dump copy to delete.....	806
Optional parameters of the DDELETE command.....	806
LASTCOPY: Invalidating the only valid dump copy of a source volume.....	806
Examples of how to code the DDELETE command.....	806
Chapter 40. DEFINE command: Defining control structures for use by DFSMSHsm.....	809
Syntax of the DEFINE command.....	810
Optional parameters of the DEFINE command.....	813
ARPOOL: Identifying the volumes for aggregate recovery.....	813
BACKUP: Specifying the backup cycle.....	814
CYCLESTARTDATE: Specifying the start date of a cycle.....	814
DUMPCLASS: Adding or changing a volume dump class.....	815
DUMPCLASS(AUTOREUSE and NOAUTOREUSE): Specifies whether DUMP volumes are automatically available for reuse when invalidated.....	816
DUMPCLASS(CLOUD TAPE): Specifying where the dump copies to reside.....	817
DUMPCLASS(DATASETRESTORE and NODATASETRESTORE): Data set restore is allowed from a full-volume dump copy in this dump class.....	818
DUMPCLASS(DAY): Specifying the target day of the dump cycle for this class.....	819
DUMPCLASS(DISABLE): Specifying the volume dump class and making it unavailable as a target of any full-volume dump.....	820
DUMPCLASS(DISPOSITION): Specifying the disposition of dump volumes.....	820
DUMPCLASS(ENCRYPT): Specifying whether to encrypt the dump data with host based encryption.....	820
DUMPCLASS(FASTREPLICATIONDUMP): Specifying whether a dump class is required or optional.....	821
DUMPCLASS(FASTREPLICATIONRECOVER): Specifying whether a dump class copy is immediately available to be mounted for recovery.....	822
DUMPCLASS(FREQUENCY): Specifying the minimum number of days that must elapse between volume dumps of a volume to this class.....	822
DUMPCLASS(HWCOMPRESS): Specifying whether to compress the data to be encrypted.....	823
DUMPCLASS(RECOVERRESET): Specifying whether to reset the data-set-changed indicator in the VTOC entry.....	823
DUMPCLASS(RESET and NORESET): Specifying whether DFSMSdss resets the change bit for each data set following a full-volume dump.....	824
DUMPCLASS(RETENTIONPERIOD): Specifying the enforcement of retention periods for the dump copies in this class.....	824
DUMPCLASS(STACK/MAXSTACK) and DUMPCLASS(MINSTACK): Specifying the maximum and minimum number of dump copies that are stacked for this dump class.....	825
DUMPCLASS(TAPEEXPIRATIONDATE): Specifying a unique expiration date for all dump copies created in a dump.....	827
DUMPCLASS(UNIT): Specifying a default tape unit name.....	827
DUMPCLASS(UNASSIGNTAPEUNIT): Specifying unassigning empty dump volumes.....	828
DUMPCLASS(VTOCCOPIES): Specifying the number of dump VTOC copy data sets to keep for dump copies created in this class.....	828

DUMPCCLASS(ZCOMPRESS): Specifying whether to use zEDC Services on the dump data.....	829
DUMPCYCLE: Specifying the automatic dump cycle.....	829
MIGRATIONCLEANUPCYCLE and SECONDARYSPMGMTCYCLE: Specifying the cycle for automatic secondary space management functions.....	830
MIGRATIONLEVEL2: Specifying DASD level 2 volumes and their associated key range structure.....	831
POOL: Identifying the non-SMS-managed volumes where the data sets with the same first qualifier are recalled.....	832
PRIMARYSPMGMTCYCLE: Specifying the cycle for automatic primary space management.....	832
SWITCHTAPES: Releasing mounted tapes for command data set backup.....	833
VOLUMEPOOL: Identifying groups of volumes where data sets are recalled.....	834
DUMPCCLASS(TAPE CLOUD): Specifying where the dump copies to reside.....	835
Examples of how to code the DEFINE command.....	836
 Chapter 41. DELETE Command: Deleting a migrated data set from a migration volume.....	839
Syntax of the DELETE command.....	839
Required parameters of the DELETE command.....	839
dsname: Specifying the data set to be deleted.....	839
Optional parameters of the DELETE command.....	839
PURGE: Specifying deletion of a data set.....	840
Examples of how to code the DELETE command.....	840
 Chapter 42. DELVOL command: Removing a volume from DFSMSHsm management.....	841
Syntax of the DELVOL command.....	841
Required parameters of the DELVOL command.....	842
volser: Specifying the volume you are deleting.....	842
BACKUP, DUMP, MIGRATION, and PRIMARY: Specifying the type of volume.....	842
Optional parameters of the DELVOL command.....	843
COPYPOOLCOPY: Deleting a copy pool dump volume.....	843
LASTCOPY: Invalidating the only valid dump copy of a source volume.....	843
MARKFULL, PURGE, REASSIGN, and UNASSIGN: Specifying the options for deleting a backup, dump, or ML2 volume.....	843
Examples of how to code the DELVOL command.....	845
 Chapter 43. DISPLAY command: Displaying DFSMSHsm storage locations.....	849
 Chapter 44. EXPIREBV command: Deleting unwanted backup versions of data sets and UNIX files..	851
Syntax of the EXPIREBV command.....	852
Required parameters of the EXPIREBV command.....	852
DISPLAY and EXECUTE: Specifying whether to delete the backup versions.....	852
Optional parameters of the EXPIREBV command.....	853
ABARSVERSIONS: Specifying that only aggregate group versions are to be processed.....	853
NONSMSVERSIONS: Specifying expiration criteria for backup versions of data sets not managed by SMS.....	854
STARTKEY and RESUME: Determining the starting point for BCDS processing during command execution.....	855
UNIXPATH: Specifying the UNIX file, empty directory, or nonempty directory to analyze for backup.....	855
ENDKEY: Determining the ending point for BCDS processing during command execution.....	857
OUTDATASET and SYSOUT: Specifying the output location for EXPIREBV DISPLAY listing.....	858
Examples of how to code the EXPIREBV command.....	859
 Chapter 45. FIXCDS command: Displaying or modifying MCDS, BCDS, and OCDS records.....	863
 Chapter 46. FRBACKUP command: Requesting a fast replication backup or dump version.....	865
Syntax of the FRBACKUP command.....	865
Required parameter of the FRBACKUP command.....	866
COPYPOOL: Specifying the name of the copy pool for backup.....	866

Optional parameters of the FRBACKUP command.....	866
BACKUPSTORAGEGROUP: Overriding the copy pool backup storage group with an alternate storage group.....	866
DUMP: Creating a fast replication DASD version followed by a dump.....	866
DUMPCCLASS: Specifying unique dump classes for fast replication dump processing.....	867
EXECUTE, PREPARE, WITHDRAW, and DUMPONLY: Specifying the backup or dump action....	867
FCINCREMENTAL: Requesting DFSMSHsm to create a copy pool version using incremental FlashCopy.....	868
FCINCREMENTALLAST: Requesting a FlashCopy incremental copy with a subsequent withdraw.....	869
FORCE: Replacing a DASD backup copy that has an incomplete dump copy.....	869
MESSAGEDATASET: Specifying the date and time used in the message data set name.....	869
NOVTOCENQ: Requesting DFSMSHsm to not serialize the VTOC of processed volumes.....	870
TOKEN: Specifying an identifier for each copy pool backup version.....	870
Examples of how to code the FRBACKUP command.....	870
 Chapter 47. FRDELETE command: Deleting fast replication backup or dump versions.....	873
Syntax of the FRDELETE command.....	873
Required parameters of the FRDELETE command.....	873
COPYPOOL: Specifying the name of the copy pool for deletion.....	873
ALL, TOKEN, and VERSIONS: Specifying the delete action.....	873
Optional parameters of the FRDELETE command.....	874
DASDONLY, DUMPONLY, and BOTH: Specifying which copies to delete.....	874
Examples of how to code the FRDELETE command.....	874
 Chapter 48. FREEVOL command: Freeing DFSMSHsm-owned volumes.....	877
Syntax of the FREEVOL command.....	878
Required parameters of the FREEVOL command.....	878
MIGRATIONVOLUME and BACKUPVOLUME: Specifying a volume to free.....	878
ML1BACKUPVERSIONS: Moving backup versions off migration volumes.....	878
Optional parameters of the FREEVOL command.....	879
AGE: Specifying data set use.....	879
TARGETLEVEL: Specifying the target to which data sets are moved.....	879
RETAINNEWESTVERSION: Preventing movement of backup versions.....	880
Examples of how to code the FREEVOL command.....	881
 Chapter 49. FRRECOV command: Requesting a fast replication recovery.....	883
Syntax of the FRRECOV command.....	884
Required parameters of the FRRECOV command.....	885
COPYPOOL: Specifying the copy pool for which to recover all backup volumes.....	885
DSNAME: Specifying the data sets to recover from a copy pool backup version.....	886
TOVOLUME: Specifying a single volume within a copy pool to recover.....	886
Optional parameters of the FRRECOV command.....	886
ALLOWPPRCP: Specifying Metro Mirror and Global Mirror primary volumes and preserve mirror options for a FlashCopy operation.....	886
ALLOWXRCP: Specifying an extended remote copy primary volume option for a FlashCopy operation.....	887
DATE, GENERATION, TOKEN, VERSION: Specifying a specific backup version to recover.....	888
FASTREPLICATION: Indicating a recovery preference.....	888
FORCE: Allowing recovery from a DASD backup copy that has an incomplete dump copy.....	889
FROMCOPYPOOL: Recovering a volume or data set that belongs to multiple copy pools.....	889
FROMDASD: Recovering a volume from DASD.....	889
FROMDUMP: Recovering a volume from a dump tape.....	889
MESSAGEDATASET: Specifying the date and time used in the message data set name.....	890
NEWNAME: Specifying a new data set name for the recovered data set.....	891
NOCOPYPOOLBACKUP: Setting an alternate return code.....	891
REPLACE: Recovering a cataloged data set.....	891
RSA: Overriding the RSA key label	891

VERIFY: Verifying that no unexpected FlashCopy relationship exists for a volume in a copy pool.....	892
Examples of how to code the FRRECOV command.....	892
Chapter 50. HOLD command: Preventing DFSMSHsm functions from running.....	895
Syntax of the HOLD command.....	896
Optional parameters of the HOLD command.....	897
ABACKUP: Preventing aggregate backup.....	897
ALL: Preventing all DFSMSHsm functions.....	898
ARECOVER: Preventing aggregate recovery.....	898
AUDIT: Ending the audit function.....	899
AUTOEXPIRATION: Preventing data sets from expiring.....	899
AUTOMIGRATION: Preventing automatic volume and automatic secondary space management.....	900
BACKUP: Preventing backups.....	900
COMMONQUEUE: Preventing common queue functions.....	901
DUMP: Preventing dumps.....	902
ENDOFDATASET: Specifying when aggregate group processing should stop.....	903
ENDOFDATASET and ENDOFVOLUME: Specifying when volume processing should stop.....	904
EVENTDRIVENMIGRATION: Preventing Interval and On-demand Migration.....	904
EXPIREBV: Ending the expire backup function.....	905
FRBACKUP: Preventing fast replication backup or dump processing.....	905
FRRECOV: Preventing fast replication recovery processing.....	905
LIST: Ending the list function.....	907
LOG: Preventing logging.....	907
MIGRATION: Preventing space management.....	907
RECALL: Preventing recall and deletion.....	907
RECOVER: Preventing recovery and restore.....	908
RECYCLE: Ending the recycle function.....	908
REPORT: Ending the report function.....	909
TAPECOPY: Preventing DFSMSHsm from copying a tape.....	909
TAPEREP: Preventing DFSMSHsm from replacing an original tape volume with an alternate.....	909
Examples of how to code the HOLD command.....	909
Chapter 51. HSEND CMD command: Issuing DFSMSHsm authorized-user commands from a TSO terminal.....	913
Syntax of the HSEND CMD command.....	913
Required parameters of the HSEND CMD command.....	913
command: Specifying DFSMSHsm authorized command.....	913
Optional parameters of the HSEND CMD command.....	913
WAIT and NOWAIT: Specifying whether to wait for command completion.....	914
Examples of how to code the HSEND CMD command.....	915
Chapter 52. HSENDU command: Issuing DFSMSHsm authorized user commands to a Filemode DFSMSHsm host.....	917
Chapter 53. LIST command: Listing information from the MCDS, BCDS, and OCDS.....	919
Syntax of the LIST command.....	920
Required parameters of the LIST command.....	925
AGGREGATE: Listing the aggregate backup and recovery activity information.....	925
BACKUPVOLUME: Listing backup volume entries.....	925
CLOUD: Listing information from cloud storage.....	925
COPYPOOL: Listing information for each version of a copy pool.....	926
COPYPOOLBACKUPSTORAGEGROUP: Listing copy pool information for each volume in the specified copy pool backup storage group.....	926
DATASETNAME and LEVEL: Listing data set entries.....	926
DUMPCCLASS: Listing dump class profiles.....	927
DUMPVOLUME: Listing information about a single dump volume or a set of dump volumes....	927

FILENAME and FILELEVEL: Listing UNIX file entries.....	928
HOST: Listing all control data sets serialized by the DFSMSHsm host.....	928
MIGRATIONVOLUME, MIGRATIONLEVEL1, MIGRATIONLEVEL2, and VOLUME: Listing migration volumes.....	929
PRIMARYVOLUME: Listing primary volumes.....	929
TAPETABLEOFCONTENTS: Listing tape volume information from the OCDS.....	930
TAPETABLEOFCONTENTS(volser): Listing tape volume information and data set names from the TTOC.....	930
USER: Listing user entries.....	931
Optional parameters of the LIST command.....	931
ALLDUMPS and BACKUPCONTENTS: Determining existence of dumps or listing incremental backup contents.....	931
ALLVOLS, DATASETS, DUMPVOLS, FASTREPLICATIONVOLS, and NOVOLS: Listing a specific type of copy pool information.....	932
BACKUPCONTROLDATASET, MIGRATIONCONTROLDATASET, and BOTH: Controlling the source of information.....	933
DATASETINFORMATION and NODATASETINFORMATION: Including or not including data set information.....	933
DATE and VERSION: Specifying the date or version of the aggregate group.....	933
DUMPCONTENTS: Listing contents of a set of dump volumes.....	934
INCLUDEPRIMARY: Listing entries for any data set that has migrated.....	934
OUTDATASET, SYSOUT, and TERMINAL: Specifying the location of output for the list.....	934
RECURSE: Examine subdirectories of the specified UNIX file path.....	935
RESET: Requesting that the host ID field indicate no serialization.....	935
SELECT: Listing only those data set or volume entries that meet selection criteria.....	936
SELECT (ACTIVE and RETAIN_DAYS): Displaying information about active and retained backup copies.....	938
SELECT (AGE): Specifying data set use by age.....	938
SELECT (ALTERNATEVOLUME and NOALTERNATEVOLUME): Listing tape volumes that have alternate tape volumes.....	938
SELECT (AVAILABLE): Listing available dump volumes for dump output.....	939
SELECT (CAPACITYMODE): Identifying tape volumes by their ability to use available tape capacity.....	939
SELECT (CONNECTED and NOTCONNECTED): List volumes that contain spanning data sets .	939
SELECT (DISASTERALTERNATEVOLUMES): Listing tape volumes that have disaster alternate volumes.....	940
SELECT (DUMPCCLASS).....	940
SELECT (DUMPSTATE, FASTREPLICATIONSTATE, INCOMPLETERECOVERY, and NONPREFERREDFRVOLS): Listing specific information about copy pools.....	940
SELECT (EFMT1, EFMT2, EEFMT2, EFMT3, EEFMT3, EFMT4, EEFMT4, ENCRYPTED, and NOTENCRYPTED): Recording format.....	941
SELECT (EMPTY, FULL, NOTFULL, ASSOCIATED, NOTASSOCIATED, ERRORALTERNATE, and RECYCLETAKEAWAY): Identifying tape volume capacity.....	941
SELECT (EXCESSIVEVOLUMES): Listing volumes with data sets spanning four or more volumes.....	942
SELECT (EXPIRED): Listing expired dump volumes.....	942
SELECT (FAILEDCREATE): Listing all tape volumes that have incomplete data set information saved in the OCDS TTOC record.....	943
SELECT (FAILEDRECYCLE): Listing only those volumes that have failed recycle.....	943
SELECT (LIBRARY and NOLIBRARY): Listing tape volume library status.....	943
SELECT (MIGRATIONLEVEL1, MIGRATIONLEVEL2, VOLUME(volser), BACKUP, and BOTH): Requesting specific information for volumes.....	944
SELECT (MULTIPLEVOLUME): Listing multiple-volume non-VSAM data sets from backup or dump VTOC copy data sets.....	944
SELECT (NORETENTIONLIMIT): List dump volumes with no retention period.....	945
SELECT (OVERFLOW and NOOVERFLOW): List overflow or non-overflow ML1 volumes.....	945
SELECT (RECALLTAKEAWAY): Listing ML2 volumes taken away by recall or ABACKUP functions.....	945

SELECT (RESUMEAUDIT): Listing tape volumes that are capable of being resumed after AUDIT MEDIACONTROLS was interrupted.....	945
SELECT (SMALLDATASETPACKING and NOSMALLDATASETPACKING): Specifying whether data sets have migrated to SDSP.....	946
SELECT (UNAVAILABLE): Listing dump volumes with invalid contents.....	946
SELECT (UNEXPIRED): Listing dump volumes that have not reached their expiration date.....	946
SELECT (VSAM): Specifying the data set organization.....	947
SUMMARY: Requesting a summary.....	947
Examples of how to code commonly used list requests.....	947
Chapter 54. LOG command: Entering data into the DFSMSHsm log.....	953
Syntax of the LOG command.....	953
Required parameters of the LOG command.....	953
data: Specifying the data for the log.....	953
Example of how to code the LOG command.....	953
Chapter 55. MIGRATE command: Requesting a space management function.....	955
Requesting a space management function for SMS-managed data sets.....	956
Syntax of the MIGRATE command for SMS-managed data sets.....	956
Summary of parameters.....	956
Required parameters of the MIGRATE command for SMS-managed data sets.....	957
DATASETNAME: Specifying migration and/or class transition for a specific data set.....	958
MIGRATIONLEVEL1: Specifying migration of data sets from level 1 to level 2 volumes.....	958
VOLUME: Specifying the space management attribute for the eligible data sets on a volume.	958
STORAGEGROUP: Specifying the space management attribute for the eligible data sets in a storage group.....	959
Optional parameters of the MIGRATE command for SMS-managed data sets.....	960
BOTH: Specifying that transition or migration of data sets should be processed.....	960
CONVERT: Specifying movement of data sets from one volume to another.....	960
CLOUD: Specifying migration of a data set directly to cloud.....	960
DAYS: Specifying migration eligibility of data sets.....	961
KEEPMIGDATE: Specifying migration of a data set should keep its original migration date, if one exists.....	961
MIGRATIONLEVEL1: Specifying migration of a data set.....	962
MIGRATIONLEVEL2: Specifying migration of a data set directly to a level 2 volume.....	962
MIGRATIONONLY: Specifying that only migration of data sets should be processed.....	962
MOVE: Specifying that only moving of data sets should be processed.....	962
TERMINAL: Requesting that volume space management messages appear at the terminal....	963
TRANSITION: Specifying that only transitions of data set should be processed.....	963
TRANSITIONONLY: Specifying that only transition of data sets should be processed.....	963
Examples of how to code the MIGRATE command for SMS-managed data sets.....	964
Requesting a space management function for non-SMS-managed data sets.....	964
Syntax of the MIGRATE command for non-SMS-managed data sets.....	965
Summary of parameters.....	965
Required parameters of the MIGRATE command for non-SMS-managed data sets.....	966
DATASETNAME: Specifying migration of a specific data set.....	966
MIGRATIONLEVEL1: Specifying migration of data sets from level 1 to level 2 volumes.....	966
PRIMARY: Specifying space management of eligible data sets on all primary volumes.....	966
VOLUME: Specifying the space management attribute for the eligible data sets on a volume.	967
Optional parameters of the MIGRATE command for non-SMS-managed data sets.....	968
CONVERT: Specifying movement of data sets from one volume to another.....	968
DAYS: Specifying migration eligibility of data sets.....	969
MIGRATIONLEVEL1: Specifying migration of a data set directly to appropriate level of hierarchy.....	970
MIGRATIONLEVEL2: Specifying migration of a data set directly to a level 2 volume.....	970
TERMINAL: Requesting that volume space management messages appear at the terminal....	970
UNIT: Specifying the type of device.....	970
Examples of how to code the MIGRATE command for non-SMS-managed data sets.....	971

Chapter 56. ONLYIF command: Running commands in ARCCMDxx conditionally.....	973
Syntax of the ONLYIF command.....	973
Required parameters of the ONLYIF command.....	974
HSMHOST: Specifying the host ID of a specific host or hosts.....	974
SYSNAME: Specifying the system name where the next line should be processed.....	974
HMSYM: Specifying the HSM system symbol and its value where the next line should be processed.....	974
Optional parameters of the ONLYIF command.....	975
BEGIN: Begin a group of commands.....	975
END: End a group of commands.....	975
Examples of how to code the ONLYIF command.....	975
Chapter 57. PATCH command: Modifying storage within DFSMSHsm.....	979
Chapter 58. QUERY command: Displaying the status of parameters, statistics, and requests.....	981
Syntax of the QUERY command.....	982
Optional parameters of the QUERY command.....	983
ABARS: Displaying aggregate backup and recovery control parameters.....	983
ACTIVE: Displaying all active requests.....	983
ARPOOL: Displaying aggregate recovery pools.....	983
AUTOPROGRESS: Displaying an indication of volumes to be processed.....	984
BACKUP: Displaying backup parameters and backup volumes.....	985
CDSVERSIONBACKUP: Displaying the control data set multiple backup support parameters.....	985
COMMONQUEUE: Displaying common queue information.....	985
CONTROLDATASETS: Displaying control data set space-use information.....	986
COPYPOOL: Displaying copy pool information.....	986
CSALIMITS: Displaying the common service area storage limits.....	986
DATASETNAME, FILENAME, REQUEST, and USER: Displaying selected requests.....	986
IMAGE: Displaying information for the DFSMSHsm address spaces active within a single z/OS image.....	987
MIGRATIONLEVEL2: Displaying key ranges and migration level 2 volumes.....	987
NETWORK: Displaying cloud endpoint statistics known to DFSMSHsm.....	987
POOL: Displaying recall pools.....	987
RETAIN: Displaying data set levels prevented from space management.....	987
SECURITY: Displaying the type of command authorization in effect.....	987
SETSYS: Displaying control parameters.....	988
SPACE: Displaying volume space-use information.....	988
STARTUP: Displaying the startup information.....	988
STATISTICS: Displaying daily statistics.....	988
TRAPS: Displaying trap requests.....	988
VOLUMEPOOL: Displaying current volume pools.....	988
WAITING: Displaying the number of requests waiting to be processed.....	988
Examples of how to code the QUERY command.....	989
Chapter 59. RECALL command: Recalling a specific migrated data set.....	991
Syntax of the RECALL command.....	991
Required parameters of the RECALL command.....	991
dsname: Specifying the name of the data set to be recalled.....	991
Optional parameters of the RECALL command.....	992
DAOPTION: Selecting target volume track length.....	992
DFDSSOPTION: Pass optional parameters to DFSMSDss.....	993
FORCENONSMS: Recalling an SMS-managed data set to a non-SMS-managed volume.....	993
UNIT: Specifying the type of device.....	993
VOLUME: Specifying the volume to receive the recalled data set.....	994
Examples of how to code the RECALL command.....	994

Chapter 60. RECOVER command: Recovering a backup version or dump copy of a data set, or UNIX file, or a volume.....	997
Syntax of the RECOVER command.....	998
Required parameters of the RECOVER command.....	1000
<i>dsname</i> : Specifying the name of the data set to be recovered.....	1000
<i>pathname</i> : Specifying the name of the UNIX file to be recovered.....	1001
Optional parameters of the RECOVER command.....	1001
DAOPTION: Selecting target volume track length.....	1001
DATE, GENERATION, and VERSION: Specifying the particular backup version or dump copy to recover.....	1002
DFDSSOPTION: Pass optional parameters to DFSMSdss.....	1003
EXCLUDE and EXCLUDEF: Specifying files or directories to be excluded from processing.....	1004
FORCENONSMS: Recovering an SMS-managed data set to a non-SMS-managed volume.....	1005
FROMDUMP: Specifying which dump copy is used for restoring data sets.....	1005
FROMVOLUME: Specifying the volume from which the backup version of a data set has been created.....	1007
NEWDIR : Recover files to a different directory.....	1007
NEWNAME: Specifying a new data set name for the recovered data set.....	1007
RECURSE: Examine subdirectories of the specified UNIX file path.....	1008
REPLACE: Specifying that the recovered backup version or dump copy is to replace any existing data set of the same name.....	1009
RSA: Specifying that the RSA parameter is to override the RSA key label	1009
TARGETVOLUME: Specifying the volume to receive the restored data sets.....	1009
TERMINAL: Requesting that volume recovery messages appear at the terminal.....	1010
TOVOLUME: Specifying the volume to receive the recovered data set.....	1010
UNIT: Specifying the type of device.....	1011
Examples of how to code the RECOVER command.....	1011
Chapter 61. RECYCLE command: Consolidating valid data to one tape from other tapes.....	1015
Syntax of the generic RECYCLE command.....	1016
Syntax of the specific RECYCLE command.....	1016
Required parameters of the RECYCLE command.....	1017
ALL, BACKUP, DAILY, ML2, SPILL and VOLUME: Specifying the tape volumes to be recycled	1017
EXECUTE, VERIFY, and DISPLAY: Specifying whether to list or to recycle tape volumes.....	1018
Optional parameters of the RECYCLE command.....	1019
CHECKFIRST: Allowing connected set to be recycled sooner.....	1019
FORCE: Forcing DFSMSHsm to permit a tape recycle.....	1019
LIMIT: Quiescing recycle processing when the desired number of tapes have been returned to scratch.....	1020
OUTDATASET: Directing recycle messages.....	1020
PERCENTVALID: Specifying the percent valid criteria for recycle eligibility.....	1021
SELECT: Specifying tape eligibility for generic recycle.....	1022
TAPELIST: Listing volumes for pulling and mounting tapes.....	1022
Examples of how to code the RECYCLE command.....	1025
Chapter 62. RELEASE command: Releasing all or some DFSMSHsm functions for processing.....	1029
Syntax of the RELEASE command.....	1030
Optional parameters of the RELEASE command.....	1031
ABACKUP: Releasing aggregate backup.....	1031
ALL: Releasing all DFSMSHsm functions.....	1031
ARECOVER: Releasing aggregate recovery.....	1031
AUDIT: Releasing the audit function.....	1032
AUTOEXPIRATION: Releasing automatic expiration.....	1032
AUTOMIGRATION: Releasing only automatic volume and automatic secondary space management.....	1032
BACKUP: Releasing backup.....	1032
COMMONQUEUE: Releasing holds on the common queue.....	1033

DUMP: Releasing dump.....	1034
EVENTDRIVENMIGRATION: Releasing Interval and On-demand Migration.....	1034
EXPIREBV: Releasing the expire backup versions function.....	1035
FRBACKUP: Releasing the fast replication backup or dump function.....	1035
FRRECOV: Releasing the fast replication recover function.....	1035
HARDCOPY: Releasing the activity logs.....	1036
LIST: Releasing the list function.....	1036
LOG: Releasing logging.....	1036
MIGRATION: Releasing space management.....	1037
RECALL: Releasing recall and deletion.....	1037
RECOVER: Releasing recovery and restore.....	1038
RECYCLE: Releasing the recycle function.....	1038
REPORT: Releasing the report function.....	1038
RMM: Releasing the DFSMSrmm function.....	1039
TAPECOPY: Releasing the tape copy function.....	1039
TAPEREMPL: Releasing the tape replace function.....	1039
Examples of how to code the RELEASE command.....	1039
 Chapter 63. REPORT Command: Requesting reports based on DFSMSHsm statistics records.....	1043
Syntax of the REPORT command.....	1044
Summary of parameters.....	1045
Optional parameters of the REPORT command.....	1045
DAILY: Requesting daily statistics.....	1045
DELETE: Deleting statistics records used as input to the report.....	1046
FROMDATE: Requesting statistics of activity on or after the specified date.....	1046
FUNCTION and NOFUNCTION: Requesting statistics by function.....	1046
FUNCTION(BACKUP): Requesting statistics of the backup function.....	1047
FUNCTION(DELETE): Requesting statistics of the delete function.....	1047
FUNCTION(MIGRATION): Requesting statistics of the migration function.....	1047
FUNCTION(RECALL): Requesting statistics of the recall function.....	1048
FUNCTION(RECYCLE): Requesting statistics of the recycle function.....	1048
FUNCTION(RECOVER): Requesting statistics of the recovery function.....	1048
FUNCTION(SPILL): Requesting statistics of the spill function.....	1049
FUNCTION(TRANSITION): Requesting statistics of the transition function.....	1049
OUTDATASET and SYSOUT: Specifying the output location.....	1049
SUMMARY: Requesting only the totals of the statistics.....	1050
TODATE: Requesting statistics of activity on or before the specified date.....	1050
VOLUMES: Requesting volume statistics.....	1050
Examples of how to code the REPORT command.....	1051
 Chapter 64. SETMIG command: Changing the space management status of non-SMS-managed data sets or volumes.....	1053
Syntax of the SETMIG command.....	1053
Required parameters of the SETMIG command.....	1053
DATASETNAME, LEVEL, and VOLUME: Changing the space management status.....	1054
Optional parameters of the SETMIG command.....	1054
COMMANDMIGRATION, MIGRATION, and NOMIGRATION: Specifying the way space management is controlled.....	1054
Examples of how to code the SETMIG command.....	1055
 Chapter 65. SETSYS command: Establishing or changing the values of DFSMSHsm control parameters.....	1057
Syntax of the SETSYS command.....	1057
SETSYS fast-path for DFSMSHsm functions.....	1075
Relationship of SMS to SETSYS parameters.....	1082
Summary of DFSMSHsm default values.....	1084
Optional parameters of the SETSYS command.....	1094
ABARSACTLOGMSGSLVL: Specifying which DFSMSdss messages are written to the log.....	1094

ABARSACTLOGTYPE: Specifying the ABARS activity log output data set type.....	1094
ABARSBUFFERS: Specifying the number of I/O buffers for ABARS.....	1095
ABARSDELETEACTIVITY: Allowing DFSMSHsm to automatically delete the ABARS activity log.....	1095
ABARSKIP: Specifying which types of data sets ABACKUP should skip.....	1095
ABARSOPTIMIZE: Adjusting performance when backing up level 0 DASD specified in INCLUDE list.....	1096
ABARSPROCNAME: Specifying the base procedure name to start the ABARS secondary address space.....	1096
ABARSTAPES: Allowing DFSMSHsm to stack the ABACKUP output files.....	1096
ABARSUNITNAME: Specifying a unit name for ABARS.....	1097
ABARSVOLCOUNT: Specifying the method for determining volume count for SMS target data set allocations done by DFSMSdss.....	1097
ACCEPTPSCBUSERID and NOACCEPTPSCBUSERID: Allowing non-RACF installations to issue authorized commands in a TMP environment.....	1098
ACTLOGMSGVL: Specifying message level for recording data sets.....	1098
ACTLOGTYPE: Specifying the type of output data set to receive messages.....	1099
ARECOVERML2UNIT: Specifying the unit when recovering migrated data sets to nonspecific volumes.....	1100
ARECOVERPERCENTUTILIZED: Specifying the percentage of DASD space for non-SMS-managed volumes.....	1100
ARECOVERGTGDS: Passing GTGDS parameter to DFSMSdss during restore processing....	1100
ARECOVERUNITNAME: Specifying tape unit type for aggregate recovery.....	1100
AUTOBACKUPSTART: Specifying when automatic backup is to start.....	1101
AUTODUMPSTART: Specifying when automatic dump is to start.....	1102
AUTOMIGRATIONSTART: Specifying the start time for automatic primary space management.....	1103
BACKUP and NOBACKUP: Specifying whether you intend to use DFSMSHsm backup, recovery, and dump.....	1104
BACKUPPREFIX: Specifying the prefix for the backup version name or the dump copy data set name.....	1107
CDSVERSIONBACKUP: Specifying whether the control data sets should be backed up to multiple data sets.....	1109
CDSVERSIONBACKUP (BACKUPCOPIES): Specifying the number of backup copies to keep for each control data set and journal data set.....	1110
CDSVERSIONBACKUP (BACKUPDEVICECATEGORY): Specifying the backup device to which the control data sets and journal will be backed up.....	1110
CDSVERSIONBACKUP (DATAMOVER): Specifying the type of data movement used when performing CDSVERSIONBACKUP.....	1112
CDSVERSIONBACKUP (BCDSBACKUPDSN): Specifying the initial characters of the backup data set name for the backup control data set.....	1112
CDSVERSIONBACKUP (MCDSBACKUPDSN): Specifying the initial characters of the backup data set name for the migration control data set.....	1113
CDSVERSIONBACKUP (OCDSBACKUPDSN): Specifying the initial characters of the backup data set name for the offline control data set.....	1113
CDSVERSIONBACKUP (JRNLBKUPDSN): Specifying the initial characters of the backup data set name for the journal data set.....	1114
CLASSTRANSITIONS: Specifying if class transitions will be performed during event-driven migration.....	1114
CLOUDMIGRATION: Specifying the type of migration to CLOUD.....	1114
CLOUD: Specifying CLOUD properties.....	1115
COMMONQUEUE: Specifying settings for the common queues.....	1117
COMMONQUEUE (DUMP(CONNECT(<i>basename</i>))) : Specifying the XCF functional group name suffix for remote dump processing.....	1117
COMMONQUEUE(DUMP(DISCONNECT)): Specifying that a system disconnect itself from using the currently connected XCF functional group for dump processing.....	1118
COMMONQUEUE (DUMP(MASTERSCHEDULERCANDIDATE)): Specifying whether the host is a master scheduler candidate for grouped function of dump.....	1118

COMMONQUEUE (RECALL(CONNECT(<i>basename</i>))): Specifying the base name of the list structure for CRQ host connection.....	1119
COMMONQUEUE (RECALL(DISCONNECT)): Specifying disconnection from the CRQ.....	1119
COMMONQUEUE RECOVER(CONNECT(<i>basename</i>)): Specifying the XCF functional group name suffix for remote full volume recover from dump processing.....	1120
COMMONQUEUE RECOVER(DISCONNECT): Specifying that a system disconnect itself from using the currently connected XCF functional group for recover processing.....	1121
COMMONQUEUE RECOVER(MASTERSCHEDULERCANDIDATE): Specifying whether the host is a master scheduler candidate for grouped function of recover.....	1121
COMPACT: Specifying when compaction should be done.....	1122
COMPACT ALL and NONE: Specifying whether to compact data sets.....	1122
COMPACT DASDBACKUP and NODASDBACKUP: Specifying whether to compact data sets during backup to DASD.....	1123
COMPACT DASDMIGRATE and NODASDMIGRATE: Specifying whether to compact data sets during migration to DASD.....	1123
COMPACT TAPEBACKUP and NOTAPEBACKUP: Specifying whether to compact data sets during backup to tape.....	1124
COMPACT TAPEMIGRATE and NOTAPEMIGRATE: Specifying whether to compact data sets during migration to tape.....	1124
COMPACTPERCENT: Specifying the percentage of space saved for compaction.....	1125
CONVERSION and NOCONVERSION: Specifying whether reblocking is to occur.....	1125
CSALIMITS and NOCSALIMITS: Specifying whether to use CSA limiting for MWE allocation.....	1126
CSALIMITS (ACTIVE): Specifying the percentage of the maximum limit to be allocated to any type of MWE.....	1126
CSALIMITS (INACTIVE): Specifying the percentage of the maximum limit to be allocated to NOWAIT MWEs.....	1127
CSALIMITS (MAXIMUM): Specifying the maximum number of CSA bytes allocated to all types of MWEs.....	1127
CSALIMITS (MWE): Specifying maximum number of NOWAIT MWEs per address space.....	1127
DAYS: Specifying the minimum migration age of a data set.....	1128
DEBUG and NODEBUG: Specifying debug mode.....	1128
DEFERMOUNT: Specifying defer mounting of tapes.....	1129
DENSITY: Specifying the tape density.....	1129
DFHSMDATASETSERIALIZATION and USERDATASETSERIALIZATION: Specifying data set serialization.....	1129
DISASTERMODE: Specifying the tape operation mode for DFSMSHsm in disaster mode.....	1130
DSBACKUP: Controlling the command data set backup environment.....	1130
DSSXMMODE: Specifying whether DFSMSdss will be loaded in its own address space using the cross memory interface, or in the DFSMSHsm address space, for backup, CDS backup, dump, migration, and full-volume and data set recovery.....	1133
DUMPIO: Specifying the DFSMSdss DASD I/O buffering technique.....	1134
DUPLEX: Allowing DFSMSHsm to create two tapes concurrently.....	1135
EMERGENCY and NOEMERGENCY: Specifying no data set movement.....	1136
ERASEONSCRATCH and NOERASEONSCRATCH: Specifying to check for erasure of DFSMSHsm-owned data sets.....	1137
EVENTDRIVENMIGRATIONQUIESCE: Specifying quiesce window(s) for Interval and On-demand Migration.....	1138
EXITOFF: Specifying inactive installation exits.....	1138
EXITON: Specifying active installation exits.....	1139
EXITS: Specifying the installation exits to be taken.....	1141
EXPIREDDATASETS: Specifying whether to scratch data sets with expired expiration dates.....	1141
EXTENDEDTTTC: Specifying whether to use extended tape table of contents (TTTC).....	1141
FASTREPLICATION: Specifying fast replication methods.....	1142
FREQUENCY: Specifying the number of days between backup versions of a data set.....	1143
INCREMENTALBACKUP: Specifying whether to back up only changed data sets during incremental volume backup.....	1144
INPUTTAPEALLOCATION: Specifying whether to wait for the input tape to be allocated.....	1145

INTERVALMIGRATION and NOINTERVALMIGRATION: Specifying whether interval migration is performed.....	1145
ISSUEARC1902: Enable/disable the issue of ARC1902I message to the console.....	1146
JES2 and JES3: Specifying the job entry subsystem.....	1147
JOURNAL and NOJOURNAL: Specifying whether to write updated control data set records in the journal data set.....	1147
MAXABARSADDRESSSPACE: Specifying the maximum number of concurrent secondary address spaces supported.....	1148
MAXBACKUPTASKS: Specifying the maximum number of concurrent volume backup tasks.....	1149
MAXCOPYPOOLTASKS: Specifying the maximum number of concurrent DFSMSdss invocations for each fast replication command.....	1149
MAXDSRECOVERTASKS: Specifying the maximum number of data set recovery tasks from DASD and tape.....	1150
MAXDSTAPERECOVERTASKS: Specifying the maximum number of data set recovery tasks from tape.....	1150
MAXDUMPRECOVERTASKS: Specifying the maximum number of concurrent volume recovery from dump tasks.....	1151
MAXDUMPTASKS: Specifying the maximum number of concurrent volume dump tasks.....	1151
MAXEXTENTS: Specifying the number of extents to cause extent reduction.....	1152
MAXINTERVALTASKS: Specifying the maximum number of automatic interval migration or on-demand migration tasks that can run concurrently.....	1152
MAXMIGRATIONTASKS: Specifying the maximum number of automatic volume space management tasks that can run concurrently.....	1153
MAXRECALLTASKS: Specifying the maximum number of active recall tasks.....	1153
MAXRECYCLETASKS: Specifying the maximum number of active recycle tasks.....	1154
MAXSSMTASKS: Specifying the maximum number of concurrent automatic secondary space management tasks.....	1154
MIGDENSITY: Specifying the tape density when allocating scratch tapes for migration.....	1155
MIGRATEPREFIX: Specifying the prefix for the migration copy name.....	1155
MIGRATIONAUTOCLLOUD: Allow the host to execute Cloud migration.....	1156
MIGRATIONCLEANUPDAYS: Specifying the number of days to keep MCDS data set records and statistics records.....	1157
MIGRATIONLEVEL1DAYS: Specifying the inactive age for data sets migrating from level 1 volumes.....	1158
MIGRATEPSMEARLY: Activate the PSM earlier checking option.....	1158
MIGRATIONSUBTASKS: Enabling multiple migration subtasks.....	1159
MIGUNITNAME: Specifying the type of unit for allocating a scratch tape during migration...	1159
ML1OVERFLOW: Manage ML1 OVERFLOW volumes.....	1160
ML2PARTIALSNOTASSOCIATEDGOAL: Specifying the maximum number of allowed partial ML2 tapes.....	1161
ML2RECYCLEPERCENT: Specifying the maximum percentage of valid data on a migration tape.....	1161
MONITOR: Specifying which informational messages to print at the system console.....	1162
MONITOR (BACKUPCONTROLDATASET): Monitoring the space used in the BCDS.....	1163
MONITOR (JOURNAL): Monitoring the space used in the journal data set.....	1163
MONITOR (MIGRATIONCONTROLDATASET): Monitoring the space used in the MCDS.....	1163
MONITOR (OFFLINECONTROLDATASET): Monitoring the space used in the OCDS.....	1164
MONITOR (SPACE and NOSPACE): Printing volume space-use messages.....	1164
MONITOR (STARTUP and NOSTARTUP): Printing DFSMSHsm startup informational messages.....	1164
MONITOR (VOLUME and NOVOLUME): Print data set messages during volume processing...	1165
MOUNTWAITTIME: Specifying the time DFSMSHsm waits for a tape mount and open.....	1165
OBJECTNAMES: Specifying the compaction-control qualifier of the object data set.....	1166
ONDEMANDMIGRATION: Specifying whether on-demand migration should be performed..	1166
ODMNOTIFICATIONLIMIT: Specifying an on-demand migration number of concurrently queued volumes notification limit.....	1167
OPTIMUMDASDBLOCKING and NOOPTIMUMDASDBLOCKING: Specifying whether DFSMSHsm should use its defined optimum block size.....	1167

OUTPUTTAPEALLOCATION: Specifying if to wait for output tape to be allocated.....	1168
PARTIALTAPE: Specifying whether to reuse partially full tapes.....	1168
PDA: Specifying whether the problem determination aid is initiated.....	1169
PLEXNAME: Specifying a name for an HSMplex	1170
PRIMARYSPMGMTSTART: Specifying the start and stop times for automatic primary space management.....	1171
PROFILEBACKUP and NOPROFILEBACKUP: Specifying whether to create backup RACF discrete profiles for cataloged data sets.....	1172
PROMOTE: Specifying whether a host is eligible for promotion.....	1172
RACFIND and NORACFIND: Specifying whether to put RACF-indication on migration copies and backup versions.....	1173
RECALL: Specifying the target volume to receive recalled data sets.....	1173
RECYCLEINPUTDEALLOCFREQUENCY: Allowing periodic deallocation of input unit during recycle processing.....	1174
RECYCLEOUTPUT: Limiting the selection and allocation of an output volume during recycle processing.....	1176
RECYCLEPERCENT: Specifying the maximum percentage of valid data on a backup tape.....	1176
RECYCLETAKEAWAYRETRY: Specifying whether to automatically generate a new RECYCLE command for a tape.....	1177
RECYCLETAPEALLOCATION: Specifying if to wait for recycle tape to be allocated.....	1177
RECYCLETAPERESIDENCE: Specifying which IBM VTS tape volumes should be included in RECYCLE processing.....	1178
REMOVECOMPACTNAMES: Removing the compaction-control qualifier for source or object data sets.....	1178
REQUEST and NOREQUEST: Specifying whether the operator's permission is required.....	1179
SCRATCHFREQUENCY: Specifying how long to retain list data sets.....	1179
SECONDARYSPMGMTDIRECTIVE: Specifying Secondary Space Management controls pertaining to Cloud and non-Cloud data.....	1179
SECONDARYSPMGMTSTART: Specifying the start and stop time for automatic secondary space management.....	1180
SELECTVOLUME: Specifying whether DFSMSHsm should select a scratch tape volume or a DFSMSHsm tape volume.....	1181
SKIPABPRIMARY and NOSKIPABPRIMARY: Specifying whether to skip automatic backup of primary volumes.....	1183
SMALLDATASETPACKING and NOSMALLDATASETPACKING: Specifying whether DFSMSHsm should use small data set packing.....	1183
SMF and NOSMF: Specifying whether DFSMSHsm writes SMF records.....	1185
SOURCENAMES: Specifying the compaction-control qualifier of the source data set.....	1185
SPIII and NOSPIII: Specifying whether DFSMSHsm does spill or cleanup processing on full DASD daily backup volumes.....	1186
STORAGEGROUFAFFINITY: Define the set of host names that have affinity to process a storage group cloud migration.....	1187
SWAP and NOSWAP: Specifying whether the DFSMSHsm address space can be swapped....	1187
SYSOUT: Directing DFSMSHsm output.....	1187
SYS1DUMP and NOSYS1DUMP: Specifying where DFSMSHsm dumps should be written.....	1188
TAPEDATASETORDER: Specifying order for processing tape.....	1188
TAPEDELETION: Specifying what to do with tapes that no longer contain valid data.....	1189
TAPEHARDWARECOMPACT and NOTAPEHARDWARECOMPACT: Specifying the data format used when writing to a 3480X tape device.....	1190
TAPEINPUTPROMPT: Specifying whether to suppress input tape messages.....	1191
TAPELIBRARYPRESELECT: Preselecting output tape volumes in IBM Tape Library tape environment.....	1191
TAPEMAXRECALLTASKS: Specifying the maximum number of concurrent tape recall tasks..	1192
TAPEMIGRATION: Specifying the type of migration to tape.....	1192
TAPEOUTPUTPROMPT: Specifying whether to suppress output tape messages.....	1194
TAPERECALLLIMITS: Specifying limits to continuously mounted ML2 tapes during multiple recalls.....	1195
TAPESECURITY: Specifying the type of security for tape volumes.....	1195

TAPESPANSIZE: Reducing tape volume spanning.....	1197
TAPETYPE: Specifying whether to use WORM media for non-ABARS functions.....	1198
TAPEUTILIZATION: Specifying the desired tape utilization.....	1198
UNITNAME: Specifying the type of unit for mounting a scratch tape during backup or dump.....	1201
UNLOAD and NOUNLOAD: Specifying whether to unload MSS virtual DASD volumes.....	1202
USECYLINDERMANAGEDSPACE: Specifying whether to allow use of cylinder managed space for migration copies and backup versions.....	1202
USERUNITTABLE and NOUSERUNITTABLE: Specifying esoteric tape unit names to DFSMSHsm.....	1202
VERSIONS: Specifying the maximum number of backup versions to keep for any data set...	1205
VOLCOUNT: Specifying the method for determining volume count for SMS target data set allocations when performed by DFSMSdss.....	1206
VOLUMEDUMP: Specifying concurrent copy options for dump volumes.....	1206
ZCOMPRESS: Specifying when compression with zEDC should be done.....	1207
ZCOMPRESS (NONE ALL): Specifying whether to use zEDC Services for data sets.....	1208
ZCOMPRESS(CLOUDMIGRATE(NO YES)): Specifying whether to use CDA compression for data sets during migration to DIRECT cloud connections.....	1208
ZCOMPRESS (DASDBACKUP (NO YES)) : Specifying whether to use zEDC Services for data sets during backup to DASD.....	1209
ZCOMPRESS (DASDMIGRATE (NO YES)) : Specifying whether to use zEDC Services for data sets during migration to DASD.....	1210
ZCOMPRESS (TAPEBACKUP (NO YES)) : Specifying whether to use zEDC Services for data sets during backup to tape.....	1210
ZCOMPRESS (TAPEMIGRATE (NO YES)) : Specifying whether to use zEDC Services for data sets during migration to tape.....	1211
Examples of how to code the SETSYS command.....	1211
Chapter 66. STOP command: Shutting down DFSMSHsm.....	1223
Syntax of the STOP command.....	1223
Optional parameters of the STOP command.....	1223
DUMP: Requesting a dump of the DFSMSHsm address space.....	1223
PROMOTE: Specifying that a specific host in a sysplex is eligible to be promoted for another host.....	1224
Example of how to code the STOP command.....	1224
Chapter 67. SWAPLOG command: Switching between the DFSMSHsm log or PDA data sets.....	1225
Syntax of the SWAPLOG command.....	1225
Optional parameters of the SWAPLOG command.....	1225
LOG: Specifying to swap the log data sets.....	1225
PDA: Specifying to swap the PDA data sets.....	1226
Examples of how to code the SWAPLOG command.....	1226
Chapter 68. TAPECOPY command: Making copies of selected cartridge-type tape volumes.....	1227
Syntax of the TAPECOPY command.....	1227
Required parameters of the TAPECOPY command.....	1228
ALL: Specifying to copy all eligible cartridge-type single-file tape volumes.....	1228
MIGRATIONLEVEL2: Specifying to create copies of all eligible migration level 2 volumes.....	1228
BACKUP: Specifying to create copies of all eligible backup tape volumes.....	1228
ORIGINALVOLUMES: Copying specified volumes.....	1228
INDATASET: Specifying to use a data set containing a volume list.....	1228
Optional parameters of the TAPECOPY command.....	1230
ALTERNATEUNITNAME: Specifying alternate unit names for a tape copy.....	1230
ALTERNATE3590UNITNAME: Specifying 3590 alternate unit name for a tape copy.....	1231
ALTERNATEVOLUMES: Specifying which volumes to copy.....	1231
EXPDT and RETPD: Specifying a tape expiration date or a retention period.....	1232
Examples of how to code the TAPECOPY command.....	1233

Chapter 69. TAPEREP command: Replacing cartridge-type tape volumes with their alternate volumes.....	1235
Syntax of the TAPEREP command.....	1235
Required parameters of the TAPEREP command.....	1235
ALL: Specifying replacement of all cartridge-type single-file tape volumes.....	1235
BACKUP: Specifying replacement of all cartridge-type single-file backup tape volumes.....	1235
INDATASET: Specifying the use of a data set containing a volume list.....	1236
MIGRATION: Specifying replacement of all cartridge-type single-file migration tape volumes.....	1236
ONLYDISASTERALTERNATES: Converting disaster alternate volumes to original volumes....	1237
ORIGINALVOLUMES: Specifying volumes to be replaced.....	1237
Optional parameters of the TAPEREP command.....	1237
ALTERNATEUNITNAME: Specifying an alternate unit name for a tape replacement.....	1237
ALTERNATEVOLUMES: Specifying the replacement volumes to use.....	1238
DISASTERALTERNATEVOLUMES: Identifying the alternate volume as the disaster alternate volume.....	1238
Examples of how to code the TAPEREP command.....	1238
Chapter 70. TRAP command: Requesting a dump when a specified error occurs.....	1241
Chapter 71. UPDATEC command: Recovering the control data sets.....	1243
Syntax of the UPDATEC command.....	1243
Required parameters of the UPDATEC command.....	1243
ALL, BACKUPCONTROLDATASET, MIGRATIONCONTROLDATASET, and OFFLINECONTROLDATASET: Specifying which control data set to update.....	1243
Optional parameters of the UPDATEC command.....	1244
JOURNAL: Specifying the journal data set to use.....	1244
Examples of how to code the UPDATEC command.....	1244
Chapter 72. Storage administrator mode for UNIX commands.....	1245
Chapter 73. Java <i>hbackup</i> command for Incremental UNIX file backup.....	1247
Syntax of the Java <i>hbackup</i> command.....	1247
Required parameters of the Java <i>hbackup</i> command	1247
directory_name: Specifying the name of the directory.....	1247
Optional parameters of the Java <i>hbackup</i> command.....	1247
Specifying the environment configuration.....	1250
Example of how to code the Java <i>hbackup</i> command	1251
Chapter 74. UPDTCDS Command: Updating the control data sets.....	1253
Syntax of the UPDTCDS command.....	1253
Required parameters of the UPDTCDS command.....	1253
COPYPOOL: Specifying the name of the copy pool.....	1253
VERSION: Specifying the version.....	1253
DUMPEXPIRATION: Indicating that the copy pool dump expiration is to be modified.....	1253
Example of how to code the UPDTCDS command.....	1254
Chapter 75. Using the AUDIT command.....	1255
Using the enhanced audit command to audit DFSMSshm control information.....	1256
Using the AUDIT ABARSCONTROLS command.....	1257
Using the AUDIT COMMONQUEUE command.....	1258
Using the AUDIT COPYPOOLCONTROLS command.....	1259
Using the AUDIT DATASETCONTROLS (BACKUP) command.....	1260
Using the AUDIT DATASETCONTROLS (MIGRATION) command.....	1261
Using the AUDIT DIRECTORYCONTROLS command.....	1263
Using the AUDIT FILECONTROLS(BACKUP) command.....	1266
Using the AUDIT MEDIACONTROLS (CLOUD) command.....	1267

Using the AUDIT MEDIACONTROLS (SDSP) VOLUMES command.....	1268
Using the AUDIT MEDIACONTROLS VOLUMES command.....	1269
Using the AUDIT VOLUMECONTROLS (BACKUP) command.....	1272
Using the AUDIT VOLUMECONTROLS (MIGRATION) command.....	1273
Using the AUDIT VOLUMECONTROLS (RECOVERABLE) command.....	1274
Summary of errors detected by the enhanced AUDIT commands.....	1276
Using the original AUDIT command to audit DFSMSHsm data set information.....	1280
Using the AUDIT DATASET NAMES and AUDIT LEVELS commands.....	1282
Using the AUDIT VOLUMES command.....	1284
Using the AUDIT BACKUPVOLUMES and AUDIT BACKUPTYPE commands.....	1286
Using the AUDIT MASTERCATALOG and AUDIT USERCATALOG commands.....	1288
Using the AUDIT MIGRATIONCONTROL DATASET command.....	1290
Using the AUDIT BACKUPCONTROL DATASET command.....	1291
Using the AUDIT OFFLINECONTROL DATASET command.....	1292
Summary of errors detected by the original AUDIT commands.....	1294
Error codes (*ERR) and diagnosis.....	1295
Unexpected errors during an audit.....	1337
Unexpected error messages.....	1337
Errors encountered during AUDIT VOLUMES, AUDIT BACKUPVOLUMES, or AUDIT BACKUPTYPE.....	1339
Other considerations when using the AUDIT command.....	1340
Multiple DFSMSHsm host considerations when using the AUDIT command.....	1340
Printing information from the AUDIT command.....	1340
Chapter 76. Using the LIST command.....	1341
Requesting information for aggregate backup and recovery activity information.....	1341
Requesting information for backup volumes.....	1345
Requesting information for cloud storage.....	1346
Requesting information for copy pools.....	1348
Requesting information for copy pool backup storage groups.....	1351
Requesting information for data sets.....	1352
Requesting data set information from the MCDS.....	1352
Requesting data set information from the BCDS.....	1355
Requesting data set information from the MCDS and BCDS.....	1359
Requesting data set information for the latest backup version.....	1360
Requesting information for dump classes.....	1361
Requesting information for dump volumes.....	1364
Requesting dump content information for dump volumes.....	1366
Requesting information for primary and migration volumes.....	1371
Requesting primary and migration volume information from the MCDS.....	1371
Requesting primary and migration volume information from the BCDS.....	1376
Requesting primary volume dump information from the BCDS.....	1378
Requesting contents of backup VTOC for a primary volume from the BCDS.....	1379
Requesting a list of records serialized by DFSMSHsm host ID.....	1381
Requesting information from the tape table of contents (TTOC).....	1381
Requesting information for all user entries or a specific user entry.....	1386
Chapter 77. Using the QUERY command.....	1389
Chapter 78. Using the REPORT command.....	1401
Requesting a report of the daily statistics for all functions.....	1401
Requesting a report of the volume statistics for all functions.....	1405
Requesting a summary of the daily or volume statistics.....	1410

82. CVQ Host Types.....	478
83. Example System for MIGRATE CONVERT.....	529
84. SMS Volume Status.....	530
85. DFSMSHsm Log and Edit Log Overview.....	607
86. Example of a List from the ARCPRLOG Program.....	612
87. Example of a List from the ARCPEDIT Program.....	613
88. Example of a Summary List from the ARCPEDIT Program.....	614
89. Handwritten note from Steve to Rick.....	629
90. Consolidated Storage Group Attributes.....	659
91. Sample Activity Log Created When You Specify ABACKUP with the VERIFY Parameter.....	696
92. ARECOVER sample activity log output.....	735
93. Identifying Authorized DFSMSHsm Users.....	757
94. Sample Printer List of Data Sets When You Specify EXPIREBV ABARSVERSIONS and DISPLAY.....	861
95. Sample Printer List of Data Sets When You Specify EXPIREBV and DISPLAY.....	861
96. Sample List of Output for AUDIT DATASETNAMES.....	1283
97. Sample Terminal Output for AUDIT DATASETNAMES.....	1283

98. Sample List of Output for AUDIT VOLUMES.....	1285
99. Sample Terminal Output for AUDIT VOLUMES.....	1285
100. Sample List of Output for AUDIT BACKUPVOLUMES.....	1287
101. Sample Terminal List for AUDIT BACKUPVOLUMES.....	1288
102. Sample List of Output for AUDIT MASTERCATALOG.....	1289
103. Sample List of Output for AUDIT USERCATALOG.....	1289
104. Sample List of Output for AUDIT MCDS.....	1290
105. Sample Terminal List for AUDIT MCDS.....	1291
106. Sample List of Output for AUDIT BCDS.....	1292
107. Sample Terminal List for AUDIT BCDS.....	1292
108. Sample List of Output for AUDIT OCDS(ALL).....	1294
109. Sample Terminal List for AUDIT OCDS(ML2).....	1294
110. Sample Terminal List when You Specify AGGREGATE(PAY1), VERSION(002) and TERMINAL.....	1344
111. Sample Printer List when You Specify AGGREGATE(PAY1), VERSION(001) and ODS.....	1344
112. Sample Printer List of All the Backup Volumes when You Specify BACKUPVOLUME.....	1346
113. Sample Printer List of a specific cloud when you specify the CLOUD(cloud_network_connection_name).....	1347
114. Sample Printer List of specific objects when you specify the CLOUD(cloud_network_connection_name) CONTAINER(container_name).....	1348
115. Sample Printer List of specific objects when you specify the CLOUD(cloud_network_connection_name) CONTAINER(container_name) PREFIX(prefix_name)...	1348
116. Sample Printer List of All the Copy Pools when You Specify COPYPOOL.....	1350
117. Sample Printer List of a Specific Copy Pool when You Specify COPYPOOL(cpname).....	1350
118. Sample Output for the LIST COPYPOOL(cpname) DATASETS command.....	1351
119. Sample printer list of a specific copy pool when you specify the COPYPOOL(cpname) parameter and one of the dump versions resides on cloud object storage.....	1351
120. Sample Printer List for COPYPOOLBACKUPSTORAGEGROUP.....	1352
121. Sample Printer List when You Specify DATASETNAME and MIGRATIONCONTROLDATASET.....	1354

122. Sample Printer List of VSAM Data Sets when You Specify DATASETNAME, SELECT(VSAM), and MIGRATIONCONTROLDATASET.....	1354
123. Sample Printer List when You Specify DATASETNAME and SUMMARY.....	1354
124. Sample Printer List Output for the LIST DATASETNAME(dsname) BACKUPCONTROLDATASET Command.....	1358
125. Sample Terminal Output for the LIST DATASETNAME(dsname) BACKUPCONTROLDATASET Command.....	1358
126. Sample Printer List Output for the LIST LEVEL(qualifier) BACKUPCONTROLDATASET Command..	1359
127. Sample Terminal Output for the LIST LEVEL(qualifier) BACKUPCONTROLDATASET Command.....	1359
128. Sample Printer List of All Data Sets when You Specify DATASETNAME, BOTH, and INCLUDEPRIMARY.....	1360
129. Sample Printer List when you specify DATASETNAME and SELECT(VOLUME(volser)).....	1361
130. Sample Terminal List when you specify DATASETNAME and SELECT(VOLUME(volser)).....	1361
131. Sample Printer List of Dump Classes of Dump Volumes when You Specify DUMPCLASS.....	1363
132. Sample Printer List of a specific dump class when you specify the DUMPCLASS parameter.....	1363
133.	1364
134. Sample Printer List for DUMPVOLUME(volser).....	1366
135. Sample Printer List for all Available Volumes when You Specify SELECT(AVAILABLE).....	1366
136. Sample Printer List of all Dump Volumes when You Specify DUMPVOLUME without (volser).....	1366
137. Sample Printer List when You Specify DUMPVOLUME(volser) and DUMPCONTENTS(srcvol).....	1370
138. Sample Printer List of cloud dump information for a specific source volume when you specify DUMPVOLUME(%CLOUD) and DUMPCONTENTS(srvol).....	1370
139. Sample Printer List of Primary Volumes from the MCDS when You Specify PRIMARYVOLUME and MIGRATIONCONTROLDATASET.....	1374
140. Sample Printer List of Migration Volumes from the MCDS when You Specify MIGRATIONVOLUME and MIGRATIONCONTROLDATASET.....	1374
141. Sample Terminal List of a Volume from the MCDS when You Specify VOLUME, MIGRATIONCONTROLDATASET, and TERMINAL.....	1374
142. Sample Printer List of Tape Migration Level 2 Volumes when You Specify MIGRATIONLEVEL2(TAPE) and MIGRATIONCONTROLDATASET.....	1376

143. Sample Printer List from the BCDS when You Specify PRIMARYVOLUME(volser) and BACKUPCONTROLDATASET.....	1377
144. Sample Terminal List from the BCDS when You Specify VOLUME, BACKUPCONTROLDATASET, and TERMINAL.....	1378
145. Sample Printer List from the BCDS for a Specific Primary Volume with Cloud Dump Classes when You Specify PRIMARYVOLUME(volser), BACKUPCONTROLDATASET.....	1378
146. Sample Printer List from the BCDS when You Specify ALLDUMPS with PRIMARYVOLUME(volser) and BACKUPCONTROLDATASET.....	1379
147. Sample Printer List of the cloud dump information for a specific primary volume when you specify ALLDUMPS with PRIMARYVOLUME(volser) and BACKUPCONTROLDATASET.....	1379
148. Sample Printer List of dump information for a specific primary volume when you specify ALLDUMPS with PRIMARYVOLUME(volser) and BCDS.....	1379
149. Sample Printer List from the BCDS when You Specify PRIMARYVOLUME(volser), BACKUPCONTENTS, and BACKUPCONTROLDATASET.....	1381
150. Sample Printer List when You Specify HOST(hostid) and RESET.....	1381
151. Sample Printer List when You Specify TAPETABLEOFCONTENTS SELECT(CONNECTED).....	1384
152. Sample Terminal List when You Specify TAPETABLEOFCONTENTS, NODATASETINFORMATION and TERMINAL.....	1384
153. Sample Printer List when You Specify TAPETABLEOFCONTENTS with DATASETINFORMATION...	1385
154. Sample Terminal List when You Specify TAPETABLEOFCONTENTS, DATASETINFORMATION and TERMINAL.....	1385
155. Sample Printer List when You Specify TAPETABLEOFCONTENTS, SELECT, NOALTERNATEVOLUMES, and LIBRARY.....	1385
156. Sample Printer List when You Specify TAPETABLEOFCONTENTS, SELECT, and DISASTERALTERNATEVOLUMES.....	1385
157. Sample Printer List when You Specify TAPETABLEOFCONTENTS, SELECT, ML2 and FAILEDRECYCLE.....	1386
158. Sample Printer List when You Specify TAPETABLEOFCONTENTS and FAILEDCREATE.....	1386
159. Sample Printer List when You Specify EXCESSIVEVOLUMES.....	1386
160. Sample Printer List when You Specify SELECT(NOTASSOCIATED).....	1386
161. Sample Printer List of User Entries when You Specify USER.....	1387
162. Sample report of daily statistics by function.....	1405

163. Sample report of volume statistics by function.....	1410

96. Headings of output when you request a volume statistics report.....	1406
---	------

About this document

This document describes the tasks that must be performed to use IBM z/OS DFSMSHsm, a component of DFSMS that manages your storage in a hierarchical manner. It contains examples of the commands needed to perform the tasks, descriptions of the processing that DFSMSHsm performs, and examples of the results of that processing.

For information about the accessibility features of z/OS, for users who have a physical disability, see [Appendix A, “Accessibility,” on page 1413](#).

Who should read this document

This document is intended for use by anyone responsible for managing storage for a computer center. It is designed to be tutorial in nature. Information presented in one topic is often based on knowledge obtained in a preceding topic.

Major divisions of this document

This document is divided into two parts, which are divided into topics. The divisions of this document are:

- **[Part 1, “DFSMSHsm Storage Administration Guide,” on page 1](#)**
 - The following topic provides an overview of DFSMSHsm.
 - [Chapter 1, “Welcome to DFSMSHsm,” on page 7](#), which describes the functions of DFSMSHsm and explains how to use this document.
 - The following topics introduce the tasks necessary to control space management functions:
 - [Chapter 2, “Space management of SMS-managed storage,” on page 23](#), which describes the tasks to be performed and the results of processing for space management of data sets managed by the storage management subsystem (SMS).
 - [Chapter 3, “Space management of non-SMS-managed storage,” on page 99](#), which describes the tasks to be performed and the results of processing for space management of data sets not managed by SMS.
 - [Chapter 4, “Other space management considerations,” on page 127](#), which describes aspects of space management that deserve consideration but are peripheral to the discussions in the two preceding topics.
 - [Chapter 5, “Space management procedures,” on page 161](#), which describes procedures for starting and stopping space management under varying conditions.
 - The following topics introduce the tasks necessary to control availability management functions:
 - [Chapter 6, “Availability management of SMS-managed storage,” on page 165](#), which describes the tasks to be performed and the results of processing for availability management of data sets managed by SMS.
 - [Chapter 7, “Availability management of non-SMS-managed storage,” on page 303](#), which describes the tasks to be performed and the results of processing for availability management of data sets not managed by SMS.
 - [Chapter 8, “Aggregate backup and recovery support \(ABARS\),” on page 319](#), which describes the command-driven functions that back up and recover a user-defined group (aggregate group) of data sets.
 - [Chapter 9, “Making disaster backup copies of DFSMSHsm-owned tape volumes,” on page 435](#), which describes how to make backup copies of DFSMSHsm-owned, cartridge-type, single-file-format tape volumes and how to recover those volumes.

- [Chapter 10, “Other availability management considerations,” on page 445](#), which describes aspects of availability management that deserve consideration but are peripheral to the discussions in the preceding topics.
- [Chapter 11, “Availability management procedures,” on page 485](#), which describes procedures for starting and stopping availability management under varying conditions.
- The following topics introduce the activities necessary to maintain DFSMSHsm-owned data sets and volumes.
 - [Chapter 12, “Maintaining DFSMSHsm control data sets,” on page 493](#), which describes the activities necessary to ensure that you can recover from damaged or lost DFSMSHsm control data sets.
 - [Chapter 13, “Managing DFSMSHsm media,” on page 527](#), which describes the activities necessary to manage data stored on DFSMSHsm-owned volumes.
 - [Chapter 14, “Obtaining information from DFSMSHsm,” on page 559](#), which describes the information that you can obtain from DFSMSHsm about its operations and the data sets and volumes that it is managing.
 - [Chapter 15, “DFSMSHsm tape libraries,” on page 589](#), which briefly explains DFSMSHsm automated and manual tape libraries.
 - [Chapter 16, “Using DFSMSHsm with DFSMSrmm,” on page 591](#), which explains the interaction between DFSMSHsm and DFSMSrmm when managing DFSMSHsm tape volumes.
 - [Chapter 17, “Operating procedures for DFSMSHsm,” on page 593](#), which describes procedures to be performed by the computing system operator.
 - [Chapter 18, “RACF considerations,” on page 617](#), which discusses pertinent RACF® information. RACF is a component of the Security Server for z/OS. This information includes the use of discrete and generic profiles with DFSMSHsm, and the use of FACILITY class profiles with regard to command control access in DFSMSHsm.
 - [Chapter 19, “Health Checker for DFSMSHsm,” on page 627](#), which describes information about Health Checker for DFSMSHsm.
- The following topic introduces data recovery scenarios.
 - [Chapter 20, “Data recovery scenarios,” on page 629](#), which describes real-life examples of data loss and recovery situations
- The following topics provide additional DFSMSHsm information:
 - [Chapter 21, “Consolidated commands, storage group definitions, and management classes for the example system,” on page 653](#)
 - [Chapter 22, “Preventive methods for avoiding data loss,” on page 661](#)
 - [Chapter 23, “Linux-z/OS DFSMSHsm dump or restore how-to,” on page 665](#)
- **[Part 2, “DFSMSHsm Storage Administration Reference,” on page 677](#)**
 - [Chapter 24, “DFSMSHsm commands,” on page 681](#) provides an overview of the DFSMSHsm commands.
 - The following topics provide detailed explanations of the operator, storage administrator, and system programmer commands, listed in alphabetical order, as follows:
 - [Chapter 25, “ABACKUP command: Backing up aggregated data sets,” on page 691](#)
 - [Chapter 26, “ADDVOL command: Adding or changing DFSMSHsm volumes,” on page 697.](#)
 - [Chapter 27, “ALTERDS command: Changing the back-ups for a non-SMS-managed data set,” on page 715.](#)
 - [Chapter 28, “ALTERPRI command: Altering the priority of queued requests,” on page 719.](#)
 - [Chapter 29, “ARECOVER command: Recovering a specified aggregate group,” on page 723.](#)
 - [Chapter 30, “AUDIT command: Auditing DFSMSHsm,” on page 737.](#)
 - [Chapter 31, “AUTH command: Identifying authorized users,” on page 755.](#)
 - [Chapter 32, “BACKDS command: Backing up a specific data set,” on page 759.](#)

- [Chapter 36, “BACKVOL command: Backing up data sets from volumes or dumping volumes,” on page 779.](#)
- [Chapter 37, “BDELETE command: Deleting backup versions of a data set,” on page 797.](#)
- [Chapter 38, “CANCEL command: Canceling a queued or active DFSMSHsm request,” on page 801.](#)
- [Chapter 40, “DEFINE command: Defining control structures for use by DFSMSHsm,” on page 809.](#)
- [Chapter 41, “DELETE Command: Deleting a migrated data set from a migration volume,” on page 839.](#)
- [Chapter 42, “DELVOL command: Removing a volume from DFSMSHsm management,” on page 841.](#)
- [Chapter 43, “DISPLAY command: Displaying DFSMSHsm storage locations,” on page 849.](#)
- [Chapter 44, “EXPIREBV command: Deleting unwanted backup versions of data sets and UNIX files,” on page 851.](#)
- [Chapter 45, “FIXCDS command: Displaying or modifying MCDS, BCDS, and OCDS records,” on page 863.](#)
- [Chapter 46, “FRBACKUP command: Requesting a fast replication backup or dump version,” on page 865.](#)
- [Chapter 47, “FRDELETE command: Deleting fast replication backup or dump versions,” on page 873.](#)
- [Chapter 48, “FREEVOL command: Freeing DFSMSHsm-owned volumes,” on page 877.](#)
- [Chapter 49, “FRRECOV command: Requesting a fast replication recovery,” on page 883.](#)
- [Chapter 50, “HOLD command: Preventing DFSMSHsm functions from running,” on page 895.](#)
- [Chapter 51, “HSEND CMD command: Issuing DFSMSHsm authorized-user commands from a TSO terminal,” on page 913.](#)
- [Chapter 53, “LIST command: Listing information from the MCDS, BCDS, and OCDS,” on page 919.](#)
- [Chapter 54, “LOG command: Entering data into the DFSMSHsm log,” on page 953.](#)
- [Chapter 55, “MIGRATE command: Requesting a space management function,” on page 955.](#)
- [Chapter 56, “ONLYIF command: Running commands in ARCCMDxx conditionally,” on page 973.](#)
- [Chapter 57, “PATCH command: Modifying storage within DFSMSHsm,” on page 979.](#)
- [Chapter 58, “QUERY command: Displaying the status of parameters, statistics, and requests,” on page 981.](#)
- [Chapter 59, “RECALL command: Recalling a specific migrated data set,” on page 991.](#)
- [Chapter 60, “RECOVER command: Recovering a backup version or dump copy of a data set, or UNIX file, or a volume,” on page 997.](#)
- [Chapter 61, “RECYCLE command: Consolidating valid data to one tape from other tapes,” on page 1015.](#)
- [Chapter 62, “RELEASE command: Releasing all or some DFSMSHsm functions for processing,” on page 1029.](#)
- [Chapter 63, “REPORT Command: Requesting reports based on DFSMSHsm statistics records,” on page 1043.](#)
- [Chapter 64, “SETMIG command: Changing the space management status of non-SMS-managed data sets or volumes,” on page 1053.](#)
- [Chapter 65, “SETSYS command: Establishing or changing the values of DFSMSHsm control parameters,” on page 1057.](#)
- [Chapter 66, “STOP command: Shutting down DFSMSHsm,” on page 1223.](#)
- [Chapter 67, “SWAPLOG command: Switching between the DFSMSHsm log or PDA data sets,” on page 1225.](#)
- [Chapter 68, “TAPECOPY command: Making copies of selected cartridge-type tape volumes,” on page 1227.](#)

- [Chapter 69, “TAPERREPL command: Replacing cartridge-type tape volumes with their alternate volumes,” on page 1235.](#)
- [Chapter 70, “TRAP command: Requesting a dump when a specified error occurs,” on page 1241.](#)
- [Chapter 71, “UPDATEC command: Recovering the control data sets,” on page 1243.](#)
- [Chapter 75, “Using the AUDIT command,” on page 1255](#) contains diagnosis, modification, and tuning information.
- You use the LIST command to determine the status of DFSMSHsm and SMS-managed volumes and data sets. [Chapter 76, “Using the LIST command,” on page 1341](#) describes the categories of information you can list, explains the output of the LIST command, and contains sample lists.
- You use the QUERY command, described in [Chapter 77, “Using the QUERY command,” on page 1389](#), to determine what values you specified with the DFSMSHsm commands, to list DFSMSHsm statistics, or to list the status of pending requests.
- You use the REPORT command, described in [Chapter 78, “Using the REPORT command,” on page 1401](#), to generate reports based on the DFSMSHsm statistics records in the MCDS.

Required product knowledge

You should have a systems background either as a system programmer or storage administrator. You should also be familiar with the basic concepts of DFSMS described in [z/OS DFSMS Introduction](#). You are presumed to have a background in using TSO and an understanding of z/OS concepts and terms.

z/OS information

This information explains how z/OS references information in other documents and on the web.

When possible, this information uses cross-document links that go directly to the topic in reference using shortened versions of the document title. For complete titles and order numbers of the documents for all products that are part of z/OS, see [z/OS Information Roadmap](#).

How to read syntax diagrams

This section describes how to read syntax diagrams. It defines syntax diagram symbols, items that may be contained within the diagrams (keywords, variables, delimiters, operators, fragment references, operands) and provides syntax examples that contain these items.

Syntax diagrams pictorially display the order and parts (options and arguments) that comprise a command statement. They are read from left to right and from top to bottom, following the main path of the horizontal line.

For users accessing the Information Center using a screen reader, syntax diagrams are provided in dotted decimal format.

Symbols

The following symbols may be displayed in syntax diagrams:

Symbol	Definition
--------	------------

- | | |
|-----|--|
| ▶ — | Indicates the beginning of the syntax diagram. |
| —▶ | Indicates that the syntax diagram is continued to the next line. |
| ▶ — | Indicates that the syntax is continued from the previous line. |
| —▶ | Indicates the end of the syntax diagram. |

Syntax items

Syntax diagrams contain many different items. Syntax items include:

- Keywords - a command name or any other literal information.
- Variables - variables are italicized, appear in lowercase, and represent the name of values you can supply.
- Delimiters - delimiters indicate the start or end of keywords, variables, or operators. For example, a left parenthesis is a delimiter.
- Operators - operators include add (+), subtract (-), multiply (*), divide (/), equal (=), and other mathematical operations that may need to be performed.
- Fragment references - a part of a syntax diagram, separated from the diagram to show greater detail.
- Separators - a separator separates keywords, variables or operators. For example, a comma (,) is a separator.

Note: If a syntax diagram shows a character that is not alphanumeric (for example, parentheses, periods, commas, equal signs, a blank space), enter the character as part of the syntax.

Keywords, variables, and operators may be displayed as required, optional, or default. Fragments, separators, and delimiters may be displayed as required or optional.

Item type

Definition

Required

Required items are displayed on the main path of the horizontal line.

Optional

Optional items are displayed below the main path of the horizontal line.

Default

Default items are displayed above the main path of the horizontal line.

Syntax examples

The following table provides syntax examples.

Table 1. Syntax examples	
Item	Syntax example
Required item. Required items appear on the main path of the horizontal line. You must specify these items.	►► KEYWORD — required_item ►◄
Required choice. A required choice (two or more items) appears in a vertical stack on the main path of the horizontal line. You must choose one of the items in the stack.	►► KEYWORD — <div>required_choice1 required_choice2</div> ►◄
Optional item. Optional items appear below the main path of the horizontal line.	►► KEYWORD — <div>optional_item</div> ►◄
Optional choice. An optional choice (two or more items) appears in a vertical stack below the main path of the horizontal line. You may choose one of the items in the stack.	►► KEYWORD — <div>optional_choice1 optional_choice2</div> ►◄

Table 1. Syntax examples (continued)

Item	Syntax example
<p>Default.</p> <p>Default items appear above the main path of the horizontal line. The remaining items (required or optional) appear on (required) or below (optional) the main path of the horizontal line. The following example displays a default with optional items.</p>	
<p>Variable.</p> <p>Variables appear in lowercase italics. They represent names or values.</p>	
<p>Repeatable item.</p> <p>An arrow returning to the left above the main path of the horizontal line indicates an item that can be repeated.</p> <p>A character within the arrow means you must separate repeated items with that character.</p> <p>An arrow returning to the left above a group of repeatable items indicates that one of the items can be selected, or a single item can be repeated.</p>	
<p>Fragment.</p> <p>The fragment symbol indicates that a labelled group is described below the main syntax diagram. Syntax is occasionally broken into fragments if the inclusion of the fragment would overly complicate the main syntax diagram.</p>	

How to provide feedback to IBM

We welcome any feedback that you have, including comments on the clarity, accuracy, or completeness of the information. For more information, see [How to send feedback to IBM](#).

Summary of changes

This information includes terminology, maintenance, and editorial changes. Technical changes or additions to the text and illustrations for the current edition are indicated by a vertical line to the left of the change.

Note: IBM z/OS policy for the integration of service information into the z/OS product documentation library is documented on the z/OS Internet Library under [IBM z/OS Product Documentation Update Policy](http://www.ibm.com/docs/en/zos/latest?topic=zos-product-documentation-update-policy) (www.ibm.com/docs/en/zos/latest?topic=zos-product-documentation-update-policy).

Summary of changes for z/OS 3.2

The following content is new, changed, or no longer included in z/OS 3.2.

New

The following content is new.

September 2025 release

Added the following details as per [OA66198: NEW FUNCTION - DFSMSHSM S3 SUPPORT FOR TCT AND DIRECT TO CLOUD](http://www.ibm.com/support/pages/apar/OA66198) (www.ibm.com/support/pages/apar/OA66198) (APAR OA66198, which applies from 3.2 and above)

- SMSPROVIDER. For more information, see [“Syntax of the SETSYS command”](#) on page 1057.
- CDAPROVIDER and SMSPROVIDER. For more information, see [“CLOUD: Specifying CLOUD properties”](#) on page 1115.
- [“ZCOMPRESS\(CLOUDMIGRATE\(NO | YES\)\)”](#): Specifying whether to use CDA compression for data sets during migration to DIRECT cloud connections” on page 1208.
- Column: CPCTL, Error Number: 205, 206, 209, 215, 218, 219, and 231. For more information, see [“Summary of errors detected by the enhanced AUDIT commands”](#) on page 1276.
- Error 231. For more information, see [“Error codes \(*ERR\) and diagnosis”](#) on page 1295.
- NETWORK parameter. For more information, see [Chapter 77, “Using the QUERY command,”](#) on page 1389.

Changed

The following content is changed.

September 2025 release

Updated the following details as per [OA66198: NEW FUNCTION - DFSMSHSM S3 SUPPORT FOR TCT AND DIRECT TO CLOUD](http://www.ibm.com/support/pages/apar/OA66198) (www.ibm.com/support/pages/apar/OA66198) (APAR OA66198, which applies from 3.2 and above)

- [“Compaction or zEDC compression during migration”](#) on page 75.
- [“Reconnecting data sets using fast subsequent migration”](#) on page 94.
- [“Object storage in the cloud”](#) on page 156.
- [“System set up to use the cloud”](#) on page 156.
- [“DASD volumes”](#) on page 156.
- [“Cloud password”](#) on page 156.
- Title only. For more information, see [“Workload distribution with TCT”](#) on page 157.
- Fast subsequent migration reconnect is attempted requirements. For more information, see [“Reconnecting data sets using fast subsequent migration”](#) on page 94.
- [“DUMPCCLASS\(TAPE | CLOUD\)”](#): Specifying where the dump copies to reside” on page 835.

- [“DUMPCCLASS\(ZCOMPRESS\): Specifying whether to use zEDC Services on the dump data”](#) on page 829.
- [“NETWORK: Displaying cloud endpoint statistics known to DFSMSHsm”](#) on page 987.
- O: ZCOMPRESS optional parameters. For more information, see [“Syntax of the SETSYS command”](#) on page 1057.
- Name(cloud_network_connection_name) description. For more information, see [“CLOUD: Specifying CLOUD properties”](#) on page 1115.
- Note. For more information, see [“DSSXMMODE: Specifying whether DFSMSdss will be loaded in its own address space using the cross memory interface, or in the DFSMSHsm address space, for backup, CDS backup, dump, migration, and full-volume and data set recovery”](#) on page 1133.
- Note. For more information, see [“DUMPIO: Specifying the DFSMSdss DASD I/O buffering technique”](#) on page 1134.
- Optional sub parameters. For more information, see [“ZCOMPRESS: Specifying when compression with zEDC should be done”](#) on page 1207.
- If there is a data set record in the MCDS section. For more information, see [“Errors detected when using AUDIT MEDIACONTROLS for cloud storage”](#) on page 1267.
- Error 215 description. For more information, see [“Error codes \(*ERR\) and diagnosis”](#) on page 1295.
- SETSYS parameter. For more information, see [Chapter 77, “Using the QUERY command,”](#) on page 1389.
- Updated REFRESH as per [OA68113: MSGADR617E GDKWRITE RC800, HWTHRQST RC106 DIAGREA: FOPEN\(//DD:SYS00001\) DURING MIGRATION TO CDA DIRECT CLOUD](#) (www.ibm.com/support/pages/apar/OA68113) (APAR OA68113, which applies from 3.1 and above). For more information, see [“CLOUD: Specifying CLOUD properties”](#) on page 1115

Deleted

The following content is deleted.

September 2025 release

- None.

Summary of changes for z/OS 3.1

The following content is new, changed, or no longer included in z/OS 3.1.

New

The following content is new.

June 2025 release

- Added REPLACE parameter. For more information, see [“REPLACE: Specifying that the recovered backup version or dump copy is to replace any existing data set of the same name”](#) on page 1009.

April 2025 release

- Added Notes 3 and 4. For more information, see [“PLEXNAME: Specifying a name for an HSMplex ”](#) on page 1170.
- The unexpected error MSG 924, MSG 925, and MSG 926 is added. For more information, see [“MSG 924”](#) on page 1339, [“MSG 925”](#) on page 1339, and [“MSG 926”](#) on page 1339.

March 2025 release

- Added Note. For more information see, [“Dump processing”](#) on page 193

February 2025 release

- Added Note. For more information, see [“MIGRATIONCLEANUPCYCLE and SECONDARYSPMGMTCYCLE: Specifying the cycle for automatic secondary space management functions”](#) on page 830.
- Added TAPELIBRARYPRESELECT parameter. For more information, see [“TAPELIBRARYPRESELECT: Preselecting output tape volumes in IBM Tape Library tape environment”](#) on page 1191.
- Added TAPELIBRARYPRESELECT parameter under SETSYS. For more information, see [Chapter 77, “Using the QUERY command,”](#) on page 1389.
- Added a new optional parameter, TAPELIBRARYPRESELECT. For more information, see [“Syntax of the SETSYS command”](#) on page 1057.
- Added TAPELIBRARYPRESELECT under Tape Environment. For more information, see [“SETSYS fast-path for DFSMSHsm functions”](#) on page 1075.

June 2024 release

- Added a new optional parameter, ISSUEARC1902. For more information, see [“ISSUEARC1902: Enable/disable the issue of ARC1902I message to the console”](#) on page 1146, [“Summary of DFSMSHsm default values”](#) on page 1084 and [“Syntax of the SETSYS command”](#) on page 1057.

February 2024 release

- Added the following restrictions to NEWNAME option with BACKDS command and added a link to the restrictions. For more information, see [“Data set backup using NEWNAME”](#) on page 454 and [“NEWNAME: Specifying a name to assign to the backup version”](#) on page 767.

September 2023 release

- None.

Changed

The following content is changed.

June 2025 release

- Updated Explanation and Note. For more information see, [“TAPETYPE: Specifying whether to use WORM media for non-ABARS functions”](#) on page 1198
- Updated Explanation. For more information see, [“BACKUPSTORAGEGROUP: Overriding the copy pool backup storage group with an alternate storage group”](#) on page 866
- Removed obsolete text. For more information see, [Chapter 23, “Linux-z/OS DFSMSHsm dump or restore how-to,”](#) on page 665

April 2025 release

- Updated MEDIACONTROLS(CLOUD(*cloud_network_connection_name*)). For more information see, [“MEDIACONTROLS VOLUMES, MEDIACONTROLS\(SDSP\) VOLUMES and MEDIACONTROLS\(CLOUD\): Requesting an audit of control information”](#) on page 748.

March 2025 release

- Updated Note 4. For more information see, [“DUMPCYCLE: Specifying the automatic dump cycle”](#) on page 829
- Updated Note 2. For more information see, [“Specifying the day on which a dump occurs”](#) on page 170

February 2025 release

- Updated Explanation section. For more information, see [“FORCE: Replacing a DASD backup copy that has an incomplete dump copy”](#) on page 869
- Updated ARC0747I to ARC0747E. For more information, see:
 - [“Considerations when using multicluster control data sets”](#) on page 502

- [“Changing backup device from DASD to tape” on page 504](#)
- [“Changing the names of the backup data sets” on page 503](#)
- [“WAIT and NOWAIT: Specifying whether to wait for command completion” on page 914](#)
- Updated [“Maintenance and use of the data set date-last-referenced field for space management” on page 78](#)
- Updated ERR 32 userdsn—EXTRANEIOUS MIGRATED DATA SET RECORD EXTENSION details in [“Error codes \(*ERR\) and diagnosis” on page 1295](#)

December 2024 release

- Recovering from a large-scale cyber event is updated. For more information, see:
 - [“Case 12: Recovering from a large-scale cyber event” on page 650](#)

October 2024 release

- Under the section SETSYS, ARC0151I is updated. For more information, see:
 - [Chapter 77, “Using the QUERY command,” on page 1389](#)
 (APAR OA66239, which also applies to z/OS 2.4 and 2.5.)

June 2024 release

- The AUDIT command is updated. For more information, see:
 - [“Diagnosis and repair action for AUDIT MEDIACONTROLS for CLOUD” on page 1268](#)
 - [“Summary of errors detected by the enhanced AUDIT commands” on page 1276](#)
 - [“Errors detected when using AUDIT MEDIACONTROLS for cloud storage” on page 1267](#)
 - [“Error codes \(*ERR\) and diagnosis” on page 1295](#)
 (APAR OA61709, which also applies to z/OS 2.5.)

January 2024 release

- The HBACKUP command is updated. For more information, see:
 - [“Syntax of the Java hbackup command” on page 1247](#)
 - [“Optional parameters of the Java hbackup command” on page 1247](#)
 (APAR OA65319, which also applies to z/OS V2R5.)

September 2023 release

- The HSEND CMD command is updated. For more information, see:
 - [“Syntax of the HSEND CMD command” on page 913](#)
 - [“WAIT and NOWAIT: Specifying whether to wait for command completion” on page 914](#)
 - [“Examples of how to code the HSEND CMD command” on page 915](#)
 (APAR OA64893)

November 2023 release

- The AUDIT FILECONTROLS(BACKUP) command has been updated. For more information, see:
 - [“Error codes \(*ERR\) and diagnosis” on page 1295](#)
 - [“Using the AUDIT FILECONTROLS\(BACKUP\) command” on page 1266](#)
 (APAR OA63126, which also applies to z/OS V2R4 and V2R5.)
- Transparent Cloud Tiering Disaster Recovery Enhancement has been updated. For more information, see:
 - [“Error codes \(*ERR\) and diagnosis” on page 1295](#)
 - [“Using the AUDIT DATASETCONTROLS \(MIGRATION\) command” on page 1261](#)

- [“Configuring migration cleanup” on page 54](#)
- [“MIGRATIONCLEANUPDAYS: Specifying the number of days to keep MCDS data set records and statistics records” on page 1157](#)
- [“Syntax of the SETSYS command” on page 1057](#)
- [“Summary of DFSMSHsm default values” on page 1084](#)
- [Chapter 77, “Using the QUERY command,” on page 1389](#)

(APAR OA63678, which also applies to z/OS V2R4 and V2R5.)

- The INUSE keyword description was updated for Chapter 32. BACKDS command. For more information, see [“INUSE: Tailoring backup processing of UNIX files in use at the time of backup” on page 766](#). (APAR OA65396, which also applies to z/OS V2R4 and V2R5.)
- The -I option description was updated for Chapter 73. Java hbackup command. For more information, see [“Optional parameters of the Java hbackup command” on page 1247](#). (APAR OA65396, which also applies to z/OS V2R4 and V2R5.)

Part 1. DFSMSHsm Storage Administration Guide

This topic describes the tasks that must be performed to use DFSMSHsm, a component of DFSMS that manages your storage in a hierarchical manner. It contains examples of the commands needed to perform the tasks, descriptions of the processing that DFSMSHsm performs, and examples of the results of that processing.

Introduction

Chapter 1, “Welcome to DFSMSHsm,” on page 7 explains how to use this document and describes the functions of the DFSMSHsm program, highlighting the following information:

- The tasks that you perform to make DFSMSHsm do useful work.
- An overview of how DFSMSHsm moves data.
- How to use this document. You are introduced to the example system, which is referred to throughout the rest of this document.

Space management

The following topics introduce the tasks necessary to control space management functions. Space management is the DFSMSHsm program function that you use to ensure that your customers have space available on DASD volumes to allocate new data sets or to extend old ones. You can make the space available by deleting data sets that have outlived their usefulness, removing unused allocated space from data sets, moving low-activity data sets from level 0 volumes to other DASD or tape volumes, and returning the moved data sets to the level 0 devices when the data sets are needed.

- Chapter 2, “Space management of SMS-managed storage,” on page 23, describes the tasks to be performed and the results of processing for space management of data sets managed by the storage management subsystem (SMS).
- Chapter 3, “Space management of non-SMS-managed storage,” on page 99, describes the tasks to be performed and the results of processing for space management of data sets not managed by SMS.
- Chapter 4, “Other space management considerations,” on page 127, describes aspects of space management that deserve consideration but are peripheral to the discussions in the two preceding topics.
- Chapter 5, “Space management procedures,” on page 161, describes procedures for starting and stopping space management under varying conditions.

Functions of space management:

- Automatically delete, remove unused space from, and move data sets on DFSMSHsm-managed volumes to provide a specified amount of free space on each volume. The space management functions begin at a specified time of day and only on a specific day of a cycle. This operation is called *automatic primary space management*. The process of removing unused space from the data sets is called *space reduction*. Moving the data sets (as opposed to deleting or removing unused space from them) is called *migration*.
- Reconnect unchanged data sets that are recalled from ML2 tapes to their original ML2 tapes with the fast subsequent migration function.
- Ensure that a specified amount of space is available on DFSMSHsm-managed volumes. If DFSMSHsm finds any volume without the specified amount of space, it performs migration from all such volumes (known as *event-driven migration*) following a space check.
- Automatically clean up migration volumes and the migration control data set (MCDS). This function and the following one are known as *automatic secondary space management*.
- Automatically, or by command, migrate data sets from level 1 migration volumes to level 2 migration volumes.

- Automatically recall needed migrated data sets to level 0 volumes.
- Recall migrated data sets to level 0 volumes by command.
- Delete eligible data sets on a non-SMS-managed volume by command.
- Delete eligible non-SMS migrated data sets on a migration volume by command.
- Migrate individual data sets or eligible data sets on a volume by command.

Availability management

The following topics introduce the tasks necessary to control availability management functions. Availability management is the function of the DFSMSHsm program that you use to ensure that your customers can retrieve usable copies of their data sets should their online copies become lost or damaged. You can make the copies available by making daily incremental backup copies of changed data sets, making periodic dump copies of the DFSMSHsm-managed and ML1 volumes, making aggregate backup copies of data sets that your operation will need if your installation is damaged, and making fast replication backup versions for sets of storage groups.

- [Chapter 6, “Availability management of SMS-managed storage,” on page 165](#), which describes the tasks to be performed and the results of processing for availability management of data sets managed by SMS.
- [Chapter 7, “Availability management of non-SMS-managed storage,” on page 303](#), which describes the tasks to be performed and the results of processing for availability management of data sets not managed by SMS.
- [Chapter 8, “Aggregate backup and recovery support \(ABARS\),” on page 319](#), which describes the command-driven functions that back up and recover a user-defined group (aggregate group) of data sets.
- [Chapter 9, “Making disaster backup copies of DFSMSHsm-owned tape volumes,” on page 435](#), which describes how to make backup copies of DFSMSHsm-owned, cartridge-type, single-file-format tape volumes and how to recover those volumes.
- [Chapter 10, “Other availability management considerations,” on page 445](#), which describes aspects of availability management that deserve consideration but are peripheral to the discussions in the preceding topics.
- [Chapter 11, “Availability management procedures,” on page 485](#), which describes procedures for starting and stopping availability management under varying conditions.

Functions of availability management:

- Automatically make backup copies of individual changed data sets on DFSMSHsm-managed volumes. This is known as incremental backup. You can specify how frequently to back up data sets on a data set basis for SMS-managed data sets and on a system-wide basis for non-SMS-managed volumes. You can specify on a system-wide basis how often backup runs.
- Automatically make dump copies of DFSMSHsm-managed level 0 volumes and ML1 volumes on a specified schedule for day and time. You can dump different groups of volumes on different days with different periods for the number of days between dumps.
- Allow your customers to issue commands to recover their own data sets.
- Allow your customer to issue the HBACKDS command from a batch environment. See [“Inline backup” on page 447](#).
- By command, back up user data sets.
- By command, back up data sets of an application to tape so they can be taken to another computer site for recovery.
- By command, recover user data sets or data sets of an application to their original system environment at another computer site.
- By command, restore a volume from a dump copy and update the restored volume from later incremental backup versions.

- By command, recover a specific data set from either a dump copy or an incremental backup version.
- By command, create a fast replication backup of a copy pool.
- Automatically or by command, create a dump copy of a fast replication DASD backup version
- By command, recover volumes that have a fast replication backup version.
- By command, recover data sets from fast replication backup versions

Backup function

Backup is the process of copying a data set from a level 0 or an ML1 volume to daily backup volume. This copy is called a backup version. The purpose of backup is to have copies of data sets in case something happens to the original data sets. The difference between dump and backup is that the dump function backs up the entire allocated space on a volume, whereas the DFSMSHsm backup function backs up individual data sets.

DFSMSHsm can create backup versions of data sets either automatically or by command. DFSMSHsm automatically creates backup versions of data sets on specified days beginning at a specified time of day. The data sets must meet eligibility criteria and must be on DFSMSHsm-managed volumes that have been designated for automatic backup.

Fast replication function

Fast replication uses volume-level fast replication to create backup versions for sets of storage groups. You can define a set of storage groups through the SMS copy pool construct. The DFSMSHsm FRBACKUP command creates a fast replication backup version for each volume in every storage group defined within a copy pool. The fast replication backup versions can be dumped to tape. The dump copies can be created by using the FRBACKUP command or with Automatic Dump processing. You can use FRBACKUP to dump an existing fast replication backup version, or when no backup version exists, create a fast replication backup version and dump it to tape. In all cases, the dump copies are associated with the original source DASD volumes in the copy pool, but not with the target DASD volumes that are actually dumped. The dump time stamps reflect when the fast replication backup version is made, not the actual time of the dumps. Recovery from a fast replication backup version can be performed at the copy pool level from a disk copy, at the individual volume level from a disk or tape copy, or at the data set level from a disk or tape copy. This Fast Replication function enables the backup and recovery of a large set of volumes to occur within a small time frame.

The term fast replication refers to the FlashCopy® function supported by IBM System Storage disk and the SnapShot function supported by IBM RAMAC Virtual Array (RVA) disk.

Dump function

Dump is the process of copying all data from a DASD volume to dump tape volumes. Full-volume dump is an extension of DFSMSHsm's availability management that invokes DFSMSdss through the DFSMSdss application interface. Full-volume dump backs up the entire allocated space of DFSMSHsm-managed DASD volumes and ML1 volumes either automatically or by command. Non-DFSMSHsm-managed volumes are dumped only by command. The purpose of the full-volume dump is to expedite the recovery process when an entire volume is lost or damaged and to supplement the incremental recovery process.

The full-volume-dump process can be one volume in and one dump copy out. It can also be one volume in and multiple dump copies out. Each dump copy is a complete image of the dumped volume, not just an incremental backup of selected data sets. Each successive full-volume dump of a volume, regardless of the number of dump copies, is a generation. Each dump copy in a generation is associated with a different dump class, which specifies how the dump copy is to be managed. DFSMSHsm allows from one to five dump copies to be made concurrently for any one full-volume dump. DFSMSdss discontinues writing to dump copies on which errors occur. DFSMSdss creates the multiple copies and continues its full-volume-dump process as long as one output copy is good. DFSMSHsm discards the contents of only the bad copies and issues an appropriate message. If all copies fail, the full-volume dump is failed.

DFSMSHsm keeps 100 generations of dump copies for any given volume unless all the copies in a generation expire. When all dump copies in any generation for a volume reach their expiration dates, DFSMSHsm deletes that generation from its records. When the 100 generations for a particular volume have been reached and the next full-volume dump for that volume is performed, the control records for the oldest generation are discarded, regardless of the retention periods of the individual copies.

Types of backup volumes

You can define the following types of tape or DASD backup volumes to DFSMSHsm:

- **Daily backup volumes:** Daily backup volumes are assigned to a specific day in the backup cycle and contain the backup versions created on that day. DFSMSHsm creates these backup versions during the backup of a level 0 volume or during the backup of migrated data sets. Daily backup volumes can also contain backup versions created by the BACKDS command. However, the daily backup volume used to contain these manually backed up versions does not necessarily correspond to the day in the backup cycle when DFSMSHsm created the backup version. Instead, the daily backup volume corresponds to the day in the backup cycle that DFSMSHsm moved the backup version from its temporary location on an ML1 volume to a daily backup volume.
- **Fast replication target volumes:** Fast replication target volumes contain the fast replication backup copies of DFSMSHsm-managed volumes. Fast replication target volumes are defined with the SMS copy pool backup storage group type.
- **Spill backup volumes:** Spill backup volumes contain older backup versions of data sets. These backup versions are moved to spill backup volumes when DFSMSHsm needs more space on DASD daily backup volumes. Tape spill volumes also receive all valid backup versions of data sets when a tape backup volume is recycled.
- **Unassigned backup volumes:** DFSMSHsm uses unassigned volumes whenever it needs more daily or spill backup volumes. There are two types of unassigned volumes: unassigned daily backup volumes and unassigned backup volumes. When DFSMSHsm selects an unassigned volume during backup processing, DFSMSHsm assigns it as a daily or spill backup volume.
 - Unassigned daily backup volumes are those volumes defined to DFSMSHsm as daily backup volumes but not associated with any day in the backup cycle. DFSMSHsm can use these volumes only as daily backup volumes, but DFSMSHsm determines which day in the backup cycle the volume should be assigned to when it first uses the volume.
 - Unassigned backup volumes are those volumes defined to DFSMSHsm as backup volumes but not specified as daily or spill backup volumes. When it first uses unassigned backup volumes, DFSMSHsm assigns the volumes as daily or spill backup volumes. If DFSMSHsm uses a volume as a daily backup volume, DFSMSHsm determines which day in the backup cycle the volume should be assigned to.

When DFSMSHsm needs another daily backup volume, it chooses an unassigned daily backup volume before it chooses an unassigned backup volume.

Recovery and restore of data sets

Recovery and restore are processes that are requested only by command, not automatically, for backed up data sets. Recovery is the process of retrieving a full-volume dump or a backup version of a data set or a volume. Restore signifies that DFSMSdss is used to retrieve dumped data from dump volumes. You can use restore or recover processing to:

- Recover a data set that has been lost or damaged.
- Recover an earlier version of the data set without deleting the current version.
- Restore a volume from a full-volume dump and update the volume from later incremental backup versions.
- Restore a data set from a dump copy.
- Restore a volume from a full-volume dump.
- Recover a volume from DFSMSHsm backup versions.

- Recover a pool of volumes from the fast replication backup versions on DASD.
- Recover a single volume from the fast replication backup versions on DASD or tape.
- Recover a data set from the fast replication backup versions on DASD or tape.

DFSMSHsm volume recovery can use incremental backups or full-volume dumps or both. One DFSMSHsm RECOVER command can be used to request both a volume restore and an incremental volume recovery.

DFSMSHsm can recover data sets from a DFSMSHsm incremental backup version or from a DFSMSHsm dump copy. DFSMSHsm automatically chooses the more recent copy of the data set if you allow users to perform data set restores (see [“Controlling restoring of individual data sets from dump tapes”](#) on page 172).

There are special considerations for full volume restores of volumes that were dumped using the BACKVOL DUMP command and whose data sets contain RLS attributes.

DFSMSHsm support activities

The following topics introduce the activities necessary to maintain DFSMSHsm-owned data sets and volumes. In addition to the activities that cause the DFSMSHsm program to perform its space management and availability management functions, certain other activities maintain the security and efficiency of DFSMSHsm itself. For example, backup copies of the control data sets should be kept, and the DFSMSHsm-owned volumes must be maintained.

- Chapter 12, [“Maintaining DFSMSHsm control data sets,”](#) on page 493, describes the activities necessary to ensure that you can recover from damaged or lost DFSMSHsm control data sets.
- Chapter 13, [“Managing DFSMSHsm media,”](#) on page 527, describes the activities necessary to manage data stored on DFSMSHsm-owned volumes.
- Chapter 14, [“Obtaining information from DFSMSHsm,”](#) on page 559, describes the information that you can obtain from DFSMSHsm about its operations and the data sets and volumes that it is managing.
- Chapter 15, [“DFSMSHsm tape libraries,”](#) on page 589, explains DFSMSHsm automated and manual tape libraries.
- Chapter 16, [“Using DFSMSHsm with DFSMSrmm,”](#) on page 591, explains the interaction between DFSMSHsm and DFSMSrmm when managing DFSMSHsm tape volumes.
- Chapter 17, [“Operating procedures for DFSMSHsm,”](#) on page 593, describes procedures to be performed by the computing system operator.
- Chapter 18, [“RACF considerations,”](#) on page 617, discusses pertinent RACF information. RACF is a component of the Security Server for z/OS. This information includes the use of discrete and generic profiles with DFSMSHsm, and the use of FACILITY class profiles with regard to command control access in DFSMSHsm.
- Chapter 19, [“Health Checker for DFSMSHsm,”](#) on page 627, describes information about Health Checker for DFSMSHsm.

Data recovery scenarios

Chapter 20, [“Data recovery scenarios,”](#) on page 629, describes real-life examples of data loss and recovery situations. It describes a variety of situations where data is lost, and what steps to take to recover that data. It also includes situations where the lost data is a control data set or journal.

Chapter 1. Welcome to DFSMShsm

DFSMShsm is a functional component of the DFSMS family, which provides facilities for managing your storage devices. DFSMShsm is a DASD storage management and productivity tool for managing low-activity and inactive data. It relieves you from manual storage management tasks and improves DASD use by automatically managing both space and data availability in a storage hierarchy. DFSMShsm cooperates with the other products in the DFSMSdftp family to provide efficient and effective storage management.

DFSMShsm provides a storage management subsystem (SMS) that allows storage administrators to control the use of storage. The storage management subsystem provides storage groups, storage classes, management classes, and data classes that control the allocation parameters and management attributes of data sets. DFSMShsm performs space management and availability management of each data set as directed by the management class attributes of that data set. In addition, the storage group controls the allocation of the data set when DFSMShsm returns the data set to level 0 (L0) storage.

Purpose of space management

Space management is the function of DFSMShsm that allows you to keep DASD space available for users in order to meet the service-level objectives for your system. The purpose of space management is to manage your DASD storage efficiently. To do this, space management automatically and periodically performs functions that (1) move low-activity data sets from user-accessible volumes to DFSMShsm volumes, (2) move data sets from one class of user-accessible volumes to another class of user-accessible volumes, and (3) reduce the space occupied by data on both the user-accessible volumes and the DFSMShsm volumes. The DFSMShsm space management functions are:

- Automatic primary space management of DFSMShsm-managed volumes, which includes:
 - Deletion of temporary data sets
 - Deletion of expired data sets
 - Release of unused, over-allocated space
 - Migration to DFSMShsm-owned migration volumes
 - Transitions between different classes of user-accessible volumes
- Automatic secondary space management of DFSMShsm-owned volumes, which includes:
 - Migration level cleanup, including deletion of expired migrated data sets and some migration control data set (MCDS) records
 - Moving migration copies from migration level 1 (ML1) to migration level 2 (ML2) volumes
- Event-driven migration and transitions, initiated when a DFSMShsm-managed volume exceeds a specified threshold
- Automatic recall of user data sets back to DASD volumes
- Space management by command
- Space-saving functions, which include:
 - Small data set packing
 - Partitioned data set compression
 - Data compaction and zEDC compression
 - Data set reblocking

Purpose of availability management

Availability management ensures that a recent copy of your DASD data set exists. Availability management ensures that lost or damaged data sets can be retrieved at the most current possible level.

To do this, availability management automatically and periodically performs functions that (1) copy all the data sets on DASD volumes to tape volumes and that (2) copy the changed data sets on DASD volumes either to other DASD volumes or to tape volumes. By copying the data sets, DFSMSHsm minimizes the space that is occupied by the data set on the backup volume. Availability management comprises the following functions:

- Aggregate backup and recovery
- Automatic physical full-volume dump
- Automatic incremental backup
- Automatic control data set backup
- Command dump and backup
- Command recovery
- Disaster backup
- Expiration of backup versions
- Fast replication backup and recovery

What you are expected to do

Making DFSMSHsm perform useful work in your system requires four sets of tasks:

- Installing DFSMSHsm and its required data sets in the system
- Specifying to DFSMSHsm the automatic and command activities that it must perform
- Monitoring and tuning the operations of DFSMSHsm
- Partitioning the DFSMSHsm activities between systems (z/OS images) that share storage which must be managed. Establishing one or more DFSMSHsm address spaces (hosts) for each of those z/OS images

The first of these sets of tasks is described in the [*z/OS DFSMSHsm Implementation and Customization Guide*](#). DFSMSHsm provides a starter set of DFSMSHsm commands used at each DFSMSHsm startup in SYS1.SAMPLIB to help you get started using DFSMSHsm.

This guide describes the second, third, and fourth sets of tasks. That is, it describes how to use DFSMSHsm to manage your storage, how to monitor and tune DFSMSHsm operations, and how to partition DFSMSHsm activities between all of the DFSMSHsm hosts. Because this document is designed as a textbook, you can learn about DFSMSHsm tasks by reading this document from beginning to end. However, because this document is organized by tasks, once you understand which tasks you want to perform, you can go to specific topics to learn all of the necessary activities for that specific task.

Related reading

- For more information about the starter set, see [*z/OS DFSMSHsm Implementation and Customization Guide*](#).
- For more information about whether and how you need to partition DFSMSHsm activities, see [Chapter 17, “Operating procedures for DFSMSHsm,”](#) on page 593.

Tasks for managing storage with DFSMSHsm

The following set of tasks for using DFSMSHsm to manage storage has been defined:

- Setting overall DFSMSHsm system parameters. This task consists of defining those parameters that DFSMSHsm uses, no matter which of its functions it is to perform.
- Performing space management. This task consists of:
 - Defining the parameters that DFSMSHsm uses for automatic space management
 - Issuing commands that cause DFSMSHsm to perform specific space management functions

- Performing availability management. This task consists of:
 - Defining the parameters that DFSMSHsm uses for automatic availability management
 - Issuing commands that cause DFSMSHsm to perform specific availability management functions
- Maintaining the control data sets. This task consists of backing up and maintaining correct contents for the data sets that DFSMSHsm uses to keep track of the data sets that it is managing.
- Managing DFSMSHsm media. This task consists of eliminating not valid data sets from DFSMSHsm volumes and in using DFSMSHsm to move data sets when new kinds of volumes are introduced into your system.
- Determining what occurs in DFSMSHsm. This task consists of using commands that cause DFSMSHsm to issue reports of what has occurred under specific conditions and of reading and interpreting the reports.
- Running DFSMSHsm in a simulation mode. This task consists of using DFSMSHsm as though you were managing storage, but having DFSMSHsm only issue a report instead of actually moving data sets. The purpose of the task is to analyze the results that would be obtained by using DFSMSHsm commands in the way you planned to use them.
- Operating DFSMSHsm. This task consists of directing the operations that start, stop, and interrupt DFSMSHsm.

Overview of DFSMSHsm functions

Figure 1 on page 10 shows the generalized flow of data in DFSMSHsm. The user's data is stored on level 0 volumes, either SMS-managed or non-SMS-managed.

Your objective in using DFSMSHsm is to make the most efficient use of all your DASD storage, primarily by making better use of the level 0 volumes. Better use of the level 0 volumes results when:

- You specify thresholds for DFSMSHsm-managed volumes, and you can assure the users that space will be available for extending old data sets or allocating new data sets (space management).
- You can assure the users that a copy of their data sets will be available if the data sets should accidentally be lost from the level 0 volumes (availability management). Such assurance that you can provide backup copies may encourage users not to unnecessarily maintain their own backup copies on level 0 volumes.

DFSMSHsm allows you to perform both availability management and space management automatically, periodically, and by issuing specific commands when manual operations are necessary or desirable. The dump and backup copies are made to tape (for dump) or to DASD or tape (for backup).

Rule: If a data set is larger than the free space on the DASD backup or migration volume, then the migration or backup will fail.

DFSMSHsm can then restore the volumes and recover the data sets when they are needed to replace destroyed or damaged data sets.

Note:

1. The term "level 0" refers to all DASD volumes that contain user-accessible data. While there is a single level 0 tier within the overall storage hierarchy, it is generally comprised of many different classes of devices. For example, solid state drives (SSD) and SATA drives represent two unique classes. For simplicity, all classes will be generally referred to singularly as level 0.
2. Only level 0 DASD volumes can be SMS managed. Migration DASD and backup DASD should never be managed by SMS. Migration, backup, and dump tapes can be SMS-managed in tape libraries.
3. DFSMSHsm allows use of the cylinder-managed space on extended address volumes (EAVs) for migration copies and backup versions. Use the SETSYS USECYLINDERMANAGEDSPACE command to manage allocation of ML1, ML2, or backup data sets on cylinder managed space. See Chapter 65, "SETSYS command: Establishing or changing the values of DFSMSHsm control parameters," on page 1057 for more information.
4. Although DFSMSHsm performs the same functions of copying, moving, and deleting data sets for both SMS-managed and non-SMS-managed volumes, the kinds and levels of control are different.

Therefore, these DFSMSShsm functions are described separately for SMS-managed volumes and for non-SMS-managed volumes.

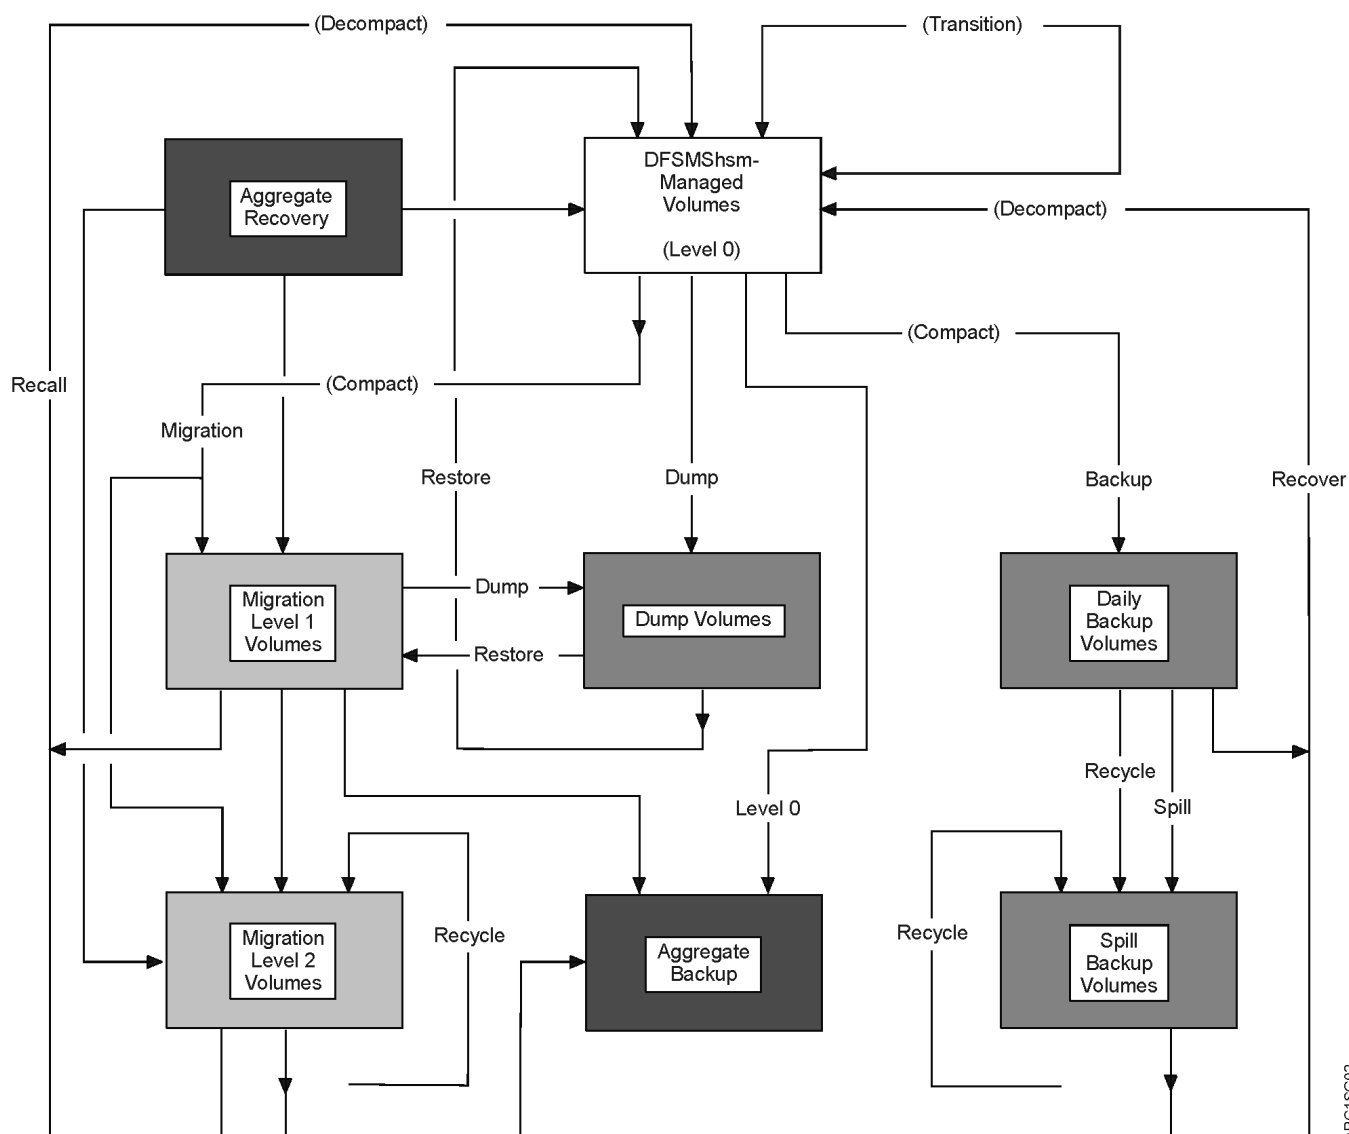

Figure 1. Data Set Flow in DFSMSShsm

DFSMSShsm functions for SMS-managed volumes

For SMS-managed level 0 volumes, the attributes specified in the storage groups and the management classes govern how DFSMSShsm performs automatic space management and incremental backup. You can override many of the attributes in the storage groups and management classes when the functions are performed by issuing specific commands. See [Figure 1 on page 10](#) when reading the following descriptions.

Note: If you have converted a non-SMS-managed L0 volume to an SMS-managed volume, you should:

- Add the volume to a storage group having the desired SMS attributes.
- DELVOL the volume to remove non-SMS attributes. Unexpected failures, for instance in autobackup processing, might occur if the volume is not DELVOLed.

Related reading

For more information about conversion, see [z/OS DFSMS Implementing System-Managed Storage](#).

Use of storage groups and management classes

By managing storage with SMS, you establish the following:

- Storage classes to define levels of service provided to data sets
- Storage groups to govern the volumes to which data sets are allocated and subject to management by DFSMSHsm
- Storage groups to define which volumes are used as target volumes of the fast replication backup versions
- Management classes to define how DFSMSHsm manages the data sets
- Data classes to govern values for initially allocating the data sets
- Automatic class selection (ACS) routines that automatically select storage classes, management classes, data classes, and storage groups to govern the data sets

DFSMSHsm is concerned mainly with DASD storage groups and with management classes. DASD storage groups allow you to pool volumes for the purpose of defining how and whether:

- Automatic dumps are performed on the volumes and to what dump classes
- Automatic backups are performed on the volumes
- Automatic volume space management is performed on the volumes and at what level of occupancy

Management classes allow you to group data sets logically and specify how they are managed by space management and availability management.

As users allocate data sets, the automatic class selection routine associates them with the appropriate storage class, storage group, management class, and data class (data and management classes are optional). If a data set is not SMS managed, SMS does not associate any class or storage group with the data set.

The storage group and the management class are related only by the needs of particular data sets. That is, SMS can allocate data sets that are associated with different management classes to the volumes assigned to a single storage group. Thus, in using DFSMSHsm to manage SMS-managed storage, you must think in terms of managing data sets rather than in terms of managing volumes. (An exception to the preceding statement is the automatic dump function, which operates on a volume basis.)

Dump and restore functions

Because automatic dump is a volume function, the attributes that govern it are taken from the storage group. As [Figure 1 on page 10](#) shows, DFSMSHsm copies the data sets from level 0 volumes to dump volumes. Dump can be performed only on complete volumes.

Restore, the reverse of dump, moves dumped data sets from dump volumes to level 0 volumes. There are conditions under which a data set, in contrast to a volume, can be restored.

Related reading

- For more information about restoring a non-VSAM data set, see [“Restoring a non-VSAM data set from a dump copy” on page 247](#).
- For more information about restoring a VSAM data set, see [“Restoring a VSAM data set from a dump copy” on page 247](#).

Backup and recovery functions

The backup function is a data-set-level function when DFSMSHsm is processing SMS-managed volumes. That is, the management class attributes define how the data set is treated for creation and retention of backup versions. Thus, on the same volume you can have data sets with different:

- Permissions for automatic backup
- Conditions for command backup

- Minimum frequencies of backup
- Numbers of backup versions
- Retention periods for backup versions

For backup, DFSMSHsm makes copies (versions) of changed data sets residing on level 0 volumes onto backup volumes. DFSMSHsm uses the management class attributes and the guaranteed backup frequency attribute of the storage group for each data set to determine whether to copy the data set. After the data sets have been backed up, DFSMSHsm determines from the management class attributes for each data set how many backup versions to keep and how long to keep them.

Backup can occur to either DASD or tape, whichever you specify. If backup is performed to DASD, your DASD volumes can become filled with the current backup versions and earlier backup versions that have not been discarded. When DASD backup volumes become full, DFSMSHsm transfers the old (non-current but valid) backup versions to spill backup volumes. Transfer of valid versions from DASD backup volumes can be either to tape or to DASD.

If the backup or the spill processes are performed to tape, the tapes eventually contain many not valid versions that have been superseded by the more current versions that have been made. When tape volumes have many not valid versions, they are selected by the recycle process, which moves valid versions to spill backup volumes.

Recovery, the reverse of backup, returns data sets from the daily backup volumes or the spill backup volumes to the level 0 volumes. Recovery can be performed only by command, for individual data sets or for complete volumes.

Aggregate backup and recovery functions

The aggregate backup and recovery support (ABARS) allows you to back up and recover a user-defined group of data sets. The user-defined group of data sets can be those belonging to an application or any combination of data sets that you want treated as a separate entity. With the aggregate backup and aggregate recovery functions, you can:

- Define the components of an aggregate
- Back up data sets by aggregate
- Recover data sets by aggregate
- Duplicate your aggregates at a remote site
- Resume business at a remote location if necessary

When the NetView File Transfer Program is installed on any two nodes, it can be used to transfer copies of aggregate backup files by running a batch job or using NetView File Transfer Program input panels. The NetView File Transfer Program is referred to as NetView FTP in this book.

Related reading

For more information about ABARS, see [Chapter 8, “Aggregate backup and recovery support \(ABARS\),” on page 319](#).

Extended address volume (EAV) considerations

SMS will determine the volume selection logic for SMS managed data sets and EAVs. See [“Controlling allocations to extended address volumes \(EAVs\)” on page 129](#) and [Modifying the SYS1.PARMLIB IGDSMSxx member in *z/OS DFSMSdfp Storage Administration*](#).

Fast replication function

DFSMS provides a volume-level fast replication function that allows you to create a backup that is managed by DFSMSHsm with minimal application outage. The fast replication function supports the FlashCopy and SnapShot functions.

With a copy pool SMS construct, you can define a set of storage groups that DFSMSHsm processes collectively for fast replication functions. For recovery purposes, you can restore the fast replication backup versions for an entire volume or copy pool, or you can recover individual data sets from the fast replication backups.

Related reading

For more information, see [“Managing volume backups with fast replication” on page 254.](#)

Space management function

Space management consists of removing appropriate data sets from the level 0 volumes and reducing the space occupied on the level 0 volumes by the data sets that remain there. In removing the data sets, you can have DFSMSHsm either delete them entirely, migrate them to migration DASD or tape volumes, or transition them to other user-accessible DASD volumes. If you move the data sets to migration DASD or tape volumes (ML1 or ML2), they can still be automatically deleted from the migration volumes when they expire.

Rule: If a data set is larger than the free space on the DASD backup or migration volume, then the migration or backup will fail.

Note: DFSMSHsm allows use of the cylinder-managed space on extended address volumes (EAVs) for migration copies and backup versions. Use the SETSYS USECYLINDERMANAGEDSPACE command to manage allocation of ML1, ML2, or backup data sets on cylinder managed space. See [Chapter 65, “SETSYS command: Establishing or changing the values of DFSMSHsm control parameters,” on page 1057](#) for more information.

The space management functions of DFSMSHsm for SMS-managed volumes are performed on a data set level basis. That is, for each data set on a volume to be managed, DFSMSHsm uses the management class attributes of the management class with which the data set is associated to determine:

- Whether to release unused overallocated space
- Whether to delete the data set based on:
 - The amount of time since the data set was created
 - The amount of time since the data set was last used
 - An explicit date
- The minimum time to leave the data set unopened on the level 0 volume before migrating it
- Whether a data set on a level 0 volume is eligible to move to an ML1 volume or directly to an ML2 volume
- Whether to move the data sets on ML1 volumes to ML2 volumes
- For data sets on ML1 volumes, the minimum time to leave the data set unopened on both the level 0 volume and the ML1 volume before moving it to an ML2 volume
- A capability to migrate older generation data groups (GDGs)
- Whether to delete or migrate rolled-off generations if the data set was a member of a GDG
- Whether to transition the data set from one class of level 0 volumes to another, based on creation date, date since last referenced, or a specific periodic timeframe

DFSMSHsm uses the attributes from the storage group to determine which level 0 volumes to process for space management, how full the volume must be before data sets are migrated or transitioned from the volume, and how much free space should be on the volume after space management has finished.

As space management processes each volume, it first tries to make space on the volume by deleting expired and temporary data sets and by releasing over-allocated space in data sets that cannot be deleted. During extent reduction, DFSMSHsm releases any unused space in the data set, both internal and on the end, and places the data set on the same volume in as few extents as possible. If deleting data sets and releasing space does not make enough space available, DFSMSHsm uses the management class

to determine which data sets are eligible to transition to a different level 0 volume and which data sets are eligible to move to a migration volume.

Rule: All ML1 volumes must be DASD. If ML1 volumes become sufficiently full, DFSMSHsm moves migrated data sets from ML1 volumes to ML2 volumes as specified by either:

- The management class attributes for each data set
- The THRESHOLD parameter on the SETSYS ML1OVERFLOW command if you are using ML1 OVERFLOW volumes. See [“ML1OVERFLOW: Manage ML1 OVERFLOW volumes”](#) on page 1160.

ML2 volumes can be either DASD or tape. You can issue a DFSMSHsm command to move data sets from DASD ML2 volumes to tape ML2 volumes. As data sets on tape ML2 volumes become not valid, you can recycle the valid data sets to other tape ML2 volumes.

Recall, the reverse of migration, moves data sets from ML1 or ML2 volumes to level 0 volumes. With the recall function, DFSMSHsm returns data sets to storage groups as specified by SMS, whether the data set migrated from a volume in a storage group or not. This allows data sets that migrated before they were SMS-managed to be put under SMS management during recall. If a data set is recalled to an SMS-managed EAV volume, then the EATTR attribute of the data set is taken into consideration for level 0 volume selection.

DFSMS sysplex name support for DFSMSHsm automatic functions

Because DFSMSHsm supports the use of DFSMS sysplex names for the MIGRATE SYSTEM/SYSPLEX NAME, BACKUP SYSTEM/SYSPLEX NAME, and DUMP SYSTEM/SYSPLEX NAME storage group system name attributes, it handles each storage group for automatic space management, data availability management, and automatic dump processing as follows. How the storage groups are handled is referred to as the "system affinity" or "host affinity."

- If the storage group system name is a system name, the storage group is processed by that specific system.
- If the storage group system name is blank, the storage group can be processed by any system.
- If the storage group system name is a sysplex name, the storage group is processed by a subset of systems.

Each automatic function (automatic space management, data availability management, or automatic dump processing) is processed independently. Therefore, the various systems used by one automatic function will not affect the other automatic functions.

DFSMSHsm functions for non-SMS-managed volumes

For non-SMS-managed volumes, DFSMSHsm uses volume parameters to determine how each data set on the volume is managed.

Dump and restore functions

The dump function for non-SMS-managed volumes is governed by parameters of the DFSMSHsm commands, but it is performed the same way as for SMS-managed volumes. However, in addition to performing the automatic dump function for level 0 volumes, DFSMSHsm also performs automatic dump for ML1 volumes.

A data set dumped from a non-SMS-managed volume can be restored to an SMS-managed volume if the data set does not already exist, if SMS is active, and if the data set is indicated by the ACS routines to be SMS-managed.

Rule: Because the ML1 volumes are not managed by SMS—even in an environment in which all level 0 volumes are SMS-managed—you must use non-SMS-managed volume parameters to perform automatic dump for ML1 volumes.

Backup and recovery functions

The volume-basis operation of DFSMSHsm for non-SMS-managed volumes causes differences in how backup is performed. For non-SMS-managed volumes:

- If automatic backup is in effect for the volume, all changed data sets that DFSMSHsm can manage are backed up.
- All data sets processed by a particular DFSMSHsm host have the same backup frequency unless the frequency has been modified for that data set by a DFSMSHsm command.
- All data sets processed by a particular DFSMSHsm host have the same number of backup versions, unless the number of backup versions has been modified for that data set by a DFSMSHsm command.

In addition, you can specify the number of days to retain backup versions of non-SMS-managed data sets only by command parameters for the entire system complex.

A data set backed up from a non-SMS-managed volume can be recovered to an SMS-managed volume if the data set does not already exist, if SMS is active, and if the data set is indicated by the ACS routine to be SMS-managed.

How the system selects non-SMS extended address volume (EAV)

DFSMSHsm checks the data set level attribute EATTR when performing non-SMS volume selection. The EATTR data set level attribute specifies whether a data set can have extended attributes (format 8 and 9 DSCBs) and optionally reside in EAS on an extended address volume (EAV). The EATTR attribute is optional. If you do specify it, valid values are NO and OPT. For more information on the EATTR attribute, see [ALLOCATE](#) and [DEFINE CLUSTER](#) in *z/OS DFSMS Access Method Services Commands*.

If an EATTR value is not specified for a data set, the following default data set EATTR values are used:

- The default behavior for VSAM data sets is OPT.
- The default behavior for non-VSAM data sets is NO.

Preference for volume selection corresponds to the EATTR values for each data set:

- When EATTR = NO, the data set has no preference to any volume. For recalls, recovers and ARECOVERs the volume with the most amount of free space will be selected but only the track-managed free space will be used for determining the free space calculations of an eligible EAV. The data set will be allocated with a format 1 DSCB indicating that it is not eligible to have extents in the EAS.

If an EAV or non-EAV is chosen for allocation, **and** the value is EATTR=NO **and** the data set had a format 8 or 9 DSCB with vendor attributes, then the data set is allocated with a format 1 DSCB, and the system issues message ARC0784I to indicate that extended attributes have not been retained for this recall, recovery or ARECOVER. In this situation format 9 information of the data set will be lost on the recall, recovery or ARECOVER.

- When EATTR = OPT, the data set will prefer EAV volumes if the size of the allocation is equal to or greater than the BreakPointValue (BPV) specified. If the requested size of the data set allocation is smaller than the BPV then EAVs and non-EAVs will have equal preference.
 - If an EAV is chosen for allocation and the data set type is EAS-eligible, then the data set will be allocated with format 8 or 9 DSCBs in either the track-managed space or the EAS.
 - If a non-EAV is chosen for the allocation and the data set had format 8 or 9 DSCBs with vendor attributes, then the data set will be allocated with a format 1 and DFSMSHsm issues message ARC0784I signifying that extended attributes have not been retained for this recall, recovery or ARECOVER. The EATTR value will always remain in the format 1 DSCB.

EAV considerations for recovery functions

You can specify the EATTR value when allocating a data set to define whether the data set can have extended attributes (format 8 and 9 DSCBs) and optionally reside in EAS. In the event that a data set is being directed to a pre-allocated data set on a RECOVER or ARECOVER function, the system uses the

EATTR value of the pre-allocated data rather than the EATTR value specified for the data set source recovery data.

ARECOVER and EATTR considerations

The following methods can be used to allow the EATTR information from the ABACKUP site to be restored, along with the dataset:

- Use the DSCONFLICT(RENAMETARGET) parameter on the ARECOVER command, then manually delete the existing dataset. Since the ARECOVER resolved the conflict by renaming the existing dataset before restoring the ABARS copy, both copies will have their own EATTR. You only need to get rid of the renamed existing dataset.
- Use the DSCONFLICT(BYPASS) parameter on the ARECOVER command, manually delete the existing dataset and existing conflict resolution data set, then rerun the ARECOVER. Only the datasets that were bypassed or failed for some other reason on the first ARECOVER will be processed. Since no conflict exists anymore, you will get the ABARS copy, complete with its EATTR.

For more information, see the EATTR parameter of the [ALLOCATE](#) command in *z/OS DFSMS Access Method Services Commands*.

Space management function

Space management consists of removing appropriate data sets from the level 0 volumes and reducing the space occupied on the level 0 volumes by the data sets that remain there. In removing the data sets, you can have DFSMSHsm either delete them entirely or move them to other DASD or tape volumes. If you move the data sets to other DASD or tape volumes (ML1 or ML2), they can be automatically deleted from the migration volumes when they expire.

Differences in the way that DFSMSHsm performs space management for non-SMS-managed data sets include:

- The deletion age and management techniques are the same for all data sets on a volume managed by the deletion (delete by age) technique.
- The deletion age and management techniques are the same for all data sets on a volume managed by the retirement (delete if backed up) technique.
- The migration age and management techniques are the same for all data sets on a volume managed by the migration technique.
- The time for the data set to remain unopened before migration from ML1 to ML2 volumes is the same for all non-SMS-managed data sets in the system complex.
- Class transitions are not supported.

A data set migrated from a non-SMS-managed volume can be recalled to an SMS-managed volume if SMS is active and if the data set meets the conditions for selecting SMS management for that data set. DFSMSHsm recalls a non-SMS-managed data set to a non-SMS-managed volume only if the data set does not meet the conditions to become an SMS-managed data set, or if a command forces the recall to a non-SMS-managed volume.

Devices supported by DFSMSHsm

DFSMSHsm supports devices other than those specifically recommended in the examples in this document. For example, ML2 volumes can be either tape or DASD. Daily backup and spill backup volumes can also be either tape or DASD.

DFSMSHsm can be used on the following device types:

- All models of 3390, 9345, and 3380 DASD
- IBM 3494 and 3495 Tape Library Dataservers
- All models of 3590-1, 3490, 3480, 3480XF (with or without cartridge loaders), and 3592 (including Model J and Model E06, Model E06, and Model E07 tape drives)

- Cache storage controls for DFSMSHsm control data sets:
 - IBM 2105
 - IBM 2107
 - IBM 3990
 - IBM 3880 Model 23
 - IBM 3880 Model 13 (only indexes)
- Object Storage with OpenStack Swift API using Keystone or tempauth authorization

Note: DFSMSHsm normally uses only non-WORM media for non-ABARS functions. DFSMSHsm uses all media, including physical and logical WORM, for ABACKUP output processing. DFSMSHsm can use WORM media for non-ABARS processing and ARECOVER to tape, if specifically allowed by your installation. See the SETSYS TAPETYPE command for details.

Tip: For improved performance, the DFSMSHsm control data sets should be on cache storage controllers.

How to use the example system

Figure 2 on page 17 and Figure 3 on page 18 show two aspects of the example system used to explain DFSMSHsm. The figures are separated into SMS-related and non-SMS-related examples to simplify the discussions. Figure 4 on page 21 shows the unified system. The following major features affect the way in which the DFSMSHsm system commands are structured.

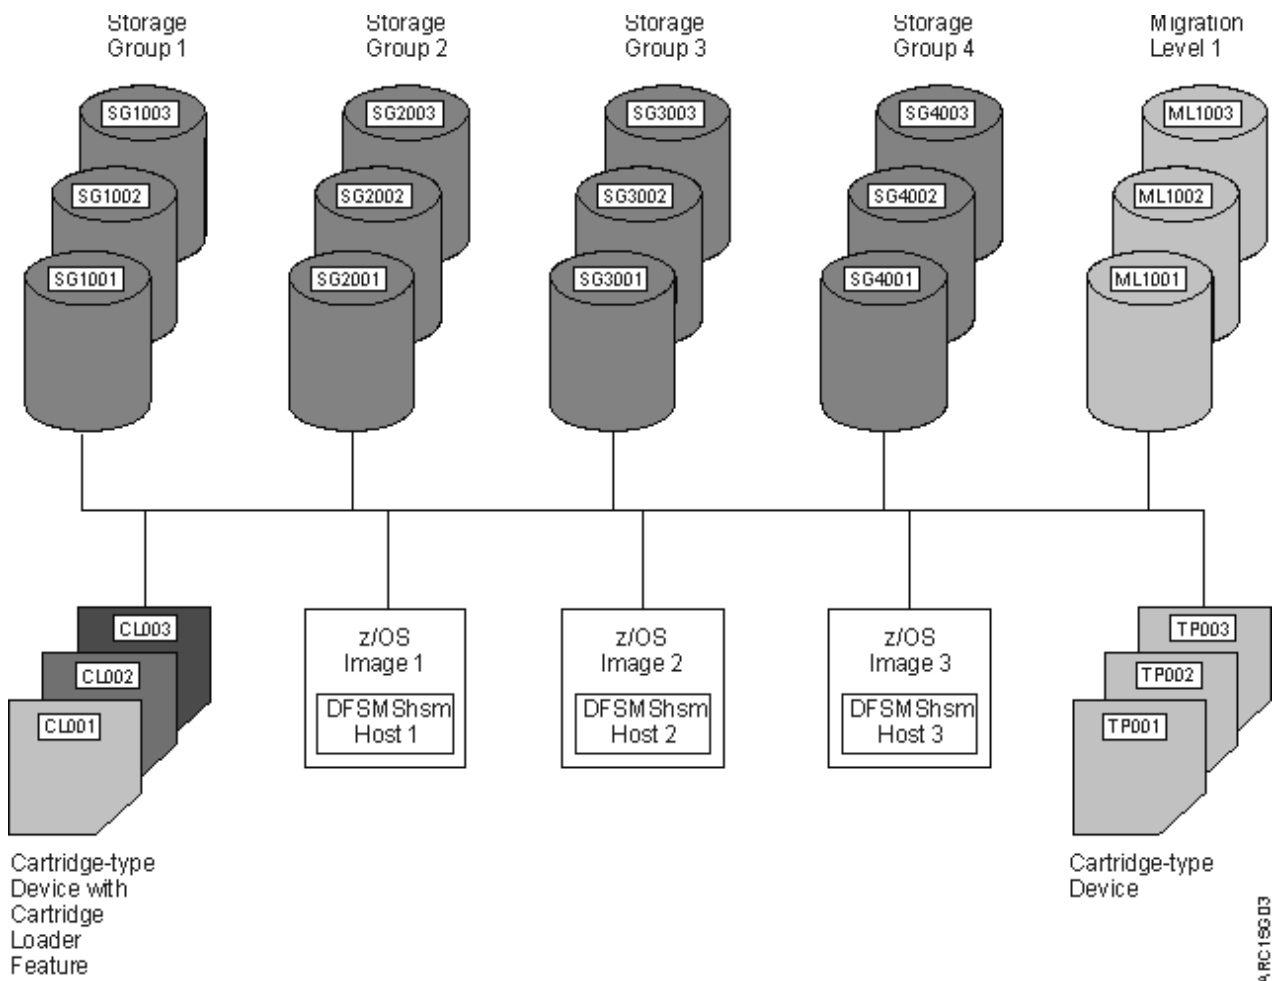

Figure 2. Example System of SMS-Managed Volumes

Note: Cartridge-type devices may be in a manual tape library (MTL) or in an automated tape library (ATL).

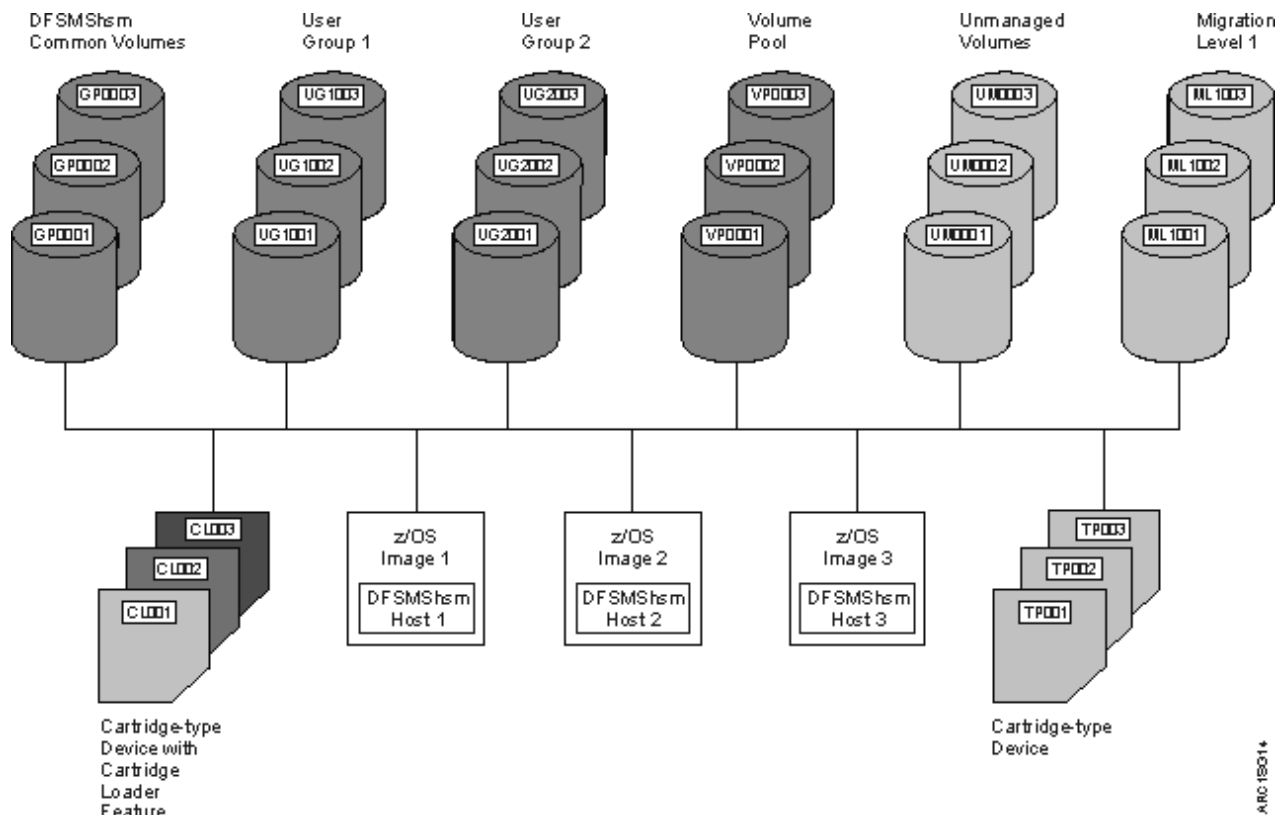

Figure 3. Example System of Non-SMS-Managed Volumes

Related reading

For more information about how to direct DFSMSHsm functions to a system-managed library, see [z/OS DFSMSHsm Implementation and Customization Guide](#).

Multiple z/OS images in the example system

Using multiple z/OS images allows the processing of a single DFSMSHsm host on one z/OS image or multiple DFSMSHsm hosts on more than one z/OS image. In the example system, there is one DFSMSHsm host per z/OS image. DFSMSHsm is shown running under JES2. However, when the use of a single z/OS image or of JES3 affects the selection of DFSMSHsm commands or the results attained with those commands, the differences that result from using JES3 instead of JES2 are explained.

Note: The z/OS images, tapes, and ML1 volumes shown in [Figure 2 on page 17](#) and [Figure 3 on page 18](#) are duplicated in both figures.

DASD storage in the example system

The example system shows only a limited number of DASD units in each classification. You can, of course, have any number of units in any of the classifications (up to the maximum channel and addressing capabilities of your system). All of the DASD is shared among all of the z/OS images. Where other sharing arrangements cause differences in the use of commands or in the results obtained, the differences are explained.

Storage groups 1 through 4

The example system uses DFSMSdftp to manage its storage. [Figure 2 on page 17](#) shows those elements of the system that are essential for using the SMS capability of DFSMSdftp. Storage groups 1 through 4 are the storage that is actually under control of the SMS at this time. The data sets on these volumes are the

ones referred to as SMS-managed. Expectations are that some of the DASD volumes shown in both this figure and in [Figure 3 on page 18](#) will be brought under SMS control as time goes on. This expectation applies only to the level 0 volumes, not to the DFSMSHsm-owned volumes.

User groups 1 and 2

User groups 1 and 2 ([Figure 3 on page 18](#)) are non-SMS-managed level 0 volumes that DFSMSHsm manages and that are reserved for particular groups of data sets. Data sets with particular high-level qualifiers in the data set names are directed to these volumes. Groups of volumes to which data sets are directed by their high-level qualifiers are known as *data set pools*.

Volume pool

The volume pool ([Figure 3 on page 18](#)) consists of non-SMS-managed volumes that are differentiated on some basis other than that of data set names. Data sets that are assigned to these volumes return to these volumes if they are migrated and recalled.

DFSMSHsm common volumes

The DFSMSHsm common volumes ([Figure 3 on page 18](#)) are the DFSMSHsm-managed volumes that contain non-SMS-managed data sets that do not belong on the volumes in either the user groups or the volume pools.

Unmanaged volumes

The unmanaged volumes ([Figure 3 on page 18](#)) are level 0 volumes that are not managed by either SMS or DFSMSHsm. DFSMSHsm operations can be performed on these volumes, but only by issuing commands. Automatic DFSMSHsm operations are not performed on these volumes.

Migration level 1

The ML1 volumes ([Figure 2 on page 17](#) and [Figure 3 on page 18](#)) are DFSMSHsm-owned volumes on which migrated data sets are stored. ML1 volumes are always DASD. As with the z/OS images, the ML1 volumes shown in both figures are the same volumes.

Tape devices in the example system

In the example system, there are two groups of tape devices, again duplicated in both figures. These devices are used for dump volumes, ML2 volumes, and backup volumes. ML2 and backup volumes can also use DASD.

Figures [Figure 2 on page 17](#), [Figure 3 on page 18](#), and [Figure 4 on page 21](#) show two groups of cartridge-type devices: those with cartridge loaders, and those without. The cartridge-type devices without cartridge loaders are used (in the example) mainly as input devices for recall and recovery because recall or recovery is always from a specific tape. The cartridge-type devices with cartridge loaders are used for output to backup, dump, and ML2 tapes because output can use scratch tapes (tapes that no longer contain valid data, and have been returned to the global scratch pool) and take advantage of the cartridge loader's ability to change tapes automatically.

Note: Cartridge-type devices may be in an MTL or an ATL.

For more information about manual tape libraries (MTLs) and automated tape libraries (ATLs), see [z/OS DFSMSHsm Implementation and Customization Guide](#).

Other assumptions in the example system

In order to understand how to use the example system, other assumptions must be made concerning your knowledge and concerning security systems for the example system.

Your knowledge

There is an assumption that you know about z/OS, DFSMSdfp, TSO, and RACF, a component of the Security Server for z/OS.

Under this assumption, if you are told to perform an action related to these products, you know how to perform that action without a discussion being necessary.

Security systems

So that you can be shown what DFSMSHsm does in relation to all types of data set protection, it is assumed that the example system provides the following:

- RACF or equivalent security system
- Expiration date protection for tapes

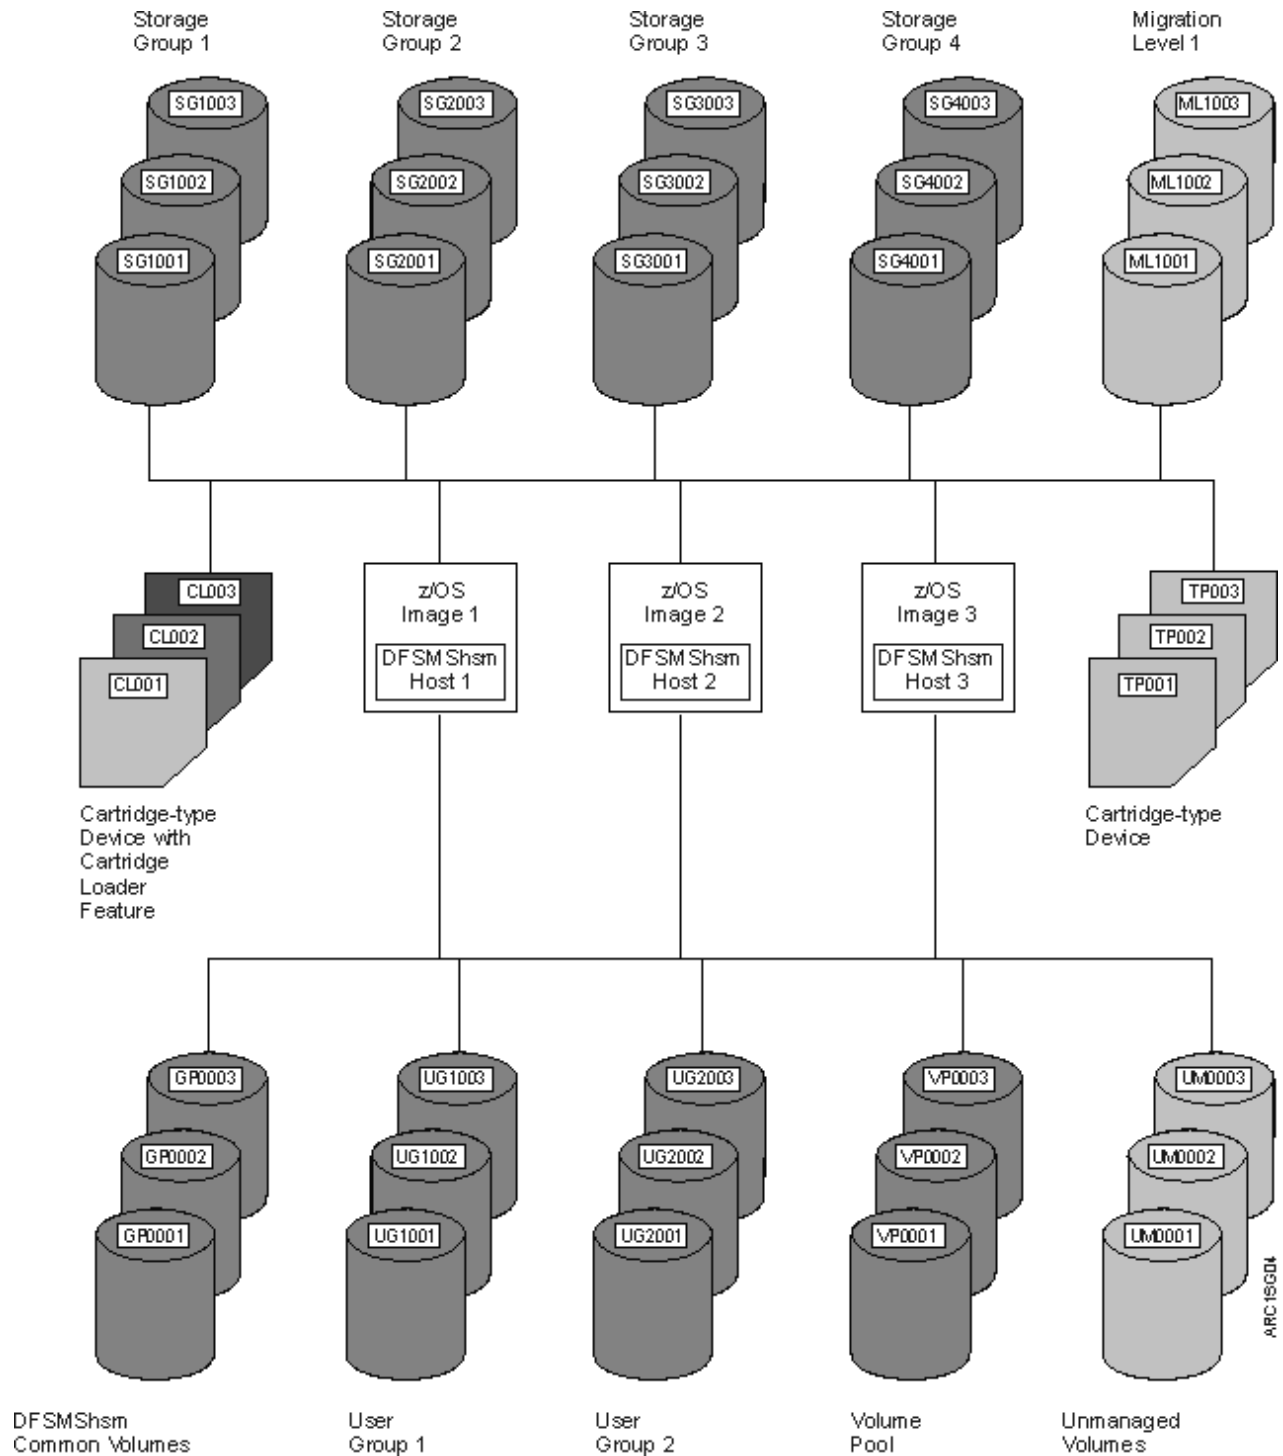

Figure 4. Comprehensive Example System

Chapter 2. Space management of SMS-managed storage

DFSMSHsm manages SMS-managed storage by data sets. That is, the specification for how to treat each data set on a volume is contained in the management class associated with that data set. The storage management subsystem determines to which volume the data set is recalled.

Related reading

To view the consolidation of all of the DFSMSHsm commands, storage group attributes, and management class attributes that show the automatic storage management of the example system, see [Chapter 21, “Consolidated commands, storage group definitions, and management classes for the example system,”](#) on page 653.

Space management functions

This topic describes the space management functions for managing SMS-managed storage:

- [“Automatic primary space management”](#) on page 23
- [“Automatic secondary space management”](#) on page 24
- [“Event-driven migration”](#) on page 24
- [“Automatic recall”](#) on page 32
- [“Automatic dynamic volume expansion space management”](#) on page 32
- [“Command space management”](#) on page 32

Related reading

Before performing space management functions on extended address volumes (EAVs) you need to understand how EAV space is managed. For details, see [“Space management of extended address volumes \(EAVs\)”](#) on page 127 and review recommendations in [“Recommendations for using extended address volumes \(EAVs\)”](#) on page 129.

Automatic primary space management

During automatic primary space management:

- All DFSMSHsm hosts delete temporary data sets and expired data sets from the DFSMSHsm-managed volumes they are processing. This is done under the control of the management class that is associated with each data set on the volume or the expiration date in the data set's volume table of contents (VTOC) entry.
- Under control of the data set management classes, all DFSMSHsm hosts release unused allocated space in physical sequential, partitioned, and extended format Virtual Storage Access Method (VSAM) data sets.
- During data set and volume processing, fast subsequent migration reconnects eligible data sets to the ML2 tape or cloud from which they were most recently recalled.
- Under the extent reduction function, all DFSMSHsm hosts also reduce the number of extents of physical sequential, partitioned, and direct access data sets that have exceeded a specified number of extents. During the process of extent reduction, they also release any unused space in the data sets and compress partitioned data sets.
- Data sets that are eligible for a class transition are transitioned. If a data set is eligible for both a class transition and migration, the data set will only be migrated. This prevents the data set from being moved from one level 0 volume to another for a transition, only to be later migrated to a migration volume.

- Data sets that are eligible for migration are migrated.

Primary space management continues until the SMS-managed volumes have the specified amount of free space. However, if deletion of expired data sets, fast subsequent migration, and space reduction of the remaining data sets achieves the specified volume free space low threshold, no actual data sets are moved.

If data sets are to be migrated during primary space management, they will be migrated in compacted form if possible. Data sets expected to be smaller than 110 KB (where 1 KB is 1024 bytes) after they are compacted are candidates for small data set packing (SDSP) if enabled.

- For other space management considerations, see [Chapter 4, “Other space management considerations,”](#) on page 127.
- For more information about space management of extended address volumes, see [“Space management of extended address volumes \(EAVs\)”](#) on page 127.

Automatic secondary space management

Automatic secondary space management schedules TAPECOPY commands for migration tape copy needed (TCN) records, deletes expired data sets from the *migration volumes*, deletes obsolete MCDs, VSRs, and DSRs during migration cleanup, and moves data sets (under control of the management class) from ML1 to ML2 volumes.

On the first day of the secondary space management cycle, DFSMSHsm will examine the containers in the clouds that are defined to DFSMSHsm and look for containers created using the current HSMplex name that do not have objects. Empty containers are deleted. If the end of the **Secondary Space Management** window has been reached and not all containers have been examined, the processing will continue in the next **Secondary Space Management** window.

Event-driven migration

Event-driven migration performs space management functions similar to primary space management, except it is event-driven instead of scheduled. Event-driven migration automatically and periodically moves low-activity data sets from DFSMSHsm-managed volumes to DFSMSHsm-owned volumes, transitions data sets from one class of user-accessible volumes to another, and reduces the space occupied by data sets on DFSMSHsm-managed volumes.

There are two event-driven migration methods:

- Interval migration. See [“Using interval migration”](#) on page 25.
- On-demand migration. See [“Using on-demand migration”](#) on page 27.

Related reading

- For a comparison of interval migration and tape mount management, see [“Comparison of interval migration and tape mount management”](#) on page 30.
- For an illustrative event-driven migration scenario, see [“Event-driven migration example scenario”](#) on page 81.
- For other space management considerations, see [Chapter 4, “Other space management considerations,”](#) on page 127.
- For more information about space management extended address volumes, see [“Space management of extended address volumes \(EAVs\)”](#) on page 127.
- For more information about how to quiesce event-driven migration during specific time windows, see [“EVENTDRIVENMIGRATION: Releasing Interval and On-demand Migration”](#) on page 1034.

Using interval migration

Interval migration is a space management function that performs *hourly* space management on eligible volumes that exceed specified volume threshold requirements. Interval migration migrates data sets to ML1 or ML2 volumes and transitions data sets from one class of user-accessible volumes to another until the low threshold is reached or there are no eligible data sets remaining.

During interval migration:

- Information about the SMS configuration is obtained:
 - A list of all volumes in all DFSMSHsm-managed storage groups is obtained.
 - A list of active management classes is obtained.
- The percent of allocated space on each volume in the obtained list is checked.
- A message is issued for unmatched data sets.
- Temporary data sets are deleted.
- Expired data sets are deleted.
- Data sets that are eligible for a class transition are transitioned. If a data set is eligible for both a class transition and migration, the data set will only be migrated. This prevents the data set from being moved for a transition, only to be later migrated.
- Data sets that are eligible for migration are migrated.

The following functions that are performed during primary space management are not performed during interval migration:

- Partial release.
- Extent reduction.

Specific interval migration eligibility requirements must be satisfied both at the volume level and the data set level. See [Interval migration eligibility requirements](#).

Enabling interval migration

Interval migration is enabled by default and there are two methods of explicitly enabling interval migration:

- Add the SETSYS INTERVALMIGRATION command to the ARCCMDxx parmlib member of SYS1.PARMLIB. Then restart DFSMSHsm.
- Issue the SETSYS INTERVALMIGRATION command after DFSMSHsm is started.

To determine if interval migration is enabled or disabled, issue QUERY SETSYS. Message ARC0151I is issued with the query response.

To use interval migration after it is enabled, eligibility requirements must be satisfied. See [Interval migration eligibility requirements](#).

Disabling interval migration

There are two methods of disabling interval migration:

- Add the SETSYS NOINTERVALMIGRATION command to the ARCCMDxx parmlib member of SYS1.PARMLIB. Then restart DFSMSHsm.
- Issue the SETSYS NOINTERVALMIGRATION command after DFSMSHsm is started.

Interval migration eligibility requirements

There are two sets of requirements that must be satisfied in order for a volume to be eligible for interval migration. The first set of requirements must be satisfied at the volume level. The second set of requirements must be satisfied at the data set level.

Requirements that must be satisfied at the *volume* level for interval migration to be performed are:

- The volume is either an SMS-managed or non-SMS-managed volume.
- The volume belongs to a storage group defined with AM=I (Auto Migrate, interval) or AM=Y (Auto Migrate, yes).
 - If the storage group is defined with AM=I, the volume must exceed the midpoint between the low and high threshold to be eligible.
 - If the storage group is defined with AM=Y, the volume must exceed the high threshold to be eligible.
 - If the storage group is defined with AM=Y, on-demand migration must not be enabled for the volume to be eligible. Otherwise, on-demand migration is performed.
- The SETSYS INTERVALMIGRATION setting is in effect.

Requirements that must be satisfied at the *data set* level for a data set to be transitioned or migrated from an eligible volume are:

- The management class for the data set is configured to allow both command or auto migration (COMMAND OR AUTO MIGRATE=BOTH)
- - For transitions:
 - The age of the data set has exceeded the management class TIME SINCE CREATION attribute value.
 - The last referenced date has met or exceeded the management class TIME SINCE LAST USE attribute value.
 - The current date has met or exceeded the PERIODIC time period specified in the management class.
- For migration, the inactive age of the data set has exceeded the management class PRIMARY DAYS NON-USAGE attribute value.
- If the data set is a candidate to be backed up:
 - It is not eligible for migration if the migration of the data set is directed to tape.
 - It is not eligible for a transition if the management class TRANSITION COPY TECHNIQUE specifies a technique other than STANDARD.

Interval migration usage notes and other considerations

1. Neither interval migration or on-demand migration is performed on SMS-managed volumes that belong to a storage group defined with AM=P (Auto Migrate, primary) or AM=N (Auto Migrate, no).
2. Interval migration is performed on volumes that belong to storage groups defined with AM=I regardless of whether interval migration is enabled or disabled.
3. When on-demand migration is enabled, on-demand migration is performed instead of interval migration on eligible SMS-managed volumes that belong to storage groups defined with AM=Y. For on-demand eligibility requirements, see [On-demand migration eligibility requirements](#).
4. If you want to require operator permission before allowing interval migration to run, issue the SETSYS REQUEST command.
5. If you want the operator to be notified of the space allocation of each volume during the interval migration space check, issue the SETSYS MONITOR(SPACE) command.
6. Data sets on SMS-managed volumes are processed in the following order:
 - a. Data sets eligible for a class transition and migration will be migrated.
 - b. Data sets eligible for a class transition will be transitioned.
 - c. Data sets eligible for migration only will be migrated. For this phase, data set size is a determining factor for the order and priority in which data sets are migrated. The largest eligible data set

migrates first, followed by the next largest. The priority for migrating data sets from volumes that belong to storage groups defined with AM=I applies when the low threshold exceeds 5% only.

7. In order for a data set to be migrated or transitioned by TIME SINCE LAST USE, the date of the current backup copy should be greater than the date-last-referenced by at least one day.
8. The current time is outside the time window(s) specified in SETSYS EVENTDRIVENMIGRATIONQUIESCE.

- For more information about storage groups and management classes, see [z/OS DFSMSdfp Storage Administration](#).

Using on-demand migration

On-demand migration is a space management function that performs *near immediate* space management on eligible SMS-managed volumes that exceed the specified volume high threshold, instead of waiting for interval migration to run at the top of each hour. On-demand migration migrates data sets to ML1 or ML2 volumes and transitions data sets from one class of user-accessible volumes to another until the low threshold is reached or there are no eligible data sets remaining.

During on-demand migration:

- DFSMSHsm listens for an ENF72 event code signal from SMS indicating a volume has exceeded the high threshold and queues the volume for processing.
- An eligible volume is selected from the queue for space management.
- The percent of allocated space on the selected volume is checked.
- A message is issued for unmatched data sets.
- Temporary data sets are deleted.
- Data sets that are eligible for class transitions are transitioned. If a data set is eligible for both a class transition and migration, the data set will only be migrated. This prevents the data set from being moved for a transition, only to be later migrated.
- Expired data sets are deleted.
- Data sets that are eligible for migration are migrated.

The following functions that are performed during primary space management are not performed during on-demand migration:

- Partial release.
- Extent reduction.

Specific on-demand migration eligibility requirements must be satisfied both at the volume level and the data set level. See [On-demand migration eligibility requirements](#).

Enabling on-demand migration

There are two methods of enabling on-demand migration:

- Add the SETSYS ONDEMANDMIGRATION(Y) command to the ARCCMDxx parmlib member of SYS1.PARMLIB. Then restart DFSMSHsm.
- Issue the SETSYS ONDEMANDMIGRATION(Y) command after DFSMSHsm is started.

On-demand migration is disabled by default.

To determine if on-demand migration is enabled or disabled, issue QUERY SETSYS. Message ARC0139I is issued with the query response.

To use on-demand migration after it is enabled, eligibility requirements must be satisfied. See [On-demand migration eligibility requirements](#).

Disabling on-demand migration

There are two methods of disabling on-demand migration:

- Add the SETSYS ONDEMANDMIGRATION(N) command to the ARCCMDxx parmlib member of SYS1.PARMLIB. Then restart DFSMSHsm.
- Issue the SETSYS ONDEMANDMIGRATION(N) command after DFSMSHsm is started.

On-demand migration eligibility requirements

There are two sets of requirements that must be satisfied in order for a volume to be eligible for on-demand migration. The first set of requirements must be satisfied at the volume level. The second set of requirements must be satisfied at the data set level.

Requirements that must be satisfied at the *volume* level for on-demand migration to be performed are:

- The volume is an SMS-managed volume.
- The volume belongs to a storage group defined with AM=Y (Auto Migrate, yes).
- The volume exceeds the high threshold.
- The SETSYS ONDEMANDMIGRATION(Y) setting is in effect.

Requirements that must be satisfied at the *data set* level for a data set to be migrated or transitioned from an eligible volume are:

- The management class for the data set is configured to allow both command or auto migration (COMMAND OR AUTO MIGRATE=BOTH)
- For transitions:
 - The age of the data set has exceeded the management class TIME SINCE CREATION attribute value.
 - The last referenced date has met or exceeded the management class TIME SINCE LAST USE attribute value.
 - The current date has met or exceeded the PERIODIC time period specified in the management class.

- For migrations, the inactive age of the data set has exceeded the management class PRIMARY DAYS NON-USAGE attribute value.
- If the data set is a candidate to be backed up:
 - It is not eligible for migration if the migration of the data set is directed to tape.
 - It is not eligible for a transition if the management class TRANSITION COPY TECHNIQUE specifies a technique other than STANDARD.

On-demand migration is **not** performed on non-SMS-managed volumes or SMS-managed volumes that belong to a storage group defined with AM=I (Auto Migrate, interval). Interval migration is performed instead.

On-demand migration in a multiple DFSMSHsm host environment

In a multiple DFSMSHsm host environment:

- Each host configured to perform on-demand migration selects eligible volumes for on-demand migration up to the configured maximum number of migration tasks (that is, the SETSYS MAXINTERVALTASKS command). As volumes are processed, each host selects from the remaining volumes until all volumes have been processed.

Note: MAXEVENTDRIVENMIGTASKS or the MAXEDMT alias can be used instead of the MAXINTERVALTASKS parameter.

- You should distribute on-demand migration workload evenly across all hosts configured to perform on-demand migration.
- You should ensure there are enough hosts to perform other critical DFSMSHsm tasks.

On-demand migration usage notes and other considerations

1. Neither interval migration or on-demand migration is performed on SMS-managed volumes that belong to a storage group defined with AM=P (Auto Migrate, primary) or AM=N (Auto Migrate, no).
2. On-demand migration is paused when interval migration or primary space management are started on the same DFSMSHsm host performing on-demand migration. On-demand migration will start again after interval migration or primary space management has ended, if there are eligible volumes to be processed.
3. Notification of the number of volumes concurrently queued for on-demand migration is issued to the operator's console (highlighted message ARC1901E). The default notification limit is 100 volumes. For more information about configuring the notification limit, see [“Specifying an on-demand migration number of concurrently queued volumes notification limit” on page 52](#)
4. After a volume is processed using on-demand migration it can remain at or above the high threshold. This happens when there are not enough eligible data sets on the volume to be space managed. To prevent continuously processing a volume that remains above the high threshold, an on-demand migration timer is started. This timer prevents on-demand migration from running again for 24 hours (default) on all volumes that remained at or above the high threshold during its duration. When the timer expires, on-demand migration is performed again on all of the volumes that remain at or above the high threshold. A patch is provided for [Changing the frequency](#) at which volumes at or above the high threshold are selected for on-demand migration again. See [z/OS DFSMSHsm Implementation and Customization Guide](#).
5. When on-demand migration is enabled, the SETSYS INTERVALMIGRATION setting and the SETSYS NOINTERVALMIGRATION setting are ignored for on-demand migration eligible volumes.
6. If you want to perform on-demand migration on TMM storage groups, you must convert AM=I (Auto Migrate, interval) TMM storage groups to AM=Y.
7. If you want the operator to be notified of the space allocation of each volume during the on-demand migration space check, issue the SETSYS MONITOR(SPACE) command.
8. Data sets on SMS-managed volumes are processed in the following order:

- a. Data sets eligible for a class transition and migration will be migrated.
 - b. Data sets eligible for a class transition will be transitioned.
 - c. Data sets eligible for migration only will be migrated. For this phase, data set size is a determining factor for the order and priority in which data sets are migrated. The largest eligible data set migrates first, followed by the next largest. The priority for migrating data sets from volumes that belong to storage groups defined with AM=I applies when the low threshold exceeds 5% only.
9. In order for a data set to be migrated or transitioned, the date of the current backup copy should be greater than the date-last-referenced by at least one day.
10. The current time is outside the time window(s) specified in SETSYS
EVENTDRIVENMIGRATIONQUIESCE.

Comparison of interval migration and tape mount management

Tape mount management (TMM) is a methodology that is used to optimize tape subsystem operation and use. It consists of hardware and software facilities, which manage tape data efficiently. By using DFSMSHsm in conjunction with your ACS routines to implement the TMM methodology, you can redirect multiple output data sets to DASD, then later have them moved to a single tape, with a single tape mount. This not only improves tape usage, but also greatly reduces the number of tape mounts that are required.

The following table illustrates the differences between normal interval migration processing and TMM processing:

Table 2. Standard Interval Migration Processing Compared to TMM Processing

DFSMShsm Options or Controls	Interval Migration	TMM with SMS
Hourly option Note: Hourly migration is not performed on a host that is currently running primary space management.	Storage group having AM=Y (Auto Migrate, yes) Note: Specifying AM=Y for a storage group requests that primary space management and event-driven migration both be performed on volumes in this storage group. An option of AM=P (Auto Migrate, primary) indicates only primary space management is performed.	Storage group having AM=I (Auto Migrate, interval) Note: This option is referred to as tape mount management (TMM).
SETSYS INTERVALMIGRATION	Volumes meeting trigger threshold may be processed hourly on this host.	Volumes meeting trigger threshold may be processed hourly on this host.
SETSYS NOINTERVALMIGRATION	Volumes are not processed hourly on this host.	Volumes meeting trigger threshold may be processed hourly on this host.
Threshold range	1–99	0–99
Trigger threshold	High threshold	Midpoint between high and low threshold.
Max interval tasks of 0	No hourly migration will be done on this host. Note: The option of NOINTERVALMIGRATION provides the same capability for this category of data.	No hourly migration will be done on this host. Note: Be aware that if you set the SETSYS MAXINTERVALTASKS parameter to zero, you are preventing hourly migration for all storage groups and non-SMS volumes on this host.
Max interval tasks x	x tasks available to do hourly migration of volumes meeting trigger threshold.	x tasks available to do hourly migrations of volumes meeting trigger threshold.
AMHOST=blank	Hourly migration can be performed on any host permitting interval migration and having interval tasks.	Hourly migration can be performed on any host having interval tasks.
AMHOST=system or system group name Note: If you want to allow hourly processing on more than one host but not on all hosts of a sysplex, then you can specify the combination of a sysplex restricting name and also specify SETSYS MAXINTERVALTASKS(0) on the hosts where you do not want to permit hourly migration.	Primary space management and hourly migration limited to this system or group.	Primary space management and hourly migration limited to this system or group.

Automatic recall

If a data set that has migrated is needed for processing, DFSMSHsm recalls the data set from the migration volume on which it resides to an SMS-managed volume. The storage management subsystem selects the SMS-managed volume to which the data set is returned. Migrated extended format VSAM data sets can be recalled only as extended format VSAM data sets. Migrated extended format sequential access method (SAM) data sets can be recalled as extended format or nonextended format data sets.

If a data set is assigned to a management class with no defined transition, then the allocation will be performed using the standard ACS routines.

If a data set is assigned to a management class with a defined transition, then the allocation will be done as follows:

- If the data set has not yet transitioned nor missed a transition, then the allocation will be performed using the standard ACS routines.
- If the data set had transitioned before being migrated, then the allocation will be performed using the class transition ACS routines to ensure that the data set is allocated back to the appropriate level.
- If the data set missed one or more transitions during the period in which it was migrated, then the allocation will be performed using the class transition ACS routines. If multiple transitions were missed, then the class transition ACS routines will be invoked for each transition that was missed (up to 5 times), to ensure that the data set is allocated on the appropriate level.

Note: To avoid circularity, DFSMSHsm will limit the number of repeated ACS routine invocations to five.

Automatic dynamic volume expansion space management

Certain DASD controllers have the ability to dynamically change the size of a logical volume. After the size of a volume is dynamically changed, the ICKDSF REFORMAT command must be run to rebuild the VTOC and INDEX on the volume. Until this is done, DFSMSHsm will not be aware of the new volume size. After the REFORMAT has been processed, DFSMSHsm automatically updates its volume records so that future processing will use the new volume size.

Note: DFSMSHsm only gets notified of volume changes when the VTOC REFORMAT is done on the same sysplex. If done on another sysplex, DFSMSHsm is not notified and will continue to use the original size until DFSMSHsm is restarted.

Command space management

DFSMSHsm provides you with the ability, by issuing individual commands, to perform space management functions. For associated command space management tasks, see [“Command space management tasks”](#) on page 88.

Tasks for automatic space management

The tasks for controlling automatic space management of SMS-managed storage require that you add DFSMSHsm commands to the ARCCMDxx member and that you specify attributes in the SMS storage groups and management classes. It is assumed that you have already defined the storage groups and management classes. The descriptions within this document are of attributes that you need to add to the previously defined storage groups and management classes. Similarly, the descriptions of DFSMSHsm commands relate to commands to be added to the ARCCMDxx member of SYS1.PARMLIB.

Specifying the storage to be managed and the space requirements

You must configure what storage DFSMSHsm manages and how much space to free on the volumes. This configuration specification comes from the storage group that the volume belongs to.

You can use the Auto Migrate attribute to specify whether DFSMSHsm performs primary space management and event-driven migration on the volumes that are assigned to the storage group. The Auto Migrate attribute specifies the type of space management that DFSMSHsm uses on the volumes that

are assigned to the storage group. Table 3 on page 33 lists the acceptable values of the Auto Migrate attribute and the space management methods that are performed based on those values.

<i>Table 3. Storage group Auto Migrate attribute values</i>			
Auto Migrate (AM) Value	Primary Space Management Performed?	Interval Migration Performed?	On-demand Migration Performed?
Y (yes)	Yes	Yes ¹	Yes ²
I (interval)	Yes	Yes	No
P (primary)	Yes	No	No
N (no)³	No	No	No

Notes:

1. Depends on whether the setting SETSYS INTERVALMIGRATION or SETSYS NOINTERVALMIGRATION is specified and whether the setting SETSYS ONDEMANDMIGRATION(Y) or SETSYS ONDEMANDMIGRATION(N) is specified.
2. Depends on whether the setting SETSYS ONDEMANDMIGRATION(Y) or SETSYS ONDEMANDMIGRATION(N) is specified.
3. Used for volumes that are managed by other products, or when you do not want space management, such as for application database or system volumes that must remain DASD-resident for other reasons.

A storage group defined with AM=Y indicates that you want the storage group space managed by primary space management, and, on occasion, by event-driven migration. If the setting SETSYS INTERVALMIGRATION is specified, volumes that belong to the storage group are eligible for interval migration. If the setting SETSYS ONDEMANDMIGRATION(Y) is specified, volumes that belong to the storage group are eligible for on-demand migration and are not eligible for interval migration, even if SETSYS INTERVALMIGRATION is specified. Specific interval migration or on-demand migration requirements must be satisfied for a volume to be eligible.

A storage group defined with AM=I indicates that you want the storage group space managed by interval migration. Primary space management can also be performed, but plays a minor role overall. Processing of a storage group defined with AM=I by interval migration is not affected by the SETSYS INTERVALMIGRATION or SETSYS NOINTERVALMIGRATION settings that apply to storage groups that are defined with AM=Y. Defining a storage group with AM=I is ideal for use with tape mount management (TMM), which redirects tape data sets to the storage group, and then lets DFSMSHsm move them to tape hourly, as needed.

AM=I storage groups also have a different trigger for interval migration to be performed. That is, when a volume exceeds the midpoint between low and high threshold, interval migration is performed. For example, if low threshold is 20 percent and the high threshold is 70 percent, then volumes that exceed 45 percent are processed.

A storage group defined with AM=P indicates that you want the storage group managed by primary space management only. This is useful when event-driven migration is determined to consume too much resource or is disruptive in other ways. Processing of a storage group defined with AM=P by primary space management is not affected by the SETSYS INTERVALMIGRATION or SETSYS ONDEMANDMIGRATION settings that apply to storage groups defined with AM=Y.

A storage group defined with AM=N indicates that you do not want automatic space management to be performed. Data sets and volumes must be migrated using commands instead. Defining a storage group with AM=N is ideal when the volumes are managed by other products or when you do not want space management performed (such as for application database or system volumes that must remain DASD-resident for other reasons).

Example

In Figure 5 on page 34, primary space management is performed on storage groups SG1 and SG2 (although event-driven migration is also performed on these storage groups). Interval migration is performed on storage group SG3. Storage group SG4 is not space managed, but has thresholds to control new data set allocation.

```
NAME ===> SG1
MIGRATE SYSTEM/SYSPLEX NAME ===>
AUTO MIGRATE ===> Y
MIGRATION AND ALLOCATION THRESHOLDS: HIGH ===> 85 LOW ===> 70

NAME ===> SG2
MIGRATE SYSTEM/SYSPLEX NAME ===>
AUTO MIGRATE ===> Y
MIGRATION AND ALLOCATION THRESHOLDS: HIGH ===> 95 LOW ===> 80

NAME ===> SG3
MIGRATE SYSTEM/SYSPLEX NAME ===>
AUTO MIGRATE ===> I
MIGRATION AND ALLOCATION THRESHOLDS: HIGH ===> 20 LOW ===> 0

NAME ===> SG4
MIGRATE SYSTEM/SYSPLEX NAME ===>
AUTO MIGRATE ===> N
MIGRATION AND ALLOCATION THRESHOLDS: HIGH ===> 95 LOW ===> 80
```

Figure 5. Storage Group Attributes for Space Management

The **Migration and Allocation Thresholds** fields configure two DFSMSHsm controls:

- How much free space is available on the volumes when space management is finished (low)
- How full the volumes must be to cause space management to be performed (high)

“Pass 1 of automatic primary space management” on page 65 (non-data-movement function in primary space management) and extent reduction are performed for all volumes in storage groups defined with AM=Y and AM=I (SG1, SG2, and SG3). “Pass 2 of automatic primary space management” on page 70 (migration) is performed only for those volumes that are above the low threshold after pass 1 and extent reduction have completed.

SMS tries to stay within these thresholds by assessing the primary space allocation of each data set before assigning it to a given DASD volume. When a volume reaches or exceeds the high threshold, SMS issues an ENF72 signal, regardless of the Auto Migrate setting. This event code is the trigger for on-demand migration.

DFSMSHsm uses the high threshold attribute to determine the need for event-driven migration. The low threshold attribute specifies the maximum level of occupied space after space management is performed.

Space management is considered complete when both thresholds have been met. This applies only to interval migration of non-SMS-managed volumes and event-driven migration of SMS-managed volumes when Auto Migrate is not I. Interval migration of SMS-managed volumes that belong to a storage group defined with AM=I is performed if the volume is at or above the midpoint between the low and high threshold.

Note: A low threshold of 0 is permitted only with AM=I.

Specifying the DFSMSHsm hosts that process each storage group

When DFSMSHsm processes an SMS-managed volume for space management, it records the time at which the volume was processed for cloud or non-cloud migrations. If another DFSMSHsm host attempts to process the same volume for space management to cloud or non-cloud migrations, it checks the time at which the volume was last processed. If the volume was processed within the last 14 hours, DFSMSHsm does not process the volume again for that type of target. A volume may be processed by one host for non-cloud migrations, and later processed by another host for cloud migrations.

Because of the time-recording process for SMS-managed volumes, DFSMSHsm does not require you to control which DFSMSHsm host processes which volumes, and you should not do such manual load balancing. However, should you find it necessary to limit processing of certain volumes to one z/OS image, you can do so with the MIGRATE SYSTEM/SYSPLEX NAME attribute in the storage group.

The system name is the system-wide identifier for the z/OS image, not the identifier assigned with the HOSTID parameter of the DFSMSHsm startup procedure.

If only z/OS to process storage group SG1 for space management, you could specify:

```
Storage group 1 (SG1)
MIGRATE SYSTEM/SYSPLEX NAME ==> PRC1
```

If you find that a single DFSMSHsm system is insufficient to complete processing of a storage group, the SETSYS STORAGEGROUPAFFINITY command can be used to allow a particular DFSMSHsm host to process storage groups assigned to other systems.

To allow DFSMSHsm on z/OS image 2 to process the storage group in the example above, you would specify the following:

```
STORAGEGROUPAFFINITY to DFSMSHsm on
z/OS image 2
F HSMIMG2,SETSYS STORAGEGROUPAFFINITY(PRC1)
```

Specifying how groups of data sets are managed

During space management, DFSMSHsm processes individual SMS-managed data sets to comply with the attributes specified in the management classes with which the data sets are associated. Management class attribute groups let you specify:

- Expiration attributes
 - EXPIRE AFTER DAYS NON-USAGE
 - EXPIRE AFTER DATE/DAYS
 - RETENTION LIMIT
- Partial release attribute
- Migration attributes
 - COMMAND OR AUTO MIGRATE
 - PRIMARY DAYS NON-USAGE
 - SIZE LESS THAN OR EQUAL TO ACTION
 - SIZE GREATER THAN ACTION
 - LEVEL 1 DAYS NON-USAGE
 - LEVEL 2 DAYS NON-USAGE
 - CLOUD NAME
- Class transition attributes
 - TIME SINCE CREATION | TIME SINCE LAST USE | PERIODIC
 - TRANSITION COPY TECHNIQUE
 - SERIALIZATION ERROR EXIT
- GDG management attributes

GDG ELEMENTS ON PRIMARY
ROLLED-OFF GDS ACTION

Specifying expiration attributes

The expiration attributes, EXPIRE AFTER DAYS NON-USAGE and EXPIRE AFTER DATE/DAYS, govern how long a data set associated with the management class is kept if no expiration date is listed in the data set VTOC entry or if the VTOC entry contains an INVALID EXPIRATION DATE. The expiration date is in the data set VTOC entry if the RETENTION LIMIT attribute does not specify a value of zero to disallow the use of explicit expiration dates and the expiration date is explicitly specified by the user or data class.

DFSMSHsm considers explicit expiration dates to be INVALID when:

- the day portion of the date is not between 1 and 366, nor is 999.

Note: Expiration dates of 99.365, 99.366, and 99.999 continue to be honored as "never expire" when explicitly specified.

- the current definition of the assigned SMS Management Class specifies a RETENTION LIMIT value of zero to disallow the use of explicit expiration dates prior to a Management Class change.

EXPIRE AFTER DAYS NON-USAGE specifies how many days must elapse from the last access of the data set until the data set becomes eligible for expiration. EXPIRE AFTER DATE/DAYS specifies an absolute date or period after the data set has been created for a data set to become eligible for expiration. The default for both attributes is NOLIMIT.

Both attributes can be used together. When both attributes have a value other than NOLIMIT, both attributes must be satisfied before the data set is expired. When both attributes are NOLIMIT, the data set does not expire. When one of the attributes is NOLIMIT, that attribute is not used to expire the data set; the expiration of the data set is based on the attribute that is not NOLIMIT.

It is possible to have a management class request both automatic backup processing—by using the AUTO BACKUP setting of Y— and expiration processing—by using the EXPIRE AFTER.... as numeric values. In this case, DFSMSHsm determines if a backup copy has been made before expiring the data set. The data set will be deleted when any of the following conditions are true:

- The data set change flag is off in the VTOC entry *and* the last backup date in the catalog is nonzero.

Note: DFSMSHsm does not verify the existence of the backup version.

- The data set change flag is off in the VTOC entry *and* the last backup date in the catalog is zero *and* the management class does not request automatic backup for this data set.
- The data set change flag is on in the VTOC entry *and* the management class does not request automatic backup for this data set.

Rule: ADMIN OR USER COMMAND BACKUP must not be NONE and AUTO BACKUP must be Y to request automatic backup.

Specifying partial release

The PARTIAL RELEASE attribute specifies whether DFSMSHsm space management processing releases unused allocated space in physical sequential, partitioned, and extended format VSAM data sets. The default for PARTIAL RELEASE is NO. The other options are YES and CONDITIONAL. CONDITIONAL means to release the space only if there is a nonzero secondary allocation quantity.

Note:

1. The CONDITIONAL option applies only to physical sequential and partitioned data sets. If specified for an extended format VSAM data set, it will be processed as if YES were specified.
2. The PARTIAL RELEASE attribute does not apply to normal migration and recall processing.

Related reading

For more information about migration and recall space allocation, see [“Additional space management during migration and recall when DFSMSHsm is the data mover” on page 87.](#)

Specifying migration attributes

The migration attributes allow you to specify:

- Whether migration is permitted for the data sets.
- When a data set is eligible to migrate from level 0.
- When a data set is eligible to migrate from level 1.
- To what level a data set is eligible to migrate.
- When a data set is eligible to migrate to cloud storage.
- The cloud storage name.
- The migration tier to move a data set to when it is less than a fixed size.
- The migration tier to move a data set to when it is greater than a fixed size.

The COMMAND OR AUTO MIGRATE attribute specifies whether to migrate the data sets automatically, by command, or not at all. If you specify BOTH, both automatic and command migration can occur. If you specify COMMAND, the data sets cannot migrate automatically, but a migrate command for individual data sets can cause the data sets to migrate, regardless of the value specified on the PRIMARY DAYS NON-USAGE attribute. If you specify NONE, the data sets cannot migrate. The default is BOTH. The COMMAND OR AUTO MIGRATE attribute does not affect Class Transition processing.

The PRIMARY DAYS NON-USAGE attribute specifies the minimum number of days a data set must remain unused on an SMS-managed volume before it becomes eligible to migrate. Eligibility to migrate does not imply that the data set will migrate the next time that space management occurs. If space management achieves the necessary free space without migrating all the eligible data sets on the volume, space management processing stops when the necessary free space is available. The default for this attribute is two days.

The SIZE LESS THAN OR EQUAL TO attribute specifies a size threshold. If a data set meets the PRIMARY DAYS NON-USAGE criteria, and the current size of the data set is less than or equal to the threshold, then the specified action is taken.

- The action can be NONE, indicating that the data set should not be migrated. This can be useful if you don't want to migrate data sets below a certain size, even if they have not been referenced.
- The action can be ML1, indicating that the data set should be migrated to the ML1 tier.
- The action can be ML2, indicating that the data set should be migrated directly to the ML2 tier regardless of the values for LEVEL 1 DAYS NON-USAGE.
- The action can be MIG, indicating that the data set should be migrated to ML1, or ML2 according to the value of LEVEL 1 DAYS NON-USAGE.
- The action can be CLOUD, indicating that the data set should be migrated to the cloud storage named in the CLOUD NAME field.
- The action can be TRANS, indicating that the data set should have class transition processing that is performed for it.

The LEVEL 1 DAYS NON-USAGE attribute serves two purposes:

- It specifies the minimum number of days that a data set must be unused before it becomes eligible for migration from level 1 to level 2. This number is the total days not used; it is not days that the data set has actually resided on an ML1 volume. All data sets that are eligible migrate at each level 1 to level 2 migration.
- It indicates what level to migrate to from either level 0 or level 1. A value of 1 to 9999 for this attribute specifies that the data set may migrate first from level 0 to level 1, then from level 1 to the specified ML2 device, either DASD or tape. A value of 0 for this attribute specifies that the data set migrates

directly from level 0 to ML2 tape. (If the data set has already migrated to ML1 before the attribute was set to 0, it migrates to the specified ML2 device, either DASD or tape.) A value of NOLIMIT specifies that the data set migrates to ML1 and is not to migrate to ML2.

If the value of LEVEL 1 DAYS NON-USAGE has been met and the data set still resides on level 0, it will migrate directly to ML2.

The default for this attribute is 60.

The LEVEL 2 DAYS NON-USAGE attribute allows migrations to be directed to cloud storage. It has two values, 0 and NOLIMIT. When NOLIMIT is specified (or defaulted to because blank), the data set will migrate to the ML2 tier based on the value of LEVEL 1 DAYS NON-USAGE. When 0 is specified, the data set will be migrated to the cloud specified in the CLOUDNAME field as long as the PRIMARY DAYS NON-USAGE value is met and the data set still resides on Level 0. The LEVEL 1 DAYS NON-USAGE value does not apply in this case. The default value for LEVEL 2 DAYS NON-USAGE is NOLIMIT.

Restriction: DFSMSHsm does not support movement of migration copies from ML1 to cloud storage.

The data set must reside on a volume that is connected to cloud storage. Additionally, the SMS Cloud construct named or CDA provider file must exist and the password for the cloud must be defined to DFSMSHsm.

Specifying class transition attributes

The class transition attributes allow you to specify:

- When a data set is eligible to transition
- Which copy technique to use to move the data set
- What action to take when there is a serialization error

There are three defined class transition attributes that can be used to specify if and when data sets should transition:

- TIME SINCE CREATION indicates the YEARS, MONTHS and/or DAYS that must elapse relative to the date that a data set was created. If left blank (the default value), this indicates that no transitions should occur based on these criteria.
- TIME SINCE LAST USE indicates the YEARS, MONTHS and/or DAYS that must elapse relative to the date that a data set was last referenced or used. If left blank (the default value), this indicates that no transitions should occur based on these criteria.
- PERIODIC indicates a MONTHLY, QUARTERLY or YEARLY cycle for which a data set should transition. If left blank (the default value), this indicates that no transitions should occur based on these criteria.

TRANSITION COPY TECHNIQUE specifies whether a point in time copy technique should be used. The available parameters are:

- STANDARD (STD)
- FAST REPLICATION PREFERRED (FRP)
- FAST REPLICATION REQUIRED (FRR)
- PRESERVE MIRROR PREFERRED (PMP)
- PRESERVE MIRROR REQUIRED (PMR)
- FC XRCPRIMARY (FCX)

These parameters function as follows:

- STANDARD (STD) specifies that only standard I/O should be used to perform the data movement. This is the default.
- FAST REPLICATION PREFERRED (FRP) specifies that fast replication should be used when possible. If fast replication cannot be used, then it is acceptable to use standard I/O to perform the data movement.
- FAST REPLICATION REQUIRED (FRR) specifies that fast replication is required. If fast replication cannot be used, then the transition fails.

- PRESERVE MIRROR PREFERRED (PMP) specifies that a Metro Mirror primary volume is allowed to become a FlashCopy target, and it would be preferable that the Metro Mirror pair does not go into a duplex pending state as a result of the FlashCopy operation when the target volume is a Metro Mirror primary volume. If the preserve mirror operation cannot be accomplished, then the FlashCopy operation is still to be attempted. If the intended FlashCopy target volume is *not* a Metro Mirror primary volume, then the rules for FAST REPLICATION PREFERRED (FRP) are followed.
- PRESERVE MIRROR REQUIRED (PMR) specifies that a Metro Mirror or Global Mirror primary volume is allowed to become FlashCopy target volumes. If the FlashCopy target volume is a Metro Mirror primary device, a Preserve Mirror option is required when performing FlashCopy operation. If the target volume is *not* a Metro Mirror or Global Mirror primary volume, then the rules for FAST REPLICATION REQUIRED (FRR) are followed.
- FC XRCPRIMARY (FCX) specifies that an XRC primary volume is allowed to become a FlashCopy target. When the FCX option is set, the PMR option is also specified to DFSMSdss.

SERIALIZATION ERROR EXIT specifies an action to take when the data set cannot be exclusively serialized for the data movement. The available parameters are:

- NONE
- DB2®
- CICS®
- ZFS
- EXIT

These parameters function as follows:

- NONE specifies that the transition should fail with no additional action. This is the default.
- Db2 specifies that Db2 should be invoked to close the data set. If there are no Db2 transactions in progress and the data set is successfully closed and unallocated, then the data set will be exclusively serialized. If exclusive access is obtained, then the data set will be transitioned. After the data set has moved, Db2 is reinvoked to allocate and open the data set. If the serialization cannot be obtained or there are active Db2 transactions then the transition will fail.
- CICS specifies that CICS should be invoked to make the data set unavailable for use by CICS and to close all files open to the data set. If these steps are successful, then the data set will be exclusively serialized and then transitioned. After the data set has moved, CICS is reinvoked to enable the CICS files to use the data set and make available the data set to be used by CICS. If the serialization cannot be obtained a second time, then the transition will fail.
- ZFS specifies that zFS should be invoked to unmount the data set. If the data set is successfully unmounted, then the data set will be exclusively serialized. The unmount will fail if the file system is currently accessing the data set. If exclusive access is obtained, then the data set will be transitioned. After the data set has moved, zFS is reinvoked to mount the data set.
- EXIT specifies that a user exit should be invoked to unserialize the data set. The exit will be invoked twice: initially to unserialize the data set, and a second time after the transition in order to reserialize the data set. The transition will be performed if the data set can be exclusively serialized after the user exit has been initially invoked.

Note:

1. When specifying a value other than NONE, ensure that only the appropriate types of data sets are assigned to the management class. For example, if Db2 is specified, then only Db2 objects should be assigned to this management class.
2. See [z/OS DFSMSdss Storage Administration](#) for more detailed information on the behavior of this option.
3. When a value of Db2 is specified, DFSMSShsm runs with DFSMSdss loaded in the DFSMSShsm address when transitioning/moving the data set.
4. When moving Db2 objects, DFSMSShsm must be authorized to the Db2 STOP and START commands.

Specifying GDG management attributes

The generation data group (GDG) management attributes let you specify migration eligibility for generation data sets based on relative generation number and what to do with rolled-off generation data sets (GDSs).

In establishing the order for migrating data sets from a DFSMSHsm-managed volume, DFSMSHsm can give high priority to generation data sets (members of generation data groups). That is, DFSMSHsm can choose to migrate generation data sets before it migrates non-generation data sets. Generation data sets that are chosen in preference to non-generation data sets are said to receive early migration. You may want to give high priority to generation data sets if old generations are used infrequently. To specify that old generations have high priority for migration and to specify how many generations have standard priority, you can specify the # GDG ELEMENTS ON PRIMARY attribute. When you specify this attribute, all non-rolled-off generations of each GDG that exceed the number you specify are given priority for early migration. If you specify 0 for this attribute, all generations of the GDGs are given priority for early migration.

The ROLLED-OFF GDS ACTION attribute specifies what to do with rolled-off GDSs. The values for this attribute are MIGRATE and EXPIRE. If you specify MIGRATE, DFSMSHsm assigns the highest migration priority to rolled-off GDSs. If you specify EXPIRE, DFSMSHsm deletes any rolled-off GDS that has met the expiration date specified in its data set VTOC entry or that has no expiration date specified in the data set VTOC entry. If a NOSCRATCH GDS rolls off while on a level 0 volume and is migrated, the GDS is expired during migration cleanup.

The GDG management attributes have no defaults. If you do not specify values for these attributes, the other migration and expiration attributes in the management class govern migration and expiration of generation data sets. If a GDS does not meet any of the criteria specified by the GDG management attributes, the other migration and expiration attributes in the management class govern migration and expiration of the data set.

Using the default management class

SMS allows you to define a management class and to specify that this management class is the default management class. Thus, any SMS data set that is not assigned to a management class by the automatic class selection routine uses the attributes specified in the default management class.

If you do not specify a default management class, DFSMSHsm generates its own default by using the default values for all of the management class attributes. Thus, in the absence of a specified default management class, DFSMSHsm uses the following values for any SMS-managed data set for which a management class is not assigned.

Management Class Attribute	Default Value
EXPIRE AFTER DAYS NON-USAGE	NOLIMIT
EXPIRE AFTER DATE/DAYS	NOLIMIT
PARTIAL RELEASE	N
PRIMARY DAYS NON-USAGE	2
SIZE LESS THAN OR EQUAL TO	No default
SIZE GREATER THAN	No default
LEVEL 1 DAYS NON-USAGE	60
LEVEL 2 DAYS NON-USAGE	NOLIMIT
CLOUD NAME	No default
# GDG ELEMENTS ON PRIMARY	No default
ROLLED-OFF GDS ACTION	No default

Management Class Attribute	Default Value
BACKUP FREQUENCY	1
NUMBER OF BACKUP VERS (Data Set Exists)	2
NUMBER OF BACKUP VERS (Data Set Deleted)	1
RETAIN DAYS ONLY BACKUP VER (Data Set Deleted)	60
RETAIN DAYS EXTRA BACKUP VERS	30
ADMIN OR USER COMMAND BACKUP	BOTH
AUTO BACKUP	Y
BACKUP COPY TECHNIQUE	S
CLASS TRANSITION	BLANK
TRANSITION COPY TECHNIQUE	STD
SERIALIZATION ERROR EXIT	NONE

Note: DFSMSHsm creates a management class called HSMDEFMC.

Management class examples

The following examples show how to use the various management classes.

Standard management class attributes

For data sets that use the standard management class (STANDMC), the following actions occur:

- The data sets expire if they are not used in 120 days and 360 days have passed since they were created.
- Unused allocated space is released from physical sequential, partitioned, and extended format VSAM data sets.
- Data sets that are not used for 10 days are migrated to ML1.
- Data sets that are not used for 60 days are migrated to ML2.

These are the management class attributes for STANDMC:

```
NAME ==>  STANDMC
          EXPIRE AFTER DAYS NON-USAGE ==> 120
          EXPIRE AFTER DATE/DAYS       ==> 360
          PARTIAL RELEASE               ==> Y
          PRIMARY DAYS NON-USAGE        ==> 10
          LEVEL 1 DAYS NON-USAGE        ==> 60
          COMMAND OR AUTO MIGRATE       ==> BOTH
          SIZE LESS THAN OR EQUAL TO
          SIZEGT OPTIONS                ==> NONE
          SIZE GREATER THAN OR EQUAL TO
          SIZELTE OPTIONS               ==> NONE
          LEVEL 2 DAYS NON-USAGE        ==> NOLIMIT
          CLOUD                        ==>
```

GDS management class attributes

Data sets in generation data groups use the GDS management class (GDSMC) for the following results:

- Data sets expire if they are not used in seven days and 90 days have passed since they were created.
- Unused allocated space is not released from any data sets.
- Data sets that are not used in five days migrate to ML1.
- Data sets never migrate to migration level 2.

Space management of SMS-managed storage

- Non-rolled-off data sets that exceed the last two generations receive priority for command and event-driven migration.
- Rolled-off generation data sets are expired.

These are the management class attributes for GDSMC:

```
NAME ==> GDSMC
      EXPIRE AFTER DAYS NON-USAGE ==> 7
      EXPIRE AFTER DATE/DAYS      ==> 90
      PARTIAL RELEASE              ==> N
      PRIMARY DAYS NON-USAGE      ==> 5
      LEVEL 1 DAYS NON-USAGE      ==> NOLIMIT
      COMMAND OR AUTO MIGRATE     ==> BOTH
      # GDG ELEMENTS ON PRIMARY   ==> 2
      ROLLED-OFF GDS ACTION       ==> EXPIRE
SIZE LESS THAN OR EQUAL TO
      SIZEGT OPTIONS              ==> NONE
      SIZE GREATER THAN OR EQUAL TO
      SIZELTE OPTIONS            ==> NONE
      LEVEL 2 DAYS NON-USAGE     ==> NOLIMIT
      CLOUD                      ==>
```

Large management class attributes

In the example system, large data sets are not to migrate to ML1 DASD. Instead, those data sets should migrate directly to ML2 tape. Data sets that use this management class (LARGEMC) receive the following processing:

- The data sets expire if they are not used in 90 days, and 180 days have passed since they were created.
- Unused allocated space is released from physical sequential, partitioned, and extended format VSAM data sets.
- Data sets that are not used for 15 days migrate to ML2 tape.

These are the management class attributes for LARGEMC:

```
NAME ==> LARGEMC
      EXPIRE AFTER DAYS NON-USAGE ==> 90
      EXPIRE AFTER DATE/DAYS      ==> 180
      PARTIAL RELEASE              ==> Y
      PRIMARY DAYS NON-USAGE      ==> 15
      LEVEL 1 DAYS NON-USAGE      ==> 0
      COMMAND OR AUTO MIGRATE     ==> BOTH
SIZE LESS THAN OR EQUAL TO
      SIZEGT OPTIONS              ==> NONE
      SIZE GREATER THAN OR EQUAL TO
      SIZELTE OPTIONS            ==> NONE
      LEVEL 2 DAYS NON-USAGE     ==> NOLIMIT
      CLOUD                      ==>
```

No-migration management class attributes

For data sets that have value as long as they are used but lose value quickly if they are not used, the no-migration (NOMIGMC) management class has been defined. Data sets that use this management class receive the following processing:

- The data sets never migrate.
- The data sets expire if they are not used in 20 days.
- Unused allocated space is released from physical sequential, partitioned, and extended format VSAM data sets.

These are the attributes for NOMIGMC:

```

NAME ====> NOMIGMC
          EXPIRE AFTER DAYS NON-USAGE ====> 20
          EXPIRE AFTER DATE/DAYS       ====> NOLIMIT
          PARTIAL RELEASE                ====> Y
          PRIMARY DAYS NON-USAGE         ====>
          LEVEL 1 DAYS NON-USAGE         ====> NOLIMIT
          COMMAND OR AUTO MIGRATE        ====> NONE
SIZE LESS THAN OR EQUAL TO
          SIZEGT OPTIONS                  ====> NONE
          SIZE GREATER THAN OR EQUAL TO  ====>
          SIZELTE OPTIONS                 ====> NONE
          LEVEL 2 DAYS NON-USAGE         ====> NOLIMIT
          CLOUD                          ====>

```

The EXPIRE AFTER DAYS NON-USAGE attribute has been set to 20 days and the EXPIRE AFTER DATE/DAYS attribute has been set to NOLIMIT. The data sets will expire after 20 days of nonusage. If both attributes are set to NOLIMIT, the data sets will never expire.

Transition data management class attributes

For data sets that need to remain online for an extended period of time, but need to be stored on a less expensive storage media after a certain time period, the standard transition (STDTRANS) management class can be defined. Data sets that use this management class receive the following processing:

- The data sets transition after 15 days of inactivity.
- Data sets do not transition if serialization cannot be obtained.
- Standard data movement is used.
- The data sets migrate to ML2 after 366 days of inactivity.
- The data sets expire after 7 years.

These are the attributes for STDTRANS:

```

NAME ====> STDTRANS
          TIME SINCE LAST USE            ====> 15
          SERIALIZATION ERROR EXIT       ====> NONE
          TRANSITION COPY TECHNIQUE      ====> STD
          PRIMARY DAYS NON-USAGE         ====> 366
          LEVEL 1 DAYS NON-USAGE         ====> 0
          COMMAND OR AUTO MIGRATE        ====> BOTH
          EXPIRE AFTER DATE/DAYS         ====> 2556
SIZE LESS THAN OR EQUAL TO
          SIZEGT OPTIONS                  ====> NONE
          SIZE GREATER THAN OR EQUAL TO  ====>
          SIZELTE OPTIONS                 ====> NONE
          LEVEL 2 DAYS NON-USAGE         ====> NOLIMIT
          CLOUD                          ====>

```

Transition Db2 data management class attributes

For Db2 data sets that need to remain online, but need to be stored on a less expensive storage media after a certain time period, the Db2 transition (DB2TRANS) management class can be defined. DB2 data sets that use this management class receive the following processing:

- The data sets never migrate.
- The data sets transition after 90 days from creation.
- The data sets are expected to be open during primary space management processing, so the Db2 exit will be invoked.
- To minimize the duration of the transition, fast replication will be preferred.
- The data sets expire after 7 years.

These are the attributes for DB2TRANS:

```

NAME ==> DB2TRANS
        TIME SINCE CREATION          ==> 90
        SERIALIZATION ERROR EXIT     ==> DB2
        TRANSITION COPY TECHNIQUE    ==> FRP
        PRIMARY DAYS NON-USAGE       ==> BLANK
        LEVEL 1 DAYS NON-USAGE       ==> NOLIMIT
        COMMAND OR AUTO MIGRATE      ==> NONE
        EXPIRE AFTER DATE/DAYS       ==> 2556
SIZE LESS THAN OR EQUAL TO
        SIZEGT OPTIONS               ==> NONE
        SIZE GREATER THAN OR EQUAL TO
        SIZELTE OPTIONS              ==> NONE
        LEVEL 2 DAYS NON-USAGE       ==> NOLIMIT
        CLOUD                        ==>

```

Enhanced management class 1 attributes

Small data sets should not be migrated, but as they grow in size, the location can be ML1 or ML2. Data sets that use this management class receive the following processing:

- The data sets expire if they are not used in 120 days and 360 days have passed since they were created.
- Unused allocated space is released from physical sequential, partitioned, and extended format VSAM data sets.
- Data sets that are not used for 10 days are eligible to migrate. If the size of the data set is less or equal to 20 tracks, it is not migrated. If the size is between 20 and 4000 tracks, it is migrated to ML1. If the size is larger than 4000 tracks, it is migrated directly to ML2.
- Data sets that are not used for 60 days are eligible for migration. If the size is less than or equal to 20 tracks, it is not migrated. If the size is greater than 20 tracks, it is migrated to ML2 if it is on level 0 DASD or ML1.

These are the attributes of ENHMC1:

```

EXPIRE AFTER DAYS NON-USAGE ==> 120
EXPIRE AFTER DATE/DAYS     ==> 360
PARTIAL RELEASE            ==> Y
PRIMARY DAYS NON-USAGE     ==> 10
SIZE LESS THAN OR EQUAL    ==> 20
        SIZELTE ACTION      ==> NONE
        SIZE GREATER THAN    ==> 4000
        SIZEGT ACTION        ==> ML2
LEVEL 1 DAYS NON-USAGE     ==> 60
LEVEL 2 DAYS NON-USAGE     ==> NOLIMIT
CLOUD NAME                 ==>
COMMAND OR AUTO MIGRATE    ==> BOTH

```

Enhanced management class 2 attributes

Small data sets in this management class are never migrated. Medium size data sets go to ML1 or ML2. Large data sets are migrated to the cloud. Data sets in this management class receive the following processing:

- The data sets expire if they are not used in 120 days and 360 days have passed since they were created.
- Unused allocated space is released from physical sequential, partitioned, and extended format VSAM data sets.
- Data sets that are not used for 10 days are eligible to migrate. If the size of the data set is less or equal to 20 tracks, it is not migrated. If the size is between 20 and 4000 tracks, it is migrated to ML1. If the size is larger than 6000 tracks, it is migrated to the cloud storage defined in the LOCALCLOUD SMS cloud construct.
- Data sets that are not used for 60 days are eligible for migration. If the size is less than or equal to 20 tracks, it is not migrated. If the size is between 20 and 6000 tracks, it is migrated to ML2 if it is on level 0 DASD or ML1.

These are the attributes of ENHMC2:

```

EXPIRE AFTER DAYS NON-USAGE ===> 120
EXPIRE AFTER DATE/DAYS      ===> 360
PARTIAL RELEASE              ===> Y
PRIMARY DAYS NON-USAGE      ===> 10
SIZE LESS THAN OR EQUAL     ===> 20
  SIZELTE ACTION             ===> NONE
SIZE GREATER THAN           ===> 6000
  SIZEGT ACTION              ===> CLOUD
LEVEL 1 DAYS NON-USAGE      ===> 60
LEVEL 2 DAYS NON-USAGE      ===> 0
CLOUD NAME                   ===> LOCALCLOUD
COMMAND OR AUTO MIGRATE     ===> BOTH

```

MOST2CLOUD management class attributes

Small data sets are not migrated. All other data sets migrate to cloud storage. Data sets that use this management class receive the following processing:

- The data sets expire if they are not used in 120 days and 360 days have passed since they were created.
- Unused allocated space is released from physical sequential, partitioned, and extended format VSAM data sets.
- Data sets that are not used for 10 days are eligible to migrate. If the size of the data set is less or equal to 150 tracks, it is not migrated. If the size is greater than 150 tracks, it is migrated to the cloud storage defined in the LOCALCLOUD SMS construct.

These are the attributes of MOST2CLOUD

```

EXPIRE AFTER DAYS NON-USAGE ===> 120
EXPIRE AFTER DATE/DAYS      ===> 360
PARTIAL RELEASE              ===> Y
PRIMARY DAYS NON-USAGE      ===> 10
SIZE LESS THAN OR EQUAL     ===> 150
  SIZELTE ACTION             ===> NONE
SIZE GREATER THAN           ===>
  SIZEGT ACTION              ===>
LEVEL 1 DAYS NON-USAGE      ===> 0
LEVEL 2 DAYS NON-USAGE      ===> 0
CLOUD NAME                   ===> LOCALCLOUD
COMMAND OR AUTO MIGRATE     ===> BOTH

```

BIG2 Cloud management class

Very big data sets migrate to cloud storage. Other sizes migrate to ML1 or ML2 normally. Data sets with this management class receive the following processing:

- The data sets expire if they are not used in 120 days and 360 days have passed since they were created.
- Unused allocated space is released from physical sequential, partitioned, and extended format VSAM data sets.
- Data sets that are not used for 10 days are eligible to migrate. If the size of the data set is less or equal to 7500 tracks, it is migrated to ML1. If the size of the data set is greater than 7500 tracks, it is migrated to the cloud storage described by the LOCALCLOUD SMS construct.
- Data sets that are not used for 20 days are eligible for migration. If the size is less than 7500 tracks, it is migrated to ML2 if it is on level 0 DASD or ML1.

These are the attributes of BIG2CLOUD

```
EXPIRE AFTER DAYS NON-USAGE ===> 120
EXPIRE AFTER DATE/DAYS      ===> 360
PARTIAL RELEASE              ===> Y
PRIMARY DAYS NON-USAGE      ===> 10
SIZE LESS THAN OR EQUAL     ===>
SIZELT ACTION                ===>
SIZE GREATER THAN           ===> 7500
SIZEGT ACTION                ===> CLOUD
LEVEL 1 DAYS NON-USAGE      ===> 20
LEVEL 2 DAYS NON-USAGE      ===> 0
CLOUD NAME                   ===> LOCALCLOUD
COMMAND OR AUTO MIGRATE     ===> BOTH
```

Specifying when automatic primary space management can process

The PRIMARYSPMGMTCYCLE parameter of the DEFINE command defines the cycle of automatic primary space management.

Example: To define an automatic primary space management cycle, use the following command:

```
DEFINE PRIMARYSPMGMTCYCLE(YNNNYNN) -
CYCLESTARTDATE(1998/09/12)
```

Although this example shows automatic primary space management running two days a week (Saturday and Wednesday), you might want to run it more often.

Specifying when automatic primary space management starts

The PRIMARYSPMGMTSTART parameter of the SETSYS command controls the processing window of automatic primary space management.

Example:

To define a processing window of 2:00 AM to 4:00 AM, use the following command:

```
SETSYS PRIMARYSPMGMTSTART(0200 0400)
```

Allowing primary space management to start at midnight

Many primary space management windows start after midnight to allow data sets to be processed as soon as their non-referenced day count reaches the threshold in the management class. The MIGRATEPSMEARLY parameter on the SETSYS command can be used to allow DFSMSHsm process a data set early. If the primary space management window begins after 6 PM, one will be added to the data set age up until the current time is midnight. Afterward, the current age is used in the calculation.

If the cutoff time of 6 PM needs to be changed, a patch (MIGCB.+98 X'hhmm') can be used to modify the cutoff time. For more information, see [Earlier checking for primary space management \(PSM\) in z/OS DFSMSHsm Implementation and Customization Guide](#).

Note: Backup of the control data sets can interfere with starting automatic primary space management.

Related reading

For more information about backing up control data sets, see [“Phase 1: Backing up the control data sets” on page 199](#).

Specifying when automatic secondary space management can process

The SECONDARYSPMGMTCYCLE parameter of the DEFINE command defines the cycle of automatic secondary space management.

Example: To define the days for secondary space management to run and the start date, use the following command:

```
DEFINE SECONDARYSPMGMTCYCLE(YNNNNYNN) -  
CYCLESTARTDATE(1998/09/12)
```

Specifying when automatic secondary space management starts

The SECONDARYSPMGMTSTART parameter of the SETSYS command controls the processing window of automatic secondary space management.

You can run automatic secondary space management any time of the day except when automatic primary space management is running (if SDSPs are used).

Example: To define a processing window of 12:30 a.m. to 2:00 a.m., use the following command:

```
SETSYS SECONDARYSPMGMTSTART(0030 0200)
```

Although secondary space management ending time is 2:00 a.m., any data set deletion management work elements (MWEs) that secondary space management built up to 2:00 a.m. would still continue to be processed. If a large number of data sets needed deletion, MWE processing could continue for a significant time after secondary space management stops building data set deletion MWEs.

Note:

1. You must specify SECONDARYSPMGMTSTART if you want it to run; it will not run by default.
2. Data set deletions generated by SSM are processed after any user recalls or user generated deletions.
3. Backup of the CDSs can interfere with the starting of automatic secondary space management. See [“Phase 1: Backing up the control data sets” on page 199](#) for discussion of this consideration.

Specifying migration of data sets to overflow volumes

You can ADDVOL migration volumes (ML1) to be OVERFLOW volumes and they will be considered for backup or migration of data sets when either one of the following are true:

- The data you are migrating or backing up is larger than a given size, as specified on the SETSYS ML1OVERFLOW(DATASETSIZE(*dssize*)) command
- DFSMSHsm cannot allocate enough space on a NOOVERFLOW volume by selecting either the least used volume or the volume with the most free space.

Related reading

- See [“OVERFLOW and NOOVERFLOW: Specifying the usage of a level 1 volume for data set migration and backup versions” on page 707 in Chapter 26, “ADDVOL command: Adding or changing DFSMSHsm volumes,” on page 697.](#)
- See [“ML1OVERFLOW: Manage ML1 OVERFLOW volumes” on page 1160 in Chapter 65, “SETSYS command: Establishing or changing the values of DFSMSHsm control parameters,” on page 1057.](#)

Specifying how to migrate data sets to migration level 2

Parameters of the SETSYS command provide the specification for how to migrate data sets to ML2.

If you are using the duplex tape option for your ML2 tapes, see [“Duplex tape option” on page 436](#) for information specific to the duplexing environment.

See the following topics:

- [“Using the SETSYS TAPEMIGRATION parameter” on page 47](#)
- [“Specifying when to migrate from ML1 to ML2” on page 48](#)

Using the SETSYS TAPEMIGRATION parameter

You can specify that DFSMSHsm use only tape volumes for ML2 volumes.

Example: You can add the following SETSYS TAPEMIGRATION command to the ARCCMDxx member in each DFSMSHsm host:

```
SETSYS TAPEMIGRATION(ML2TAPE(TAPE(ACL)) RECONNECT(ALL))
```

The TAPEMIGRATION parameter of the SETSYS command specifies how migration to tape occurs. The ML2TAPE subparameter specifies that migration occurs from ML1 to ML2 tape. The TAPE(ACL) option of the ML2TAPE subparameter limits the kind of tape unit that is selected to the kind of unit that is specified. This example specifies that only units that are identified by the esoteric name of ACL can be used as output tape units for ML2 volumes.

The RECONNECT parameter of the SETSYS TAPEMIGRATION command controls whether DFSMSHsm attempts to reconnect a data set that is recalled from a single ML2 tape to that migration copy when the data set is next migrated.

The ALL keyword of the fast subsequent migration RECONNECT parameter specifies that you want all eligible data sets to reconnect to their ML2 tapes. You want this to occur even if the data sets would otherwise be migrated to ML1.

Note: Only data sets that are directed to ML1 by the FORCML1 parameter (on the ARCHMIG macro) are excluded from reconnection.

Alternative subparameters that have meaning to SMS-managed data sets are NONE and NONE(ROUTETOTAPE).

The NONE subparameter specifies that ML2 volumes are DASD. NONE(ROUTETOTAPE(*unittype*)) specifies that although ML2 volumes are DASD, any management class with a value of 0 in the LEVEL 1 DAYS NON-USAGE attribute causes data sets to migrate directly to tape of the kind specified by *unittype*. The *unittype* subparameter restricts the kind of unit for the ML2 tape unit.

If you specify TAPEMIGRATION(NONE) or TAPEMIGRATION(NONE(ROUTETOTAPE(*unittype*))), you can define key ranges to be stored on different DASD ML2 volumes. The MIGRATIONLEVEL2 parameter of the DEFINE command specifies the key ranges for DASD ML2 volumes.

Guideline: If you do not intend to use tape, do not specify TAPEMIGRATION. If you do, an offline control data set is required.

With SMS, both DASD and tape can be used together by specifying the NONE or (NONE(ROUTETOTAPE)) subparameters of the TAPEMIGRATION parameter and specifying LEVEL 1 DAYS NON-USAGE = 0 in some management classes. Under those specifications, level 1 to level 2 migration is to DASD but migration from DFSMSHsm-managed volumes is to tape for data sets in the appropriate management classes.

When migrating SMS volumes and both PRIMARY DAYS NON-USAGE and LEVEL 1 DAYS NON-USAGE have been satisfied in an ML2 tape environment, the SMS data sets are moved directly to ML2 tape. In an ML2 DASD environment, the target is ML1 DASD unless LEVEL 1 DAYS NON-USAGE is 0.

Related reading

- For more information about enabling fast subsequent migration, see [Enabling fast subsequent migration](#).
- For more information, see [Chapter 40, “DEFINE command: Defining control structures for use by DFSMSHsm,” on page 809](#).

Specifying when to migrate from ML1 to ML2

If you back up or migrate data sets to ML1 OVERFLOW volumes (see “Specifying migration of data sets to overflow volumes” on page 47), you can specify the percentage of occupied space that must be in the ML1 OVERFLOW volume pool before the migration of data sets to ML2 volumes occurs during automatic secondary space management.

As shown in the example below, the default setting for the ML1 OVERFLOW volume pool threshold is 80%. This requires the occupied space of the entire overflow volume pool reach 80% full before any data is moved off of OVERFLOW volumes to ML2 volumes.

```
SETSYS ML1OVERFLOW(THRESHOLD(80))
```

In this case, the percentage of occupied space for each ML1 OVERFLOW volume will be calculated and then DFSMSHsm will compare the average value with the specified threshold (80%). If the average of the ML1 OVERFLOW volume pool has an occupancy that is equal to or greater than the threshold, then secondary space management will be started and move data from ML1 to ML2. See [“ML1OVERFLOW: Manage ML1 OVERFLOW volumes”](#) on page 1160.

Specifying how to do extent reduction

The MAXEXTENTS parameter of the SETSYS command specifies how many extents a non-VSAM single-volume data set can have before it is reduced to fewer extents.

Example: You can add the following command to the ARCCMDxx member in each DFSMSHsm host:

```
SETSYS MAXEXTENTS(11)
```

Note:

1. The daily statistics report output shows the number of extent reductions done each day. You can use this information to tune the SETSYS MAXEXTENTS parameter.
2. DFSMSHsm does not perform extent reduction for extended format data sets.
3. Using a low MAXEXTENTS value might cause extent reduction to occur more frequently than you want. If you specify a MAXEXTENTS value, try using a value of 5 or more.

Specifying how to scratch expired data sets

During automatic primary space management, the example scratches expired data sets that have valid explicit expiration dates in the data set's VTOC entry. The EXPIREDDATASETS parameter of the SETSYS command specifies the SCRATCH subparameter indicating for DFSMSHsm to scratch any data set that has passed the expiration date. See the explanation of VALID EXPIRATION DATES under [“Specifying expiration attributes”](#) on page 36.

Example: You can add the following command to the ARCCMDxx member in each DFSMSHsm host:

```
SETSYS EXPIREDDATASETS(SCRATCH)
```

The expiration attributes in the management class control the expiration of non-VSAM data sets that do not have an expiration date in their data set VTOC entry or VSAM data sets that do not have an expiration date in the base cluster catalog entry. The management class does not control data sets with an expiration date in the data set VTOC or catalog entry. These data sets require the EXPIREDDATASETS(SCRATCH) parameter of the SETSYS command.

Note: For multivolume non-VSAM data sets, DFSMSHsm looks at the VTOC of the first volume.

An alternative subparameter for the EXPIREDDATASETS parameter is NOSCRATCH. NOSCRATCH is the default value and prevents DFSMSHsm from scratching data sets that have passed the expiration date indicated in the data set's VTOC entry during space management processing.

Specifying the maximum automatic volume space management tasks and subtasks

DFSMSHsm allows up to 15 automatic volume space management (primary space management, interval migration, and on-demand migration) tasks to run concurrently in each DFSMSHsm host during space management. Use the MAXMIGRATIONTASKS parameter of the SETSYS command to control the

maximum number of tasks that you want to run concurrently. If you do not specify this parameter on any SETSYS command, the default value for the maximum number of concurrent automatic volume space management tasks is 2.

Example: You can add the following command to the ARCCMDxx parmlib member of SYS1.PARMLIB of each DFSMSHsm hosts to handle automatic volume space management:

```
SETSYS MAXMIGRATIONTASKS(5)
```

If migration is to tape, each concurrent primary space management task that migrates a data set directly to tape requires a tape unit. If you are using the duplex tape option, two tape units per task are required. Tape units are allocated when a task encounters the first data set that is being migrated to tape, and the task does not release the tape units until it has completed processing all volumes. If migration is to SDSP data sets, each concurrent primary space management task being performed needs an SDSP data set. An SDSP data set is allocated when a task encounters the first data set that is being migrated to an SDSP. The task does not release the SDSP until the entire volume has been processed unless it remains unused for 30 seconds or the functions RECALL or ABACKUP need the SDSP data set.

Note: The actual number of migration tasks can be equal to the number of tasks specified on the MAXMIGRATIONTASKS or the MAXINTERVALTASKS and up to twice the specified number of tasks because of DFSMSHsm's preprocessing enhancement. This is reflected in a number of ARC0161I messages issued in response to the QUERY ACTIVE or QUERY ACTIVE(TCB) commands. MIGRATING, MIGRATION PREPROCESSING, FREEVOL PROCESSING, and DBA/DBU PROCESSING differentiate the type of space management DFSMSHsm is performing and these are displayed in the ARC0161I message.

Migration tasks perform all space management tasks, including class transitions. Class transitions have a higher priority than migrations and will be processed first during the data movement phase. If a data set is eligible for both a class transition and migration, then it will be migrated.

DFSMSHsm can also run multiple subtasks concurrently under each migration task for primary space management, on-demand migration, and interval migration on level 0 volumes that migrate data sets to ML1 or ML2 volumes. This can improve throughput by reducing the elapsed time for any migration function involving multiple data sets. Use the MIGRATIONSUBTASKS parameter of the SETSYS command to enable this function.

If you wish to specify additional subtasks under each migration task, you can do this dynamically with the ADDITIONALSUBTASKS(*nn*) subparameter. Up to 10 additional subtasks are allowed. Specifying a value of zero will remove all previously-defined additional subtasks.

Example: You can add the following command to the ARCCMDxx parmlib member of SYS1.PARMLIB of each DFSMSHsm host to enable migration subtasks, and also specify two additional subtasks for each migration task:

```
SETSYS MIGRATIONSUBTASKS(YES ADDITIONALSUBTASKS(2))
```

Note that specifying an ADDITIONALSUBTASKS(*nn*) value greater than 0 should be done with caution, as the additional concurrent subtasks may increase the amount of below the line storage used by DFSMSHsm.

Note, also, that when MIGRATIONSUBTASKS(YES) is specified, concurrent cell pool activity may increase in cell pool 5. It is therefore recommended to review the value specified by the CELLS parameter in the DFHSM startup procedure for CELL POOL 5. See "Specifying the size of cell pools" and "Adjusting the size of cell pools" in the [z/OS DFSMSHsm Implementation and Customization Guide](#) for more information.

Specifying the maximum automatic secondary space management tasks

DFSMSHsm allows up to 30 secondary space management tasks to run concurrently within a single DFSMSHsm host during automatic secondary space management. Use the MAXSSMTASKS parameter of the SETSYS command to control the maximum number of automatic secondary space management tasks that you want to run concurrently. Up to 15 tasks are available for cleanup functions and up to 15

tasks are available for tape movement functions. Secondary space management cleanup consists of the following functions:

- Expiration of migrated data sets.
- Deletion of MCDS records that are no longer needed.
- Deletion of SDSP records that are no longer needed.

Tape movement functions consists of moving ML1 data to ML2 tape, which is also referred to as *ML1-to-ML2 data movement*.

The MAXSSMTASKS(EMPTYCONTAINERDELETION(n)) parameter on the SETSYS command allows management of the processing of empty containers. A value of 0 or 1 can be specified.

- DFSMSHsm does not examine the known clouds for empty containers if 0 is specified.
- If 1 is specified, DFSMSHsm looks for empty containers to delete. Only empty containers created using the current HSMplex name will be found. This function will not find empty containers that were created using an HSMplex name other than the current HSMplex name.

This SETSYS MAXSSMTASKS parameter is dynamic. If you change the number of tape movement tasks or cleanup tasks while secondary space management is active, the new number of tasks are immediately effective.

If you do not specify this parameter on any SETSYS command, the default value for the maximum number of concurrent cleanup tasks is 2 and the default value for the maximum number of concurrent tape movement tasks is 1. To aid in the processing of the deletions initiated by secondary space management, the default for the number of recall tasks is 15. You can use the SETSYS MAXRECALLTASKS command to change this default.

Example: You can add the following command to the ARCCMDxx member in each DFSMSHsm host to handle automatic secondary space management:

```
SETSYS EMPTYCONTAINERDELETION(1) MAXSSMTASKS(CLEANUP(2) TAPEMOVEMENT(1))
```

Note: Each task that you specify for tape movement requires a tape unit. If you are using the duplex tape option, two tape units per task are required.

The MAXSSMTASKS(EMPTYCONTAINERDELETION(n)) parameter on the SETSYS command allows management of the processing of empty containers. A value of 0 or 1 can be specified.

- DFSMSHsm does not examine the known clouds for empty containers if 0 is specified.
- If 1 is specified, DFSMSHsm looks for empty containers to delete.

Specifying the maximum interval migration or on-demand migration tasks

DFSMSHsm allows up to 15 interval migration or on-demand migration tasks to run concurrently in each DFSMSHsm host during automatic interval or on-demand space management. Use the MAXINTERVALTASKS parameter of the SETSYS command to control the maximum number of interval migration or on-demand migration tasks that you want to run concurrently. If you do not specify MAXINTERVALTASKS on any SETSYS command, it defaults to the value of MAXMIGRATIONTASKS.

Note: MAXEVENTDRIVENMIGTASKS or the MAXEDMT alias can be used instead of the MAXINTERVALTASKS parameter.

If migration is to tape, a tape unit is required for each concurrent interval migration or on-demand migration task that migrates a data set directly to tape. If using the duplex tape option, two tape units per task are required. Tape units are allocated when a task encounters the first data set being migrated to tape, and the task does not release the tape units until it has completed processing all volumes. If migration is to SDSP data sets, an SDSP data set is needed for each concurrent interval migration or on-demand migration task being performed. An SDSP data set is allocated when a task encounters the first data set that is being migrated to an SDSP. The task does not release the SDSP until the entire volume has been processed unless it remains unused for 30 seconds or the functions RECALL or ABACKUP need the SDSP data set.

Note: The actual number of migration tasks can be equal to the number of tasks specified on the MAXMIGRATIONTASKS or the MAXINTERVALTASKS and up to twice the specified number of tasks because of DFSMSHsm's preprocessing enhancement. This is reflected in a number of ARC0161I messages issued in response to the QUERY ACTIVE or QUERY ACTIVE(TCB) commands. MIGRATING, MIGRATION PREPROCESSING, FREEVOL PROCESSING, and DBA/DBU PROCESSING differentiate the type of space management DFSMSHsm is performing and these are displayed in the ARC0161I message.

Migration tasks perform all space management tasks, including class transitions. Class transitions have a higher priority than migrations and will be processed first during the data movement phase. If a data set is eligible for both a class transition and migration, then it will be migrated.

Specifying an on-demand migration number of concurrently queued volumes notification limit

Notification of the number of volumes that are concurrently queued for on-demand migration is issued to the operator's console (highlighted message ARC1901E). The SETSYS ODMNOTIFICATIONLIMIT(*limit*) command is used to specify a custom notification limit. The *limit* parameter is a decimal number 1 to 99999. The default notification limit is 100 volumes.

Example: You can use the following command to change the notification limit to 50 volumes.

```
SETSYS ODMNOTIFICATIONLIMIT(50)
```

When the number of volumes eligible for on-demand migration falls below the notification limit, message ARC1901E is removed from the operator's console.

Specifying recall tasks

DFSMSHsm can perform multitasking operations on a maximum of 15 tasks that recall data sets from DASD or tape and that delete migrated data sets. These are called *recall tasks*.

The MAXRECALLTASKS parameter of the SETSYS command controls the number of recall tasks that can be processed at the same time. The TAPEMAXRECALLTASKS parameter specifies how many of these tasks can be recalling data sets on ML2 tape volumes. The number of tape recall tasks must be less than or equal to the maximum number of recall tasks. If the number of active tape recalls is less than or equal to the number specified by the TAPEMAXRECALLTASKS parameter, DFSMSHsm performs multitask DASD recall operations up to the number specified by the MAXRECALLTASKS parameter.

Example: In the following example, if you specified 15 recall tasks and 6 tape recall tasks and if only 3 tape recall tasks were running, DFSMSHsm would start as many as 12 recall tasks from DASD. You can add this command to the ARCCMDxx member in each DFSMSHsm host.

```
SETSYS MAXRECALLTASKS(15) TAPEMAXRECALLTASKS(6)
```

Specifying small data set packing

The SMALLDATASETPACKING parameter of the SETSYS command controls the sending of data sets to the SDSP data sets.

In specifying small data set packing, you specify the actual physical size of the data sets to be considered as candidates for migration to an SDSP data set. You can specify sizes as large as 800 KB. A candidate data set is eligible for migration to an SDSP data set if its estimated size, after compaction, is less than or equal to 400 KB or to the value you specify, whichever is smaller. The compaction size is estimated using an internal default of 50%. If the data set is not compacted, it is a candidate for migration to an SDSP if its actual size is less than or equal to 400 KB or to the value you specify, whichever is smaller.

Small data set packing causes data sets that are smaller than the size specified to be written as records in special VSAM data sets that you have allocated on the ML1 volumes. Because the minimum allocation unit is a track, writing small data sets as records in a larger data set results in saving space on the ML1 volumes.

The number of SDSP data sets defined must be at least equal to the maximum number of concurrent volume migration tasks that could be executing in your complex.

Example: You can add the following command, the command to be added to the ARCCMDxx member in each DFSMSHsm host:

```
SETSYS SMALLDATASETPACKING(KB(110))
```

Recommendation: Configure recall and ABARS use more SDSP data sets in case some data sets become full during migration.

Related reading

For more information about small data set packing, see [“Managing SDSP data sets” on page 555](#).

Specifying the first qualifier for names of migrated data sets

When DFSMSHsm migrates a data set, it leaves the original data set name in the catalog. For use in its own records, DFSMSHsm generates its own name for the data set. The form of the data set name that DFSMSHsm generates is:

```
prefix.HMIG.Tssmmhh.user1.user2.Xydd
```

If patch-enabled, the following dataset name will be generated:

```
prefix.HMIG.Tcccchh.user1.user2.Xydd
```

For more information, refer to [Changing DFSMSHsm backup and migration generated data set names to reduce contention for similar names and eliminating a possible performance degradation in z/OS DFSMSHsm Implementation and Customization Guide](#).

The MIGRATEPREFIX parameter of the SETSYS command specifies the *prefix* (high-level qualifier) of the generated name. If you do not specify a migrate prefix, DFSMSHsm uses the UID that you specified in the startup procedure.

The migrate prefix is used in the ACS filters that prevent DFSMSHsm-owned data sets from being allocated on SMS-managed volumes. In addition, the use of the prefix allows you to use RACF generic profile protection for all your migration copies.

Example: You can add the following command to the ARCCMDxx member in each DFSMSHsm host:

```
SETSYS MIGRATEPREFIX(HSM)
```

Related reading

- For more information about data set names, see [“Names of migrated data sets” on page 73](#).
- For more information about the migrate prefix, see [z/OS DFSMSHsm Implementation and Customization Guide](#).

Specifying if class transitions should be performed during event-driven migration

While most class transitions occur during primary space management, class transitions may also be performed during interval migration and on-demand migration. Class transitions should *not* be performed during the event-driven migration functions if the data is assigned a management class for which a serialization exit is invoked to close a data set for a transition, but it would not be appropriate to take that action during the time frame that the event-driven migration functions process.

Example: In the following example, class transitions will not be performed during event-driven migration. You can add the following command to the ARCCMDxx member in each DFSMSHsm host:

```
SETSYS CLASSTRANSITIONS(EVENTDRIVENMIGRATION(N))
```

Configuring migration cleanup

During automatic secondary space management, DFSMSHsm cleans up the migration control data set (MCDS) and the migration volumes by:

- Deleting expired migrated data sets
- Cleaning up SDSP data sets
- Deleting certain data sets that were not scratched during recall, deletion, or GDS roll-off
- Deleting old daily statistics and volume statistics records
- Deleting old MCDS records

You can control the age of the MCDS records and statistics records to be deleted, the number of cleanup tasks that run concurrently, and the days on which migration cleanup is done.

Data sets that are eligible for ML2 reconnection with the fast subsequent migration function may have their MCD records retained for a longer period of time than for nonreconnectable data sets. This increases the likelihood of a reconnection when the data set next migrates. However, keeping the MCD records longer (while increasing the likelihood of reconnection) also causes growth in the size of the MCDS.

The MIGRATIONCLEANUPDAYS parameter of the SETSYS command follows the form:

```
SETSYS MIGRATIONCLEANUPDAYS(recalldays statdays reconnectdays clouddays)
```

Replace *recalldays* with a decimal number between 1 and 999 that specifies the number of days that DFSMSHsm keeps MCDS data set records for recalled data sets that are not compacted, or are compacted and meet or exceed the current value of SETSYS COMPACTPERCENT. For data sets that are compacted but do not meet the current value of SETSYS COMPACTPERCENT, the MCDS data set records are retained for 90 days.

Replace *statdays* with a decimal number from 1 to 999 that specifies the number of days DFSMSHsm keeps the daily and volume statistics records. The REPORT command uses these records, which the IDCAMS DCOLLECT function also collects.

Replace *reconnectdays* with the number of days that you want to add to the predicted remigration date to control retention of the MCD record for reconnectable data sets. The predicted remigration date is based on the number of days that the data set was unreferenced before the date of its last migration. MCD records for reconnectable data sets are kept until they meet both the *recalldays* and the *reconnectdays* criteria.

Replace *clouddays* with the number of days that you want to keep old cloud migration copies of a data set around once a new modified version of the same data set has been remigrated. A value of 0 will indicate to DFSMSHsm that no old cloud migration copies will be kept.

You can specify different ages for MCDS records and statistics records.

Example: You can specify the following command to the ARCCMDxx member in each DFSMSHsm host:

```
SETSYS MIGRATIONCLEANUPDAYS(25 10 3)
```

In this example, the length of time to keep MCDS records is a period of 25 days. This is because 20 days is the longest period of residence on a specified DFSMSHsm-managed volume. Therefore, any data set that is recalled has a chance to migrate again before its MCDS record is scratched. Daily statistics and volume statistics records are kept for a period of 10 days. MCDS records for data sets that are marked as eligible for reconnection are kept 3 days beyond their predicted remigration date. The *reconnectdays* value can be adjusted up or down, if the data set is expected to reside on level 0 for a shorter or longer period before its next migration as compared to its most recent migration.

Note: The `MIGRATIONCLEANUPDAYS(recalldays)` parameter of the `SETSYS` command is one of the criteria that are used for deleting the MCD record of a recalled data set. However, if the data set was compacted during migration and is not eligible for compaction again, the MCD record is kept for at least 90 days. The 90 day retention occurs regardless of the value specified by *recalldays*. Also the MCD record specifies a count of the number of times that a data set by this name has migrated. This historic information is lost when the MCD record is deleted. If you plan to use this field, use this information to influence the value that you use for *recalldays*.

Identifying migration level 2 volumes to DFSMSHsm

If you use DASD ML2 volumes or tape volumes that are set aside only for DFSMSHsm use, you must identify the volumes to DFSMSHsm. The `ADDVOL` command does this. An example command that could be issued in at least one DFSMSHsm host if you were using DASD ML2 volumes is:

```
ADDVOL ML2001 UNIT(3390) MIGRATION(MIGRATIONLEVEL2)
```

Specifying duplexing for migration level 2 tapes

The duplex tape option creates two identical tapes in parallel, with one tape designated as the original and one the alternate. To create duplex migration level 2 tapes, specify

```
SETSYS DUPLEX(MIGRATION(Y))
```

If duplexing is not desired for your migration level 2 tapes, specify

```
SETSYS DUPLEX(MIGRATION(N))
```

The DFSMSHsm default is no duplexing.

Specifying the allowed target tiers

The `MIGRATIONAUTOCLOUD` parameter on the `SETSYS` command can tailor the migration tiers that a DFSMSHsm host can target. Migrating data sets to cloud storage can be time-consuming and might possibly cause all planned migrations to not complete during the existing primary space management window. You might want to have some DFSMSHsm hosts only perform migrations to ML1 and ML2, and other hosts only target cloud storage for the migrations.

If `MIGRATIONAUTOCLOUD(CLOUDONLY)` is in effect during the automatic migration (Primary Space Management, Interval Management, On Demand Management), only data sets that meet the criteria to migrate to cloud storage are moved. All other eligible data sets that would be migrated to ML1 or ML2 or transitioned would not be migrated by this host. `MIGRATIONAUTOCLOUD(NOCLOUD)` is the default if a value is not specified.

If `MIGRATIONAUTOCLOUD(ALL)` is in effect, eligible data sets are migrated to the tier indicated by the management class.

If `MIGRATIONAUTOCLOUD(NOCLOUD)` is in effect, only data sets that would target ML1 or ML2, or transition are processed. Any eligible data sets that would target cloud storage are not migrated by this host during the automatic migration. `MIGRATIONAUTOCLOUD(NOCLOUD)` is the default if a value is not specified.

Integrity age for space management

When DFSMSHsm does space management on a volume, it maintains data set integrity by processing only data sets that meet a certain *integrity age*. This integrity age specifies the minimum time that must elapse since the data set was last used before the data set can be processed by space management. The integrity age is affected by the DFSMSHsm host environment and by the method of serialization.

Note: A multiple DFSMSHsm-host environment is determined by DFSMSHsm at startup time by examining whether the index component of the migration control data set resides on a DASD volume that has been SYSGEN'd as SHARED or SHAREDUP. If this is the case, DFSMSHsm performs what is called *multiple host serialization*.

Integrity age is established as follows:

- If serialization is DFHSM DATASET SERIALIZATION and the processing environment is a single DFSMSHsm-host environment, the integrity age is one day.
- If serialization is DFHSM DATASET SERIALIZATION and the processing environment is a multiple DFSMSHsm-host environment, the integrity age is two days.
- If serialization is USER DATASET SERIALIZATION, the integrity age is zero days.
- For temporary SMS-managed data sets in a JES3 environment, the integrity age is two days.

Automatic space management operation examples

It has been previously pointed out how the commands to control DFSMSHsm are structured. In the text that follows, examples are used to describe what DFSMSHsm does in the process of automatic space management. Automatic primary and secondary space management, event-driven migration, and automatic recall are shown.

Automatic space management

Figure 6 on page 57 shows the start of automatic space management. The data set names above the names of each of the groups of DASD devices and below the groups of tape devices are the names of data sets that are stored on the devices. Only the names of data sets that DFSMSHsm processes during this example are shown.

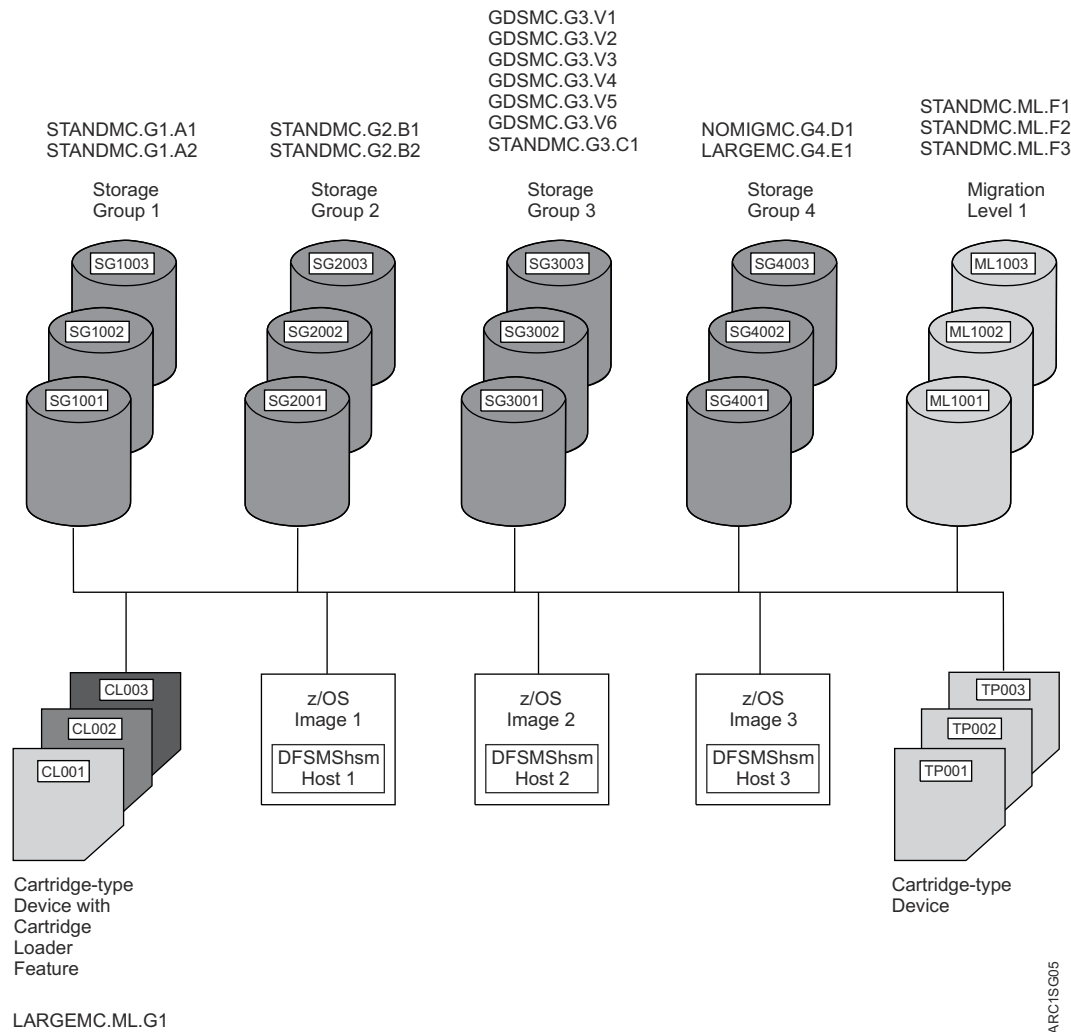

Figure 6. Example System of SMS-managed volumes before start of automatic space management

Note: The names of the management classes have been used as high-level qualifiers for the data set names. This was done to make it easier for you to associate the data sets with the management classes. This is merely a teaching aid. You are not required to use the management class name as any part of the name of the data set.

Table 4 on page 57 shows the characteristics of each of the data sets used in Figure 6 on page 57. The names of the data sets are not precisely as the system might generate them. They have been shortened and modified for convenience in using them for examples.

Table 4. Data set characteristics for automatic space management example				
Data set name	Days since created	Last usage (days)	Size (KB)	GDG Status
GDSMC.G3.V6	1	1	217	Not rolled off
GDSMC.G3.V5	2	2	215	Not rolled off
GDSMC.G3.V4	8	5	210	Not rolled off
GDSMC.G3.V3	10	5	207	Not rolled off
GDSMC.G3.V2	11	5	205	Not rolled off
GDSMC.G3.V1	15	5	200	Rolled off
LARGEMC.G4.E1	50	16	1200	None

Table 4. Data set characteristics for automatic space management example (continued)

Data set name	Days since created	Last usage (days)	Size (KB)	GDG Status
NOMIGMC.G4.D1	25	21	20	None
LARGEMC.ML.G1	183	120	1100	None
STANDMC.G1.A1	361	180	200	None
STANDMC.G1.A2	60	7	200	None
STANDMC.G1.A3	60	7	200	None
STANDMC.G2.B1	54	12	600	None
STANDMC.G2.B2	30	14	100	None
STANDMC.G3.C1	110	61	400	None
STANDMC.ML.F1	181	120	190	None
STANDMC.ML.F2	380	121	3	None
STANDMC.ML.F3	120	62	240	None

Note: 1 KB = 1024 bytes.

Integrating cloud storage into a DFSMSHsm automatic space management environment

Because cloud migration takes longer as opposed to migrating data sets to ML1, ML2, or CLOUD but uses less CPU time, you might want to set up a separate DFSMSHsm host that will perform migrations to cloud storage. When you set up the separate host, keep the following facts in mind:

- To tailor the processing that is done by the DFSMSHsm hosts, use the MIGRATIONAUTOCLOUD, STORAGEGROUPAFFINITY, and MIGRATEPSMEARLY parameters on the SETSYS command.
- HSM1 and HSM2 are hosts that should process migrations to ML1 and ML2.
- HSMC is a host that should process migrations to cloud storage.
- SYS1 is the system that HSM1 runs on. Storage group SG1 is defined to be processed by SYS1. Similarly, SYS2 is the system HSM2 runs on and storage group SG2 is defined to be processed by the SYS2.

Steps to take

To assign the cloud processing to HSMC, use the following specifications.

1. Specify MIGRATIONAUTOCLOUD(CLOUDONLY) to HSMC.
2. Specify MIGRATIONAUTOCLOUD(NOCLOUD) to HSM1 and HSM2.
 - HSM1 and HSM2 will skip any data sets it finds in SG1 and SG2, respectively, that are eligible to migrate to cloud storage as they perform primary space management.
 - HSMC will skip any data sets it finds that are not directed to cloud storage.
3. Specify STORAGEGROUPAFFINITY(SYS1, SYS2) to HSMC.
 - SG1 and SG2 will be processed even though HSMC runs on SYSC. (SG1 and SG2 are storage groups that are associated with both SYS1 and SYS2 in the MIGRATE SYSTEM/SYSPLEX NAME field of the storage group definition.)
4. Specify the EARLYMIGRATION(YES) parameter to HSMC, along with PRIMARYSPMGMTSTART(1800 0400).
 - The HSMC host will start its primary space management processing at 6 PM.

- HSMC will check the data sets for cloud migration eligibility and will migrate data sets at 6 PM that are eligible now or will be eligible after midnight. Thus, data sets that are eligible for migration after midnight can be migrated before midnight.

Starting automatic secondary space management

The REQUEST parameter of the SETSYS command can affect whether automatic secondary space management runs. When REQUEST is specified, DFSMSHsm requests the operator's permission before starting automatic secondary space management. If the operator replies NO, automatic secondary space management does not run until the next Y day in the cycle. If the operator replies YES, automatic secondary space management runs immediately after the reply, regardless of the amount of time that elapsed before the reply.

At the beginning of automatic secondary space management, DFSMSHsm requests a list of all defined management classes from SMS. If SMS does not return the list, DFSMSHsm considers SMS inactive and issues a message that automatic secondary space management cannot be performed for SMS-managed data sets.

DFSMSHsm also checks the last time automatic secondary space management ran, if the ending time was reached, and if all processing was complete. If the ending time was reached but processing was not complete, then the next time processing is scheduled to start, DFSMSHsm will resume processing at approximately the point it stopped, if the planned start time has not been changed.

Automatic secondary space management saves the resume key for every 50,000 MCD records read. The value 50,000 is stored in the MGCRCDS# field and can be patched to any other desired value.

The order of running migration cleanup and level 1 to level 2 migration depends on the point of resumption. The level 1 to level 2 migration could have run before migration cleanup if the automatic secondary space management stopped at level 1 to level 2 migration during the last run and did not complete. The threshold of level 1 migration volumes will not be checked again before the running of level migration if the automatic secondary space management functions resume processing at a point other than the beginning.

Using secondary host promotion, you can enable another host to take over secondary space management from a failed host. Secondary space management is typically run from only one host, so the ability to run the function from another host, should the need arise, can be quite useful.

Related reading

- For more information about the exceptions to obtaining a new list of management classes, see [“DFSMSHsm retrieval of management classes and storage groups” on page 154](#).
- For more information about secondary host promotion, see the sysplex topic in [z/OS DFSMSHsm Implementation and Customization Guide](#).

Migration cleanup

Before automatic secondary space management starts migration cleanup, it determines if there is any migration cleanup task running in another DFSMSHsm host. If there is, the migration cleanup will not be performed on this DFSMSHsm host. This avoids any unexpected results that might be created by running two migration cleanup tasks against the same MCDS at the same time.

When migration cleanup starts, it checks to see if any internal TAPECOPY processing is needed, and if so, schedules the internal TAPECOPY MWEs. Internal TAPECOPY processing could be needed because of duplexing errors or ABARS recovery of ML2 volumes.

Migration cleanup deletes the following:

- Expired migrated data sets. Migration cleanup deletes the data sets if:
 - For both SMS-managed and non-SMS-managed data sets, the data set has passed the expiration date indicated in the data set's VTOC entry and the EXPIREDDATASETS(SCRATCH) parameter is specified in the SETSYS command.

- For SMS-managed data sets, the data set does not have an expiration date but has passed the expiration attributes specified in the management class to which it is associated.
- For an SMS-managed NOSCRATCH GDS, the data set rolled off while on a level 0 volume and migrated, with rolled off GDG=EXPIRE in the management class and no expiration date in the VTOC.

See [“Specifying expiration attributes” on page 36](#) and [“Specifying how to scratch expired data sets” on page 49](#) for details on SMS-managed data sets.

- Migration copies of the data sets recalled from SDSP data sets. Because multiple recall tasks can access the small data set packing data sets concurrently, recall does not erase the migration copy.

Even though SDSP data sets used during migration cleanup are periodically released when not in use, and SDSP data sets needed by recall or aggregate backup are released when needed, it is recommended that you do not run secondary space management when automatic primary space management is running in order to avoid contention for SDSP data sets.

Every 30 seconds, migration cleanup checks to determine if recall or aggregate backup needs an SDSP data set. The value 30 is stored in the MCVT#CHK field and can be patched to any other desired value.

- MCDS data set (MCD) records for nonreconnectable data sets that are older than the number of days that are specified by the *recalldays* value of the SETSYS MIGRATIONCLEANUPDAYS command.
- MCDS data set (MCD) records for reconnectable data sets that have passed their predicted remigration date by the number of days that are specified by the *reconnectdays* value of the SETSYS MIGRATIONCLEANUPDAYS command. This occurs only if the *recalldays* criterion is also met.
- Daily statistics records and volume statistics records that are older than the number of days specified by the *statdays* value from the SETSYS MIGRATIONCLEANUPDAYS command.
- Migration copies not scratched during recall, deletion, or GDG roll-off of non-SMS-managed migrated data sets. These copies exist if an error occurred during recall or deletion, or if a generation data set had not passed its expiration date when the roll-off occurred.

Migration cleanup example

[Figure 7 on page 61](#) shows an example of SMS-managed volumes after migration cleanup has occurred for the conditions shown in [Figure 6 on page 57](#). Data set STANDMC.ML.F2 is deleted from the ML1 volumes because it has passed the EXPIRE AFTER DAYS NON-USAGE and EXPIRE AFTER DATE/DAYS values from management class STANDMC. Data set LARGEMC.ML.G1 is deleted from the ML2 tapes because it has passed the EXPIRE AFTER DAYS NON-USAGE and the EXPIRE AFTER DATE/DAYS values from the management class LARGEMC.

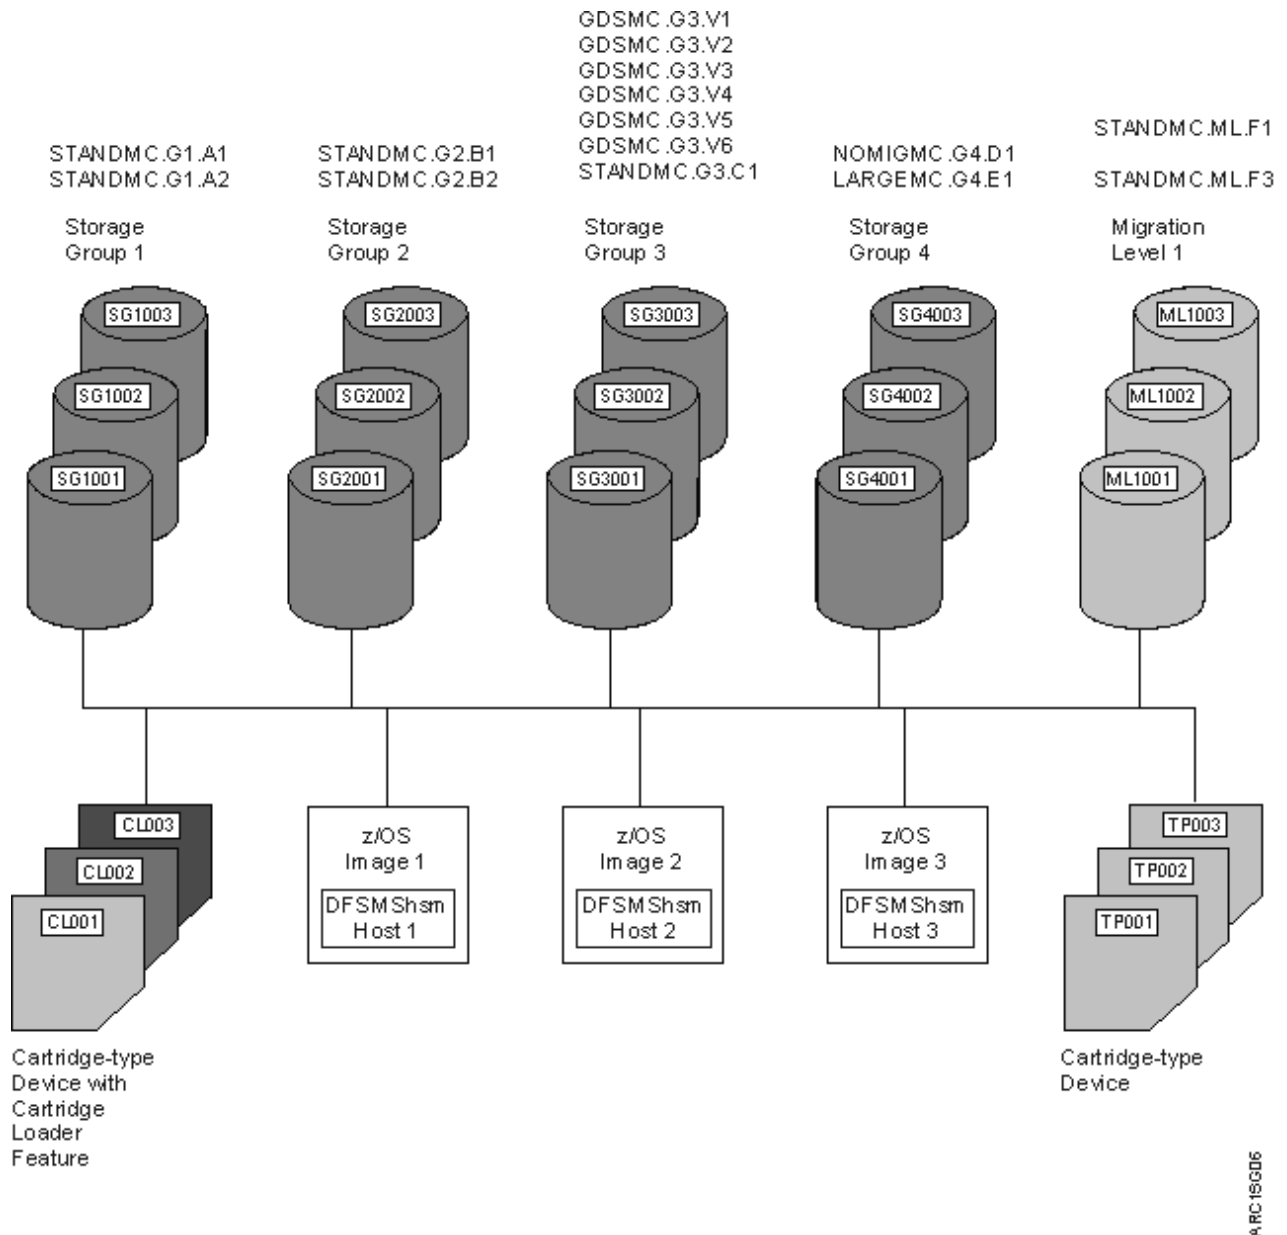

Figure 7. Example System of SMS-Managed Volumes after Migration Cleanup

Level 1 to level 2 migration

Before automatic secondary space management starts level 1 to level 2 migration, it performs the following checks:

- Checks to see there is any command level 1 to level 2 running. If yes, the level 1 to level 2 migration of automatic secondary space management will not start. There is no reason to run two level 1 to level 2 migrations at the same time.
- Performs a space check on the all ML1 volumes. If any NOOVERFLOW ML1 volume has an occupancy that is equal to or greater than its high threshold, then all eligible data sets migrate from the NOOVERFLOW ML1 volume to ML2 volumes. For OVERFLOW volumes, the percentage of occupied space for each ML1 OVERFLOW volume will be calculated and then DFSMSHsm will compare the average value with the specified threshold. Secondary space management is started for all eligible ML1 OVERFLOW data sets if the overflow volume pool threshold is met or exceeded. If you choose to use OVERFLOW volumes, you can specify the average overflow volume pool capacity threshold at which you want automatic secondary space management to migrate ML1 OVERFLOW volumes to ML2 volumes using the SETSYS ML1OVERFLOW command:

```
SETSYS ML1OVERFLOW(THRESHOLD(threshold))
```

Eligible SMS-managed data sets are those data sets that have passed the value you specified with the LEVEL 1 DAYS NON-USAGE attribute in their management class. Eligible non-SMS-managed data sets are those that have passed the value you specified with the MIGRATIONLEVEL1DAYS parameter of the SETSYS command.

ML2 volumes can be either DASD or tape. The TAPEMIGRATION parameter of the SETSYS command specifies what type of ML2 volume is used. The SETSYS command for DFSMSHsm host 2 specifies ML2 migration to tape.

Related reading

For more information about data set eligibility from Level 1 to Level 2, see [“Specifying when data sets become eligible for level 1 to level 2 migration”](#) on page 101. For information about the SETSYS ML1OVERFLOW command, see [“ML1OVERFLOW: Manage ML1 OVERFLOW volumes”](#) on page 1160.

Migration from SDSP data sets

Although SDSP data sets used during SSM migration cleanup are periodically released when not in use, it is still recommended that you do not run secondary space management when automatic primary space management is running in order to avoid possible contention for SDSP data sets.

Every 30 seconds, level 1 to level 2 migration checks to determine if recall or aggregate backup needs an SDSP data set. The value 30 is stored in the MCVT#CHK field and can be patched to any other desired value.

Migration to a tape migration level 2 volume

At the beginning of a level 1 to level 2 migration task, DFSMSHsm selects the partial tape with the largest percentage that is written. This might be one of the following tapes:

- The tape last used by this task
- A tape ML2 volume from the list of not-associated, partially empty tape volumes
- An empty tape (if available), but only if no partially empty tape is available

DFSMSHsm selects tapes differently if you are using the duplex tape option for migration tapes.

DFSMSHsm does not migrate a data set to a tape ML2 volume if the data set needs to be backed up.

When a tape unit and a tape volume are allocated, they remain allocated and mounted until the migration is completed or the volume becomes full or is needed by another function. When level 1 to level 2 migration is completed, the tape volume is deallocated and demounted.

Related reading

- For more information about the duplex tape option, see [“Duplex tape option”](#) on page 436.
- For more information about contention for migration volumes, see [“Tape migration level 2 volume contention”](#) on page 136.

Migration to a DASD level 2 volume

For each data set that migrates from an ML1 volume to DASD ML2, DFSMSHsm uses the set of initial characters of the data set name and the key ranges that you defined to choose the DASD ML2 volume. The *key range* is the total set of data set names whose initial characters are between a low key and a high key in collating sequence.

If DFSMSHsm fails the migration of data sets from an ML1 volume to an ML2 volume because the ML2 volume being used with that key range does not have enough space, DFSMSHsm does the following:

1. Disassociates the full volume from the key range.

2. Tries to assign an available DASD ML2 volume to the key range in place of the full volume. An available DASD ML2 volume is a volume that meets all of the following criteria:
 - It has been added to DFSMSHsm as an ML2 volume. The ADDVOL *valid* MIGRATION(MIGRATIONLEVEL2) command adds ML2 volumes to DFSMSHsm.
 - It has not been associated with a key range. The DEFINE MIGRATIONLEVEL2(KEYS(*key* . . .) VOLUMES(*valid* . . .)) command associates ML2 volumes with key ranges.
 - DFSMSHsm has never chosen it as a replacement for an ML2 volume.
 - It does not have the DRAIN attribute in its ADDVOL command.
3. Retries the migration of the data set one time.

If there is no ML2 volume to choose as a replacement volume, DFSMSHsm stops level 1 to level 2 migration for the key range defined for the full ML2 volume. DFSMSHsm continues migrating data sets for all other key ranges.

Related reading

- For more information about how to define key ranges, see [“MIGRATIONLEVEL2: Specifying DASD level 2 volumes and their associated key range structure” on page 831.](#)
- For more information about what to do to make new ML2 volumes available when all ML2 volumes are full, see [“Making migration level 2 key range volumes available” on page 551.](#)

Output media error handling

During level 1 to level 2 migration of automatic secondary space management processing, if an error condition occurs on any output media (tape or DASD), a message is sent to the operator's console to inform the operator of the error condition, and the task is stopped. DFSMSHsm does not remove this message from the console; therefore, the operator must enter a console command to remove the message.

If you are using the duplex tape option for your migration tapes, and the error condition occurs on the alternate volume, the function is not stopped.

When the error condition that caused the level 1 to level 2 migration to end is corrected, the operator can restart level 1 to level 2 migration if the current time is within the automatic secondary space management window. You can use one of the following commands to restart level 1 to level 2 migration:

- RELEASE MIGRATION(AUTO)
- RELEASE MIGRATION
- ADDVOL (volume of the device type in error) and RELEASE MIGRATION or RELEASE MIGRATION(AUTO)

Related reading

For more information about the duplex tape option, see [“Duplex tape option” on page 436.](#)

Installation exits called during level 1 to level 2 migration

Two installation exits can be called during level 1 to level 2 migration: the tape data set exit and the second-level migration data set exit.

The tape data set exit (ARCTDEXT) receives control (if it is enabled) when an output tape data set is opened if the tape security option is expiration date (EXPIRATION) or expiration date including password-protected data sets (EXPIRATIONINCLUDE). You can use the tape data set exit to change the expiration date to be recorded in the tape label to a date other than 99365.

The second-level migration data set exit (ARCMEXT) receives control when a migrated data set is selected for migration. You can use this exit to further control whether data sets migrate from ML1 volumes to other migration volumes. For example, you can use this exit to hold small data sets in SDSP data sets on ML1 volumes instead of allowing them to migrate to ML2.

Related reading

For more information about DFSMSHsm exits, see [z/OS DFSMS Installation Exits](#).

Example of level 1 to level 2 migration

Figure 8 on page 64 shows SMS—managed volumes after level 1 to level 2 migration. In this figure, at least one of the ML1 volumes had reached or exceeded its threshold of occupancy when DFSMSHsm performed its space check. Data set STANDMC.MLF3 migrates from the ML1 volumes to the tape ML2 volumes (a cartridge-type device) because it has passed the LEVEL 1 DAYS NON-USAGE value from management class STANDMC.

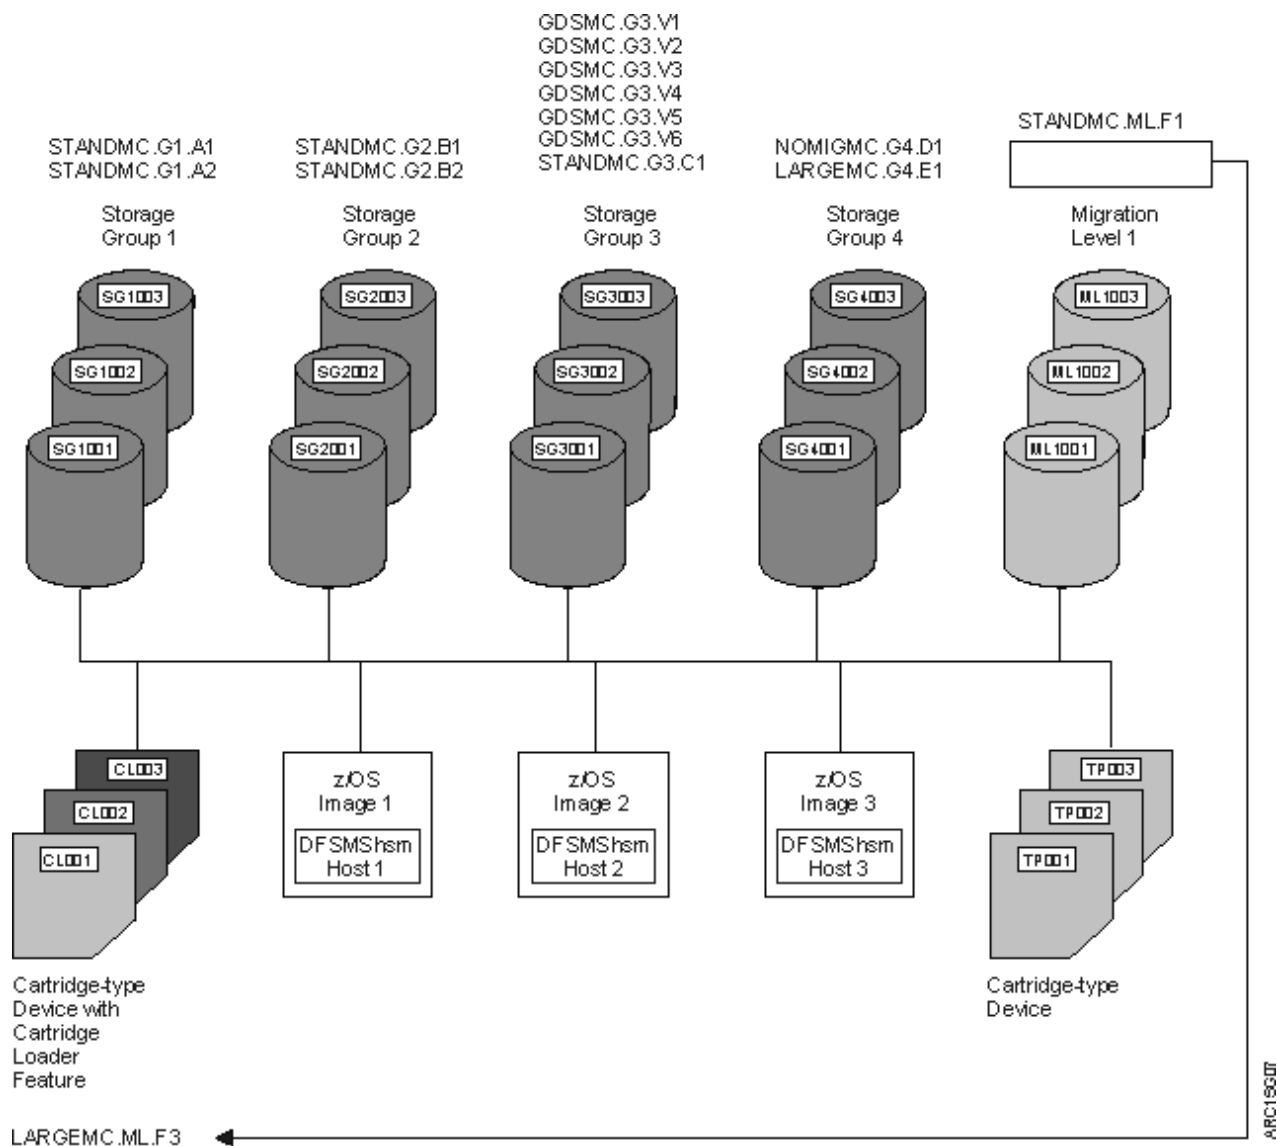

Figure 8. Example System of SMS-Managed Volumes after Level 1 to Level 2 Migration

Starting automatic primary space management

At the beginning of automatic primary space management in each of the DFSMSHsm hosts, if SMS is active, DFSMSHsm requests a list of all defined management classes and storage groups from SMS if the SMS configuration has changed since the last time DFSMSHsm requested this information. If you have not provided any management class definitions, DFSMSHsm builds a default management class definition. If SMS does not return any storage group definitions, DFSMSHsm considers SMS to be inactive.

If SMS is active, DFSMSHsm processes any SMS volumes that the z/OS image is allowed to process and that have the AM=Y, AM=I, or AM=P attribute, and any non-SMS-managed primary volumes. If SMS is not installed and active, DFSMSHsm processes only non-SMS-managed primary volumes. For purposes of the example, it is assumed that SMS is installed and active.

Related reading

For more information about the exceptions to obtaining a new list of management classes, see [“DFSMSHsm retrieval of management classes and storage groups” on page 154.](#)

Automatic primary space management

At the beginning of automatic primary space management, DFSMSHsm determines which volumes are candidates for processing. Volumes in storage groups that have a z/OS image specified by the MIGRATE SYSTEM/SYSPLEX NAME have a z/OS image affinity.

DFSMSHsm uses the following order of processing as a method of controlling input path contention. This order is subject to prioritizing for SMS volumes restricted to processing by one z/OS image.

1. Affinity SMS volumes
2. Retry of in-use affinity SMS volumes
3. Non-SMS and non-affinity SMS volumes

After DFSMSHsm has attempted to process all the candidate volumes eligible for automatic primary space management, it retries the selection of any of these volumes that were found to be in use by another DFSMSHsm function.

If multiple DFSMSHsm hosts perform automatic primary space management, only the first host to process a given volume performs the function.

Specifying a storage group priority for space management functions

The storage group processing priority of the volumes assigned to an SMS storage group may be specified within the storage group definition. The default value is 50. DFSMSHsm will process all of the SMS volumes in the order of the processing priority, with 100 being the highest and 1 being the lowest. This processing priority can help ensure that storage groups that need to be processed first during interval migration, on-demand migration, and primary space management are done so in order.

Note: This processing priority can help ensure that storage groups that will be receiving data sets as the result of class transitions are processed first, in order to free up the necessary space for the expected new allocations.

Overview of two-pass automatic primary space management

DFSMSHsm-managed volume space management is performed in two passes, as follows:

1. **Pass 1** deletes the appropriate data sets, releases unused space, performs fast subsequent migration, and determines which data sets on the volume are candidates for migration, class transitions, or extent reduction. Performs class transitions with management class changes only.
2. **Pass 2** processes the candidates for extent reduction, transitions data sets, and migrates data sets until the low threshold of occupancy is reached.

Pass 1 of automatic primary space management

During pass 1, DFSMSHsm examines every data set on a volume, independent of the occupancy of the volume, without moving data sets. Unless the data set is an unmatched data set, DFSMSHsm compares the integrity age with the unused age to make sure that it is allowed to process the data set. The unused age is the difference between the current date and the date-last-referenced.

Rule: The unused age must be greater than or equal to the integrity age.

Pass 1 of DFSMSHsm-managed volume space management performs the following functions:

- Issues a message for unmatched data sets
- Deletes temporary data sets
- Deletes expired data sets
- Determines data sets that are eligible for migration
- Excludes from migration to tape those data sets that are eligible to be backed up
- Determines data sets that are eligible for extent reduction
- Releases unused space for eligible data sets
- Performs fast subsequent migration for eligible data sets
- Determines data sets that are eligible for class transitions
- Performs class transitions with management class changes only

For each of the data sets, DFSMSHsm uses the attributes specified in the management class with which the data set is associated. If no management class is associated with the data set, DFSMSHsm uses the default management class.

Related reading

- For more information about the integrity age, see [“Integrity age for space management” on page 56](#).
- For more information about unmatched data sets, see [“Unmatched data sets” on page 66](#).
- For more information about default management classes, see [“Using the default management class” on page 40](#).

Unmatched data sets

If the catalog entry, the data set VTOC entry, or both are missing, the data set is an unmatched data set. For an unmatched data set, the space management and backup exit (ARCSAEXT) is invoked, if the exit is enabled. If the exit indicates that processing continues, or if the exit is not enabled, DFSMSHsm issues a message, does no further processing on the unmatched data set, and begins processing the next data set. If the exit indicates that processing is not to continue, DFSMSHsm begins processing the next data set without issuing any message.

Deleting temporary data sets

If for some reason (such as a system outage) SMS-managed temporary data sets are not deleted at end of job, DFSMSHsm attempts to delete them during automatic primary space management. A flag in the data set VTOC entry indicates that a data set is temporary.

If no cross-system serialization exists, or if cross-system serialization is not performed for temporary data sets, an in-use temporary data set can be deleted. In a JES3 environment, the data set must be two days old before it can be deleted.

Deleting expired data sets

If the EXPIREDDATASETS(SCRATCH) parameter is specified in the SETSYS command, DFSMSHsm deletes any non-VSAM data set whose VTOC entry shows that the data set has passed its expiration date and any VSAM data set whose catalog entry shows that the data set has passed its expiration date. The management class expiration attributes control the expiration of non-VSAM data sets that do not have a valid expiration date in their data set VTOC and VSAM data sets that do not have a valid expiration date in their base cluster catalog entry.

Note: For multivolume non-VSAM data sets, DFSMSHsm looks at the VTOC of the first volume.

If concurrent copy was used to back up the data set and a system failure or cancel of DFSMSHsm occurred after the concurrent copy session was established, then the data-set-changed indicator can be off even

though the data set was not successfully backed up. This can result in the data set prematurely meeting the expiration criteria.

DFSMSHsm provides a patch byte that enables users to override the requirement that an SMS-managed data set have a backup copy before it is expired. For more information about this patch, see [Tuning DFSMSHsm in z/OS DFSMSHsm Implementation and Customization Guide](#).

DFSMSHsm deletes rolled-off generation data sets that meet either of the following conditions, regardless of the EXPIREDDATASETS parameter of the SETSYS command.

- It is associated with a management class that has the attribute ROLLED-OFF GDS ACTION=MIGRATE and both of the following apply:
 - It does not have an expiration date in the data set VTOC entry.
 - It has passed the date and time limit specified by the EXPIRE AFTER DAYS NON-USAGE and EXPIRE AFTER DATE/DAYS attributes in the management class.
- It is associated with a management class with the attribute ROLLED-OFF GDS ACTION = EXPIRE and it has no expiration date in the data set VTOC entry.

Note: DFSMSHsm deletes active generation data sets in the same way it deletes non-GDS data sets.

Determining eligible data sets for class transitions and migration

DFSMSHsm checks the COMMAND OR AUTO MIGRATE attribute in the management class to which the data set is associated. If the value of the attribute is BOTH, DFSMSHsm determines whether the data set is eligible for a class transition or migration.

A data set is eligible for a class transition if the data set has met or exceeded any of the three class transition criteria specified within the assigned management class (TIME SINCE CREATION, TIME SINCE LAST USE, or PERIODIC). If a data set transitions to a new management class, then the data set will be eligible for another transition when the volume is next space managed, based on the criteria within the newly assigned management class. If a different management class is not assigned during a transition, then a data set will not transition again if either TIME SINCE CREATION or TIME SINCE LAST USE are the criteria that is used. If a PERIODIC value is specified, then a data set will transition as often as needed.

Four conditions determine whether a data set is eligible for migration:

- The MIGRATE value of the ROLLED-OFF GDS ACTION attribute
- Whether the data set is a generation that exceeds the value specified by the # GDG ELEMENTS ON PRIMARY attribute in the management class
- Whether the data set is an SMS-managed MVS or IMS GSAM checkpointed data set
- The number of days since the data set was last used

Rolled-off generation data sets that belong to a management class with the attribute ROLLED-OFF GDS ACTION=MIGRATE are always identified as migration candidates with the highest migration priority.

Non-rolled-off generation data sets that exceed the value specified with the # GDG ELEMENTS ON PRIMARY attribute for their management class are always identified as candidates with priority for early migration. The priority of such data sets is just below that for rolled-off generation data sets.

For both command and event-driven migration, DFSMSHsm determines whether the data set being migrated is a checkpointed data set. DFSMSHsm migration, including extent reduction, is delayed for a fixed number of days for SMS-managed MVS and IMS GSAM checkpointed data sets. The default delay is five days. If the data set is checkpointed, DFSMSHsm determines whether the data set is eligible for migration. A checkpointed data set is eligible for migration when the date-last-referenced, plus the number of days the data set is to be treated as unmovable, are less than or equal to the current date. For data set command migration, error messages are issued for ineligible data sets.

DFSMSHsm provides a patch byte that enables users to modify the number of days that must have elapsed since the date-last-referenced for a checkpointed data set to be eligible for migration. For more information about this patch, see [Tuning DFSMSHsm in z/OS DFSMSHsm Implementation and Customization Guide](#).

Checkpointed data sets must meet a minimum age value before being considered for migration. The default is five days and can be changed using a patch. Once the minimum age value is met, the checkpointed data sets can be identified as migration candidates if the time since they were last used meets or exceeds the value specified by the PRIMARY DAYS NON-USAGE attribute for their management class.

All other data sets, including generation data sets that were not given special migration priority, are identified as migration candidates if the time since they were last used meets or exceeds the value specified by the PRIMARY DAYS NON-USAGE attribute for their management class.

If the COMMAND OR AUTO MIGRATE attribute in a data set's management class is set to BOTH, with the PRIMARY DAYS NON-USAGE attribute set to 9999, and the # GDG ELEMENTS ON PRIMARY attribute set to 1, then relative zero-generation data sets can remain on a user's primary disk for up to 30 years. (The # GDG ELEMENTS ON PRIMARY attribute overrides the PRIMARY DAYS NON-USAGE attribute.) When a generation moves from zero to -1, it becomes eligible to migrate immediately, independent of the PRIMARY DAYS NON-USAGE value.

When a data set is identified as a migration candidate, it is also identified for the target migration volume device type: DASD or tape. The device type chosen depends on the value in the LEVEL 1 DAYS NON-USAGE attribute of its management class. If the value of the attribute is 0, the data set is identified for migration to ML2 tape. If the value of the attribute is 1–9999 or NOLIMIT, the data set is identified for migration to ML1 DASD.

Determining eligible data sets for backup

After DFSMSHsm determines that a data set is eligible for a class transition or migration, it checks whether the data set needs to be backed up.

For class transitions, a data set must be backed up if the TRANSITION COPY TECHNIQUE specifies that fast replication should be used or preserve mirror is preferred. If the data set has not been backed up and fast replication or preserve mirror are preferred, then standard data movement will be performed. If the data set has not been backed up and fast replication is required, then the transition will fail. A backup copy is not required when FC XRC Primary is set.

A backup copy is required whenever a fast replication technique other than preserve mirror required or FC XRC primary is used because DFSMSHsm processing for the data set completes before the data set is physically copied. If the TRANSITION TECHNIQUE preserve mirror required is specified to allow FlashCopy to Global Mirror Primaries, a valid backup copy must exist before the data set residing on a Global Mirror primary volume is transitioned. While unlikely, it is possible for the physical copy to fail. Requiring a backup copy of the data set ensures the availability of the data set should the physical copy fail. Preserve mirror and Remote Pair FlashCopy (RPF) for XRC ensures that the data set is physically copied at both the local and remote site, which protects against errors.

For migration, a data set must be backed up if all of the following criteria are met:

- The data-set-changed indicator in the data set VTOC entry indicates that the data set has been changed.
- The management class contains the attribute AUTO BACKUP=Y.
- The management class ADMIN OR USER COMMAND BACKUP attribute contains either of the values ADMIN or BOTH.
- The storage group has the attribute AUTO BACKUP=Y.

DFSMSHsm identifies any migration-eligible data set that must be backed up. If the data set that must be backed up is identified for migration to tape, DFSMSHsm removes the identification as a migration candidate.

If concurrent copy was used to backup the data set and a system failure or cancel of DFSMSHsm occurred after the concurrent copy session was established, then the data-set-changed indicator can be off even though the data set was not successfully backed up. If this happens, migration will not identify the data set as needing a backup copy.

Determining eligible data sets for extent reduction

After determining if the data set is eligible for backup, DFSMSHsm determines if the data set is eligible for extent reduction. DFSMSHsm identifies a non-VSAM single-volume data set as eligible for extent reduction if all of the following criteria are met:

- The data set has as many extents or more than the value specified by the MAXEXTENTS parameter of the SETSYS command.
- The data set also meets data integrity age.
- If the data set is an SMS-managed MVS or IMS GSAM checkpointed data set, it meets the requirements for date-last-referenced plus the number of days the data set is to be treated as unmovable.
- The value of the COMMAND OR AUTO MIGRATE attribute is BOTH.

Note:

1. DFSMSHsm does not perform extent reduction on any extended format sequential data set.
2. Extent reduction will not occur on SMS-managed data sets with COMMAND OR AUTO MIGRATE=NONE specified, or on non-SMS-managed data sets with SETMIG NOMIGRATION specified.

Releasing unused space

For all physical sequential, partitioned, and extended format VSAM KSDS single-volume data sets that belong to a management class with the attribute PARTIAL RELEASE=Y (or C for VSAM), DFSMSHsm invokes the PARTREL function of DADSM if either of the following conditions is met:

- The data set is not a candidate for extent reduction.
- At least one track will be released by PARTREL.

DFSMSHsm issues a message indicating the result of the partial release and the number of tracks freed for each data set if the activity logging message level is FULL or REDUCED.

Performing fast subsequent migration

Fast subsequent migration allows unchanged data sets that are recalled from a single ML2 tape to be reconnected to the ML2 tape from which they were most recently recalled. For a data set to be eligible for reconnection, it must meet standard migration eligibility requirements as well as fast subsequent migration eligibility requirements.

Related reading

- For more information about fast subsequent migration, see [“Reconnecting data sets using fast subsequent migration”](#) on page 94.
- For a list of reconnection eligibility requirements, see [Fast subsequent migration \(reconnection\) eligibility requirements](#).

Performing class transition with management class changes only

Change the data set management class if the storage group and storage class are not changed.

Pass 1 processing example

Figure 9 on page 70 shows the results of pass 1 processing. Data set STANDMC.G1.A1 was deleted because it exceeded the EXPIRE AFTER DATE/DAYS and EXPIRE AFTER NON-USAGE values of the STANDMC management class. Data set GDSMC.G3.V1 was deleted because it is a rolled-off GDS with

the EXPIRE value in the ROLLED-OFF GDS ACTION attribute in GDSMC management class. Data set NOMIGMC.G4.D1 was deleted because it exceeded the EXPIRE AFTER DAYS NON-USAGE attribute of the NOMIGMC management class. Data set STANDMC.G1.A3, which has not changed from Figure 8 on page 64, was recalled from ML2. It is reconnected during Pass 1 to its original ML2 tape.

Note: The data sets in the NOMIGMC management class never migrate because the COMMAND OR AUTO MIGRATE attribute has the value of NONE, but they are processed for expiration and for PARTIAL RELEASE.

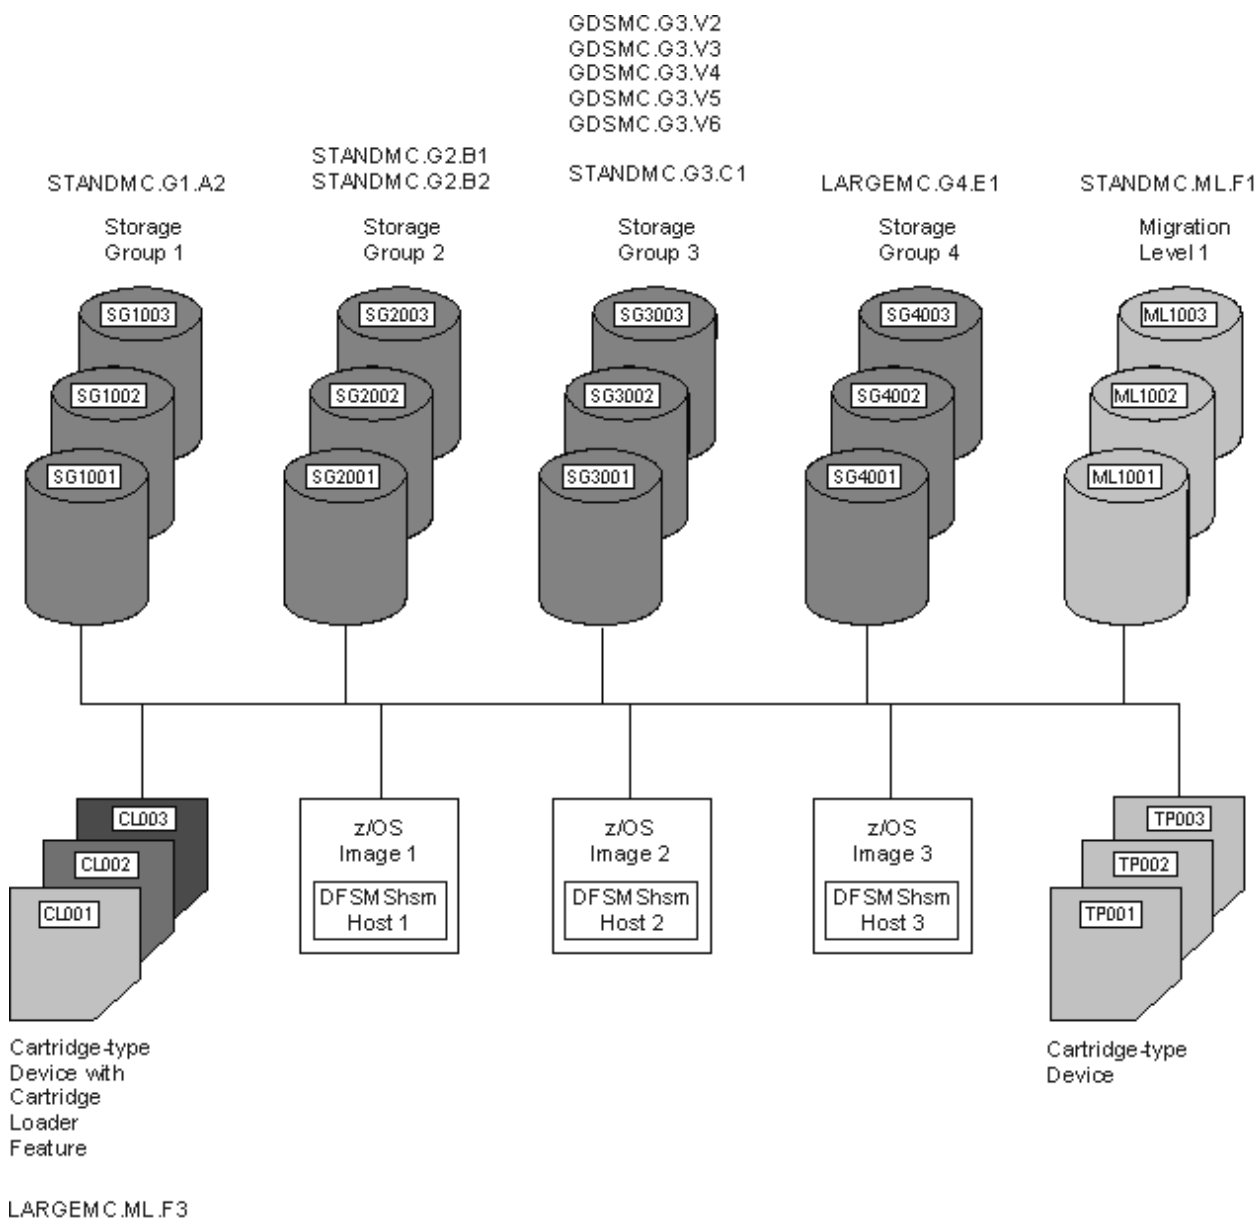

Figure 9. Example System of SMS-Managed Volumes after DFSMSHsm-Managed Volume Management Pass 1

Pass 2 of automatic primary space management

During pass 2 of automatic primary space management, DFSMSHsm transitions or migrates data sets from the volumes until the space occupied on the volumes is equal to or less than the space specified by the low-threshold attributes contained in the storage groups to which the volumes belong. DFSMSHsm migrates only those data sets that have been identified for class transitions, migration, or extent reduction by pass 1 of DFSMSHsm-managed volume space management. The following steps are performed in pass 2:

1. Transition data sets that are candidates both for a class transition and extent reduction.
2. Migrate data sets that are candidates both for migration and for extent reduction.
3. Migrate data sets that are candidates only for extent reduction. Schedule a recall for each data set.
4. Transition data sets that are candidates for a class transition in FIFO until the low threshold of occupancy is reached.
5. Migrate data sets in priority order until the low threshold of occupancy is reached.

Note: If a data set is eligible for both a class transition and migration, then the data set will migrate.

Transition data sets that are candidates for a class transition

Data sets that are eligible for a class transition are processed first. If a data set is eligible for both a class transition and migration, then the data set will be migrated.

When a data set meets the management class criteria for a class transition, then DFSMSHsm invokes the ACS routines with the ACS environment SPMGCLTR to determine if there is a newly assigned management class, storage class or storage group. If that data set is assigned a new management class and the storage class and storage group remain unchanged, then DFSMSHsm will ALTER that data set to reassign the data set to the newly assigned management class. No data movement will occur. The newly assigned management class will be used to determine how the data set is managed during future space management processing.

If a data set is assigned a new storage class or storage group, then the data set will be moved. DFSMSHsm will invoke DFSMSdss to move the data set with the logical data set copy and delete operation. This process will invoke SMS to use the newly assigned storage class and/or storage group for the allocation.

Data sets are transitioned until the occupied space is equal to or less than the low threshold specified by the storage group or until no more class transition candidates exist on the volume. If the low threshold has been met, DFSMSHsm ends automatic primary space management processing for that volume. If the low threshold has not been met, then primary space management processing continues for migration and extent reduction candidates.

DFSMSHsm does not keep any records for transitioned data sets within its control data sets. Function Statistics Records (FSR) are used to track transition processing. Storage administrators may use the various reporting techniques available for FSR records to analyze DFSMSHsm's class transition processing. A sample report is provided for the DFSMS Report Generator. (See [“Running new reports with report generator” on page 575.](#)) The DFSMSHsm REPORT function also provides basic reporting information.

By default, failing messages are not issued for data sets that fail a transition because exclusive serialization could not be obtained. It is recommended that these data sets be analyzed by post processing the FSR records with failing return code RC68 and reason code REAS410. If desired, the patch offset which enables these messages is:

```
PATCH .MGCB.+EF BITS(...1...)
```

Migrate candidates for both migration and extent reduction

Any data set that is identified as a candidate for extent reduction always migrates. However, a data set that is identified as a candidate for both migration and extent reduction is not recalled.

Migrate candidates for extent reduction

DFSMSHsm migrates the data sets that are candidates for extent reduction and schedules recalls for those same data sets. During the migration, DFSMSHsm moves only the valid data from the data sets. Therefore, when the data sets are recalled into fewer extents, they may occupy less space.

Note, also, the following rules:

- If the data set is eligible for a class transition with data movement (DSS Copy/Delete) and extent reduction, then only the class transition will be performed.

- If the data set is eligible for a class transition without data movement (i.e. only the management class is changing) and extent reduction, then extent reduction will be performed after the class transition (again, with only the management class changing, without data movement).
- If the data set is eligible for a class transition, migration and extent reduction, then only the migration will be performed.
- If the data set is eligible for extent reduction only, then the data set will be processed after all data sets eligible for extent reduction and class transition, and after all the data sets eligible for extent reduction and migration have been processed.

Place candidate data sets in priority order for migration

After performing class transitions and migrating data sets for extent reduction, DFSMSHsm places the remaining candidates for migration in order by priority. DFSMSHsm gives the highest priority for migration to rolled-off generation data sets. It gives second priority to non-rolled-off generation data sets that have been identified for early migration. These are the non-rolled-off data sets that exceed the number specified by the # GDG ELEMENTS ON PRIMARY attribute.

After the two highest priority groups, priority is assigned to all other data sets on the basis of size and age. The age, for migration priority purposes, is an eligibility age determined from the last-used date and the value of the PRIMARY DAYS NON-USAGE parameter. Small data sets must be eligible for a longer time to attain the same or higher priority as larger data sets.

Migrate data sets

After putting the candidate data sets in priority order, DFSMSHsm compares the occupied space on the volume to the low threshold for the volume. If the occupied space is more than the low threshold, DFSMSHsm migrates the highest priority data set. Data set size is a determining factor for the order in which data sets are migrated. Managing an entire extended address volume (EAV) with one threshold is not sufficient because average data set size in the cylinder-managed space will likely exceed the average data set size in track-managed space. This will result in data sets allocated in the cylinder-managed space being migrated at a higher rate than data sets allocated in the track-managed space, potentially causing no space in the track-managed space being freed. To prevent this, a unique threshold for the track-managed space (track-managed threshold) is used to manage the free space separate from the free space on the entire volume (volume-level threshold).

Data sets that fail reconnection remain eligible for normal migration. Data sets that fail reconnection because there is no ability to serialize either the data set or the target ML2 volume are assigned the lowest migration priority.

Data sets are migrated until the occupied space is equal to or less than the low threshold specified by the storage group or until no more migration candidates exist on the volume. At that point, DFSMSHsm ends automatic primary space management processing for that volume.

As DFSMSHsm selects each data set for migration, it transfers control to the space management exit (ARCMDEXT) if the exit is installed and enabled.

Table 5 on page 72 shows the rules governing migration versus class transition, based on eligibility and the return code from the migration exit.

<i>Table 5. Rules for migration versus class transition, based on eligibility and return code from migration exit</i>			
Eligibility Status	Migration Exit RC=0 (Allow Migration)	Migration Exit RC=8 (Disable Migration)	Migration Exit RC=52 (Disable Migration and Class Transition)
Eligible for migration only	Migration	Data set processing fails with RC=45, reason 92	Data set processing fails with RC=45, reason 92
Eligible for migration and class transition	Migration	Class transition	Data set processing fails with RC=45, reason 92

Table 5. Rules for migration versus class transition, based on eligibility and return code from migration exit (continued)

Eligibility Status	Migration Exit RC=0 (Allow Migration)	Migration Exit RC=8 (Disable Migration)	Migration Exit RC=52 (Disable Migration and Class Transition)
Eligible for class transition only	Class transition	Class transition	Data set processing fails with RC=45, reason 92

If any data set is directed to tape during DFSMSHsm-managed volume space management, a tape volume is allocated and mounted. If you are using the duplex tape option for migration, two tape volumes are allocated and mounted. When a tape volume is allocated for DFSMSHsm-managed volume migration, it remains allocated until it becomes full or is needed for some other DFSMSHsm function. When the DFSMSHsm host finishes DFSMSHsm-managed volume migration, DFSMSHsm deallocates and demounts the tape volume.

Output media error handling

Class transitions may only be directed to DASD, via the SMS ACS routines.

You can use both tape and DASD as migration devices concurrently. During such an operation, if migration to either tape or DASD is ended because of an error condition, a message is issued, but migration continues to the device type that is not affected by the error condition. A highlighted message is sent to the operator’s console to inform the operator of the error condition. DFSMSHsm does not remove this message from the console; the operator must issue a console command to remove it.

After correcting the error condition that caused the migration to tape or DASD to end, the operator can allow DFSMSHsm to resume migration to the device that was in error by issuing one of the following commands:

- RELEASE MIGRATION(AUTO)
- RELEASE MIGRATION
- ADDVOL (for a volume of the device type in error)

If error conditions make both tape and DASD unavailable as migration targets, migration processing ends, a message is issued to the operator, and migration is held.

Names of migrated data sets

When DFSMSHsm migrates a data set, it changes the catalog entry for that data set. The data set retains its name, so the users of the data set know how to address it, but the location is changed to MIGRAT. However, DFSMSHsm gives the migration copy of the data set a name of the form:

```
prefix.HMIG.Tssmmhh.user1.user2.Xydd
```

If patch-enabled, the following dataset name will be generated:

```
prefix.HMIG.Tcccchh.user1.user2.Xydd
```

where:

- *prefix* is the prefix you specify with the SETSYS MIGRATEPREFIX command.

- HMIG and T are constants.

Note: If two or more data sets with the same first two high-level qualifiers are migrated during the same second on the same day, DFSMSHsm assigns a letter other than T to one of these data sets.

- *ssmmhh* is the time in seconds, minutes, and hours.

If the format is *Tcccchh*, then *cccchh* is the time in hundredths of seconds from the beginning of the hour converted to four alphabetic characters, and *hh* is hours.

The four characters *cccc* may be converted to time as follows:

1. Create a variable for each character of the string *cccc*, using *p1* through *p4*, from left to right. Then assign a value 0 thru 24 for each character A thru Y in the sequence. (Note that 25 characters are used, for A through Y, but not Z.)
2. Find the total hundredths of seconds from the beginning of the hour using this formula:

```
hunds_seconds_begin_hour = p1+(p2*25)+(p3*625)+(p4*625*25)
```

3. Find the minutes, seconds, and hundredths using these formulae (% = integer division):

```
minutes = hunds_seconds_begin_hour%(60*100)
seconds = (hunds_seconds_begin_hour-minutes*60*100)%100
hundredths = hunds_seconds_begin_hour-minutes*60*100-seconds*100
```

- *cccchh* is the time in hundredths of seconds from the beginning of the hour converted to four alphabetic characters (*cccc*) and hours (*hh*).

The four characters *cccc* may be converted to time as follows:

1. Create a variable for each character of the string *cccc*. Assume these variables are *p1* thru *p4*, from left to right. Assign a value 0 thru 24 for each character A thru Y, in sequence (25 characters are used A - Y, but not Z).
2. Find the total seconds from the beginning of the hour:

```
hunds_seconds_begin_hour = p1+(p2*25)+(p3*625)+(p4*625*25)
```

3. Find minutes, seconds, and hundredths (% = integer division):

```
minutes = hunds_seconds_begin_hour%(60*100)
seconds = (hunds_seconds_begin_hour-minutes*60*100)%100
hundredths = hunds_seconds_begin_hour-minutes*60*100-seconds*100
```

For more information, refer to [Changing DFSMSHsm backup and migration generated data set names to reduce contention for similar names and eliminating a possible performance degradation in z/OS DFSMSHsm Implementation and Customization Guide](#).

- *user1* and *user2* are the first two qualifiers of the data set name.
- *Xydd* is the year and day. X is replaced with a letter that represents the decade as follows:

G = 1970	B = 2020
H = 1980	C = 2030
I = 1990	D = 2040
J = 2000	E = 2050
A = 2010	F = 2060

If, for example, I9012 replaces *Xydd*, then I9012 represents January 12, 1999.

If you need to access a single-file format tape, you must specify a valid data set name for the single file that comprises up to 255 tape volumes. The following migrated data set name is valid for each set of cartridge-type tape volumes in single-file format:

```
prefix.HMIGTAPE.DATASET
```

Only the last 17 characters (.HMIGTAPE.DATASET) are recorded in the tape label. To access the single-file format data set, you must supply any valid *prefix* along with the .HMIGTAPE.DATASET qualifiers.

The following tape data set name for each copy of a cartridge-type tape volume is created by the TAPECOPY command or the duplex tape option:

```
prefix.COPY.HMIGTAPE.DATASET
```

Compaction or zEDC compression during migration

If you specify the compaction during migration option, DFSMSHsm compacts each data set as it migrates. The first time the data set migrates, DFSMSHsm always compacts it. If a migrated data set is recalled and is again a candidate for migration, DFSMSHsm checks the compaction history in the MCDS for that data set. If the compaction from the earlier migration did not result in saving at least the percentage of space that you specified with the COMPACTPERCENT parameter of the SETSYS command, DFSMSHsm does not perform compaction again.

Note: If the data set is a SAM or VSAM compressed data set, DFSMSHsm suspends compaction during migration and records in the MCDS that the data set is striped, compressed, or both.

If the data set is to migrate to an SDSP, the compaction size is always estimated using an internal default of 50%. Previous compaction history is not considered.

Alternately, if you specify zEDC compression instead of compaction (via the ZCOMPRESS parameter of the SETSYS command), zEDC compression will be done instead of compaction. If zEDC Services are *not* available, DFSMSHsm will use the SETSYS COMPACT settings to determine what type of software compaction is used for migration. See [“ZCOMPRESS: Specifying when compression with zEDC should be done” on page 1207](#) for more information.

If the data set is being migrated to a cloud object store defined in the SMS network connection construct that supports transparent cloud tiering compression, then the data set can be compressed by TCT compression if it is not already compressed, encrypted, or compressed and encrypted. If the migrated data set is TCT compressed, then the percentage of space saved for the data set is stored in the MCDS and FSR records. DFSMS selects a TCT compression capable primary volume when the TCT compressed migrated data set is recalled.

If the data set is being migrated to a DIRECT cloud provider defined with a CDA provider file and SETSYS ZCOMPRESS(ALL | CLOUDMIGRATE(YES)) has been specified, DFSMSHsm will request CDA compression to be used during migration.

Space management of VSAM data sets

DFSMSHsm migration functions that exist for non-VSAM data sets also exist for VSAM data sets that are listed in the integrated catalog facility catalog.

The migration of a VSAM data set is performed only on a complete VSAM sphere. The base cluster and all alternate index clusters defined on the base cluster are migrated as part of the data set and are not specified separately. Paths are included automatically in the data set migration command.

When DFSMSHsm migrates a VSAM data set, it tracks a maximum of eight component names for that data set. See [Figure 10 on page 76](#), which shows component name limitations when DFSMSHsm is recalling a migrated VSAM data set.

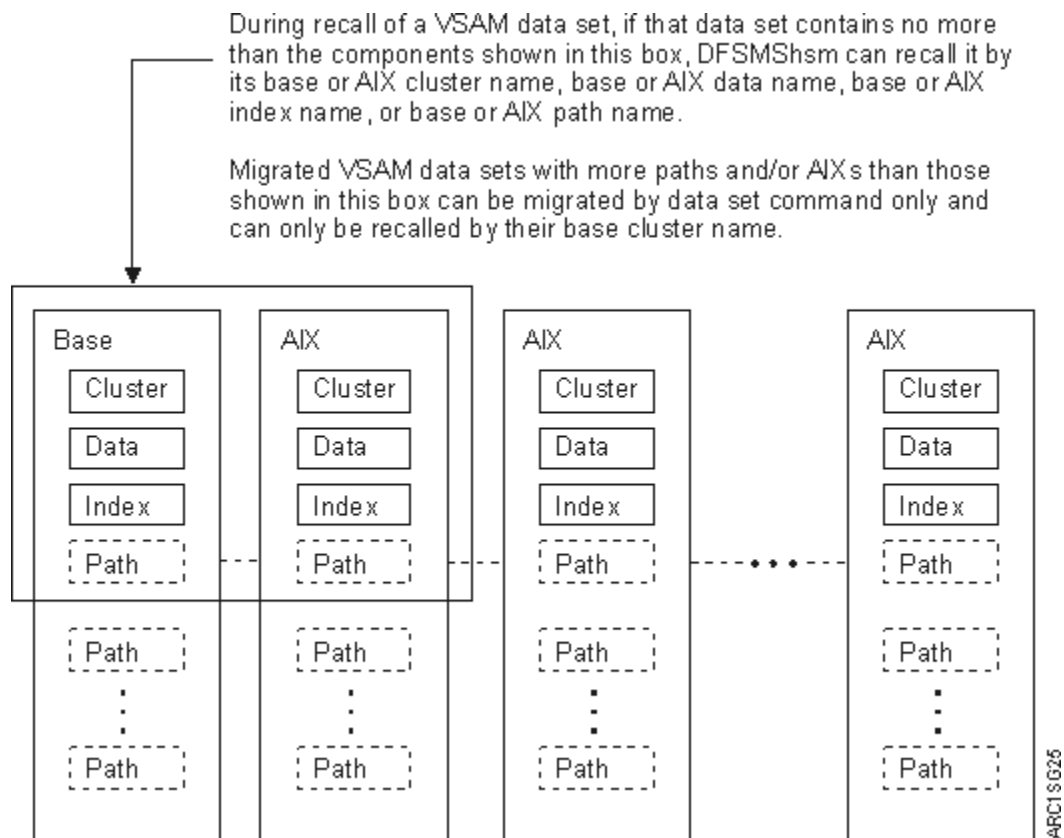

Figure 10. Component Name Limitations when Recalling Migrated VSAM Data Sets

DFSMSHsm can migrate multiple-volume SMS-managed VSAM data sets when it processes the volume containing the base data component. DFSMSHsm does not migrate a sphere that has a component that needs to be verified.

Data sets cataloged in the integrated catalog facility catalog with more than one alternate index (AIX), more than one path on the base, or more than one path defined on the AIX are not selected for migration during volume processing. These data sets can be migrated by data set command.

DFSMSHsm does not migrate a VSAM data set marked for forward recovery, or one with retained locks.

Size eligibility for data sets to migrate to an SDSP

Data sets that meet certain size requirements can be migrated to SDSP data sets. Data set size is determined as follows:

- **Physical sequential data sets**—by the high-used track, which is stored in the data set VTOC entry
- **Physical sequential data sets with zero secondary allocation**—by allocated size
- **Partitioned data sets (not PDSE)**—by the high-used track, which can include unused space within the data set

Partitioned data sets can only migrate to SDSPs when the following two conditions are met: (1) the migration request is for a volume (not for a data set) and (2) an AX cell exists in the catalog for the PDS. In these cases, eligible PDSs are migrated to SDSPs using DFSMSdss as the data mover.

- **Direct access data sets**—by allocated size
- **VSAM data sets**—by allocated size address (RBA)
- **PDSE data sets**—by the high-used page, which is obtained from DFSMSdftp
- **HFS data sets**—by the high-used page, which is obtained from DFSMSdftp
- **Unmounted zFS data sets**—by allocated size address (RBA)

A candidate data set is eligible for migration to an SDSP data set if its estimated size is less than or equal to the number of KB or 3380 tracks that you specify with the `SMALLDATASETPACKING` parameter of the `SETSYS` command. (See [“Specifying small data set packing”](#) on page 52 for an explanation of small data set packing.) A data set’s source size in KB in DFSMSHsm is calculated as the number of bytes per track for the device type times the number of tracks used by the data set. For each device type in DFSMSHsm the number of bytes per track is as follows:

Device Type	Bytes per Track
3380	47,476
3390	56,664

Note: If you specify the size eligibility in tracks, DFSMSHsm converts the tracks value to KB with an assumed track size of a 3380 device type.

SDSP selection

When a user data set meets the criteria to be migrated to an SDSP data set, DFSMSHsm selects the SDSP data set with the most free space. When an SDSP is allocated and opened, it remains open until the DFSMSHsm-managed volume has been completely processed, the SDSP goes unused for 30 seconds, or if the SDSP is needed for recall or aggregate backup.

When a data set fails to migrate because it will not fit into the selected SDSP, DFSMSHsm selects a different SDSP when it migrates the next data set to an SDSP. You should consider two error conditions:

- If no SDSP is available to a DFSMSHsm host (they have all become full), the data set migrates, but not into an SDSP data set. To avoid this type of migration, define more SDSP data sets than the maximum number of concurrent migration tasks. Because each ML1 volume has no more than one SDSP data set, you must have more ML1 volumes available than the maximum number of migration tasks.
- Do not run automatic secondary space management while you are running automatic primary space management.
- If all SDSP data sets are busy, the migration of the data set fails.

Out-of-space condition during migration

For each data set that migrates to an ML1 volume and not into an SDSP data set, DFSMSHsm chooses the ML1 volume with the lowest activity or, as a secondary consideration, the most available space. An out-of-space condition on the ML1 volumes never causes immediate migration from an ML1 volume to an ML2 volume. An out-of-space condition occurs when DFSMSHsm:

- Performs migration on a volume and no space exists on any ML1 volume
- Tries to allocate the migration copy and an out-of-space failure occurs

To prevent a large amount of unproductive processing when there is little free space on any ML1, the migration of data sets—caused by an out-of-space failure—retries to the ML1 volume having the most available free space. (The activity to the volume is not considered.) If a second out-of-space condition occurs while targeting the ML1 volume that has the most free space, DFSMSHsm does the following:

- If the failing data set is small (less than five tracks), and if this is the first time during this processing that a small data set did not fit on an ML1 volume, the task that encountered the out-of-space condition determines the free space on all ML1 volumes, and the migration of the data set is retried. If the task encounters the out-of-space condition again, the free space determination is not done. In this case, the volume migration is terminated and, if ML1 volumes are the only target devices for the volume migration, migration is held. If tape is being used, that part continues.
- If the data set is not small (greater than or equal to five tracks), DFSMSHsm fails the migration for the data set but continues migration with the next data set on the source volume.

The previous processing does not occur if the out-of-space condition is caused by a full VTOC for a volume. In this case, DFSMSHsm marks the ML1 volume full and tries another.

Catalog considerations for migration

DFSMSHsm migrates only cataloged data sets. When a data set migrates, the volume serial number of the data set is replaced with MIGRAT in the catalog. DFSMSHsm uses the volume serial number of MIGRAT to specify that a data set has migrated. Therefore, an installation must not have any volume with a volume serial number of MIGRAT. If it has, data access failures could result.

DFSMSHsm does not recognize JOBCAT and STEPCAT DD statements, so any data sets that require JOBCAT or STEPCAT DD statements appear as uncataloged to DFSMSHsm. Because DFSMSHsm does not recognize JOBCAT or STEPCAT DD statements, DFSMSHsm uses only catalogs available through the standard catalog search. Multilevel alias support is part of the standard catalog search.

Maintenance and use of the data set date-last-referenced field for space management

DFSMSHsm initializes the date-last-referenced field of supported data sets in the data set VTOC entry when the volume is first processed for volume space management. When a data set is opened after that, the open routine writes the current date in the date-last-referenced field. DFSMSHsm refers to the date-last-referenced field and the PRIMARY DAYS NON-USAGE and LEVEL 1 DAYS NON-USAGE attributes to determine if a data set is eligible for space management. Since the date-last-referenced is set when a data set is opened, a data set that is open for several days can be eligible for migration shortly after it is closed. Allow extra days in the management class parameters for this situation.

If the date-last-referenced field is zero during volume space management, DFSMSHsm places the current date into the field. Zeros in the date-last-referenced field mean that volume space management has never processed the data set.

For the majority of ways that DFSMSHsm recalls can be initiated, the recall is considered a reference to the data set, so the date-last-referenced field of the data set is set to the current date. As a result, you can schedule work by recalling data sets that will be required during a later work session. DFSMSHsm normally does not automatically migrate these recalled data sets before you can use them.

Certain DFSMSHsm activities produce recalls for which the date-last-referenced field is not set to the current date. The date-last-referenced field is not set to the current date during recalls for:

- Certain indirect references causing a recall, such as the MODEL parameter of the IDCAMS DEFINE command, or a catalog access done by CICS® using the ALTER command
- Renaming data sets
- Extent reduction
- Conversion of data sets from one level 0 volume to another level 0 volume

Instead, the date-last-referenced field (DS1REFD) is set to the date-last-referenced value when the data set was originally migrated.

The date-last-referenced field is not updated when a data set is moved as a result of a class transition.

Writing to a cartridge-type, single-file-format tape during migration

During volume migration, DFSMSHsm opens the output data set when it processes the first eligible user data set. DFSMSHsm writes the migration copy and then updates the control data set records. After current processing has been completed, the tape is already positioned to receive the next migrated data set. If a failure occurs, DFSMSHsm marks the cartridge-type tape volume full and selects another tape volume. Migration processing continues.

When the volume migration task has no more volumes to process, the DFSMSHsm tape data set is closed and the output tapes are deallocated.

If an I/O error occurs on the source data but does not prevent DFSMSHsm from using the cartridge-type tape volume, DFSMSHsm adds a data set entry to the TTOC for the failing data set and immediately invalidates the entry.

When end-of-volume is reached while DFSMSHsm is writing a 16KB block on a cartridge-type, single-file-format tape volume, DFSMSHsm does normal end-of-volume processing.

When individual user data sets migrate to a cartridge-type tape volume, DFSMSHsm closes the DFSMSHsm tape data set only after all individual data set requests on the migration queue have been processed.

End of level 0 volume processing

At the end of space management of each level 0 volume, DFSMSHsm determines the amount of free space remaining on the level 0 volume just processed and the volume's fragmentation. At this time DFSMSHsm also passes control to the space management volume exit (ARCMVEXT) if it is turned on.

At the end of processing a level 0 volume, DFSMSHsm writes messages ARC0519I and ARC0523I to the migration activity log. The messages record:

- The number of tracks freed by partial release of over-allocated space
- The number of data sets migrated and deleted
- The number of tracks freed by migration
- The time

Pass 2 processing example

[Figure 11 on page 80](#) shows the results of pass 2 processing. It is assumed that the low thresholds for the volumes have not been reached by pass 1 processing. Compare [Figure 9 on page 70](#) and [Figure 11 on page 80](#).

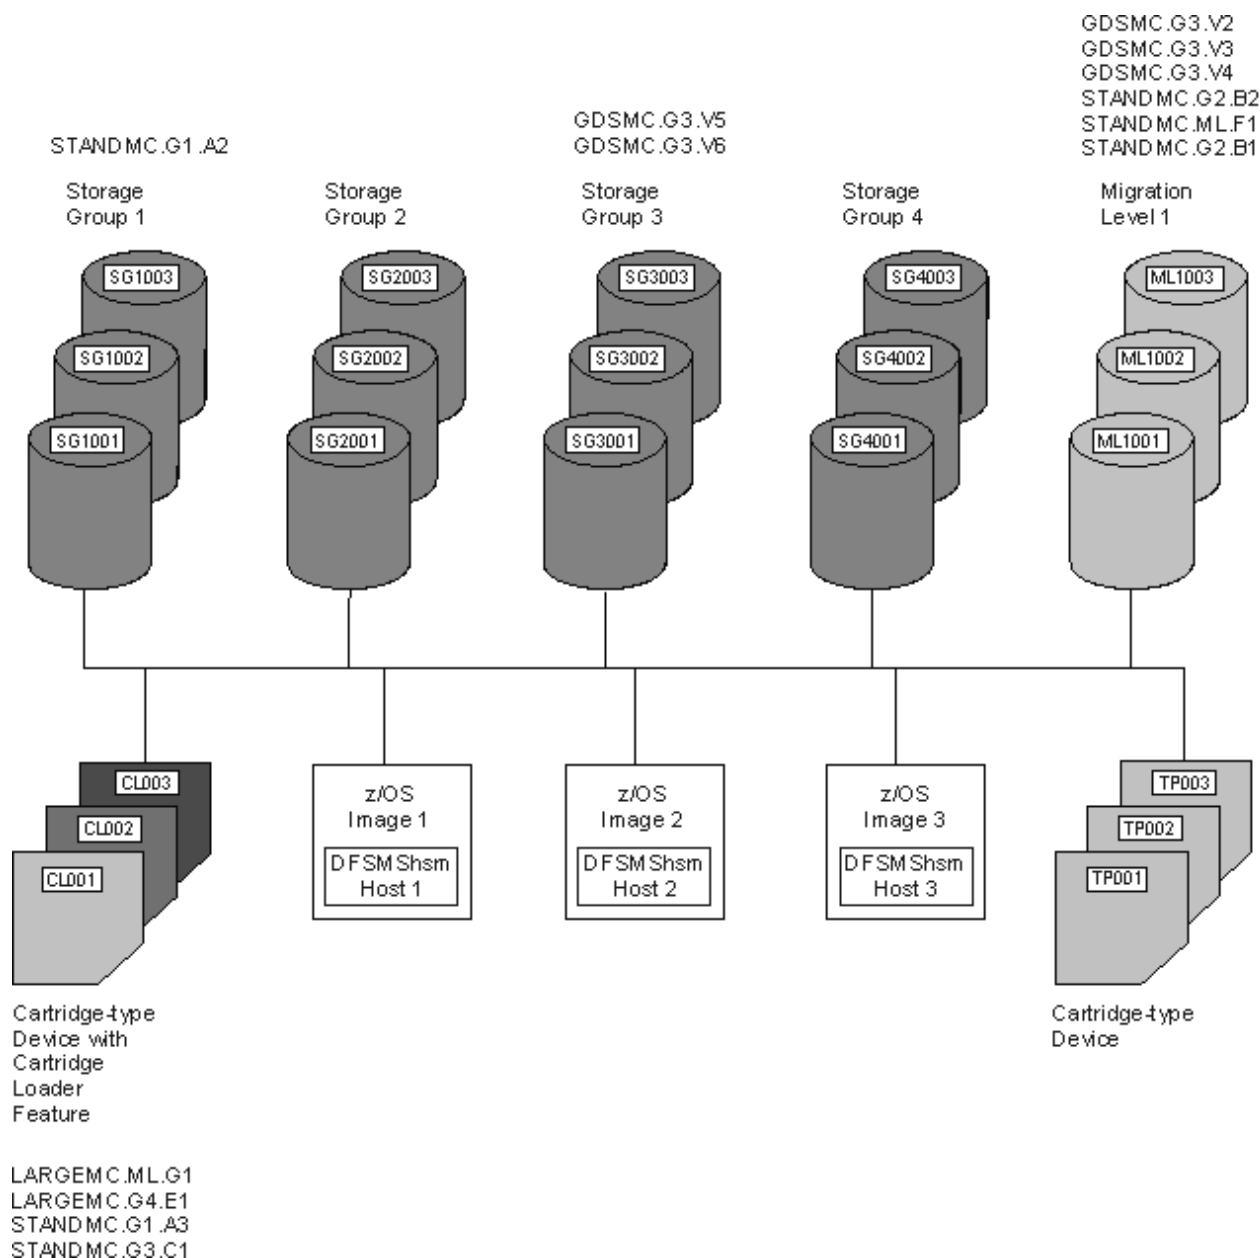

Figure 11. Example System of SMS-Managed Volumes after DFSMSHsm-Managed Volume Management Pass 2

First look at storage group 1. Because data set STANDMC.G1.A2 has not passed the value for PRIMARY DAYS NON-USAGE (see Table 4 on page 57), it does not migrate.

Now look at storage group 2. Because both STANDMC.G2.B1 and STANDMC.G2.B2 exceed the PRIMARY DAYS NON-USAGE value, both migrate.

Now look at storage group 3. Data sets GDSMC.G3.V3 and GDSMC.G3.V2 migrate first because they exceed the value in the # GDG ELEMENTS ON PRIMARY specification for their management class. Because both are candidates for early migration, either one can be the first one migrated. Next, STANDMC.G3.C1 migrates because its size gives it a priority over GDSMC.G3.V4. Notice that because the unused age of STANDMC.G3.C1 is greater than the value that is specified for LEVEL 1 DAYS NON-USAGE, the data set migrates directly to level 2. Last, GDSMC.G3.V4 migrates because it has exceeded the value for PRIMARY DAYS NON-USAGE.

Finally, look at storage group 4. Data set LARGEMC.G4.E1 migrates because it has passed the PRIMARY DAYS NON-USAGE value. Because the LEVEL 1 DAYS NON-USAGE value for its management class is 0, LARGEMC.G4.E1 migrates to ML2 tape.

You can also compare [Figure 11 on page 80](#) with [Figure 6 on page 57](#) to see how many data sets have been removed or migrated from the DFSMSHsm-managed volumes.

Event-driven migration example scenario

In the following event-driven migration example scenario, there are three DFSMSHsm hosts which manage three storage groups. A portion of the ARCCMDxx parmlib member of SYS1.PARMLIB is shown for each host. The basic storage group definitions are shown for each storage group.

DFSMSHsm host 1:

```

:
/* Start secondary space management at 12:30 AM. */
SETSYS SECONDARYSPMGMTSTART(0030 0200)
DEFINE SECONDARYSPMGMTCYCLE(YNNNYNN -
    CYCLESTARTDATE(2011/09/12))
:
/* Do not perform event-driven migration. */
SETSYS NOINTERVALMIGRATION
SETSYS ONDEMANDMIGRATION(N)
:

```

DFSMSHsm host 2:

```

:
/* Start primary space management at 2 AM. */
SETSYS PRIMARYSPMGMTSTART(0200 0400)
DEFINE PRIMARYSPMGMTCYCLE(Y -
    CYCLESTARTDATE(2011/09/12))
:
/* Perform event-driven migration (on-demand). */
SETSYS NOINTERVALMIGRATION /* Ignored when SETSYS ODM(Y) is specified. */
SETSYS ONDEMANDMIGRATION(Y)
:

```

DFSMSHsm host 3:

```

:
/* Perform event-driven migration (on-demand). */
SETSYS NOINTERVALMIGRATION /* Ignored when SETSYS ODM(Y) is specified. */
SETSYS ONDEMANDMIGRATION(Y)
:

```

The storage groups are defined:

```

NAME ==> SG1
MIGRATE SYSTEM/SYSPLEX NAME ==>
AUTO MIGRATE ==> Y
MIGRATION AND ALLOCATION THRESHOLDS: HIGH ==> 85 LOW ==> 70
:
NAME ==> SG2
MIGRATE SYSTEM/SYSPLEX NAME ==>
AUTO MIGRATE ==> Y
MIGRATION AND ALLOCATION THRESHOLDS: HIGH ==> 95 LOW ==> 80
:
NAME ==> SG3
MIGRATE SYSTEM/SYSPLEX NAME ==>
AUTO MIGRATE ==> N
MIGRATION AND ALLOCATION THRESHOLDS: HIGH ==> 20 LOW ==> 0

```

Immediately after SMS issues an ENF72 event code signaling a volume in storage group SG1 or SG2 has exceeded the high threshold (85% for SG1 and 95% for SG2), DFSMSHsm host 2 and DFSMSHsm host 3 perform on-demand migration (immediate space management) on eligible volumes that belong to SG1 and SG2. DFSMSHsm host 2 and DFSMSHsm host 3 perform on-demand migration on eligible volumes in these storage groups because the SETSYS ONDEMANDMIGRATION(Y) setting is specified and the storage groups are defined with AM=Y (Auto Migrate, yes). On-demand migration is performed on SG1 and SG2 as needed throughout the day on both hosts, except when primary space management is running between 2:00 AM and 4:00 AM on DFSMSHsm host 2. During this time, DFSMSHsm host 3 is available to perform

on-demand migration and on-demand migration is paused on DFSMSHsm host 2. After primary space management completes, DFSMSHsm host 2 is available to perform on-demand migration again.

DFSMSHsm host 1 is reserved for handling high priority DFSMSHsm requests. The only space management task DFSMSHsm host 1 performs is secondary space management between 12:30 AM and 2:00 AM. DFSMSHsm host 1 does not perform interval migration because the SETSYS NOINTERVALMIGRATION setting is specified. Additionally, DFSMSHsm host 1 does not perform on-demand migration because the SETSYS ONDEMANDMIGRATION(N) setting is specified.

None of the DFSMSHsm hosts perform event-driven migration on volumes that belong to storage group SG3 because it is defined with AM=N (Auto Migrate, no).

All eligible volumes are processed by event-driven migration until the low threshold is reached or until there are no eligible data sets to migrate.

Class transitions for Db2 objects example scenario

As Db2 objects age, it is desirable to keep the objects online in order to maintain immediate access, but it is also desirable to minimize the cost of maintaining them online. To achieve this, a class transition environment is configured such that the Db2 objects are allocated and maintained on standard DASD for 90 days. After this time, they are transitioned to less expensive SATA DASD. Transitioning the objects to SATA DASD enables the objects to be kept online at a lower cost.

If any object in general remains unreferenced for 95 days, it will become eligible for migration to ML2 tape. Because the Db2 objects are expected to always be allocated and open after 90 days, the SERIALIZATION EXIT will therefore indicate that Db2 should be invoked to close and reopen the objects around the time of this transition. To minimize the period in which these objects are closed to Db2, fast replication will be the preferred data movement technique. The storage group containing the SATA DASD will be given a higher processing priority to help ensure that any objects eligible for migration are migrated off of the SATA DASD to maximize the available space for the objects that will transition to the SATA DASD from the standard DASD.

The storage groups are defined:

```
NAME ===> STANDARD
MIGRATE SYSTEM/SYSPLEX NAME ===>
AUTO MIGRATE ===> P
MIGRATION AND ALLOCATION THRESHOLDS: HIGH ===> 85 LOW ===> 20

:
PROCESSING PRIORITY ===> 50

NAME ===> SATA
MIGRATE SYSTEM/SYSPLEX NAME ===>
AUTO MIGRATE ===> P
MIGRATION AND ALLOCATION THRESHOLDS: HIGH ===> 95 LOW ===> 1

PROCESSING PRIORITY ===> 75
```

The management class is defined:

```
NAME ==> DB2TRANS
      TIME SINCE CREATION      ==> 90
      SERIALIZATION ERROR EXIT ==> DB2
      TRANSITION COPY TECHNIQUE ==> FRP
      PRIMARY DAYS NON-USAGE    ==> 95
      LEVEL 1 DAYS NON-USAGE    ==> 0
      COMMAND OR AUTO MIGRATE   ==> AUTO
      EXPIRE AFTER DATE/DAYS    ==> NOLIMIT
```

During primary space management, the volumes within storage group SATA will be processed first. Any objects that have been unreferenced for more than 95 days will be migrated to tape. After all of the volumes within storage group SATA have been processed, the volumes assigned to storage group STANDARD will be processed. Any object that is 90 days or older will be transitioned to a volume assigned to the SATA storage group. Fast replication will be the preferred data movement technique.

Automatic recall

Recall occurs automatically when a data set is referred to by a TSO user, JCL, or a program. The reference to the data set may cause a request that DFSMSHsm recall the data set either to a specific volume or to any volume. Unlike non-SMS-managed data, no special considerations apply for SMS-managed data sets between JES2 and JES3 systems. When DFSMSHsm receives the request to recall the data set, it passes the following information to the automatic class selection (ACS) routine of DFSMSdfp:

- The name of the data set.
- The name of the storage class associated with the data set when the data set migrated. If the data set was not SMS-managed when it migrated, no storage class is passed.
- The name of the management class associated with the data set when the data set migrated. If the data set used the default management class or was not SMS-managed when it migrated, no management class is passed.
- The name of the data class associated with the data set when the data set migrated. If the data set had no data class or was not SMS-managed when it migrated, no data class is passed.
- The volume serial number and unit type of the volume where the data set originally resided or of the volume specified by the request.

Note: If your storage class ACS routine checks for a valid DASD unit name, be sure to include any unit names that may have existed in your installation at one time and are no longer in use, because the data set could have resided on such a unit when it was migrated.

- If the data set was never transitioned and did not miss a transition while it was migrated, an environment indicator of RECALL.
- If the data set was transitioned before the migration and the Last Successful Class Transition Date (LSCTD) is set, or if one or more class transitions were missed while the data set was migrated, then an environment indicator of SPMGCLTR.

Passing the SPMGCLTR indicator ensures that the data set is recalled to the same storage class and storage group as when it transitioned. If the data set missed multiple transitions while it was migrated, then the ACS routines will be invoked for each transition that was missed.

Note: DFSMSHsm will check to see if a class transition was missed as many as five times. DFSMSHsm will limit the number of repeated ACS routine invocations to avoid circularity.

The Last Successful Class Transition Date (LSCTD) field is set and used by DFSMSHsm to manage class transitions. DFSMSHsm will use this field to determine if a data set has already been transitioned and should not be reprocessed, as shown in [Table 6 on page 84](#). The LSCTD can be displayed for a particular data set with the LISTCAT command, if it exists and the value is non-zero, and DCOLLECT.

<i>Table 6. Last Successful Class Transition Date (LSCTD) setting rules during class transitions and recalls</i>	
Action	LSCTD value
Management class is changed during class transition	The LSCTD is set to zero
Management class is not changed during class transition	The LSCTD is set to the current date
Management class is changed during recall when one or more class transition were missed while the data set was migrated	The LSCTD is set to zero
Management class is not changed during recall when one or more class transition were missed while the data set was migrated	The LSCTD is set to the current date
Management class is not changed during recall when the data set was transitioned before migration and the LSCTD was set	The LSCTD is set to the current date

- The RACF user ID and group ID for non-DFSMSHsm-authorized users.
- The data set size in KB.
- The data set expiration date.
- A generation data group indication.
- The data set organization.
- The record organization for VSAM data sets.

If SMS is installed and active, the ACS routine may return to DFSMSHsm with a storage class and, optionally, a management class. If the ACS routine returns a storage class, DFSMSdfp selects a volume. The volume selected is not necessarily the volume that was specified by the recall request. The catalog is updated to reflect the current status.

If SMS is installed and active but the ACS routine does not return a storage class, DFSMSHsm processes the data set as a non-SMS-managed data set. If the ACS routine does not return a storage class for a data set that was extended format when it was migrated, DFSMSHsm fails the recall.

If SMS is not installed and active and the data set was not SMS managed when it migrated, DFSMSHsm processes the data set as a non-SMS-managed data set.

If SMS is not installed and active and the data set was SMS managed when it migrated, DFSMSHsm fails the recall. If the data set migrated as an SMS-managed data set, DFSMSHsm assumes that the data set is still SMS managed and cannot be processed without SMS.

Table 7 on page 84 summarizes the recall results.

Table 7. Recall Destination Summary

SMS Active	Storage Class Returned	Data Set Migrated As	Data Set Recalled As
Yes	Yes	Either	SMS-managed
Yes	No	Either	Not SMS-managed
No	Not applicable	SMS-managed	Failed
No	Not applicable	Not SMS-managed	Not SMS-managed

Note: For a general discussion of recall requests with regard to the common recall queue, see [“Common recall queue”](#) on page 129.

Related reading

For more information about recalling non-SMS-managed data sets, see [“Recall” on page 119](#).

Automatic recall with DFSMSdss

When DFSMSdss is used as the data mover, DFSMSHsm determines if the data set is SMS managed as described under [“Automatic recall” on page 83](#). However, DFSMSHsm allows DFSMSdss to determine which volumes the data set is recalled to.

If a multivolume data set is no longer SMS managed, DFSMSHsm attempts to recall the data set. A list of up to five volumes is passed to DFSMSdss. If space permits, the data set is recalled to a single volume. Otherwise, it is recalled as a multivolume data set.

During recall processing with DFSMSdss as the data mover, if a data set was never transitioned and did not miss a transition while it was migrated, then the &ACSENVIR field contains RECALL for the storage class and management class ACS routines, and RECOVER for the storage group ACS routine. If the data set was transitioned before the migration or if one or more class transitions were missed while the data set was migrated, then the &ACSENVIR field contains SPMGCLTR for all ACS routines. &ACSENVIR is a read-only variable that indicates the environment in which the ACS routine is invoked.

Recalling extent-reduced data sets

When a data set migrates for extent reduction, DFSMSHsm immediately requests a recall for that data set to the same volume. Under these circumstances, DFSMSHsm recalls the data set to the specified volume with the same storage class, management class, and data class as were in effect when the data set migrated. DFSMSHsm does not invoke the ACS routine for these data sets.

Note: DFSMSHsm can be directed to use the ACS routines for volume selection by using the Return-Priority exit (ARCRPEXT). For more information about the ARCRPEXT exit, see [z/OS DFSMS Installation Exits](#).

Automatic recall during data set allocation

When the allocation process is trying to find a data set, DFSMSHsm intercepts the locate and tries to recall the data set if the data set is migrated.

Automatic recall for command deletion of VSAM AIX clusters

When a command is issued to delete an AIX cluster, the sphere may have been migrated. DFSMSHsm intercepts the deletion request, and if the sphere is migrated, DFSMSHsm recalls the data set.

Automatic recall for data set renaming

When a rename or alter request is issued for a migrated data set, DFSMSHsm first recalls the data set and then lets the rename or alter process continue, with the exception of an IDCAMS ALTER command issued to change the storage class or management class, or both, of a migrated data set. When an IDCAMS ALTER command is issued to change either the storage or management classes, or both, of a migrated data set, the change is made without recalling the data set. Both DFSMSHsm's and catalog's records are updated to reflect the change.

When data sets are recalled for a rename or alter request, DFSMSHsm does the following:

- Sets the last backup date to zero
- Sets the data-set-changed indicator in the data set VTOC entry to On
- Sets the date-last-referenced field to the date that the data set had when it migrated

The results of the preceding actions are as follows:

- The renamed data set is backed up the next time that backup runs.

- The renamed data set probably will migrate soon because the date-last-referenced field indicates a long period since the data set was opened.

Automatic recall during catalog updates

A data set, either VSAM or non-VSAM, could be on a migration volume when it is about to have its catalog entry altered. If the catalog routine is requested to UNCATALOG, RECATALOG, DELETE/NOSCRATCH, or ALTER the catalog entry of a data set on a volume with a volume serial of MIGRAT, DFSMSHsm first recalls the data set and then lets the catalog routine continue. In this case, DFSMSHsm handles the volume selection for the recall request in the same manner as it handles the allocation recall requests. It does not recall the data set to a specific volume.

An IDCAMS ALTER command issued to change the storage class or management class, or both, of a migrated data set is an exception. When an IDCAMS ALTER command is issued to change either the storage or management classes, or both, of a migrated data set, the change is made without recalling the data set. Both DFSMSHsm's and catalog's records are updated to reflect the change.

In a non-RACF environment, this function is bypassed, which permits any user to perform catalog maintenance without recalling data sets. In a RACF environment, this function is bypassed for UNCATALOG, RECATALOG, and DELETE/NOSCRATCH if the current RACF logon group is ARCCATGP, which permits only authorized users to perform these requests without recalling data sets.

Note: Automatic recall is bypassed if DFSMSHsm receives the DELETE command before any other command. In cases where another component performs an action that invokes DFSMSHsm before the DELETE command, an automatic recall occurs. For example, issuing a DELETE command on a migrated data set using some TSO options causes DFSMSHsm to recall that data set before processing the DELETE command.

The access methods services REPRO/MERGECA and CONVERT CATALOG commands do not cause a data set recall, because the catalog entries are not being altered.

A recall may be retried multiple times and lengthen processing time if the necessary resources are not available.

Related reading

For more information about performing RACF catalog maintenance, see [*z/OS DFSMSHsm Implementation and Customization Guide*](#).

Additional recall considerations

When DFSMSHsm recalls data sets from tape ML2 volumes, the tape remains allocated and mounted until DFSMSHsm has processed all recall requests requiring only that volume, or a TAPERECALLLIMITS parameter has been met. For tape devices before IBM 3480s, the additional requests are processed by file sequence order. For 3480 (single-file-format tape cartridge) and later tape devices, the additional requests are processed by priority. When the recall queue no longer has any recall requests requiring that mounted tape volume, DFSMSHsm sets a short timer and waits for another request. If a request needing that single tape arrives, it is started immediately. If the timer expires, DFSMSHsm deallocates and demounts the tape volume.

Note: In a common recall queue environment, a single tape mount processes all outstanding requests from all DFSMSHsm hosts that require the same tape.

To manage your space better and to reduce job-failure exposures, do not specify volume and unit information in JCL to refer to non-VSAM and VSAM data sets on DFSMSHsm-managed volumes. If a non-SMS-managed volume is specified in the JCL, DFSMSdfp and DFSMSHsm cannot cooperate in choosing the target volume for the recall. If the data set is non-SMS-managed, the specified non-SMS-managed volume is used as the target of the recall. If the data set is SMS-managed, the recall fails.

Relying on the standard catalog search allows DFSMSHsm, DFSMSdfp, and DFSMSdss if specified, to cooperate in choosing the volume and recalling the data set during allocation processing.

The SETSYS VOLCOUNT(NONE | ANY) command affects how the allocation of SMS-managed data sets are performed when DFSMSdss is the datamover. The environment established by the SETSYS VOLCOUNT command can be overridden on command recalls by specifying the DFDSSOPTION(VOLCOUNT(N(nn) | ANY)) option of the RECALL command.

Reblocking during recall

The purpose of reblocking is to make the most efficient use of available space on your DASD. Physical sequential data sets are moved with DFSMSdss. Specifying SETSYS CONVERSION(REBLOCKTOANY) will cause them to be reblocked during recall.

Nonkeyed, blocked, physical sequential data sets that were migrated with DFHSM 2.6.0 (or an earlier release) are also reblocked during recall when SETSYS CONVERSION(REBLOCKTOANY) is used. Partitioned data sets (DSORG=PO) are not reblocked during recall.

Marking data sets eligible for fast subsequent migration during recall

During recall of a data set, if the data set satisfies fast subsequent migration eligibility requirements, the data set is marked eligible for fast subsequent migration (that is, it is marked for reconnection to the ML2 tape from which it was recalled). If a data set is not marked eligible for fast subsequent migration, it will not be considered for reconnection during future migration processing.

Related reading

- For more information about fast subsequent migration, see [“Reconnecting data sets using fast subsequent migration”](#) on page 94.
- For a list of fast subsequent migration requirements, see [Fast subsequent migration \(reconnection\) eligibility requirements](#).

Additional space management during migration and recall when DFSMSHsm is the data mover

Note: Although DFSMSdss is the data mover for most data set types, the following topic refers to exception cases for which DFSMSHsm is the data mover, including most PDS data sets, as well as special cases of PS, VSAM, and other organizations.

When DFSMSHsm is used as the data mover during the migrating and recalling of PS, PDS, and VSAM data sets, it can automatically move a data set to a different device type. Thus, for these data sets, the requested space is always converted by DFSMSHsm to a space of approximately equivalent capacity when a device-type change occurs. Also, the original allocation type (that is, the cylinder, track, or average block) and the CONTIG option are maintained.

When DFSMSHsm recalls a migrated PS or PDS data set, it requests a primary allocation size approximately equal to the space used (all extents) by the original data set, unless the secondary allocation size is zero. When the secondary allocation size of the original data set is zero, DFSMSHsm requests a primary allocation size approximately equal to the space allocated (all extents) at the time of migration. For secondary allocation size, DFSMSHsm always keeps approximately that much of the original data set space. The option to release unused space is requested when a nonzero secondary allocation size is specified; release of unused space is not requested when secondary allocation is zero. For PDS data sets, the original number of directory blocks is retained.

For PDS data sets, the migrate and recall results in the freeing of embedded free space (compression), and the user information in the data-set-directory user field is retained.

When the DAOPTION is not used, the allocation for recall of migrated BDAM data sets differs from that of PS and PDS data sets. The primary allocation contains the same number of tracks (including all extents) allocated to the original data set at the time of migration. DFSMSHsm maintains the secondary allocation size in a similar manner; that is, the number of tracks is at least as large as that of the secondary allocation size of the original data set. When DFSMSHsm recalls a BDAM data set, it does not select a device that has a different track length than that of the device from which the data set was migrated.

However, you can direct the recall of a BDAM data set to a device that has a different track length. When DFSMSHsm moves BDAM data sets, it moves one input track of data to one output track of data. The data from an original track must fit on a track of the output device. If you direct the recall of a BDAM data set to a particular device, you are responsible for ensuring that the data is accessible in this form on that device. Release of unused space is never requested for BDAM data sets.

The recall of VSAM data sets includes translating space allocation when device types are changed and retaining the type of allocation (cylinder, track, or average block) changes. DFSMSHsm does not do any extent consolidation for VSAM data sets. The recall data set is processed in accordance with your original DEFINE request, which can cause the allocated space to grow if you request distributed free space.

Recommendation:: You should have a nonzero secondary allocation size if you request distributed free space.

The migration and recall of non-VSAM data sets normally results in a reduction of the number of extents for multiple-extent data sets, because DFSMSHsm's primary allocation size is large enough to contain the entire data set in one extent. If DFSMSHsm cannot find such an extent and the CONTIG option is not specified, up to five non-contiguous extents can be used. If DFSMSHsm cannot find such an extent and CONTIG is specified, the request fails.

Command space management tasks

In addition to its automatic volume space management functions for SMS-managed volumes, DFSMSHsm provides you with the ability, by issuing individual commands, to perform space management functions.

Deleting migrated data sets

To delete migrated SMS-managed data sets, you can use one of the following methods:

- DFSMSHsm DELETE command
- Access Method Services DELETE command
- TSO DELETE command
- IEHPROGM utility

Table 8 on page 89 shows what happens when you specify one of these commands or use the IEHPROGM utility to delete a migrated data set.

Table 8. Commands for Deleting Migrated Data Sets

Command or Utility	Result
DFSMSHsm DELETE, Access Method Services DELETE, TSO DELETE or IEHPROGM utility SCRATCH function for SMS-managed data set	<p>Scratches a data set on a DASD migration volume without recalling the data set or marks the data set not valid in the TTOC for any tape ML2 volumes that contain the data set. DFSMSHsm then uncatalogs the data set. DFSMSHsm deletes all control data set records related to the migration copy. If the data set is migrated to an SDSP, the MCD is updated to indicate that the migration copy needs to be scratched. If a discrete RACF data set profile exists, DFSMSHsm deletes it.</p> <p>Note:</p> <ol style="list-style-type: none"> 1. If the optional parameter NON-VSAM is specified on the Access Method Services DELETE command, the migrated data set is recalled before deletion. 2. If DFSMSHsm is down when you specify the optional parameters GDG FORCE on the Access Method Services DELETE command, IDCAMS does not invoke DFSMSHsm. Therefore, you must then issue the DFSMSHsm DELETE command for each of the now-uncataloged migration copies.
IEHPROGM utility SCRATCH function for non-SMS-managed data set	<p>Scratches a migrated data set if:</p> <ul style="list-style-type: none"> • The specified volume is the same one the data set migrated from • The volume is not SMS managed • The data set is not SMS managed <p>DFSMSHsm scratches the migration copy of the data set and deletes the MCDS data set record. The data set remains cataloged.</p>

If the deleted data set has backup versions, DFSMSHsm keeps the backup versions.

If a data set has been deleted by one of the preceding commands and you want to recover a backup version of the data set, see [“Data set recovery and restore” on page 241](#).

Using the DELETE command

You can delete migrated data sets under the following conditions:

- For VSAM data sets, make the name specified in the command the name of the base cluster. Specifying the name of any other component causes the command to fail.
- The name specified for the data set (for either VSAM or non-VSAM data sets) must be the name in the catalog. You cannot specify the name that DFSMSHsm assigned to the migrated data set.

DFSMSHsm fails any DFSMSHsm DELETE command that specifies a member name of a partitioned data set.

Deleting data sets that have not expired

If the data set has an expiration date and the date has not been reached, DFSMSHsm deletes the data set only if the PURGE parameter of the DELETE command is specified. If a data set does not have an expiration date, the PURGE parameter does not apply, and DFSMSHsm deletes the data set.

Migrating an individual data set

You can cause individual SMS-managed data sets to migrate by using the MIGRATE or HMIGRATE command. (The HMIGRATE command is a non-DFSMSHsm-authorized command that is available to

users.) You can migrate a data set by command from either a level 0 volume or an ML1 volume. The migrating data set can move from a level 0 volume to either an ML1 volume or an ML2 volume.

When you issue a MIGRATE (or HMIGRATE) command, DFSMSHsm obtains the definition of the management class associated with the data set from SMS. If the management class definition cannot be obtained, DFSMSHsm issues an error message and does not migrate the data set. If the data set has no management class associated with it, DFSMSHsm uses the default management class.

Data set command migration overrides the management class attributes that control when an SMS-managed data set is eligible to migrate. However, for command data set migration to occur, the COMMAND OR AUTO MIGRATE attribute in the data set's management class must have the value COMMAND or BOTH.

DFSMSHsm may perform fast subsequent migration when it migrates an individual data set. If the fast subsequent migration fails, the data set migrates in the normal manner.

Command migration can occur for either migrated or non-migrated SMS-managed data sets. The data sets can migrate to either ML1 or ML2. Sample commands to migrate data sets are:

```
MIGRATE DATASETNAME(SAMPLE.DATASET)
MIGRATE DATASETNAME(SAMPLE.DATASET1) MIGRATIONLEVEL2
```

Consider the first example. If the data set is on an SMS-managed volume, the LEVEL 1 DAYS NON-USAGE attribute in its management class controls where the data set migrates to. If the value of the LEVEL 1 DAYS NON-USAGE attribute is not zero, the data set migrates to ML1. If the value of the LEVEL 1 DAYS NON-USAGE attribute is zero, the data set migrates to an ML2 tape volume. If the data set has already migrated to an ML1 volume, the data set does not migrate to an ML2 volume because the MIGRATIONLEVEL2 parameter is not specified.

Now consider the second example. If the data set is on an SMS-managed volume or an ML1 volume, it migrates to an ML2 volume no matter what value is specified in the LEVEL 1 DAYS NON-USAGE attribute.

If the target migration device type is tape and the data set needs to be backed up, the data set does not migrate and an error message is issued.

Two installation exits are invoked from the MIGRATE or HMIGRATE commands: the data set migration exit (ARCMDEXT) and the second-level migration data set exit (ARCMMEXT).

DFSMSHsm invokes ARCMDEXT whenever a data set command migration request causes a data set to migrate from a Level 0 volume to a DFSMSHsm Level 1 or Level 2 volume. In addition, an indicator in the ARCMDEXT parameter list indicates a data set that is migrating by a data set command (rather than by volume migration).

DFSMSHsm invokes ARCMMEXT whenever a data set command migration request causes a data set that is already on ML1 to migrate to ML2 (using the ML2 keyword on the data set migration command). In addition, an indicator in the ARCMMEXT parameter list indicates that this data set is migrating by a data set command (rather than by volume migration).

For more information about fast subsequent migration, see [“Reconnecting data sets using fast subsequent migration”](#) on page 94.

Transitioning an individual data set

You can drive SMS-managed data sets through class transition processing by using the MIGRATE or HMIGRATE command. When you issue a MIGRATE (or HMIGRATE) command with the TRANSITION keyword, DFSMSHsm invokes the ACS routines with the SPMGCLTR environment variable to determine the new management class, storage class and/or storage group to which the data set should be assigned. This is performed even when the data set is not eligible for a transition based on the class transition criteria for the currently assigned management class. If neither management class, storage class nor storage group changes, then no processing occurs. If only management class changes, then the data set is assigned the management class without any data movement. If either the storage class or storage

group changes, then the data is moved. When data movement is performed, the management class transition copy technique and serialization error exit values are used.

For example, if a Db2 object is assigned a management class with a transition copy technique of PMREQ and serialization error exit value of Db2, and is assigned new storage group AGEDDATA, then a MIGRATE DSNAME(*db2.object*) TRANSITION command results in the object being closed by Db2 (if there are no active transitions), moved to a volume in storage group AGEDDATA using preserve mirror, and reopened by Db2 after the movement has completed.

Note: If a management class transition copy technique other than STANDARD, PRESERVE MIRROR REQUIRED, or FC XRCPRIMARY is specified, then a valid backup copy must exist before the data set is transitioned. This ensures that if an error occurs while physically moving the data through a storage controller function, then a backup is available to recover the data set.

If the transition technique PRESERVE MIRROR REQUIRED is specified to allow FlashCopy to Global Mirror Primaries, a valid backup copy must exist before the data set residing on a Global Mirror primary volume is transitioned. You can set one of the following patches to override this requirement:

```
PATCH .MGCB.+111 BITS(.....1.)
PATCH .MGCB.+111 BITS(.....1)
```

Migrating and transitioning an SMS-managed volume

You can cause data sets to migrate or transition from an SMS-managed volume by using the MIGRATE command. The MIGRATE VOLUME command can override some management class attributes that control when an SMS-managed data set is eligible to migrate or transition, depending on the form of the command. The default is that both migrations and transitions are processed. To process only migrations, specify the MIGRATIONONLY parameter. To process only transitions, specify the TRANSITIONONLY parameter. The MIGRATE VOLUME command migrates data sets for which the management class COMMAND OR AUTO MIGRATE attribute has the value of BOTH only. The MIGRATE VOLUME command transitions data sets that meet the management class class transition attribute.

When you issue a MIGRATE VOLUME command for an SMS-managed volume:

- Migration is from level 0 volumes to ML1 or ML2 volumes only.
- Class transitions are to the volume determined by the ACS routines.
- The volume is considered to be DFSMSshm-managed. DFSMSshm maintains control records for the volume until a DELVOL command is issued for that volume.
- A list of the management class definitions required for processing the SMS-managed data sets on the volume is obtained.

Table 9 on page 91 summarizes the various conditions that can be encountered when obtaining a list of management class definitions and the system action taken as a result.

Table 9. Conditions that can be encountered when obtaining a list of management class definitions during migration of an SMS-managed data set

If...	Then...
the list cannot be obtained.	the command fails and an error message is issued.
the management class definition for a data set cannot be found in the list.	the data set is not processed and an error message is issued.
the data set does not have a management class associated with it.	the default management class is used.

Fast subsequent migration can be performed when a data set is migrated as a result of a MIGRATE VOLUME command. If fast subsequent migration fails, the data set is migrated in the normal method.

Example commands used to migrate data sets SMS-managed volumes

The commands in [Figure 12 on page 92](#) are examples of commands that can be used to migrate data sets from an SMS-managed volume.

```
MIGRATE VOLUME(SG1001)
MIGRATE VOLUME(SG2003 MIGRATE(0))
MIGRATE VOLUME(SG1002) DAYS(0)
```

Figure 12. Example commands used to migrate data sets from SMS-managed volumes

Consider the first the command in the example: `MIGRATE VOLUME(SG1001)`. This command requests DFSMSHsm to process the volume in the same method as described in [“Automatic primary space management” on page 65](#). Both migration and class transitions are processed.

Next, consider the second command in the example: `MIGRATE VOLUME(SG2003 MIGRATE(0))`. This command overrides the PRIMARY DAYS NON-USAGE attribute of the management class so that all data sets on the volume that have the COMMAND OR AUTO MIGRATE attribute value of BOTH migrate. Any data set with a LEVEL 1 DAYS NON-USAGE attribute value of 1–9999 or NOLIMIT migrates to an ML1 volume. Any data set with a LEVEL 1 DAYS NON-USAGE attribute value of 0 migrates to an ML2 tape volume. If an attempt to migrate a data set fails, error message is issued and data set remain on the SMS-managed volume. If a nonzero value or no value is specified for the MIGRATE or DAYS parameter, the command fails and an error message issued.

For the third example, the DAYS(0) parameter behaves differently based on the keywords specified. Transition processing behaves differently than migration processing as follows:

- For migration processing, all data sets that are eligible to migrate are migrated off of the volume, regardless of whether or not they met their age criteria. Conversely, transition processing requires the transition criteria to be met. During transition processing, the low threshold does not stop processing of data sets on the volume. All data sets on the volume are processed for migration and transition eligibility, even after the low threshold has been met.
- If MIGRATIONONLY is specified, processing remains unchanged.
- If BOTH is specified, since all data sets eligible for migration are migrated and migration takes precedence over transitions, essentially all data sets eligible for migration are migrated. Only data sets that cannot migrate but are eligible to be transitioned are transitioned. These data sets must meet the transition eligibility criteria.
- If TRANSITIONONLY is specified, all data sets eligible to be transitioned are processed, regardless of the low threshold on the volume.

Related reading

- For more information about using the MIGRATE command, see [Chapter 55, “MIGRATE command: Requesting a space management function,” on page 955](#).
- For more information about fast subsequent migration, see [“Reconnecting data sets using fast subsequent migration” on page 94](#).

Migrating and transitioning a storage group

The STORAGEGROUP keyword enables migration and transition processing to be performed for each volume defined to a storage group. The `MIGRATE STORAGEGROUP(sgname)` command initiates primary space management processing for a storage group. For more information, refer to [“Automatic primary space management” on page 23](#)

Recalling SMS-managed data sets

You can recall individual SMS-managed data sets from migration volumes to level 0 SMS-managed volumes by using the RECALL and HRECALL commands. (The HRECALL command is a non-DFSMSHsm-authorized command that is available to users.)

When you issue a RECALL or HRECALL command for an SMS-managed data set, processing is the same as that for automatic recall (see [“Automatic recall”](#) on page 83).

When a data set is recalled to a non-SMS-managed volume, the volume to which it is recalled is selected as described in [“Recall”](#) on page 119.

If you want to return an SMS-managed data set to a non-SMS-managed volume, you can use the FORCENONSMS parameter of the RECALL command. If you use the FORCENONSMS parameter, the volume to which the data set is recalled is selected as described in [“Recall”](#) on page 119.

Migrated extended format VSAM data sets can be recalled only as extended format VSAM data sets. Migrated extended format sequential access method (SAM) data sets can be recalled as extended format or nonextended format data sets.

If FORCENONSMS is specified on the RECOVER command to force an extended format data set to be recovered or restored to a non-SMS-managed volume, the data set is recovered as a nonextended data set. The maximum size of the non-SMS SAM data set is one volume.

If an out-of-space condition causes the recall of an SMS-managed data set to fail, the RECALL DFDSSOPTION(VOLCOUNT(N(nn) | ANY)) command can be used to ensure the successful recall of the data set. The RECALL DFDSSOPTION(VOLCOUNT(N(nn) | ANY)) command overrides the environment established by the SETSYS VOLCOUNT command. You can use the QUERY SETSYS command to determine the current operating environment.

Recalling direct access data sets

Target volume selection for command recalls of BDAM data sets can be influenced by using the DAOPTION parameter of the RECALL command. This parameter allows you to specify the acceptable target volume device types (in terms of track size) and how the recalled data is accessed (relative track or relative block). For instance, using the RELBLK option of the DAOPTION parameter allows a data set to be recalled to a device type with a smaller track size than the original level 0 volume. In this case, data is moved to “fill out the track” rather than in a track to track image as is the case for the RELATER and SMATTER options.

You can only use the DAOPTION parameter when recalling a data set as non-SMS-managed. You can use the FORCENONSMS parameter to recall a data set that would otherwise be returned as SMS managed.

Moving data sets

Use the MOVE parameter with the MIGRATE command to move individual SMS-managed data sets from one L0 volume to another L0 volume. Specify MOVE with the MIGRATE DATASETNAME, MIGRATE VOLUME or MIGRATE STORAGEGROUP commands. MOVE causes DFSMSHsm to drive the standard allocation ACS routines to determine the volume to which the data set should be moved. DFSMSHsm then performs class transitioning processing for the data set. When VOLUME or STORAGEGROUP processing is being performed, all data sets on each volume are processed, regardless of threshold. When data movement is performed, the management class transition copy technique and serialization error exit values are used.

The MOVE parameter is intended to assist with the process of moving data off of one or volumes onto another. The typical cases for using MOVE are:

- Move data from one storage group to another (the basic case). The steps are as follows:
 1. Update the ACS routines such that new allocations go to the new storage group.
 2. Move existing data from the original storage group to the new storage group. When the move is being done, the ACS routines are already defined to drive the data to the new storage group.
- Move data from one volume to another within the same storage group. Moving within storage groups doesn't require any value here, because the allocation needs to be within the existing storage group. The existing ACS logic is usable because it just selects the same storage group. To prevent any new allocations from going to the source volume, this volume should be put into DISNEW or DISALL state. If allocations to the source volume are not prevented, then the MIGRATE MOVE command may fail if SMS selects one or more volumes on which the data set currently resides.

Note:

1. During MOVE processing, the statistic records (DSR and VSR) are created with the class transition function code.
2. The MOVE processing uses the transition processing messages.
3. The management class Transition Copy Technique setting can be also used to specify copy technique for MOVE processing. Note that if a copy technique other than STANDARD, PRESERVE MIRROR REQUIRED, or FC XRCPRIMARY is specified, then a valid backup copy must exist before the data set is transitioned. This ensures availability of the backup if an error occurs while physically moving.

If the transition technique PRESERVE MIRROR REQUIRED is specified to allow FlashCopy to Global Mirror Primaries, a valid backup copy must exist before the data set residing on a Global Mirror primary volume is transitioned. You can set one of the following patches to override this requirement:

```
PATCH .MGCB.+111 BITS(. . . . .1.)
```

```
PATCH .MGCB.+111 BITS(. . . . .1)
```

4. When moving Db2 objects, DFSMSHsm must be authorized to the Db2 STOP and START commands.

Reconnecting data sets using fast subsequent migration

Using the standard migration and recall method, a data set can be migrated to an ML2 tape volume or cloud container and later be recalled. When the data set is recalled, the migrated copy of the data set remains on the ML2 tape volume or cloud container and is marked *not valid* in the CDS record for the data set. If the recalled data set is later migrated using the standard migration method, it is *moved* to a new ML2 tape volume or cloud container (even if the data set has not changed). This process results in unnecessary data movement and if stored on an ML2 tape volume, causes the original ML2 tape volume to become fragmented which requires the tape to be recycled.

Fast subsequent migration allows an unchanged data set that is recalled from a single ML2 tape volume or cloud container to be *reconnected* to that ML2 tape volume or cloud container during data set or volume migration. Using fast subsequent migration:

- eliminates the unnecessary data movement and tape mounts caused by migrating a data set again that is unchanged.
- involves creating and updating DFSMSHsm control records only.
- reduces the need for recycling the ML2 tape.

Specific fast subsequent migration eligibility criteria must be satisfied both at time of recall and when a fast subsequent migration reconnect is attempted on a data set. See [“Fast subsequent migration \(reconnection\) eligibility requirements”](#) on page 95.

Enabling fast subsequent migration

There are four methods of enabling fast subsequent migration:

- Add the SETSYS TAPEMIGRATION command with the RECONNECT(ALL) or RECONNECT(ML2DIRECTEDONLY) parameter to the ARCCMDxx parmlib member of SYS1.PARMLIB. Then restart DFSMSHsm.
- Issue the SETSYS TAPEMIGRATION command with the RECONNECT(ALL) or RECONNECT(ML2DIRECTEDONLY) parameter after DFSMSHsm is started.
- Add the SETSYS CLOUDMIGRATION command with the RECONNECT(ALL) parameter to the ARCCMDxx parmlib member of SYS1.PARMLIB. Then restart DFSMSHsm.
- Issue the SETSYS CLOUDMIGRATION command with the RECONNECT(ALL) parameter after DFSMSHsm is started.

To use fast subsequent migration after it is enabled, the data set must also satisfy fast subsequent migration eligibility requirements. See [“Fast subsequent migration \(reconnection\) eligibility requirements”](#) on page 95.

Disabling fast subsequent migration

There are four methods of disabling fast subsequent migration:

- Add the SETSYS TAPEMIGRATION command with the RECONNECT(NONE) parameter to the ARCCMDxx parmlib member of SYS1.PARMLIB. Then restart DFSMSHsm.
- Issue the SETSYS TAPEMIGRATION command with the RECONNECT(NONE) parameter after DFSMSHsm is started.
- Add the SETSYS CLOUDMIGRATION command with the RECONNECT(NONE) parameter to the ARCCMDxx parmlib member of SYS1.PARMLIB. Then restart DFSMSHsm.
- Issue the SETSYS CLOUDMIGRATION command with the RECONNECT(NONE) parameter after DFSMSHsm is started.

Fast subsequent migration (reconnection) eligibility requirements

There are two sets of requirements that must be satisfied in order for a data set to be eligible for fast subsequent migration. The first set of requirements must be satisfied when a data set is recalled. The second set of requirements must be satisfied when a fast subsequent migration reconnect is attempted on a data set. In addition to the two sets of eligibility requirements, there are conditions which always prevent fast subsequent migration regardless of whether all other requirements are satisfied.

Conditions that *always prevent* fast subsequent migration are:

- The data set is an HFS file.
- The data set is a VSAM data set with an alternative index (AIX) or path defined.
- The data set has changed since it was recalled.
- The data set spans multiple ML2 tape volumes.
- The MIGRATE command was issued with the CONVERT parameter.
- The ARCHMIG macro is used with the FORCML1=YES parameter to direct the data set to an ML1 volume.
- The SETSYS TAPEMIGRATION command with the RECONNECT(NONE) setting is in effect.
- The SETSYS CLOUDMIGRATION command with the RECONNECT(NONE) setting is in effect for migrations directed to cloud.

Requirements that must be satisfied when the data set is *recalled* are:

- The data set is recalled from a single ML2 tape volume or from cloud storage.
- The SETSYS USERDATASETSERIALIZATION setting is in effect.
- The SETSYS TAPEMIGRATION command with the RECONNECT(ALL) or RECONNECT(ML2DIRECTEDONLY), or SETSYS CLOUDMIGRATION command with the RECONNECT(ALL) setting is in effect.

Requirements that must be satisfied when a *fast subsequent migration reconnect is attempted* on the data set are:

- The data set was marked reconnectable when recalled.
- No changes have been made to the data set since it was recalled.
- The catalog entry for the data set has not been altered since it was recalled.
- The MCDS record for the data set has not been deleted (for example, when migration cleanup is performed).
- The ML2 tape volume has not been recycled since the data set was recalled.

- The SETSYS USERDATASETSERIALIZATION setting is in effect.
- The SETSYS TAPEMIGRATION command with the RECONNECT(ALL) or RECONNECT(ML2DIRECTEDONLY) setting is in effect.
- The cloud provider definition has not changed since the previous migration, or the cloud provider properties remain compatible.

Note:

1. Data sets that were migrated to an ML2 tape volume without requiring a backup copy (such as when using tape mount management) are eligible for fast subsequent migration as long as all other requirements are satisfied.
2. If a data set fails fast subsequent migration it is still eligible for standard migration.
3. A default date for fast subsequent migration is predicted when an eligible data set is recalled. The default date is the date the eligible data set was recalled plus the number of days the data set was unreferenced when it was last migrated. Fast subsequent migration is performed if the eligible data set is not referenced before that date and if the data set satisfies all fast subsequent migration and standard migration requirements.

Delaying migration cleanup of fast subsequent migration eligible data sets

Migration cleanup is performed on the MCDS records of fast subsequent migration eligible data sets a default number of days after the predicted remigration date if the data set was not reconnected (that is, fast subsequent migration was not performed). The default number of days is the default value of the SETSYS MIGRATIONCLEANUPDAYS command *reconnectdays* parameter.

Specify a *reconnectdays* value greater than the default to improve the likelihood of performing fast subsequent migration on eligible data sets by delaying migration cleanup of the MCDS records for those data sets.

Attention: The size of the MCDS might need to be increased to accommodate the extended life of MCDS records for fast subsequent migration eligible data sets.

Programming Interface Information

= Using ARCMDEXT to control fast subsequent migration eligibility

You can use the ARCMDEXT installation exit to redirect migrations that target ML1 volumes so that they target ML2 tape volumes instead. If you specified the SETSYS TAPEMIGRATION command with the RECONNECT(ALL) parameter, you can use this exit to deny reconnection for specific data sets. The ARCMDEXT exit is passed information in the parameter list, when fast subsequent migration is performed, as to whether a specific data set is reconnectable.

End Programming Interface Information

Chapter 3. Space management of non-SMS-managed storage

Eligibility for DFSMSHsm space management of non-SMS-managed storage is determined on a volume basis. Non-SMS-managed volumes that are to be automatically managed by DFSMSHsm are known as *primary* volumes. That is, all the data sets on a volume are managed to the same specification, whether for days-not-used on the primary volume, age for deletion, or permission for automatic migration. In addition, DFSMSHsm chooses the volume to receive the recalled data sets based on the volume pools you have defined, as well as the characteristics given the volumes when you defined them.

Differences between processing for SMS-managed and non-SMS-managed data sets are as follows:

- Two additional space management functions are available for non-SMS-managed volumes:
 - Deletion (delete by age)
 - Retirement (delete if backed up)
- Deletion of list and utility data sets.
- Level 1 to level 2 migration is controlled on a processing-unit-wide basis rather than on a data set management class basis.
- Target volumes for recall are selected by DFSMSHsm rather than by DFSMSdftp.
- Volumes are individually identified to DFSMSHsm using the ADDVOL command.

Related reading

- Before performing space management functions on extended address volumes (EAVs) you need to understand how EAV space is managed. For details, see [“Space management of extended address volumes \(EAVs\)”](#) on page 127 and review recommendations in [“Recommendations for using extended address volumes \(EAVs\)”](#) on page 129.
- For information about using DFSMSHsm with Linux®, see [Chapter 23, “Linux-z/OS DFSMSHsm dump or restore how-to,”](#) on page 665.

Differences in what the example system shows

The non-SMS-managed-storage space management example performs the same functions as were described for SMS-managed storage:

- Automatic space management
- Interval migration
- Automatic recall
- Command space management

During automatic primary space management, DFSMSHsm deletes certain list, utility, and expired data sets. DFSMSHsm does not perform partial release for unused allocated space on non-SMS-managed data sets but does perform extent reduction. In addition, the fast subsequent migration function allows unchanged data sets that are recalled from ML2 tape to reconnect to that original tape.

Tasks for space management of non-SMS-managed storage

To manage non-SMS-managed storage, you perform the same tasks as for managing SMS-managed storage except for the tasks involved with specifying storage management attributes to SMS. That is, you issue all the same SETSYS, ADDVOL, and DEFINE commands that have been specified so far. You do not define storage groups or management classes. In addition, you perform the following tasks:

- Specify the age for deleting list and utility data sets.
- Specify the minimum age for data sets to migrate if no age is specified when the volume is defined to DFSMSHsm.
- Specify when data sets become eligible for level 1 to level 2 migration.
- Specify recall characteristics for primary volumes.
- Define primary volumes to DFSMSHsm.
- Define pools of volumes.

Specifying the age for deleting list and utility data sets

During automatic space management, DFSMSHsm deletes list and utility data sets from primary volumes. DFSMSHsm does not migrate utility or list data sets during space management, nor does it back up utility and list data sets during availability management. However, it does process them if they are specified in the MIGRATE DATASETNAME(*dsn*) or BACKDS(*dsn*) commands.

All utility data sets must be at least two days old before DFSMSHsm scratches them. The utility data sets that are deleted by DFSMSHsm have the following types of data set names:

Data Set Name
HSM.MDB.Dnnnnn from HSM.MVS.Dccc
mcvtuid.MDB.Dccc
SYSnnnnn.Tnnnnnn.?Fccc
SYSnnnnn.Tnnnnnn.?Vccc
SYSnnnnn.Tnnnnnn.?Accc
N---N.FORMAT.Dnnnnn.Tnnnnnnnc
N---N.SUBMIT.Dnnnnn.Tnnnnnnnc
N---N.MERGE.Dnnnnn.Tnnnnnnnc
N---N.RUN.Dnnnnn.Tnnnnnnnc
N---N.SUB.Dnnnnn.Tnnnnnnnc
N---N.R.Dnnnnn.Tnnnnnnnn
N---N.M.Dnnnnn.Tnnnnnnnn
N---N.SPRINT.Dnnnnn.Tnnnnnnnc
N---N.DOSPR.Dnnnnn.Tnnnnnnnc
*SYSUT
<p>The variables shown in the data set names have the following values:</p> <ul style="list-style-type: none"> • <i>nnnnn</i> is a string of numeric characters whose length is represented by the number of <i>n</i>'s. This string typically consists of a time when preceded by a T or a date when preceded by a D. • <i>ccccccs</i> is an arbitrary length of arbitrary characters for the remaining portion of the data set name. • <i>N---N</i> represents the first qualifier in the data set name. • <i>mcvtuid</i> is the DFSMSHsm-authorized user identification specified with the UID parameter in the DFSMSHsm startup procedure. • <i>????s</i> is a string of arbitrary characters whose length is represented by the number of <i>?</i>'s.

All data set names must comply with the MVS data set naming conventions.

Before a list data set is scratched and uncataloged, it must meet the current DFSMSHsm value for the SCRATCHFREQUENCY parameter of the SETSYS command. List data sets that are deleted by DFSMSHsm have the following last qualifiers:

- LIST
- LINKLIST
- OUTLIST

In the example system, because only DFSMSHsm hosts 1 and 3 do automatic space management for the non-SMS-managed volumes, the following command is added to the ARCCMDxx member in DFSMSHsm hosts 1 and 3:

```
SETSYS SCRATCHFREQUENCY(5)
```

Specifying the minimum age for migrating data sets

The DAYS parameter of the SETSYS command specifies the minimum age for migrating data sets. If you do not specify this parameter, the minimum age is the same as the minimum you can specify for the serialization and processing-unit environment in your system. In the example system, the minimum age is specified as:

```
SETSYS DAYS(7)
```

The value specified by the DAYS parameter of the SETSYS command is used only if no value is specified for the MIGRATE parameter of the ADDVOL command or the MIGRATE parameter of the MIGRATE command. An ADDVOL command with the MIGRATE(0) parameter specified also causes SETSYS DAYS to determine the migration age.

Specifying when data sets become eligible for level 1 to level 2 migration

For non-SMS-managed storage, the age at which data sets become eligible for migration from level 1 to level 2 is the same for all non-SMS-managed data sets in the system. The MIGRATIONLEVEL1DAYS parameter of the SETSYS command specifies the minimum time that a data set must remain unused on the combination of level 0 and level 1 before it becomes eligible to migrate from level 1 to level 2. For example, for a MIGRATIONLEVEL1DAYS value of 31, a data set might stay unused on level 0 for 31 days, or it could stay on level 0 until it is eligible to migrate to level 1 and reside on level 1 until it was unused for a total of 31 days. In the example system, the following command is added to the ARCCMDxx member in DFSMSHsm host 2:

```
SETSYS MIGRATIONLEVEL1DAYS(60)
```

(The command is added only in DFSMSHsm host 2 because only DFSMSHsm host 2 does automatic level 1 to level 2 migration.)

If you want DFSMSHsm to do automatic migration from ML1 to ML2 volumes, you must specify the thresholds of occupancy parameter (of the ADDVOL command) for the ML1 volumes.

Specifying recall characteristics for the type of volume

For non-SMS-managed data sets, DFSMSHsm selects the type of volume to which a data set can be recalled. The characteristics for a volume to be eligible to receive recalled data sets are the same for all non-SMS-managed data sets in the system. The RECALL parameter of the SETSYS command specifies the general volume destinations for the recalled data sets. In the example system, the following command is added to the ARCCMDxx member in all DFSMSHsm hosts:

```
SETSYS RECALL(ANYSTORAGEVOLUME(LIKE))
```

This command causes any volume with the use attribute of storage and availability for automatic recall to be eligible for selection as a destination for any recalled data set not directed to a pool volume.

An alternative value for the subparameter of the RECALL command is PRIVATEVOLUME. The PRIVATEVOLUME subparameter specifies that data sets not directed to a pool can be recalled to any volume with the use attribute of public, private, or storage that has AUTORECALL specified in the ADDVOL command.

The LIKE subparameter that was specified causes DFSMSHsm to select as a target volume for recall only a volume with recall attributes like those of the volume from which the data set migrated. The alternative UNLIKE subparameter allows DFSMSHsm to select a volume with unlike recall attributes.

Related reading

- For more information about pool volumes and recall, see [“Defining pools of volumes” on page 105](#).
- For more information about recall attributes, see [“Recall attributes” on page 104](#).

JES3 considerations

The RECALL parameter should be consistent among the ARCCMDxx members of all the JES3 DFSMSHsm hosts. The subparameter to be used is selected in the DFSMSHsm host that performs the converter/interpreter locate function.

Defining primary volumes to DFSMSHsm

If multiple DFSMSHsm hosts are requested to process automatic primary space management, only the first DFSMSHsm host to process a given volume will perform the function. However, should you find it necessary to limit processing of certain volumes to one DFSMSHsm host, you can do so with the following parameters:

- Specifying the AUTOMIGRATION parameter on the ADDVOL command in the DFSMSHsm host that you want to perform automatic primary space management on the volume.
- Specifying the NOAUTOMIGRATION parameter on the ADDVOL command in the DFSMSHsm hosts that you do not want to perform automatic primary space management on the volume.

At the same time that you make the volume known to DFSMSHsm, you specify the following characteristics:

- Whether to perform automatic space management on the volume
- Whether the volume is available for automatic recall of all data sets
- The space management technique for the volume

The ADDVOL command defines non-SMS-managed volumes to DFSMSHsm. You cannot use the ADDVOL command for SMS-managed volumes. Non-SMS volumes that are added with the AM parameter on the ADDVOL command work in a similar way to a volume added with an AM=Y storage group. See [Table 2 on page 31](#) for a discussion of standard interval migration processing.

Note: A maximum of eight z/OS images can ADDVOL a primary volume at the same time.

For the example system, the following ADDVOL commands are added to the ARCCMDxx member in DFSMSHsm hosts 1 and 2:

```
ADDVOL GP0001 UNIT(3390) PRIMARY(AUTOMIGRATION -  
    AUTORECALL MIGRATE(12)) THRESHOLD(95 80)  
  
ADDVOL GP0002 UNIT(3390) PRIMARY(AUTOMIGRATION -  
    AUTORECALL MIGRATE(12)) THRESHOLD(95 80)  
  
ADDVOL GP0003 UNIT(3390) PRIMARY(AUTOMIGRATION -  
    AUTORECALL MIGRATE(12)) THRESHOLD(95 80)  
  
ADDVOL UG1001 UNIT(3390) PRIMARY(AUTOMIGRATION -  
    NOAUTORECALL MIGRATE(12)) THRESHOLD(95 80)
```

```

ADDVOL UG1002 UNIT(3390) PRIMARY(AUTOMIGRATION -
NOAUTORECALL MIGRATE(12)) THRESHOLD(95 80)

ADDVOL UG1003 UNIT(3390) PRIMARY(AUTOMIGRATION -
NOAUTORECALL MIGRATE(12)) THRESHOLD(95 80)

ADDVOL UG2001 UNIT(3390) PRIMARY(AUTOMIGRATION -
NOAUTORECALL MIGRATE(12)) THRESHOLD(95 80)

ADDVOL UG2002 UNIT(3390) PRIMARY(AUTOMIGRATION -
NOAUTORECALL MIGRATE(12)) THRESHOLD(95 80)

ADDVOL UG2003 UNIT(3390) PRIMARY(AUTOMIGRATION -
NOAUTORECALL MIGRATE(12)) THRESHOLD(95 80)

ADDVOL VP0001 UNIT(3390) PRIMARY(AUTOMIGRATION -
NOAUTORECALL MIGRATE(12)) THRESHOLD(95 80)

ADDVOL VP0002 UNIT(3390) PRIMARY(AUTOMIGRATION -
NOAUTORECALL MIGRATE(12)) THRESHOLD(95 80)

ADDVOL VP0003 UNIT(3390) PRIMARY(AUTOMIGRATION -
NOAUTORECALL MIGRATE(12)) THRESHOLD(95 80)

```

The first parameter of the command specifies the volume serial number. Notice that each of the volumes to be managed individually must be added. Primary volumes must be online and permanently resident or reserved.

The second parameter specifies the unit type.

The third parameter specifies that the volume is to be added as a primary volume. Notice that this parameter has subparameters that define whether and how automatic space management is to be performed.

The AUTOMIGRATION subparameter specifies that DFSMSShsm is to perform automatic volume space management on the volume. The alternative NOAUTOMIGRATION prevents DFSMSShsm from performing automatic volume space management.

The AUTORECALL|NOAUTORECALL subparameter specifies whether the volume is generally available as a recall volume. Notice that AUTORECALL is specified only for volumes GP0001, GP0002, and GP0003. The UG and VP volumes are indicated as NOAUTORECALL because they are members of pools. See the discussion of recall to pools in [“Defining pools of volumes”](#) on page 105.

The DELETEBYAGE|DELETEIFBACKEDUP|MIGRATE subparameters specify the management technique for the volume. For all volumes in the example system, DFSMSShsm migrates the data sets that have not been opened in the number of days specified with the MIGRATE subparameter. You can specify any value equal to or larger than the integrity age up to 999. If you specify the DELETEBYAGE subparameter, DFSMSShsm deletes any data set without an expiration date or with an expiration date that has passed, and that has not been opened in the number of days specified with the DELETEBYAGE subparameter. You can specify any value equal to or larger than the integrity age (see [“Integrity age for space management”](#) on page 56) up to 999. If you specify the DELETEIFBACKEDUP subparameter, DFSMSShsm deletes any data set that has not been opened in the number of days specified with the DELETEIFBACKEDUP subparameter if a current backup version of the data set exists. You can specify any value equal to or larger than the integrity age up to 999.

If you do not specify a value for the number of days with the MIGRATE subparameter, DFSMSShsm uses the value specified with the DAYS parameter of the SETSYS command.

The THRESHOLD parameter in these ADDVOL commands operates in the same way as the THRESHOLD attribute in the storage groups. However, for volumes managed by DELETEBYAGE and DELETEIFBACKEDUP techniques, the thresholds are ignored and all eligible data sets on the volume are processed.

Attributes of primary volumes

When you use the ADDVOL command to add a primary volume to DFSMSShsm, you assign attributes to that primary volume. You can choose the following primary volume attributes:

- AUTOMIGRATION or NOAUTOMIGRATION
- AUTORECALL or NOAUTORECALL
- AUTOBACKUP or NOAUTOBACKUP
- BACKUPDEVICECATEGORY
- AUTODUMP or NOAUTODUMP

The use of the first two primary volume attributes is described in this topic. The use of the last three attributes is described in [Chapter 7, “Availability management of non-SMS-managed storage,”](#) on page 303.

Each DFSMSShsm host can decide whether primary volumes are processed by automatic space management, automatic backup, or automatic dump. However, if an automatic process controls a primary volume in any DFSMSShsm host, DFSMSShsm considers the volume to be automatically controlled for that process. For example, assume you specify the following in DFSMSShsm hosts 1 and 2:

```
ADDVOL VOL006 PRIMARY(AUTOMIGRATION) UNIT(3390)
```

Then you specify the following in DFSMSShsm host 3:

```
ADDVOL VOL006 PRIMARY(NOAUTOMIGRATION) UNIT(3390)
```

DFSMSShsm considers VOL006 to be controlled by automatic space management.

Recall attributes

The primary volume attributes of AUTOMIGRATION, AUTOBACKUP, and BACKUPDEVICECATEGORY are also designated as recall attributes. That is, DFSMSShsm considers the values of these attributes in selecting target volumes for recalling non-SMS-managed data sets. The relationship of these attributes to those of the available volumes is what you specify when you use the LIKE and UNLIKE values with the ANYSTORAGEVOLUME and PRIVATEVOLUME subparameters of the RECALL parameter of the SETSYS command.

Because DFSMSShsm hosts 1 and 2 are to do all automatic space management for the non-SMS-managed volumes, you can add the following commands to the ARCCMDxx member in DFSMSShsm host 3:

```
ADDVOL GP0001 UNIT(3390) PRIMARY(NOAUTOMIGRATION -  
    AUTORECALL MIGRATE(12)) THRESHOLD(95 80)  
  
ADDVOL GP0002 UNIT(3390) PRIMARY(NOAUTOMIGRATION -  
    AUTORECALL MIGRATE(12)) THRESHOLD(95 80)  
  
ADDVOL GP0003 UNIT(3390) PRIMARY(NOAUTOMIGRATION -  
    AUTORECALL MIGRATE(12)) THRESHOLD(95 80)  
  
ADDVOL UG1001 UNIT(3390) PRIMARY(NOAUTOMIGRATION -  
    NOAUTORECALL MIGRATE(12)) THRESHOLD(95 80)  
  
ADDVOL UG1002 UNIT(3390) PRIMARY(NOAUTOMIGRATION -  
    NOAUTORECALL MIGRATE(12)) THRESHOLD(95 80)  
  
ADDVOL UG1003 UNIT(3390) PRIMARY(NOAUTOMIGRATION -  
    NOAUTORECALL MIGRATE(12)) THRESHOLD(95 80)  
  
ADDVOL UG2001 UNIT(3390) PRIMARY(NOAUTOMIGRATION -  
    NOAUTORECALL MIGRATE(12)) THRESHOLD(95 80)  
  
ADDVOL UG2002 UNIT(3390) PRIMARY(NOAUTOMIGRATION -  
    NOAUTORECALL MIGRATE(12)) THRESHOLD(95 80)  
  
ADDVOL UG2003 UNIT(3390) PRIMARY(NOAUTOMIGRATION -  
    NOAUTORECALL MIGRATE(12)) THRESHOLD(95 80)  
  
ADDVOL VP0001 UNIT(3390) PRIMARY(NOAUTOMIGRATION -  
    NOAUTORECALL MIGRATE(12)) THRESHOLD(95 80)  
  
ADDVOL VP0002 UNIT(3390) PRIMARY(NOAUTOMIGRATION -  
    NOAUTORECALL MIGRATE(12)) THRESHOLD(95 80)
```

```
ADDVOL VP0003 UNIT(3390) PRIMARY(NOAUTOMIGRATION -
NOAUTORECALL MIGRATE(12)) THRESHOLD(95 80)
```

Defining pools of volumes

To ensure that recalled non-SMS-managed data sets go to the correct volumes, you can organize your non-SMS-managed volumes into pools. You can define either pools that accept only specified data set names during recall or pools that accept for recall any data set that migrated from them. In this topic, you are first shown how to define the pools, and then the effects of the pools are described.

You use the DEFINE command to define pools of volumes. The DEFINE command associates a pool ID with a list of volume serial numbers. In the example system, the commands added to the ARCCMDxx member in all DFSMSHsm hosts are:

```
DEFINE POOL(GROUP1 VOLUMES(UG1001 UG1002 UG1003))
DEFINE POOL(GROUP2 VOLUMES(UG2001 UG2002 UG2003))
DEFINE VOLUMEPOOL(SAMPLE VOLUMES(VP0001 VP0002 VP0003))
```

The first two examples specify data set pools. The data set pool list specifies DFSMSHsm primary volumes where DFSMSHsm is to recall data sets whose set of initial characters match that pool ID. For the first example, data sets with an initial character sequence of GROUP1 are recalled to it. For the second example, data sets with an initial character sequence of GROUP2 are recalled to it.

The third example specifies a volume pool. A volume pool associates volumes from which data sets migrate with other volumes, to aid in the selection of target volumes for recall.

You can specify nonresident volumes in a volume pool, to allow recall of data sets that migrated from volumes that no longer exist in the system. Not all volumes in a volume pool are required to be managed by DFSMSHsm. You can specify SMS-managed volumes in volume pools, although they will never be selected from the pool for non-SMS-managed data.

Data sets that migrate from a volume in a volume pool are recalled to an online volume that has been added to the list of volumes managed by DFSMSHsm using the ADDVOL command. The target volume selection is based on the volume pool configuration at the time of recall. To change the definition of a volume pool (adding or deleting volumes from the pool), the DEFINE command must include all the volumes you want as part of the pool, including any volumes you selected with a previous DEFINE command if you still want them as part of the pool. The volume pool is limited to 140 volumes.

All volumes in a pool need to have the same geometry. For example, you could have a volume pool that included a 3390 Model 3, and a 3390 Model 9 because they share the same geometry. This means that a data set originally allocated on one model could be recalled to a different model.

A primary volume can be in any number of data set or volume pools and can also be available for general recall use if it is online, permanently resident or reserved, and has the AUTORECALL subparameter in its ADDVOL command.

In a loosely coupled multiple DFSMSHsm-host environment:

- A data set or volume pool should be the same in all DFSMSHsm hosts.
- Volumes that are available for general recall must be accessible to all DFSMSHsm hosts.
- A volume that is removed from the environment should be removed from DFSMSHsm by the DELVOL command on *all* DFSMSHsm hosts, and from any ADDVOL commands that may be in the startup member. It may remain in the pool definition. In this way, DFSMSHsm can translate a recall request to a currently active volume in the pool.

Pools in systems running under JES2

In systems running under JES2, you can define two kinds of pools: data set pools and volume pools. Data set pools and volume pools are known as *user-defined* pools. You can define these pools at any time, either during the startup procedure or after DFSMSHsm has been started. Similarly, you can use the ADDVOL command to add volumes to DFSMSHsm control at any time.

Any volume that has the AUTORECALL subparameter in its ADDVOL command is eligible to be used for recall of any data set that is not restricted to a pool of volumes. This provides a kind of default pool.

Pools in systems running under JES3

In systems running under JES3, three kinds of pools exist. In addition to the user-defined pools that you define as described earlier, DFSMSHsm configures a general pool from the unit control block associated with primary volumes and from information obtained from the ADDVOL command. The general pool is a collection of all primary volumes that:

- Are online.
- Are permanently resident or reserved.
- Have a primary volume attribute of AUTORECALL.
- Are mounted with the use attribute of storage or private. (The private volumes are included only if you specify the SETSYS RECALL(PRIVATE) command.)

Volumes in the general pool can also be defined in one or more data set or volume pools. The general pool is the default pool where DFSMSHsm recalls migrated data sets if they are not restricted for recall to a user-defined pool.

Specifying pools in systems running under JES3

Because DFSMSHsm returns a list of volumes to JES3 at converter/interpreter time, the system pools that are running under JES3 have restrictions on when they can be established. You can specify pool configurations and recall options only at designated times. You must specify the pool configuration command in the ARCCMDxx member that is used when you start DFSMSHsm with HOSTMODE=MAIN. (A pool configuration that is specified when you are starting HOSTMODE=AUX is ignored.) You cannot change pool configurations until the MAIN DFSMSHsm restarts. Pool configurations and recall options must be consistent in all z/OS images that run DFSMSHsm with the appropriate HOSTMODE and perform the JES3 locate function.

The ADDVOL, DEFINE, DELVOL, and SETSYS commands determine the configuration of pools of volumes. When DFSMSHsm is used with JES3, the DFSMSHsm general pool and user-defined pools can be configured only as a result of the commands in the ARCCMDxx member processed when DFSMSHsm is being initiated. Certain variations of these DFSMSHsm commands are accepted only during that initialization period. The one exception is the DELVOL command. The DELVOL command is accepted at any time after initialization by any DFSMSHsm that is running in the JES3 image. Therefore, JES3 does not expect a data set on a volume that is unusable. For example, you could use the DELVOL command to delete a primary volume that has I/O errors, so that DFSMSHsm does not tell JES3 to use that volume.

To ensure that pools function correctly in a system running under JES3, consider the following conditions:

1. Before you can define pools in each z/OS image, you must specify the following commands for each DFSMSHsm host that you are starting in that image:
 - A SETSYS JES3 command. The JES3 parameter of the SETSYS command determines the need for the general pool. For a JES3 system, DFSMSHsm builds the general pool when you start HOSTMODE=MAIN. Because information from the ADDVOL command is used to build the general pool, DFSMSHsm must know that JES3 is the job entry system before the first ADDVOL command is issued for a primary volume. Once the job entry subsystem is determined, you cannot change it until DFSMSHsm is restarted.
 - A SETSYS RECALL command with its appropriate subparameter. The ANYSTORAGEVOLUME and PRIVATEVOLUME subparameters of the RECALL parameter of the SETSYS command are not accepted after the initialization period of DFSMSHsm has passed, because the method of recalling data sets determines the volumes that qualify for the general pool.
 - An ADDVOL command for primary volumes that DFSMSHsm is to manage. You must specify the PRIMARY parameter of the ADDVOL command for a volume before that volume is included in any pool. Subsequent ADDVOL commands for the same DFSMSHsm primary volume must not change the information used by DFSMSHsm to define pools. The volume must still:

- Be online (see the note in item “2” on page 107)
- Be permanently resident or reserved
- Have the same automatic recall parameters specified

The ADDVOL command can be issued at any time for volumes other than DFSMSHsm primary volumes just as in a DFSMSHsm environment without JES3.

Note: Be sure that you include the ADDVOL command specifications in the ARCCMDxx member of SYS1.PARMLIB so that DFSMSHsm recognizes the volumes at each startup. If ADDVOL commands for ML1 volumes are not in the ARCCMDxx member, DFSMSHsm does not recognize that they are available unless you issue an ADDVOL command at the terminal for each ML1 volume.

2. The POOL parameter of the DEFINE command can be issued only during initialization of DFSMSHsm. DFSMSHsm does not accept more than one DEFINE command for the same pool ID during initialization. All DEFINE commands issued for volumes to be included in a data set pool must be preceded by an ADDVOL command for each volume.

Note: For data set pooling, volumes that are offline at DFSMSHsm startup time are added to DFSMSHsm as offline and are not added to the data set pool. When these volumes become available, DFSMSHsm must be restarted to add the volumes as online and include them in the data set pool.

3. The VOLUMEPOOL parameter of the DEFINE command can be issued only during initialization of DFSMSHsm. DFSMSHsm will not accept more than one DEFINE command for the same pool ID during initialization. At least one volume in the volume pool must have been added with a previous ADDVOL command to the list of volumes DFSMSHsm manages or owns.
4. You can specify other parameters of the DEFINE command as if in a DFSMSHsm environment without JES3.
5. Be sure that you define the same data set and volume pools in all z/OS images that can process the volumes.
6. To ensure that recall is to a volume that you choose, do not refer to any data set eligible for space management before the appropriate pool configuration in that z/OS image has been defined to DFSMSHsm.
7. Specify each DFSMSHsm primary volume with the same parameters (for a given volume) in each z/OS image. The mount status of permanently resident or reserved prevents DFSMSHsm primary volumes from being demounted. One of these attributes must be in effect for each DFSMSHsm primary volume.
8. When a local z/OS image assumes the function of the global image, any required DFSMSHsm functions that are performed by the previous global image must be active on the new global image. Specify the same pool configuration on each image to protect this type of JES3 activity.
9. Each JES3 z/OS image can have unique user-defined pools. However, if your system uses unique user-defined pools whose volumes are not accessible to the global z/OS image, you must use job classes or JES3 JCL to direct all jobs that access the unique user-defined pools to the z/OS image that can access them. This is a requirement when both the global and the local z/OS images request JES3 locates. If any z/OS image has access to a primary volume in a data set pool, it must have access to all primary volumes in that data set pool, or the job could fail. If you decide not to give all JES3 z/OS images access to all primary volumes, use caution when you define and operate with unique data set pool configurations.
10. If any device containing a volume in a data set pool is designated as a device managed by JES3, all other volumes in that data set pool must reside on JES3-managed devices. JES3 schedules jobs only on z/OS images that have access to all volumes that the jobs require.
11. Any z/OS image that runs the job must have access to all the volumes passed to JES3 by DFSMSHsm.

Example of JES3 pooling

Figure 13 on page 108 shows three z/OS images in a JES3 and DFSMSHsm environment. The following describes some pertinent facts about the figure:

- Volumes A, B, C, D, F, G, X, and Y make up the primary volume list. All the z/OS images have access to the online storage volumes X and Y. However, because only X and Y have the AUTORECALL primary volume attribute, non-pooled data sets are recalled only to volumes X and Y.
- Local z/OS images 1 and 3 have access to volumes A and B.
- Volumes A and B are both in data set pools USER1 and USER3. Jobs that access these volumes can be run only by z/OS image 1 and z/OS image 3, even though z/OS image 2 can set up the jobs.
- z/OS image 1 has access to volume Q. DFSMSHsm does not manage volume Q.
- z/OS image 3 has access to volumes F and G, which make up data set pool USER2.
- Volumes C and D are in a volume pool. If a data set migrated from either volume C or D with a high-level qualifier other than USER1, USER2, or USER3, the migrated data set is recalled to either volume C or D.

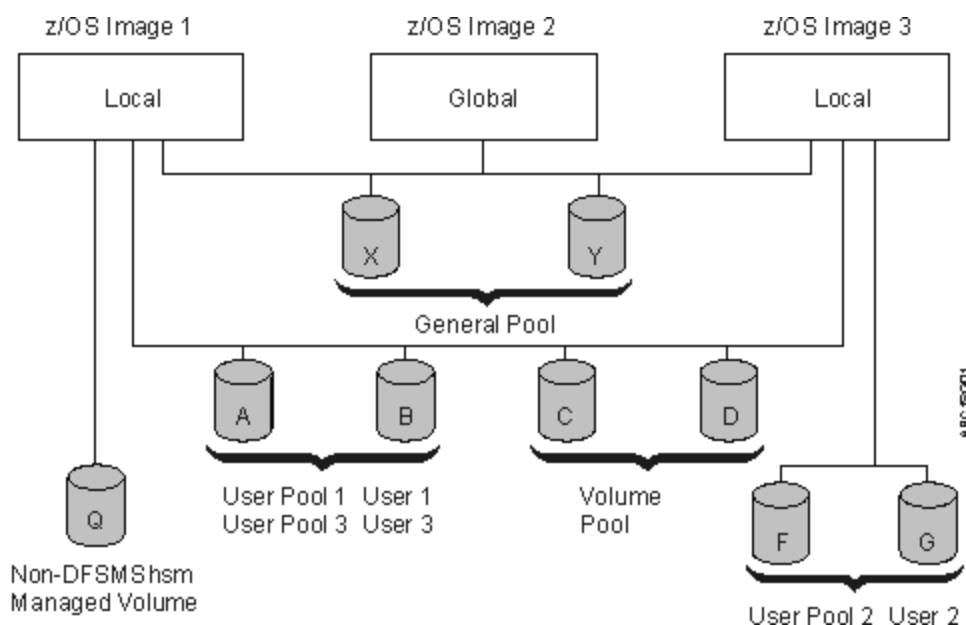

Figure 13. Multiple-Processing Units in a JES3 and DFSMSHsm Environment

You must issue these commands on all DFSMSHsm hosts on all three z/OS images:

```
SETSYS JES3 RECALL (ANYSTORAGEVOLUME)
ADDVOL X UNIT(3390) PRIMARY(AUTORECALL)
ADDVOL Y UNIT(3390) PRIMARY(AUTORECALL)
ADDVOL A UNIT(3390) PRIMARY(NOAUTORECALL)
ADDVOL B UNIT(3390) PRIMARY(NOAUTORECALL)
ADDVOL C UNIT(3390) PRIMARY(NOAUTORECALL)
ADDVOL D UNIT(3390) PRIMARY(NOAUTORECALL)
ADDVOL F UNIT(3350) PRIMARY(NOAUTORECALL)
ADDVOL G UNIT(3350) PRIMARY(NOAUTORECALL)
DEFINE POOL(USER1 VOLUMES(A B))
DEFINE POOL(USER3 VOLUMES(A B))
DEFINE POOL(USER2 VOLUMES(F G))
DEFINE VOLUMEPOOL(SHARED VOLUMES(C D))
```

Any of the three z/OS images in [Figure 13](#) on [page 108](#) can successfully run a JES3 locate routine if the appropriate catalogs are accessible.

Automatic space management processing for non-SMS-managed storage

Processing of non-SMS-managed storage differs from that of SMS-managed storage.

In the example system, DFSMShsm performs space management on the system configuration shown in Figure 14 on page 110. Remember, however, that the system for which the example system is built is that shown in Figure 4 on page 21 and that Figure 14 on page 110 is merely a subset that is used for simplification. When space management starts (first on DFSMShsm host 1 and later on DFSMShsm hosts 2 and 3), the space management is being done for all of the systems shown in Figure 4 on page 21. Table 10 on page 109 shows the characteristics for each data set in the various groups of volumes shown in Figure 14 on page 110. The names of the data sets are not precisely as the system would generate them. They have been shortened and modified for convenience in using them as examples.

Table 10. Data Set Characteristics for Automatic Space Management Example (Non-SMS-Managed Volumes)

Data Set Name	Inactive Age (Days)	Size (KB)	GDG Status
GROUP1.SAMPLE.A1	16	217	None
GROUP1.SAM.LIST	6	21	None
GROUP2.SAMPLE.B1	5	210	None
U1234.G3.G4	20	20	None
U1234.G3.G5	16	605	None
U2345.G3.G6	61	350	None
LARGE.ML.C1	16	1100	None

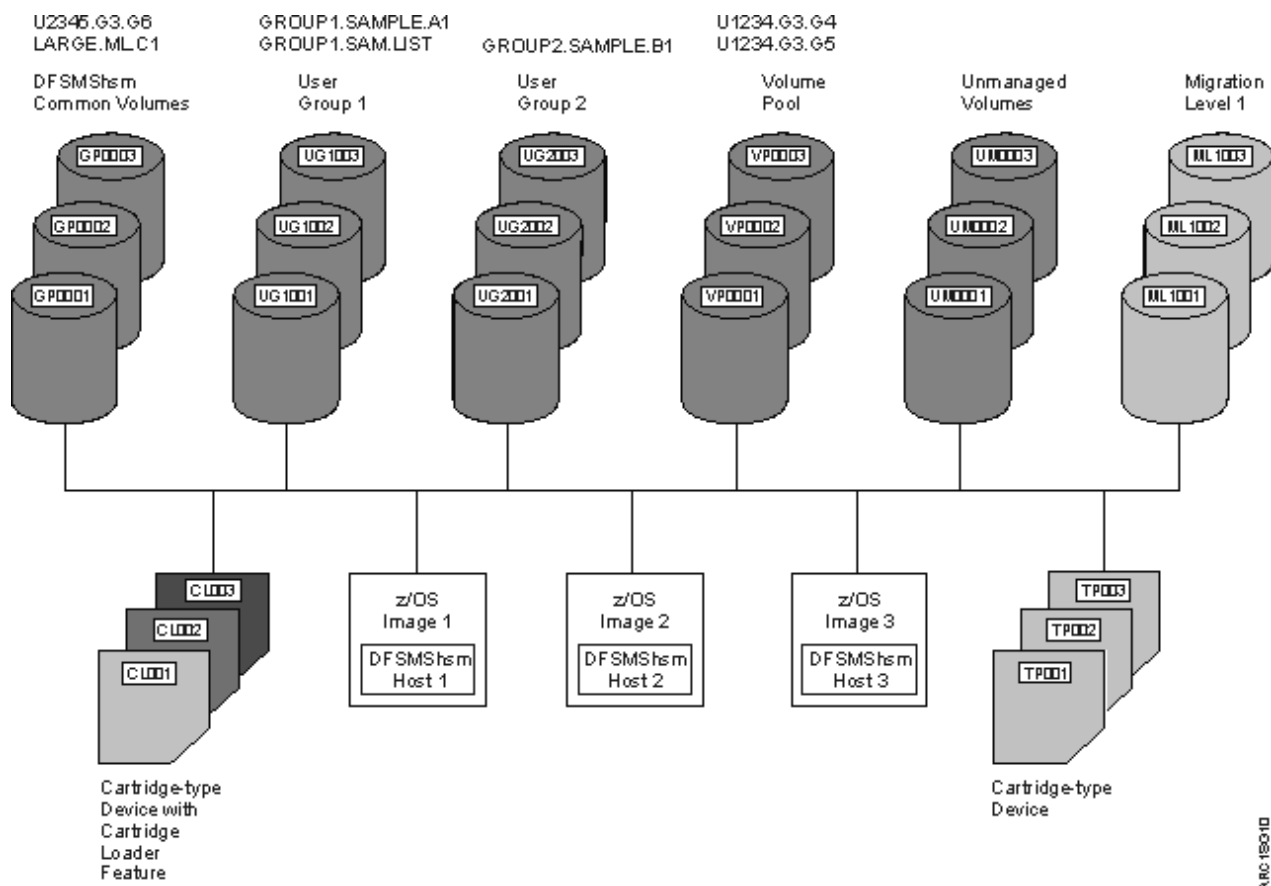

Figure 14. Example System of Non-SMS-Managed Volumes before Automatic Space Management

Automatic secondary space management

Although migration cleanup and level 1 to level 2 migration are performed on non-SMS-managed data sets, they operate the same whether the system is processing SMS-managed or non-SMS-managed storage. In the example system, they are performed by DFSMSHsm host 2.

During migration cleanup, DFSMSHsm uses the EXPIREDDATASETS(SCRATCH) parameter of the SETSYS command to determine whether to delete expired non-SMS-managed data sets. It uses the *statdays* and *recalldays* subparameters of the MIGRATIONCLEANUPDAYS parameter of the SETSYS command to determine when to delete statistics records and MCD records for recalled data sets respectively. The use of these parameters is discussed in [“Migration cleanup”](#) on page 59.

During level 1 to level 2 migration of non-SMS-managed data sets, DFSMSHsm uses the MIGRATIONLEVEL1DAYS parameter of the SETSYS command to determine when to migrate data sets from migration level 1 to migration level 2.

For performance reasons, level 1 to level 2 migration is not performed during automatic secondary space management in a non-SMS and direct-to-tape migration environment. DFSMSHsm assumes there are no migrated data sets on any ML1 volumes that need to be moved to ML2 volumes in this environment. If, for any reason, there are migrated data sets residing on any ML1 volumes that are to be moved to ML2 volumes in a non-SMS and direct-to-tape migration environment, the MIGRATE ML1 command should be used.

Related reading

For more information about the use of the MIGRATIONLEVEL1DAYS parameter, see [“Specifying when data sets become eligible for level 1 to level 2 migration”](#) on page 101.

Automatic primary space management

During automatic primary space management, DFSMSHsm does space management on each primary volume with the AUTOMIGRATION primary volume attribute. The space management technique that you specify with the ADDVOL command determines the kind of space management that DFSMSHsm does: data set deletion, data set retirement, or migration.

Automatic primary space management for non-SMS-managed volumes is performed in two passes.

Pass 1

During pass 1, DFSMSHsm examines every data set on the volume (independent of the occupancy of the volume), and checks the integrity age to ensure that it can process the data set. The inactive age must be more than or equal to the integrity age. The inactive age is the difference between the date of processing (current date) and the value in the date-last-referenced field of the data set VTOC entry. (For a discussion of integrity age, see [“Integrity age for space management” on page 56.](#)) However, for non-SMS-managed data sets, DFSMSHsm does not perform the following actions:

- Issue a message for unmatched data sets
- Delete temporary data sets
- Release unused space in non-VSAM data sets
- Expire data sets by inactive age or age since creation

For non-SMS-managed data sets, DFSMSHsm does perform the following actions:

- Delete list and utility data sets
- Delete data sets that have passed their expiration dates
- Determine eligible data sets for migration, including fast subsequent migration
- Determine eligible data sets to be backed up
- Determine eligible data sets for extent reduction

For each data set on the volume, DFSMSHsm uses the parameters specified in the SETSYS and ADDVOL commands in that DFSMSHsm host.

Programming Interface Information

<p>As DFSMSHsm considers each data set for eligibility for processing, it passes control to the space management and backup installation exit (ARCSAEXT) if the installation exit is enabled. (Refer to z/OS DFSMS Installation Exits manual for a discussion of ARCSAEXT.) If the installation exit indicates that processing is to continue (or the installation exit is not enabled), DFSMSHsm processes the data set. If the installation exit indicates that processing is not to continue, DFSMSHsm begins processing the next data set.</p>
--

End Programming Interface Information

Deleting list and utility data sets

As DFSMSHsm processes each data set, it deletes those utility data sets that are more than two days old and whose names follow one of the formats listed under [“Specifying the age for deleting list and utility data sets” on page 100](#). It also deletes those list data sets having names with the final qualifier as specified under [“Specifying the age for deleting list and utility data sets” on page 100](#), and older than the age specified with the SCRATCHFREQUENCY parameter of the SETSYS command.

Deleting expired data sets

For non-SMS-managed data sets, DFSMSHsm deletes those data sets that have passed their expiration date. For non-VSAM data sets this would be the expiration date in the data sets' VTOC entries and for VSAM data sets this would be the expiration date in the data sets' catalog entries. For these data sets, the EXPIREDDATASETS parameter of the SETSYS command controls whether the data sets are deleted.

Note: For multivolume non-VSAM data sets, DFSMSHsm looks at the VTOC of the first volume.

Determining eligible data sets for migration

For non-SMS-managed data sets, the criteria for whether a data set is eligible for migration include the inactive age of the data set compared to the *days* value specified with the migration technique parameter of the ADDVOL command for the volume on which the data set resides. If the inactive age is larger than or equal to the *days* value, the data set becomes eligible for migration. If no *days* value has been specified on the ADDVOL command or the *days* value is equal to zero, DFSMSHsm uses the value specified with the DAYS parameter of the SETSYS command. The *days* value, whether taken from the ADDVOL command or the DAYS parameter of the SETSYS command, is called the minimum migration age.

Related reading

- For more information about how to determine the inactive age, see [“Pass 1” on page 111](#).
- For more information about the reconnection function, see [“Reconnecting data sets using fast subsequent migration” on page 94](#).

Determining eligible data sets for backup

DFSMSHsm must determine which data sets are eligible for backup so that it can schedule the data sets for backup if they migrate or prevent migration if the migration target volume is a tape volume. A non-SMS-managed data set is eligible for backup if all of the following apply:

- The data-set-changed indicator in the data set VTOC entry indicates that the data set has been changed.
- The volume on which the data set resides has the AUTOBACKUP attribute in *any* DFSMSHsm host in the system.
- The data set is supported for automatic backup, as indicated in the availability management data mover support table in [z/OS DFSMSHsm Implementation and Customization Guide](#).

Determining eligible data sets for extent reduction

The criteria for whether a data set is eligible for extent reduction are the same as for SMS-managed data sets.

Pass 1 processing example

Figure 15 on page 113 shows the results of pass 1 processing for non-SMS-managed volumes in the example. Data set GROUP1.SAM.LIST is deleted because it is a list data set that is older than the SCRATCHFREQUENCY value set with the SETSYS command.

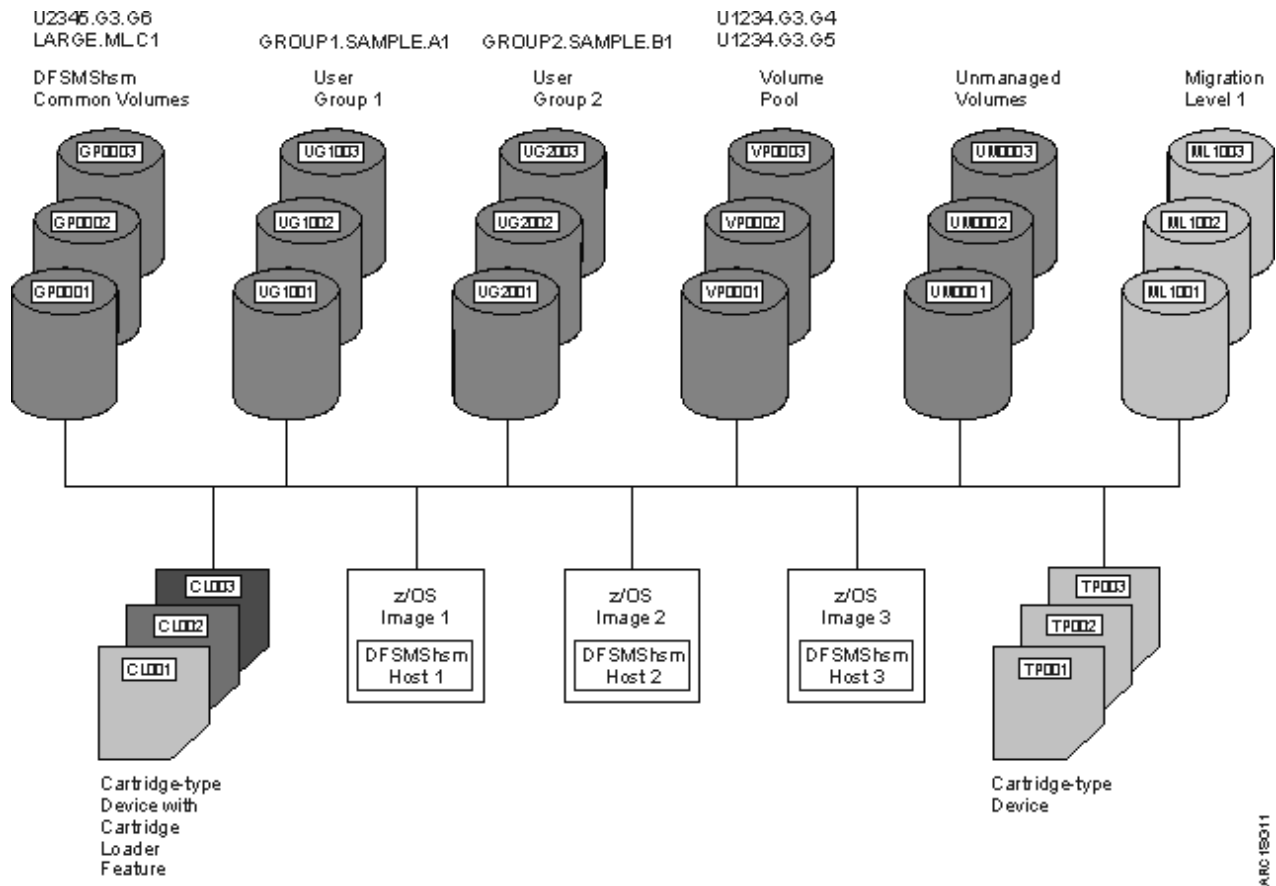

Figure 15. Example System of Non-SMS-Managed Volumes after Primary Volume Management Pass 1

Pass 2

Although the functions performed in pass 2 of primary volume space management for non-SMS-managed volumes are similar to those for phase 2 processing of SMS-managed volumes, the manner of processing is considerably different. Pass 2 processing does the following tasks:

- Sorts the candidates for migration into priority order
- Performs space management on the volume

Sorting the candidate data sets into priority order

For volumes that have the space management technique of migration, DFSMSHsm sorts the names of the data sets into migration priority order, high priority to low priority. No consideration is given to generation data sets; all data sets on the volume receive their priority on the basis of age and size. Note, however, that the age used for the computation is the inactive age as opposed to the eligibility age used for SMS-managed data sets.

Performing space management on the volume

During primary space management for non-SMS-managed volumes, DFSMSHsm processes the volume according to the one technique specified by the ADDVOL command for the volume. Thus, all the eligible data sets on the volume are managed to the same inactive age and by the same management technique. The available techniques are:

- Delete by age (deletion)
- Delete if backed up (retirement)
- Migration (with or without thresholds of occupancy)

Data set deletion

For those primary volumes with the DELETEBYAGE space management technique, DFSMSHsm scratches low-activity cataloged and uncataloged data sets based on the inactive age of the data sets. You specify the inactive age when you specify the space management technique. DFSMSHsm scratches only data sets whose expiration dates have been reached or data sets without expiration dates. For data set deletion, DFSMSHsm ignores any thresholds you specify and scratches all eligible data sets.

As DFSMSHsm examines each data set for deletion, it passes control to the data set deletion installation exit (ARCADEXT).

Related reading

For more information about the ARCADEXT installation exit, see [*z/OS DFSMS Installation Exits*](#).

Data set retirement

For those primary volumes with the DELETEIFBACKEDUP space management technique, DFSMSHsm checks the backup control data set (BCDS) to be sure that a current backup version of the data set exists before DFSMSHsm scratches the data set based on its inactive age. You specify the inactive age when you specify the space management technique. DFSMSHsm scratches a data set even if the expiration date has not been reached.

DFSMSHsm creates backup versions when automatic or command backup runs. If a backup version is made on the date the data set is last opened, DFSMSHsm does not consider the backup version to be current. This means that DFSMSHsm must make a backup version of a cataloged data set on the calendar day *after* the last activity of the data set. For non-VSAM data sets, the backup must be made after the last-referenced day. For VSAM data sets, the backup must be made after the last-update day. Therefore, if you want to use data set retirement often, schedule backup to run soon after midnight.

By running backup soon after midnight, you reduce your exposure to having the last backup made on the same date that the data set was last changed. If the data set is changed before midnight, automatic backup only occurs on the next calendar date, so the dates would not be the same. There are two possible scenarios where exposures might occur:

- Data sets that were changed and then backed up by command on the same day
- Data sets that were changed between midnight and the time that automatic backup encountered them in the course of its processing

Table 11 on page 114 shows what DFSMSHsm considers to be the current backup version of migrated and unmigrated data sets.

Table 11. Current Backup Version of Data Sets	
Type of Data Set	Current Backup Version
Not migrated VSAM	DFSMSHsm made the backup version since the last day someone updated the data set.
Not migrated, cataloged, non-VSAM	The update flag is off and the date-last-referenced that existed when the data set was backed up is earlier than the date the data set was last backed up.
Uncataloged, non-VSAM	The update flag is off and DFSMSHsm made a backup version of the data set from the volume being processed.
Migrated VSAM	The update flag is off and DFSMSHsm created the backup version after the date DFSMSHsm last migrated the data set.
Migrated non-VSAM	The update flag is off and the date-last-referenced that existed when the data set was migrated is earlier than the date the data set was last backed up.

During data set retirement, DFSMSHsm marks the latest backup version as a retirement version and gives it special protection against inadvertent deletion.

As DFSMSHsm examines each data set for retirement, it passes control to the data set deletion installation exit (ARCADEXT).

Migration

For those primary volumes with the MIGRATE space management technique defined on the ADDVOL command, DFSMSHsm uses the minimum migration age or the low threshold of occupancy specified for the volume to determine how many data sets are to be migrated. You specify the minimum migration age when you specify the space management technique. During primary volume space management, DFSMSHsm uses the priority order determined in the earlier step if thresholds have been specified for the volume. If no thresholds have been specified, DFSMSHsm just migrates each candidate data set that it finds on the volume. The end of DFSMSHsm's migration of data sets depends on whether you have specified thresholds of occupancy for the primary volume.

As DFSMSHsm examines each data set for migration, it passes control to the data set migration installation exit (ARCMDEXT).

With thresholds of occupancy

Data sets migrate in priority order from the primary volume until the low threshold of occupancy is reached or until the age of the oldest remaining data set is less than the minimum migration age.

Example: If a primary volume has a low threshold of occupancy of 80% and a minimum migration age of four days, DFSMSHsm migrates data sets until at least 20% of the volume is available or until all data sets not referred to within the last three days have migrated.

Without thresholds of occupancy

DFSMSHsm uses the minimum migration age of the data sets in selecting data sets to migrate from the volume.

Example: If the minimum migration age is seven days, data sets migrate from the primary volume until DFSMSHsm finds that all remaining data sets have been referred to within the last six days. The minimum migration age is limited by the integrity age.

Space management of VSAM data sets

DFSMSHsm migration functions that exist for non-VSAM data sets also exist for VSAM data sets cataloged in the integrated catalog facility catalog.

The migration of a non-SMS-managed VSAM data set is performed only on a complete VSAM sphere. The base cluster and all alternate index clusters defined on the base cluster are migrated as part of the data set and are not specified separately. Paths are included automatically in the data set command migration.

When DFSMSHsm migrates a VSAM data set, it tracks a maximum of eight component names for that data set. [Figure 16 on page 116](#) shows component name limitations when DFSMSHsm is recalling a migrated VSAM data set.

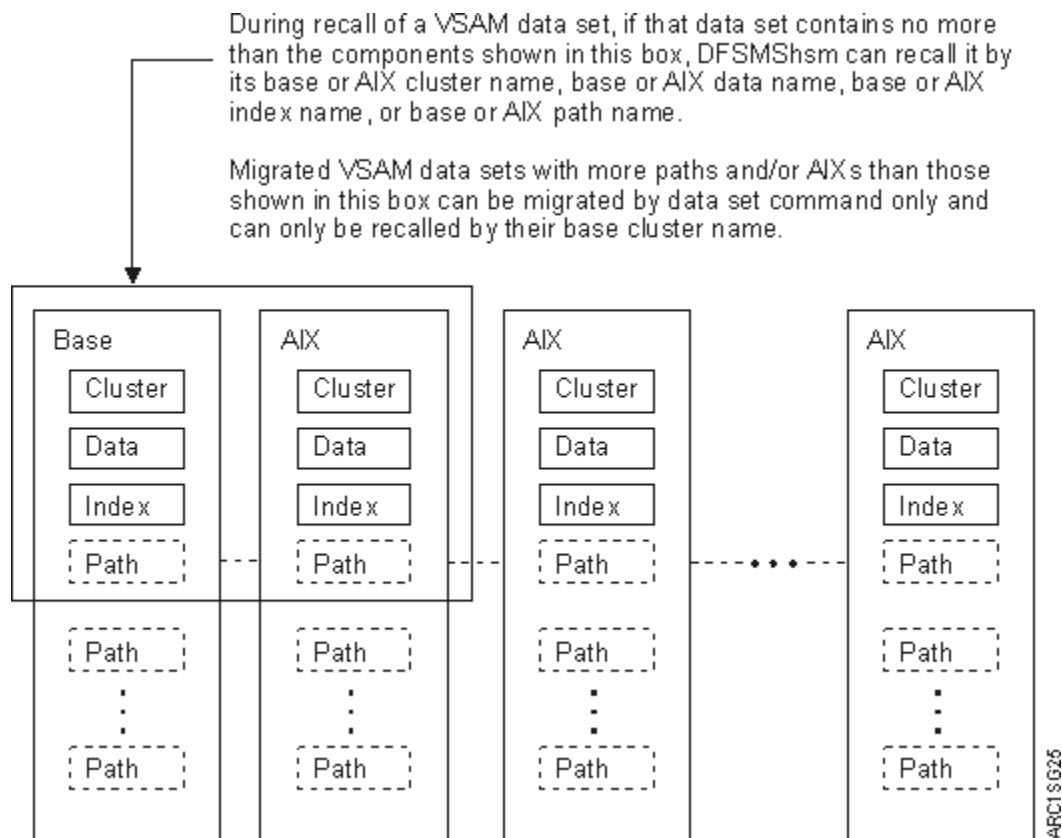

Figure 16. Component Name Limitations When Recalling Migrated VSAM Data Sets

A non-SMS-managed VSAM data set can be migrated only if it is completely contained on one volume. DFSMSHsm does not migrate a sphere that has a component that needs to be verified.

Data sets cataloged in the integrated catalog facility catalog with more than one alternate index (AIX), more than one path on the base, or more than one path defined on the AIX are not selected for migration during volume processing. These data sets can be migrated by data set command migration.

DFSMSHsm does not migrate a VSAM data set marked for forward recovery, or one with retained locks.

JES3 considerations

For the recall of SMS-managed data sets, JES2 and JES3 appear to be the same. However, for non-SMS-managed data sets, the following differences can occur when DFSMSHsm is used on a single DFSMSHsm-host or a multiple DFSMSHsm-host configuration in a JES3 environment using the benefits of JES3 data set reservation as provided by JES3 setup.

- Volumes are considered in terms of data set pools, volume pools, and general pools. The general pool, configured by DFSMSHsm, is the default pool that contains primary volumes that are online and permanently resident or reserved and that have the automatic recall attribute. From this set, volumes are selected for undirected recall.
- For migrated data sets, JES3 associates the requested data set with a subset of five or fewer candidate pool volumes supplied by DFSMSHsm. JES3 treats the data set as a multiple-volume data set.
- For data sets that have not migrated, JES3 associates the requested data set to the serial number of the primary volume on which the data set resides. DFSMSHsm prevents migration of the data set for today and three more days.

- DFSMSHsm recalls the migrated data set to a specific volume serial number in the candidate volume list when the data set is opened or to the best candidate primary volume in the subset of five or fewer pool volumes when the data set is allocated.

This discussion is concerned only with the function of delaying migration. Associating migrated data sets with volumes for recall is described in [“Recall” on page 119](#), a discussion of automatic recall for non-SMS-managed data sets.

During the post-scan phase, JES3 calls its locate module to locate the cataloged data sets. When the JES3 locate routine finds a primary volume serial number for a requested data set in the computing system catalog, JES3 associates the specified data set with that volume serial number. Asynchronously with the JES3 locate routine, DFSMSHsm passes a management work element (MWE) to prevent migration of the requested data set for up to three days (default value) by recording the primary volume serial number and a prevent-migration date in the MCDS data set (MCD) record. The prevent-migration date is the last day that migration is prevented. If the job does not run within a prevent-migration period, the prevent-migration date expires, and the data set can migrate automatically or by command.

A JES3/DFSMSHsm migration window exists between the asynchronous processing of the JES3 locate routine and the DFSMSHsm management work element. If migration of the data set occurs in the JES3/DFSMSHsm migration window, DFSMSHsm modifies the MCD record so that the recall of the migrated data set occurs to that primary volume serial number that was returned to JES3. If you enter a command to migrate a data set associated with a volume that has a current prevent-migration date, DFSMSHsm fails the command. A message is issued to indicate that JES3 has an outstanding request for the data set, and migration is prevented until the prevent-migration date has expired.

The prevent-migration period is a default value of 3 in the management communication vector table (MCVT). The default value is added to the current date to create the prevent-migration date and the hold-volumes date in the MCD record. You can change this value. Although the value can range from 0–255, the value should be consistent with the maximum time a job can exist in JES3 before it is run.

JES3 directed-recall and prevent-migration requests are processed as DFSMSHsm commands. In a multiple DFSMSHsm-host environment, these requests may not be processed until the completion of a command that is currently being processed. Normally, the delay has little effect on the time required to process the JES3 request. However, some performance degradation may be noticed if the DFSMSHsm command processor is waiting for the availability of a resource.

Related reading

For more information about using the PATCH command for the prevent-migration period, see [z/OS DFSMSHsm Implementation and Customization Guide](#).

Performing extent reduction on the volume

After DFSMSHsm performs migration for the non-SMS-managed volumes, it performs extent reduction. Extent reduction for non-SMS-managed data sets is performed in the same way as for SMS-managed data sets.

Note: DFSMSHsm does not do extent reduction if you have specified SETSYS TAPEMIGRATION(DIRECT) and you have not specified an ML1 volume. The extent-reduction process would cause contention between migration and recall for the target tape ML2 volume.

Installation exits during automatic primary space management

Programming Interface Information

Control is passed to installation exits during automatic primary space management for non-SMS-managed data sets in the same way as for SMS-managed data sets. Delete by age and delete if backed up are not applicable to SMS-managed data sets; therefore, ARCADEXT is not called in processing SMS-managed data sets.

Pass 2 processing example: Figure 17 on page 118 shows the results of automatic primary space management after the second pass. Data set GROUP1.SAMPLE.A1 migrated because its inactive age is

greater than the minimum migration age specified on the ADDVOL command. Because it is small enough that compaction will probably reduce it to less than 110KB (1KB = 1024 bytes), it migrated to an SDSP data set. Data set GROUP2.SAMPLE.B1 did not migrate because it has not passed the minimum migration age.

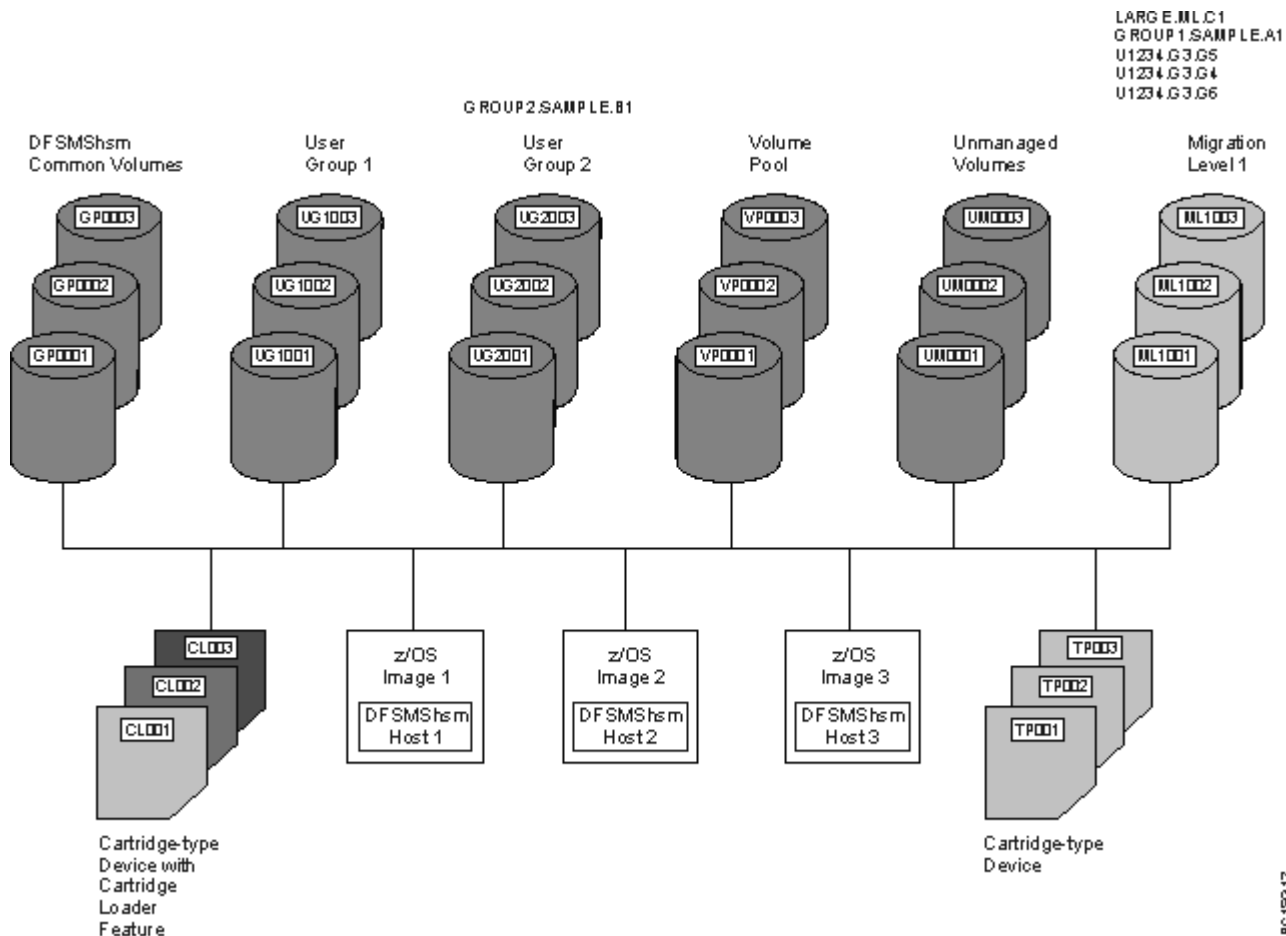

Figure 17. Example System of Non-SMS-Managed Volumes after Primary Volume Management Pass 2

Data sets U1234.G3.G4 and U1234.G3.G5 migrated because of their inactive ages. Assuming that both were on the same volume, U1234.G3.G5 migrated first because of the priority algorithm.

Data sets U2345.G3.G6 and LARGE.ML.C1 migrated because of their inactive ages. Observe that although U2345.G3.G6 has exceeded the MIGRATIONLEVEL1DAYS parameter specified in the SETSYS command, it migrated to ML1. If it is not recalled, it migrates to ML2 the next time that level 1 to level 2 migration is performed.

Observe also that LARGE.ML.C1 is of a size that would put it in management class LARGEMC so that it would migrate directly to tape if it were SMS-managed. However, the example leaves it migrating to ML1 DASD because direct-to-tape migration for non-SMS-managed data sets has not been provided. Its migration could be prevented, or it could be directed to tape by using the migration installation exit (ARCMDEXT) that is called for each data set that is migrated.

End Programming Interface Information

Related reading

For more information about the ARCMDEXT installation exit, see [z/OS DFSMS Installation Exits](#).

Automatic interval migration

For non-SMS-managed volumes, interval migration occurs only from primary volumes that possess the following conditions:

- Have defined thresholds of occupancy
- Have exceeded their high threshold of occupancy
- Have the primary volume attribute of automatic migration
- Have been added for automatic migration in a DFSMSHsm host that has interval migration specified
- Have the space management technique of migration

DFSMSHsm performs interval migration for non-SMS-managed data sets in the same way as for SMS-managed data sets. However, after DFSMSHsm finishes migrating eligible data sets on non-SMS-managed volumes during interval migration, it performs extent reduction for the volumes.

Recall

Recall for non-SMS-managed data sets that are not recalled to SMS-managed volumes differs from that for SMS-managed data sets primarily in that, for non-SMS-managed data sets, DFSMSHsm selects the volumes to which the data set is recalled. For recall target volume selection, DFSMSHsm considers volumes in the following terms:

- Data set pools
- Volume pools
- General pool (JES3), a single pool that DFSMSHsm configures

Related reading

- For more information about how to define pools, see [“Defining pools of volumes” on page 105](#).
- For more information about recall requests and the common recall queue, see [“Common recall queue” on page 129](#).

Recall volume selection

When DFSMSHsm receives a non-directed recall request (either by command or by allocation with no volume specified), it builds a list of up to five primary volumes with the most available space. The space on the volumes is based on the last space check performed on the primary volumes. DFSMSHsm selects the primary volumes as follows:

1. If the data set being recalled has a high-level qualifier that matches that of a data set pool, the five volumes come from the data set pool.
2. If the volume from which the data set migrated is part of a volume pool, the candidate volumes come from the volume pool.
3. If the data set is not restricted to be recalled to a user-defined pool, DFSMSHsm selects volumes that were assigned to the default pool. Whether a volume is selected is based on:
 - The subparameters selected for the RECALL parameter of the SETSYS command
 - The volumes having the AUTORECALL subparameter specified in the ADDVOL command and having MIGRATE as the space management technique
 - The volumes being online
 - The use attribute of the volume
 - Attribute of storage for the RECALL(ANYSTORAGEVOLUME) parameter
 - Attribute of storage, public, or private for the RECALL(PRIVATEVOLUME) parameter

In building the list of candidate volumes from the default pool, DFSMSHsm considers the recall attributes described in [“Recall attributes” on page 104](#) and the LIKE|UNLIKE subparameters specified with the

RECALL parameter of the SETSYS command. If LIKE is specified, DFSMSHsm builds the list only from volumes with recall attributes that match the recall attributes of the volume from which the data set migrated. If fewer than five volumes have like attributes, the list of candidate volumes contains fewer than five volumes.

If UNLIKE is specified, DFSMSHsm builds the list from all the volumes in the default pool in the following order:

1. If five or more volumes exist with like recall attributes, all the volumes in the candidate list have recall attributes that match those of the volume from which the data set migrated.
2. If not enough like volumes exist, DFSMSHsm selects as many volumes with recall attributes that match those of the volume from which the data set migrated as possible, then selects unlike volumes in the following order:
 - a. Volumes with matching backup attributes (AUTOBACKUP|NOAUTOBACKUP and BACKUPDEVICECATEGORY)
 - b. Volumes with matching migration attributes (AUTOMIGRATION|NOAUTOMIGRATION)
 - c. Volumes with no matching attributes

Within this group, each subgroup is placed in order by the amount of available space on the volume. Thus, the volumes with like attributes are placed (in order by free space) ahead of the volumes with unlike attributes.

DFSMSHsm never requires matching recall volume attributes for data sets under the following conditions:

- A data set being recalled to a user-defined pool
- A data set migrated by command from a volume with the DELETEBYAGE management technique
- A data set migrated by command from a volume not managed by DFSMSHsm
- A data set that migrated from a primary volume that was added to only one host in a multiple DFSMSHsm-host environment

A primary volume managed by DELETEIFBACKEDUP or DELETEBYAGE space management techniques will never be selected by DFSMSHsm as the target of a nondirected recall.

Calling the recall exit

Programming Interface Information

After the list of candidate volumes has been assembled, DFSMSHsm passes control to the recall installation exit (ARCRDEXT) if the installation exit is active. DFSMSHsm passes the complete list of eligible volumes, not just the five that it has selected, to the installation exit. The five volumes that DFSMSHsm has selected are at the top of the list. The installation exit can change the volume selection so that different volumes are the five volumes at the top of the list, thereby changing the volumes that DFSMSHsm uses for the recall. Another point of divergence from the processing for SMS-managed data sets is that control is not passed to the installation exit during the recall of SMS-managed data sets.

Note: In a common recall queue environment, the ARCRDEXT exit is invoked by the host that selects the request for processing.

End Programming Interface Information

Allocating recalled data sets to volumes

After the list of candidate volumes has been assembled from the installation exit, DFSMSHsm or DFSMSdss requests that the data set be allocated to the first volume on the candidate list. If the allocation fails for lack of space, DFSMSHsm or DFSMSdss requests allocation to the next volume on the list. If this allocation also fails for lack of space, DFSMSHsm or DFSMSdss tries the next volume, and proceeds down the list until either a volume with adequate space is found, or all the volumes on the list have been tried.

When DFSMSHsm is the data mover, a recall can fail even though enough total space exists on the volume if the space is too fragmented to allocate the total space for the data set in five extents.

Automatic recall during non-VSAM data set opening

If the user specifies both volume and unit information during allocation of a non-SMS-managed volume or if the allocation process is not done, a migrated data set will still be on a migration volume when the open routine tries to open the data set. When the non-VSAM open routine does not find the data set VTOC entry for a non-VSAM data set, DFSMSHsm intercepts the abnormal end and tries to recall the data set. Enough space must exist for DFSMSHsm to recall the data set to the volume the open routine specifies. Otherwise, the recall fails and the open routine abnormally ends.

If a user allocates an uncataloged data set and mistakenly specifies the wrong volume, the user receives a VTOC entry-not-found abnormal end. However, if a migrated data set exists with the same data set name as the data set the user is allocating, DFSMSHsm can recall the migrated data set to a user's volume. The user might be able to open the data set, if it is unprotected, even though it could belong to someone else.

Automatic recall during VSAM data set opening

If the user specifies both volume and unit information during allocation of a non-SMS-managed volume or if the allocation process described in “Recall volume selection” on page 119 is not done for the data set, a migrated data set to be opened will still be on a migration volume when the open routine tries to open the VSAM data set. The VSAM open routine issues a catalog locate request to get information about the cluster from the catalog. DFSMSHsm intercepts the locate request, recalls the data set to the primary volume it migrated from, and returns the catalog information that the VSAM open routine requested. Enough space must exist for DFSMSHsm to recall the data set to the volume the open routine specifies; otherwise, the VSAM open routine fails.

Automatic recall for data set command scratching

A non-SMS-managed, non-VSAM data set could be on a migration volume when it is about to be scratched. If a scratch is requested for a data set from a volume with a volume serial number of MIGRAT, DFSMSHsm translates the request into a request to delete a migrated data set.

If the scratch request does not specify MIGRAT and results in a VTOC entry-not-found condition, the data set still could have migrated. If the scratch routine cannot find the VTOC entry for the data set on the specified volume, DFSMSHsm receives a request to delete the data set if the volume specified with the VTOC entry-not-found condition is the same volume the data set migrated from last. If both of these conditions are met, DFSMSHsm processes the scratch request; otherwise, the scratch fails.

A data set is not scratched or deleted by DFSMSHsm if the expiration date of the data set in the data set VTOC entry is not reached and if the purge bit in the scratch parameter list is not on. When DFSMSHsm receives the request to delete the migrated data set, it recalls the data set, and the scratch request continues for the recalled data set. The volume that the scratch request specified is used for the data set recall must contain enough available space to recall the data set. Otherwise, the recall and the scratch request for the data set fail.

JES3 considerations

When the JES3 converter/interpreter is processing a data set that is migrated, it requests a list of recall volumes from DFSMSHsm. DFSMSHsm selects a list of recall volumes as described in “Recall volume selection” on page 119 and returns the list to the JES3 converter/interpreter. DFSMSHsm also records the list of volumes in the MCD record. For a subsequent request for that data set from the JES3 converter/interpreter, DFSMSHsm returns the same list of volumes.

When DFSMSHsm returns the list of volumes, the JES3 converter/interpreter associates those volumes with the data set. Because DFSMSHsm returned five or fewer volumes, JES3 associates the data set as a multiple-volume data set.

When volumes are selected from a pool, DFSMSHsm uses a count of the number of migrated data sets associated with each pool volume in the general pool and the available volume space determined by the

last space check. The migrated data sets are those that have been directed to a volume but have not been recalled yet. Therefore, the algorithm spreads the association of migrated data sets to all volumes in the pool.

DFSMSHsm holds each subset of five or fewer volumes today and three more days by recording in the MCD record a hold-volumes date and the five or fewer volume serial numbers. The *hold-volumes date* is the last date that DFSMSHsm restricts recalls for the data set to the five or fewer volumes.

DFSMSHsm recalls migrated data sets when MVS allocates (nonspecific request and the volume serial number is MIGRAT) or opens (specific request and the VTOC entry is not found) the data set on a volume managed by DFSMSHsm. For a subset of five or fewer pool volumes—either data set, volume, or general—DFSMSHsm directs the recall of the migrated data set to one of the five or fewer volumes. DFSMSHsm fails the recall request if not enough space is available on any of the volumes.

If you direct the recall of a migrated data set to a DFSMSHsm-managed volume other than the subset associated by JES3 and before the hold-volumes date expires, DFSMSHsm fails the recall. A message is issued to indicate that the volume serial number you requested is not on the JES3 list. If you enter a command to delete a migrated data set before the hold-volumes date expires, DFSMSHsm fails the command. A message is also issued to indicate why the delete request failed.

If space is not made available on these volumes and you must recall the data set before the hold-volumes date expires, you can reset the hold-volumes date by issuing the command:

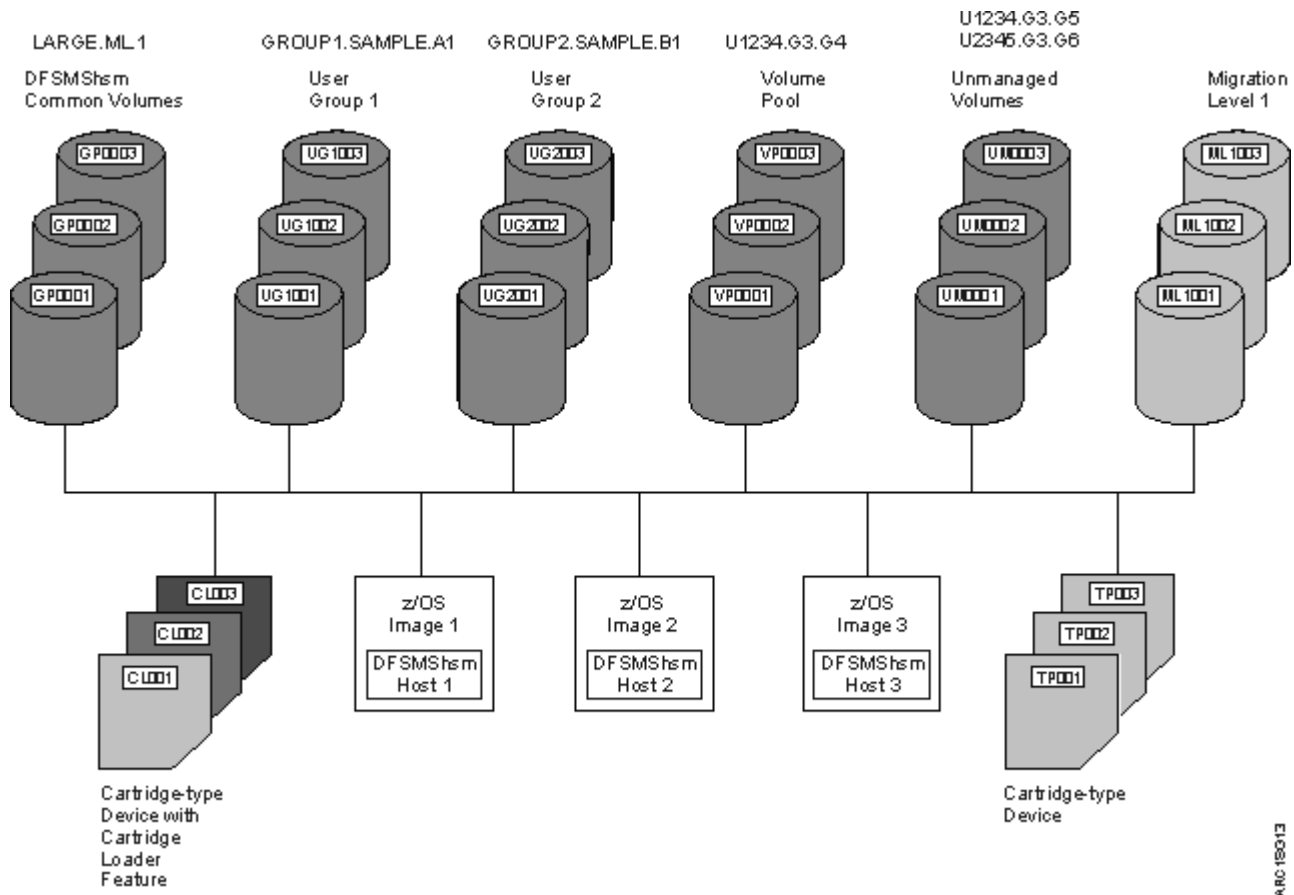

```
HSEND CMD FIXCDS D dsn PATCH(X'60' X'000000')
```

Be sure that the appropriate volume and pool configuration of the z/OS image that will eventually process a job is described to the z/OS image where the JES3 converter/interpreter locate request is initiated during JES3 setup of the job. The DFSMSHsm hosts in those z/OS images must have the same SETSYS RECALL subparameter specified.

Recall example

Figure 18 on page 123 shows the results of recalls (either automatic or by command) that allow DFSMSHsm to select the volume to which the data set is recalled. Because GROUP1.SAMPLE.A1 has the high-level qualifier of GROUP1, for which a data set pool that contains the volumes in User Group 1 was defined, it is recalled to one of the volumes in that user group. Because U1234.G3.G4 migrated from a volume in Volume Pool and a volume pool that contains those volumes was defined, U1234.G3.G4 returns to one of the volumes in the pool. LARGE.ML.1 returns to one of the common volumes (general pool in JES3) because neither of the following applies:

- It does not have the high-level qualifier to direct it to one of data set pools defined for the user groups.
- It did not migrate from one of the volumes in the volume pool.

ARC1801E

Figure 18. Example System of Non-SMS-Managed Volumes after Undirected Recall of Data Sets

Command space management

For non-SMS-managed storage, you can perform the same command space management as you can for SMS-managed storage:

- Delete migrated data sets
- Migrate data sets
- Migrate level 0 volumes
- Migrate level 1 volumes
- Recall data sets

For non-SMS-managed data sets, migrating level 0 volumes works somewhat differently. In addition, for non-SMS-managed data sets you can:

- Migrate from a single primary volume all data sets not used within the number of days you specify
- Delete by age from a single primary volume all data sets not used within the number of days you specify
- Delete if backed up from a single primary volume all data sets not used within the number of days you specify
- Migrate data sets from all non-SMS-managed primary volumes
- Control migration of individual data sets, groups of data sets, or volumes
- Recall a data set to a specific volume
- Recall an SMS-managed data set to a non-SMS-managed volume

Command volume space management

Two forms of the MIGRATE command control volume space management for DFSMSHsm-managed volumes:

```
MIGRATE VOLUME(valid)
MIGRATE VOLUME(valid DELETEBYAGE(days) |
DELETEIFBACKEDUP(days) | MIGRATE(days))
```

The MIGRATE VOLUME command cannot be used for ML1 volumes.

For the first form, DFSMSHsm performs space management for the volume in the same way as if the volume were being processed by automatic primary space management. That is, it performs all the functions described in [“Automatic primary space management”](#) on page 111 for the volume, using the parameters specified in the ADDVOL command for the volume. Thus, the management technique and the inactive days specification from the ADDVOL command apply to this processing of the volume.

For the second form of the MIGRATE command, the processing described in [“Automatic primary space management”](#) on page 111 is performed, but the management technique and the number of inactive days is taken from the MIGRATE command. Thus, you can apply different technique and inactive day specifications to the volume when you do command volume migration.

Related reading

For more information about the commands to use for volume space management of DFSMSHsm-owned volumes, see [Chapter 13, “Managing DFSMSHsm media,”](#) on page 527.

Command volume space management (primary)

You can cause all non-SMS-managed primary volumes to be processed by issuing the following command:

```
MIGRATE PRIMARY
```

This command has the same effect for all level 0 volumes that have been added to the system with an ADDVOL command as if the primary volume space management part of automatic primary space management for non-SMS-managed volumes had begun.

Controlling migration of data sets and volumes

You can use the SETMIG command to control migration for specific data sets, groups of data sets, or volumes. The control you can exercise is to allow all migration, to allow migration only by command, or to allow no migration. For example, if you issue the following command:

```
SETMIG VOLUME(GP0002) NOMIGRATION
```

no migration can occur from volume GP0002 until the SETMIG command is reissued to allow migration or until DFSMSHsm is reinitialized. The SETMIG command for volumes and data sets is not normally included in the ARCCMDxx member. The SETMIG command for levels (groups of data sets) is typically included in the ARCCMDxx member.

Recalling a data set to a specific volume

You can recall a non-SMS-managed data set to a specific non-SMS-managed volume. For an example, see [Figure 17 on page 118](#). If data set GROUP1.SAMPLE.A1 were recalled with either an automatic or command undirected recall, it would return to one of the volumes in User Group 1. However, if you issue the following command:

```
RECALL GROUP1.SAMPLE.A1 UNIT(3390) VOLUME(VP0003)
```

the data set is recalled to volume VP0003. If the ACS routine converts the data set to an SMS-managed data set (returns a storage class), SMS selects the volume to which the data set is recalled.

Recalling an SMS-managed data set to a non-SMS-managed volume

You cannot recall an SMS-managed data set to a specific SMS-managed volume. You can, however, recall an SMS-managed data set to a specific non-SMS-managed volume and remove the data set from SMS management. For an example, see [Figure 11 on page 80](#) and [Figure 17 on page 118](#). If you issue the following command:

```
RECALL GDSMC.G3.V5 UNIT(3390) VOLUME(GP0003) FORCENONSMS
```

the data set is recalled to GP0003 and is no longer under SMS management.

Recalling an SMS-managed BDAM data set to a non-SMS-managed volume

You can direct the recall of an SMS-managed BDAM data set to a non-SMS volume with a smaller track size than the volume from which it was migrated, using the DAOPTION and the FORCENONSMS parameters of the RECALL command. If, for instance, data set DA00001.V1 was migrated from a 3390 volume, you could recall that data set to a 3380 volume (GP3380) by issuing the following command:

```
RECALL DA00001.V1 UNIT(3380) VOLUME(GP3380) -  
  DAOPTION(RELBLK) FORCENONSMS
```

The data set is recalled to GP3380, no longer under SMS management, and is ready to be accessed through relative block accessing.

Recalling an SMS-managed sequential extended-format data set to a non-SMS-managed volume

You cannot recall an SMS-managed sequential extended-format data set to a non-SMS-managed volume by modifying your ACS routine to filter the data set to such a volume. However, if you issue the following command:

```
RECALL dsname FORCENONSMS
```

you can recall an SMS-managed sequential extended-format data set to a non-SMS-managed volume as a data set that is not sequential extended-format.

Chapter 4. Other space management considerations

In addition to the aspects of space management discussed in [Chapter 2, “Space management of SMS-managed storage,”](#) on page 23 and [Chapter 3, “Space management of non-SMS-managed storage,”](#) on page 99, you need to consider the following topics:

- [“Space management of extended address volumes \(EAVs\)”](#) on page 127
 - [“Track management for SMS-managed volumes”](#) on page 128
 - [“Track management for non-SMS-managed volumes”](#) on page 128
 - [“Controlling allocations to extended address volumes \(EAVs\)”](#) on page 129
 - [“Recommendations for using extended address volumes \(EAVs\)”](#) on page 129
- [“Common recall queue”](#) on page 129
- [“Processing priority of recalls and deletions”](#) on page 135
- [“Migration volume contention priorities”](#) on page 136
- [“Specifying the desired number of ML2 partial tapes”](#) on page 141

Space management of extended address volumes (EAVs)

An extended address volume (EAV) is defined to be any volume that has more than 65,520 cylinders. Volumes that are configured with 65,520 cylinders or less are defined to be non-EAVs. An EAV will consist of two areas of managed space. The first 65,520 cylinders of an EAV will be considered the *track-managed space*. The last cylinder in this managed space is at cylinder address 65,519. The space above 65,520 cylinders will be considered the *cylinder-managed space* on the volume. The first cylinder in this managed space is at cylinder address 65,520.

Data set size is a determining factor for the order in which data sets are migrated. Managing an entire extended address volume (EAV) with one threshold is not sufficient because average data set size in the cylinder-managed space will likely exceed the average data set size in track-managed space. This will result in data sets allocated in the cylinder-managed space being migrated at a higher rate than data sets allocated in the track-managed space, potentially causing no space in the track-managed space being freed. To prevent this, a unique threshold for the track-managed space (track-managed threshold) is used to manage the free space separate from the free space on the entire volume (volume-level threshold).

DFSMSHsm examines both volume level thresholds and track-managed thresholds for L0 EAVs. If either threshold has been exceeded then migration eligibility will be performed for data on the volume. If track-managed threshold values are not specified, the default is to use the volume-level threshold values. Data set eligibility will be further qualified by the location of the first three extents of the data set. If any of the first three extents are allocated in track-managed space the data set will be eligible to be processed when the track-managed space or entire volume space is managed. If none of the first three extents are allocated in track-managed space, the data set will be eligible to be processed when the entire volume space is being managed. [Table 12 on page 128](#) summarizes the eligibility criteria for migration.

Table 12. Eligibility Criteria for Migration

Track-managed threshold exceeded	Volume threshold exceeded	Data set selection
Yes	No	Only data sets with one or more of the first three extents allocated in track-managed space
No	Yes	All data sets
Yes	Yes	All data sets
No	No	Data sets are not selected

Space management (interval migration and primary space management) will be considered complete after DFSMSHsm determines both thresholds have been met. This applies only to hourly (interval migration) space management of non-SMS LO EAVs and when the AUTOMIGRATE attribute is not equal to I (immediate) for SMS-managed EAVs. Hourly space management (interval migration) of SMS-managed EAVs having the AUTOMIGRATE=I attribute in storage groups will be performed if either the midpoint between the high and low volume threshold values is met or if the midpoint between the high and low track-managed threshold values is reached or exceeded. Daily space management (primary space management) will be performed regardless of the high volume threshold and high track-managed threshold values.

Track management for SMS-managed volumes

DFSMSHsm will use the track-managed low and high threshold values and the volume level low and high threshold values associated with each storage group.

Track management for non-SMS-managed volumes

The ADDVOL command has an optional keyword TRACKMANAGEDTHRESHOLD(*high low*).

- Alias: TMT
- TMT is only valid with the PRIMARY keyword
- *High* and *low* are required parameters

TRACKMANAGEDTHRESHOLD can be used to define the high and low thresholds for the track-managed space of a non-SMS PRIMARY EAV. If TRACKMANAGEDTHRESHOLD is not specified, then the corresponding values for THRESHOLD will be used. If no threshold values are specified, then all threshold values will use the default values. If TRACKMANAGEDTHRESHOLD is specified for a non-EAV, the ADDVOL command will fail. For example:

```
ADDVOL PRIM01 PRIMARY UNIT(3390) TRACKMANAGEDTHRESHOLD(80 40) THRESHOLD(85 60)
```

In the above example the parameter TRACKMANAGEDTHRESHOLD(80 40) defines a high track-managed threshold of 80 percent and low track-managed threshold of 40 percent. If TRACKMANAGEDTHRESHOLD is not specified, then the corresponding values for THRESHOLD will be used.

If no THRESHOLD keyword values are specified, then all threshold values will use the default values. The default high value is 100, and the default low value is 0. Therefore, a primary volume has no valid default thresholds in this case. If the attributes of a volume are being changed but track-managed space threshold values are not specified, the track-managed space thresholds are not changed. If, however, the new high track-managed threshold is less than or equal to the low track-managed threshold or is equal to 100, the volume threshold values will be used as track managed threshold values.

For more information, see [“TRACKMANAGEDTHRESHOLD: Specifying the high and low threshold for the track-managed space of a non-SMS level 0 extended address volume”](#) on page 710 in Chapter 26, [“ADDVOL command: Adding or changing DFSMSHsm volumes,”](#) on page 697.

Controlling allocations to extended address volumes (EAVs)

You can use the USEEAV parameter for a system on either the SETSMS command or in the IGDSMSxx parmlib member to specify whether SMS is to select extended address volumes during volume selection processing. This check applies to both new allocations and to extending data sets to a new volume. You can enter an operator command to change the value of this keyword.

Related reading

- There are a number of important implications to specifying or defaulting to USEEAV=NO, see [Modifying the SYS1.PARMLIB IGDSMSxx member in z/OS DFSMSdfp Storage Administration](#).
- The setting for USEEAV is stored in the SSI vector table. To look at the SSI vector table, see [Formatting the SSI vector table in z/OS DFSMSdfp Diagnosis](#).
- See also [SETSMS command to alter the setting of USEEAV in z/OS DFSMSdfp Storage Administration](#).

Recommendations for using extended address volumes (EAVs)

- You can use EAVs as backup, ML1, and ML2 volumes. You can enable allocation of backup, ML1, and ML2 data sets in cylinder-managed space using SETSYS parameter USECYLINDERMANAGEDSPACE. See [“USECYLINDERMANAGEDSPACE: Specifying whether to allow use of cylinder managed space for migration copies and backup versions” on page 1202](#).
- You should evaluate the SMS and non-SMS breakpoint values to limit the over allocation of small data sets in the cylinder-managed space on backup, ML1, and ML2 extended address volumes. Depending on the breakpoint value, over allocation might still occur for large data sets, however, the percent of over allocation is small in comparison to the total disk space request. Small data sets should be allocated in track-managed space and large data sets allocated in cylinder-managed space to limit over allocation. For more information, see the topic about [Extended Address Volumes in z/OS DFSMS Using Data Sets](#).
- EAVs configured as L0 volumes should **not** be used as a repository for small data sets. Doing so will negatively impact performance.

Common recall queue

The common recall queue (CRQ) is a single recall queue that is shared by multiple DFSMSHsm hosts. This queue is implemented through the use of a coupling facility (CF) list structure. The CRQ balances the recall workload across multiple address spaces and enables optimization for priority and single-tape mounts. In some parallel sysplex configurations, all hosts are not connected to all devices. The CRQ enables hosts that are not connected to a device, like a tape drive, to place recall requests on the CRQ. Once on the CRQ, the request can be selected by hosts that are connected to the device.

Figure 19. The Common Recall Queue

As Figure 19 on page 130 shows, a CRQplex consists of one or more DFSMSHsm hosts that are connected to the same CRQ. There may be multiple CRQplexes within a single HSMplex. In general, each HSMplex maintains a unique CRQ.

This CRQ support provides the following enhancements to recall processing:

Workload Balancing

Alternating with all other participating hosts in the CRQplex, each host attempts to select requests from the CRQ. Each host selects requests while it has available recall tasks and the CRQ is not empty.

Priority Optimization

Because all recall requests are placed and sorted on a common queue, the highest priority outstanding requests in the CRQplex are selected before lower priority requests. This prioritization occurs regardless of which system the requests originated on.

Tape Mount Optimization

When a recall task mounts an ML2 tape to perform a recall, that task processes all outstanding single tape recall requests in the CRQ that require that tape. Thus, a single tape mount recalls multiple recall requests that require the same tape, even if those requests originated on different hosts.

Request Persistence

Outstanding recall requests on the CRQ are maintained even when the originating DFSMSHsm host shuts down or fails, or the originating system fails. Additionally, those requests are eligible for processing by other active hosts, even while the original host is unavailable.

Flexible Configurations

The CRQ support enables configurations in which not all hosts are connected to all devices, and in which not all hosts process recalls. For example, you can configure a host that is not connected to any tape drives to process only recalls that do not require ML2 tapes. Also, you can configure the HSMplex so that all hosts accept recall requests and place them on the CRQ, but only a subset of the hosts actually process the requests.

Related reading

For more information about how to configure each host in an HSMplex for a CRQ environment, see [z/OS DFSMSHsm Implementation and Customization Guide](#).

Connecting to a common recall queue list structure

Before the CRQ function can be used, an appropriately defined list structure must be configured in the active coupling facility resource manager (CFRM) policy. After configuring the CFRM policy, update your DFSMSHsm ARCCMDxx member to include SETSYS COMMONQUEUE(RECALL(CONNECT(*basename*))).

When SETSYS COMMONQUEUE(RECALL(CONNECT(*basename*))) is specified in ARCCMDxx, DFSMSHsm connects to the specified structure during startup processing. If the SETSYS command is issued after startup, DFSMSHsm connects to the structure and then moves any requests on the host's local recall queue to the CRQ.

If the attempt to connect fails due to an environmental error, DFSMSHsm retries the connection when the coupling facility signals that the structure is available. Even though the connection may be unsuccessful, the DFSMSHsm host is associated with the specified CRQ until a SETSYS COMMONQUEUE(RECALL(DISCONNECT)) command is issued.

A CRQ cannot be shared between separate HSMplexes. To enforce this, each CRQ is associated with the HSMplex that allocated it. DFSMSHsm fails any attempt to connect to a CRQ that is not associated with the HSMplex in which a connection request originates.

Related reading

For more information about configuring the list structure, see [z/OS DFSMSHsm Implementation and Customization Guide](#).

Populating the common recall queue

A host that is participating in CRQplex-wide recall processing attempts to place all of its recall requests onto the CRQ. Requests are placed on the CRQ if the following conditions are true:

- The host has a successful connection to the CRQ.
- The hold status of the host and CRQ eligibility allows the request to be placed on the CRQ. The following conditions must be true to allow placement on the CRQ:
 - The host must not have HOLD COMMONQUEUE(RECALL(PLACEMENT)) or higher level of Hold in effect.
 - For WAIT requests, at least one host that is connected to the CRQ must be eligible to process the request. This is what is meant by “CRQ eligibility”. This requirement prevents a WAIT request from being placed onto the CRQ and waiting indefinitely to be processed. For example, if HOLD RECALL(TAPE) is in effect on all hosts connected to the CRQ, then all WAIT recall requests that require an ML2 tape will fail. If at least one host does not have HOLD RECALL(TAPE) in effect, then those requests are placed.
- The CRQ is less than 95% full. Or, if it recently exceeded the 95% threshold, it has dropped back below 85%.

If recall requests are unexpectedly not placed onto the CRQ, issue the QUERY ACTIVE command and examine message ARC1540I. It will indicate which of the above conditions is not being met.

Any request that cannot be placed onto the CRQ is placed on the local queue of the originating host.

Recall requests that can be placed onto the CRQ are sorted by WAIT or NOWAIT status and priority. WAIT requests are always a higher priority than NOWAIT requests. Requests of the same priority are sorted in FIFO order, with the exception that NOWAIT requests of priority 50 are subsorted with requests from multiple users. This subsorting prevents a single user with many requests from blocking other users' requests for an extended period of time.

The host that initiates the recall request invokes user exit ARCRPEXT, if the exit is enabled. The processing host invokes user exit ARCRDEXT, if the exit is enabled. You can ensure consistent processing by using common RD exits throughout the CRQplex. The RP exit may be used to assign requests that originate on one host a higher or lower priority in relation to the priorities set by RP exits on other hosts.

The default priority for these requests is 50. Refer to *z/OS DFSMS Installation Exits* for a description of these user exits.

The SETSYS EMERGENCY command does not affect the placement of recall requests onto the CRQ. This allows a host that is in emergency mode to place its requests onto the CRQ and enables other active hosts to process those requests. Use the HOLD COMMONQUEUE(PLACEMENT) command to prevent recalls from being placed onto the CRQ when the emergency mode is in effect.

Selecting requests from the common recall queue

Alternating with other hosts, each host attempts to select requests from the CRQ as long as the host has available recall tasks and the CRQ is not empty. Hosts select the highest priority request that they are capable of processing. Also, hosts select recall requests that are on the host's local queue before requests on the CRQ that are of the same or lower priority. (Requests may be on a host's local queue if the requirements for placement, as mentioned in the previous topic, have not been met.)

When a host selects a request that requires a single ML2 tape, that host processes all single tape requests on the CRQ from that tape. After processing each request from the tape, the processing host selects the next highest priority request that requires that tape. Requests with the same priority are processed in first-in-first-out order. After processing all the requests and after a short wait for any additional requests, the tape is demounted.

If recall requests are unexpectedly not being selected for processing, issue the QUERY ACTIVE command and examine message ARC1541I. A status of anything other than CONNECTED or a hold level of anything other than NONE are probable reasons why certain recall requests are not being selected.

Another cause for certain recall requests not to be selected is that they require an unavailable ML2 tape. If the ML2 tape does not become available within 30 minutes, these requests will time out.

Processing recall requests on the common recall queue

A host processes a request selected from the CRQ just like a request that is submitted on its own system, with two exceptions. First, messages that are routed to TSO are sent to the original host to issue to the appropriate user. Second, when the processing host completes a recall request, it notifies the original host which then posts any WAIT requests as complete.

The processing host issues console and operator messages; messages directed to the DFSMSHsm logs go to the logs for the processing host. Only the processing host creates and stores functional statistics records (FSRs). The originating host, if different from the processing host, does not have an FSR for the recall. The processing host accumulates the daily statistics record (DSR) statistics, and the DSR stores recall statistics for the entire HSMplex.

A recall request can be canceled until the point that it has been selected for processing by a host in the HSMplex. The cancel request must be submitted on the same host that originated the recall request that is to be canceled.

Note: The DFSMSHsm host that places the recall request on the CRQ is the host that checks the user's authority to issue the recall command. Authority checking is performed using the DFSMSHsm AUTH command or with the RACF FACILITY class. In a common recall queue environment, there is the possibility that when a recall command is placed on the CRQ (which is not checked by RACF), a DFSMSHsm host can select the same recall request. This same recall request is not checked by RACF, because RACF checking is performed before placing the recall on the CRQ.

Disconnecting from the common recall queue

To disconnect a host from the CRQ, use the optional parameter SETSYS COMMONQUEUE(RECALL(DISCONNECT)). When the DISCONNECT command is received, the DFSMSHsm host disconnects itself from the CRQ by performing the following actions:

- Directing all new recall requests to its local queue instead of the CRQ
- Moving all of its requests currently on the CRQ to its local queue

- Completing any remote requests that it had previously selected
- No longer selecting requests from the CRQ

You must wait for the disconnection to complete before attempting to connect to another CRQ. A message indicates when the disconnection is complete.

Note: Disconnecting from the CRQ should be done only on an exception basis.

Processing of common recall queue requests during shutdown

With the CRQ, individual DFSMSHsm hosts automatically disconnect from the structure during shutdown processing. Therefore, for normal processing, do not issue SETSYS COMMONQUEUE(RECALL(DISCONNECT)) before shutting down DFSMSHsm. Doing so moves all of the host's requests back to the local queue, which causes WAIT requests to be failed with message ARC1192I and to be purged from the CSA.

When a host is connected to the CRQ when shutdown processing is initiated, an outstanding WAIT recall request that is on the CRQ is failed, but a new NOWAIT request replaces this request, so that this request is preserved. The new request has the same priority as the original request, but is a NOWAIT request instead of a WAIT request. The new request is eligible for processing by any eligible host still connected to the CRQ. NOWAIT requests remain available in the CRQ.

Note: Batch WAIT requests are not converted. They remain in the CSA queue so that the request can time-out if it is not processed in a timely manner.

Deleting the common recall queue structure

If you need to delete the CRQ structure, perform the following steps:

1. Verify that the CRQ is empty by using the following command:

```
QUERY COMMONQUEUE(RECALL)
```

2. Disconnect all DFSMSHsm hosts from the CRQ structure by using the following command:

```
SETSYS COMMONQUEUE(RECALL(DISC))
```

3. Verify that all DFSMSHsm hosts have disconnected by using the following command:

```
D XCF,STR,STRNAME=SYSARC_basename_RCL
```

4. Delete the CRQ structure by using the following command:

```
SETXCF FORCE,STRUCTURE,STRNAME=SYSARC_basename_RCL
```

Processing failures in a common recall queue environment

DFSMSHsm processes the following types of failures or errors:

- Coupling facility or coupling facility structure failures
- Coupling facility link communication failures
- z/OS image failures
- DFSMSHsm primary address space failures
- Full list structure failures

Coupling facility or coupling facility structure failure

If the coupling facility fails in such a way that the CRQ list structure is lost, each DFSMSHsm host responds in the following ways:

1. Each host continues processing requests on its local queue and remote requests that are already selected.
2. Each host places onto its local queue the local copies of its outstanding requests and all new requests.
3. If a host starts a local request that is currently being recalled by a remote host, the user is notified that the request is currently being processed by another host.
4. Each host attempts to reconnect to the CRQ until the connection is successful. After a host successfully reconnects to the CRQ, it moves all of its unselected local requests from its local queue onto the CRQ. Requests that are currently running continue to completion.
5. The host resumes normal processing.

Coupling facility link failure

If one or more hosts lose their connection to the CRQ, the CRQ list structure remains intact, but those hosts can no longer participate in the CRQ activities. A host that loses its connection performs the same steps as with a coupling facility failure. Hosts that remain connected while another host has lost its connection respond in the following ways:

- Each host finishes the remote requests that originated on the host that lost connectivity.
- Each connected host continues to select and process the requests that the failed host placed onto the CRQ before losing connectivity.

z/OS image failure

If a z/OS image fails, the DFSMSHsm host on that system also fails, but all of the recall requests that originated on that host remain intact on the CRQ. The coupling facility notifies the remaining connected hosts of the failure. The requests that originated on the failed host remain eligible for selection. In-process requests on the failed host remain on the queue and are made available for other hosts to restart them.

If the failing host is processing a request from ML2 tape, then all requests from that tape cannot be selected until the failing host is restarted. The tape is marked as "in-use" by the failing host, and that indication will not be reset until the failing host restarts. If the failing host is not restarted for some time, enter the LIST HOST(*hostid*) RESET command, where *hostid* is the DFSMSHsm host id of the host that has failed.

DFSMSHsm primary address space failure

If a DFSMSHsm host fails, all of its recall requests on the CRQ remain intact and eligible for processing by other active hosts. The coupling facility notifies the remaining connected hosts of the failure. In-process requests on the failed host remain on the queue and are available for other hosts to restart them.

If the failing host is processing a request from ML2 tape, then all requests from that tape cannot be selected until the failing host is restarted. The tape is marked as "in-use" by the failing host, and that indication will not be reset until the failing host restarts.

Full list structure failure

If the list structure becomes 95% full, DFSMSHsm routes all new requests to the local queues. Routing recall requests to the CRQ resumes once the structure drops below 85% full. The list structure is not allowed to become 100% full so that requests that are in-process can be moved between lists within the structure without failure. When the structure approaches maximum capacity, you should increase the size by altering the structure to a larger size or by rebuilding it. A rebuild must be done if the maximum size has already been reached. (The maximum size limit specified in the CFRM policy must be increased before the structure is rebuilt.) DFSMSHsm relies on the XES structure full monitoring support to issue warning messages about the fullness of a structure.

Rule: If one of the above failures occurs, issue the AUDIT COMMONQUEUE command after each of the hosts has restarted or reconnected, or both.

Related reading

For more information about altering or rebuilding a list structure, see [z/OS MVS Programming: Sysplex Services Guide](#) and [z/OS MVS System Commands](#).

Processing priority of recalls and deletions

You may receive complaints from end users that an inordinate amount of time was required to service a long series of NOWAIT requests for recalls or deletions. The delay occurs only if DFSMSHsm is heavily loaded with recall and deletion requests in relation to the number of tasks that are permitted to process them. The delay is caused by the priority scheme that DFSMSHsm uses to prevent one user from monopolizing the system and from tape mount optimization processing.

The same queue of management work elements (MWEs) processes all recall and deletion requests that are submitted to one DFSMSHsm host. This queue is called the recall queue. DFSMSHsm gives all WAIT requests a higher priority (position) on the queue than NOWAIT requests. The NOWAIT requests are interleaved according to the user ID of the submitter. All users start one NOWAIT request before any user starts a second NOWAIT request. Processing of the requests is generally from the oldest to the newest requests.

An exception to the order of processing is when doing recalls from tape, where DFSMSHsm reduces the number of mounts by doing several recalls from a given tape while the tape is continuously mounted. If a recall task has just completed a recall from a tape, it processes the highest-priority request that is currently on the queue for that same tape, no matter where the request is positioned on the queue. DFSMSHsm continues to process only recalls from this single tape for a duration of time that is specified by the TAPERECALLLIMITS parameter. After the time specified by the TAPERECALLLIMITS parameter is reached, DFSMSHsm determines whether a higher-priority recall request that needs this tape exists on another DFSMSHsm host. If so, it ends the recall processing on the tape by the current DFSMSHsm host, freeing the tape for use by other hosts. If no higher-priority request exists, DFSMSHsm continues to process any recalls requested from the tape. DFSMSHsm checks after every recall for a higher-priority recall request from other hosts.

When performing recalls from tape, DFSMSHsm also determines if there is a higher-priority tape recall request from the same host, for a different tape, that cannot be performed because DFSMSHsm is already processing at the maximum permitted tape recall task limit. If so, it ends recall processing on the tape that has met the specified TAPERECALLLIMITS processing time, enabling the higher-priority recall request from DASD or a different tape to take place.

Programming Interface Information

You can use the return-priority installation exit ARCRPEXT to change the priorities of these requests as the requests are put on the queue. ARCRPEXT allows you to assign a relative queuing priority such that WAIT requests can be prioritized relative to other WAIT requests and NOWAIT requests prioritized relative to other NOWAIT requests. You can, for example, give recalls a higher priority than deletes, or give interactive requests a higher priority than requests from batch processing. You can even negate the interleaving scheme described earlier in this topic for interactive NOWAIT requests. (In the case of a NOWAIT request that is initiated from a volume recover request, the queuing priority is initialized with the value that is propagated from the volume recover request passed earlier to the exit.) For more details on ARCRPEXT, see [z/OS DFSMS Installation Exits](#).

Note: With regard to the common recall queue, ARCRPEXT is invoked by the host that the request originated on.

End Programming Interface Information

You can also affect the order in which data sets are recalled from a single tape by specifying the SETSYS command with TAPEDATASETORDER. For more information about the TAPEDATASETORDER keyword, see [“Specifying the order in which data sets from a single tape are processed”](#) on page 136.

Specifying the order in which data sets from a single tape are processed

You can use the SETSYS TAPEDATASETORDER command to specify the order in which you want DFSMSHsm to recall or recover data sets from a tape. The command provides the installation with additional flexibility to handle circumstances in which ascending FBID order offers significant reduction in tape repositioning.

To recall data sets in ascending FBID order, enter the following command:

```
SETSYS TAPEDATASETORDER(RECALL(FBID))
```

To recall data sets in PRIORITY order, enter the following command:

```
SETSYS TAPEDATASETORDER(RECALL(PRIORITY))
```

You can specify the order in which data sets are recovered from a tape, by using the following command:

```
SETSYS TAPEDATASETORDER(RECOVER(FBID | PRIORITY))
```

When deciding whether to specify PRIORITY or FBID, you should consider that a lower priority request might be processed prior to a higher priority request. If you do not specify the TAPEDATASETORDER option, DFSMSHsm uses PRIORITY as default. For more information about the TAPEDATASETORDER, see [“TAPEDATASETORDER: Specifying order for processing tape” on page 1188](#).

Migration volume contention priorities

Because DFSMSHsm migration volumes can also be involved in recall, recycle, tape copying, and aggregate backup activities, you must understand the usage priorities for your migration volumes. DASD ML1 volumes with small data set packing data sets allocated on them and tape ML2 volumes can interact with other functions that have a greater usage priority. When this interaction occurs, you may not get the results you are expecting.

Related reading

- For more information about the contention issues that can arise with DASD ML1 volumes with SDSP data sets allocated on them and tape ML2 volumes, see [“SDSP data set contention” on page 142](#) and [“Tape migration level 2 volume contention” on page 136](#).
- For more information about the contention details related to the common recall queue, see [“Common recall queue environment” on page 141](#).

Tape migration level 2 volume contention

A tape ML2 volume can be in use in only one of the following ways at any single point in time:

- As a target volume for migration data output. Primary space management, interval migration, secondary space management, and data set and volume command management all generate migration data output.
- As a target volume for recycle.
- As a source volume for recycle.
- As a source volume for recall.
- As a source volume for TAPECOPY.
- As a source volume for ABACKUP.
- As a target volume for ARECOVER.

This topic describes what DFSMSHsm does to resolve volume contention among the different tasks that request the same tape ML2 volume.

Single DFSMSHsm-host environment

This topic describes the processing that occurs when a tape migration volume is needed but is not available because another task is using the tape volume.

Migration or recycle output needs volume

Independent of what type of migration or recycle task needs an output tape, if the tape initially selected is in use by any task in DFSMSHsm, then the output task selects another target tape.

Recall needs volume

If recall needs a data set that is on a tape volume being used for ML2 output, then recall causes the output task to relinquish that tape and continue its output using a different tape. This applies to all forms of migration: primary space management, interval migration, secondary space management, command data set migration, and command volume migration. It also applies to recycle output.

The recall function also causes tapes to be taken away from other tasks, such as recycle input, TAPECOPY input, and from recall itself.

- For recycle input, the recycle function ends processing on the input connected set and moves on to the next best connected set.
- For TAPECOPY input, the tape takeaway function is optional. After the first recall attempt there is a time allowance before the function initiates the takeaway. This gives TAPECOPY a chance to complete. All the copying done up to the point of the tape takeaway is discarded if the TAPECOPY task does not complete.
- There is a form of recall versus recall contention, and takeaway within a host. If the maximum number of tape recall tasks are running and taking a long time, a high-priority recall for a different tape may not get started because there are no available tasks. This is possible when many requests exist for each tape and you are using tape mount optimization. For this condition DFSMSHsm provides a task takeaway consideration at a specified amount of time after a tape is first mounted for recalls. After the specified amount of time is met, a higher-priority request causes recall processing to end on the current tape, freeing a task for the highest-priority request.

Because a takeaway does not happen instantaneously, the recall task does not wait, but leaves this recall on the queue to be retried at approximately two-minute intervals. This enables recalls that are readily performed to proceed. When migration or recycle processing is complete for the data set being processed, the allocated volume is released and a new volume is selected for migration or recycle processing.

The recall function can also contend with ABACKUP and ARECOVER.

- If ABACKUP is reading an ML2 tape and recall needs that tape, there are two possibilities:
 - If the recall request is a NOWAIT request, recall repeatedly tries to access the tape until it reaches the specified limit for retries. A NOWAIT recall does not take tapes away from ABACKUP.
 - If the recall request is a WAIT request, recall repeatedly tries to access the tape. However, it does not flag ABACKUP to give up the tape until ten minutes after the first time recall finds the tape is in use. This ten minute delay gives ABACKUP time to complete its use of the tape. After ABACKUP is notified, recall repeatedly tries to access the tape until (unlikely in this case) it reaches the specified limit for retries.
- If ARECOVER is writing an ML2 tape and recall needs that tape, then recall keeps retrying to access that tape until it reaches the specified limit for retries. Recall does not take tapes away from ARECOVER.

When recall completes its use of a tape taken away from other tasks, the tape is released and is available for continued use by other tasks.

If a tape needed by recall does not become available to the recall task after 15 retries, DFSMSHsm sends message ARC0380A to the operator. The operator can give one of the following answers:

WAIT

This reply causes the recall task to reset its count of attempts, and begin another sequence of up to 15 retries at two-minute intervals.

CANCEL

This reply causes the recall task to end without even allocating the tape, which causes the recall to fail. If you know that the tape will not become available in a reasonable amount of time, use this choice.

MOUNT

This reply causes the recall to go ahead and request that the subject tape be allocated and mounted. Use this choice only when you are certain the tape can be mounted. An example is if DFSMSHsm says that the tape is in use by a host that is down and is not running.

Related reading

- For more information about the delay time associated with ABACKUP and how to change the delay time, see [z/OS DFSMSHsm Implementation and Customization Guide](#).
- For more information about changing the number of recall retries, see [z/OS DFSMSHsm Implementation and Customization Guide](#), under supported patches. If the number of retries is patched to zero, the recall immediately fails.

ABACKUP needs input volume

If ABACKUP needs the migration tape that is in use by recall, ABACKUP performs retries at 20-second intervals until the tape becomes available. It continues to retry for a period of 30 minutes, whichever occurs first. If the time expires, then the operator has the option to retry or to fail the ABACKUP. There is no takeaway function by ABACKUP from recall.

The ABACKUP function can cause takeaway from recycle input and from TAPECOPY input.

RECYCLE

The recycle function ends the input connected set and moves on to the next best connected set.

TAPECOPY

The TAPECOPY function is optional, and there is a time allowance after the ABACKUP function is first attempted before it initiates the takeaway. This occurs so that the TAPECOPY might complete, rather than discard, its work.

If ABACKUP needs the migration tape that is in use by migration or recycle output, ABACKUP initiates a tape takeaway. It then performs retries at 20 second intervals until the tape becomes available, or for a period of 30 minutes, whichever occurs first. If the time expires, the operator has the option to redo the set of retries or to fail the ABACKUP processing, as described in message ARC6254A.

If ABACKUP needs the migration tape that is in use by another ABACKUP, then it skips processing that tape and proceeds to process other migration and user tapes. It later reattempts to process the tape that was in use.

Recycle input volume in use

If migration or recall is using the volume that is needed as a source volume for recycle, and the recycle request is a specific RECYCLE VOLUME(volser) request, the recycle fails. If the recycle request is a generic RECYCLE request, then the recycle of that connected set is skipped and message ARC0845I is issued to indicate such. Recycle processing continues with the next eligible connected set. If someone issues a RECYCLE command for a specific volume and that volume is the target recycle volume, DFSMSHsm selects another target ML2 volume. DFSMSHsm then recycles the specified volume.

Table 13 on page 138 is a summary of possible volume contention in a single DFSMSHsm-host environment or within the same DFSMSHsm host in a multiple DFSMSHsm-host environment.

Table 13. Volume Contention in a Single DFSMSHsm-Host Environment

Function That Has Volume	Function That Needs Volume	Result
Migration	Migration	No contention.
Recall	Migration	Migration selects a new target volume.
Recycle (source)	Migration	Migration selects a new target volume.

Table 13. Volume Contention in a Single DFSMSHsm-Host Environment (continued)

Function That Has Volume	Function That Needs Volume	Result
Recycle (target)	Migration	No contention.
Migration, Recycle	Recall	Recall initiates a tape takeaway, and periodically retries the recall. When migration or recycle processing is complete for the data set being processed, the allocated volume is released and a new volume is selected for migration or recycle processing.
Recall	Recall	Terminate in favor of a higher priority recall from a different tape if running at maximum tape tasks, and it has been greater than specified amount of time since tape began to be continuously mounted.
ABACKUP	Recall	Recall periodically retries accessing the data set on the tape. If Recall is a WAIT request, after a delay, it initiates a tape takeaway, which causes ABACKUP to skip any remaining data sets that are needed by ABACKUP on the tape and process from other migration and user tapes. ABACKUP later tries to process those data sets that were skipped earlier.
ARECOVER	Recall	Recalls are retried until the tape is available or a retry limit is reached.
TAPECOPY (source)	Recall	If tapecopy takeaway is enabled, Recall retries for 15 minutes before requesting tape takeaway. If TAPECOPY has not completed its copy within one minute of the tape takeaway request, the copy fails.
Migration	Recycle (source)	Recycle of this volume fails. Recycle of other eligible volumes continues.
Recall	Recycle (source)	Recycle of this volume fails. Recycle of other eligible volumes continues.
Recycle (source)	Recycle (source)	No contention.
Recycle (target)	Recycle (source)	Recycle selects a new target volume.
Migration	Recycle (target)	No contention.
Recall	Recycle (target)	Recycle selects a new target volume.
Recycle (source)	Recycle (target)	Recycle selects a new target volume.
Recycle (target)	Recycle (target)	Recycle selects a new target volume.
Migration, Recycle	ABACKUP	ABACKUP initiates a tape takeaway and periodically retries the data set. When migration or recycle processing is complete for the data set being processed, the allocated volumes are released. A new target tape is selected for migration or recycle output contention, or a new connected set is selected if there is recycle source contention.
Recall	ABACKUP	ABACKUP is retried until the tape is available or a retry limit is reached.
ABACKUP	ABACKUP	ABACKUP skips over the tape in use and processes from other migration tapes. It reattempts to process the skipped tape later.
TAPECOPY (source)	All except Recall and ABACKUP	Function fails.
TAPECOPY (source)	ABACKUP	If tapecopy takeaway is enabled, ABACKUP retries for 15 minutes before initiating a tape takeaway. If TAPECOPY has not completed its copy within one minute of noting the takeaway request, the copy fails.

Multiple DFSMSHsm-host environment

This topic describes the processing that occurs when a tape ML2 volume is needed but is not available because either another task in this DFSMSHsm host, or a task in another host is using the tape volume. The contention processing is so similar for multiple tasks or hosts to the processing described in

the preceding topics for a single host environment, that only the differences are discussed here. The differences include the following situations:

Recall needs tape in use by recall on a different host

The following occurs when DFSMSHsm is doing recall mount optimization, which means that several recalls occur end to end while a tape is continuously mounted. Since this could go on for an indefinite length of time, DFSMSHsm has the SETSYS option TAPERECALLLIMITS. TAPERECALLLIMITS provides a time value after which a tape can be taken away from recall by recall on another DFSMSHsm host. The takeaway occurs only if the request on the other host is of higher priority than the request that would otherwise be performed without demounting the tape. The priority is typically based on time of arrival, but the priority can be changed by using the ARCRPEXT installation exit.

Note: A common recall queue environment needs only one tape mount. The host that mounts the tape processes all requests regardless of which hosts originate the requests.

Recycle needs tape in use by recycle on a different host

Since recycle can occur concurrently on different DFSMSHsm hosts, it is possible for a user on one host to request recycle of a tape that is currently in use by recycle on another host. In this case the request fails, regardless of whether the request was for use of the tape for recycle input or recycle output.

Table 14 on page 140 is a summary of possible volume contention in a multiple DFSMSHsm-host environment.

Table 14. Volume Contention in a Multiple DFSMSHsm-Host Environment

Function That Has Volume	Function in Other Host That Needs Volume	Result
Migration	Migration	No contention.
Recall	Migration	Migration selects a new target volume.
Recycle (source)	Migration	Migration selects a new target volume.
Recycle (target)	Migration	No contention.
Migration, Recycle	Recall	Recall initiates a tape takeaway, and periodically retries the recall. When migration or recycle processing is complete for the data set being processed, the allocated volume is released and a new volume is selected for migration or recycle processing.
Recall	Recall	A specified period of time after an ML2 tape is mounted, and when a recall completes, the tape is taken away if a request exists on another host that is of higher priority than the request that normally would have been performed on the recalling host from the already mounted tape.
ABACKUP	Recall	Recall periodically retries accessing the data set on the tape. If Recall is a WAIT request, after a delay, it initiates a tape takeaway, which causes ABACKUP to skip any remaining data sets that are needed by ABACKUP on the tape and process from other migration and user tapes. ABACKUP later tries to process those data sets that were skipped earlier.
ARECOVER	Recall	Recalls are retried until the tape is available or a retry limit is reached.
TAPECOPY (source)	Recall	If tapecopy takeaway is enabled, Recall retries for 15 minutes before requesting tape takeaway. If TAPECOPY has not completed its copy within one minute of noting the tape takeaway request, the copy fails.
Migration	Recycle (source)	Recycle of this volume fails. Recycle of other eligible volumes continues.
Recall	Recycle (source)	Recycle of this volume fails. Recycle of other eligible volumes continues.
Recycle (source)	Recycle (source)	Recycle skips the volume because another host is recycling it.

Table 14. Volume Contention in a Multiple DFSMSHsm-Host Environment (continued)

Function That Has Volume	Function in Other Host That Needs Volume	Result
Recycle (target)	Recycle (source)	Recycle fails.
Migration	Recycle (target)	No contention.
Recall	Recycle (target)	Recycle selects a new target volume.
Recycle (source)	Recycle (target)	Recycle selects a new target volume.
Recycle (target)	Recycle (target)	No contention.
Migration, Recycle	ABACKUP	ABACKUP initiates a tape takeaway and periodically retries the data set. When migration or recycle processing is complete for the data set being processed, the allocated volumes are released. A new volume is selected for migration or recycle output contention, or a new connected set is selected if there is recycle source contention.
Recall	ABACKUP	ABACKUP is retried until the tape is available or a retry limit is reached.
ABACKUP	ABACKUP	ABACKUP skips over the tape in use and processes from other migration tapes. It reattempts to process the skipped tape later.
TAPECOPY (source)	All except Recall and ABACKUP	Function fails.
TAPECOPY (source)	ABACKUP	If tapecopy takeaway is enabled, ABACKUP retries for 15 minutes before initiating a tape takeaway. If TAPECOPY has not completed its copy within one minute of noting the takeaway request, the copy fails.

Common recall queue environment

With all hosts in an HSMplex connected to the same common recall queue (CRQ), no contention for the same tape exists within the recall function. This makes the recall tape takeaway from recall function obsolete. With multiple CRQplexes in the same HSMplex, recall tape takeaway from recall manages contention between the separate CRQplexes. With one or more hosts not connected to a CRQ, recall tape takeaway from recall manages contention between the unconnected hosts and the CRQ.

For hosts connected to a CRQ, recall task takeaway becomes involved only when recalls are directed to a host's local queue. It then becomes possible for that host's tape tasks to process multiple requests from single tapes while a higher priority tape request is on its local queue.

Using the recall takeaway function, any host that is connected to the CRQ can process the recalls from a tape that was marked for takeaway by another host that was connected to the same CRQ.

Related reading

For more information about CRQplex configuration, see [z/OS DFSMSHsm Implementation and Customization Guide](#).

Specifying the desired number of ML2 partial tapes

ML2 tapes are written by the various migration functions and by the recycle of ML2 tapes. A relatively small number of ML2 partially filled tapes are needed as substitutes for tapes that are receiving output when they are taken away by a recall task. The partially filled ML2 tapes that are used as substitutes are not currently associated with specific ML2 output tasks for any hosts.

These substitute tapes are ML2 "floaters." To have the recycle process limit the number of floaters to *nnn*, specify:

```
SETSYS ML2PARTIALSN0TASSOCIATEDGOAL(nnn)
```

To allow an unlimited number, specify:

```
SETSYS ML2PARTIALSNOTASSOCIATEDGOAL(NOLIMIT)
```

Floater tapes are writeable ML2 tapes that are not assigned or associated with a specific task in a specific host. When a floater substitutes for a tape that is taken away, it becomes an associated tape, restricted for output to that one specific task.

An output tape taken away by recall is not immediately available to receive output again. It becomes available for output on the host where the recall occurred as the recall completes. A long queue of recalls from that tape would likely cause a delay in considering such a tape for output again.

DFSMSHsm hosts other than the one doing the recall do not become aware of a tape's availability for output until their own in-storage selection table is depleted and rebuilt. For performance reasons, in-storage selection tables are not rebuilt more often than every 45 minutes.

A configuration where a storage group uses multiple SMS tape libraries can affect the number of floaters that are needed. As functions such as primary space management, interval migration, or recycle start, they can allocate a drive from any of the libraries associated with the storage group. A tape must be in the same library as the drive that is allocated. This tends to increase the number of floaters needed, even without a high tape take-away rate. The tape associated with the previous processing of a task may not be part of the library that contains the allocated drive. In this case, a floater is used, and the previously associated tape is placed in its host's TVT.

From the preceding descriptions, you can see how data usage and configuration can result in a need for a higher number of ML2 floaters. Having floaters is a trade-off between having a few additional under-utilized ML2 tapes, or recycling the additional few under-utilized ML2 tapes. The DFSMSHsm design is to extend a partially filled ML2 tape instead of using an empty tape. However, in cases where partially filled ML2 tapes do not exist, DFSMSHsm requests a scratch tape.

It is *only* when recycle of ML2s occurs that the value specified by ML2PARTIALSNOTASSOCIATEDGOAL is used. The default used for ML2PARTIALSNOTASSOCIATEDGOAL is 10. This value applies to the total number of ML2 not-associated partial tapes in an entire HSMplex, but only for tapes that meet the recycle selection criteria of PERCENTVALID and any SELECT filters. If the number of such floaters, at the time a recycle command runs, exceeds the specified value, then the excess tapes are included as candidates for recycle. The floaters that are thus recycled are those having the lowest percentage of valid data.

You can use the LIST TTOC SELECT(NOTASSOCIATED) command to get a list of all not-associated ML2s if you want to know how many or which ones they are. If you observe a large number of not-associated ML2 partials being recycled, and this seems to occur consistently, then you probably want to increase the SETSYS specification to reduce the recycle load. This is just a trade-off between having the few under-utilized tapes or recycling the tapes so you do not have them (at least for a while).

You can use the LIST TTOC SELECT(ASSOCIATED) command to get a list of all ML2 partials that are associated with specific ML2 output tasks. If some of these are associated with tasks that are unused, or seldom used, then you may want to specify DELVOL UNASSIGN so that they will be part of the set of floaters. To find out which ML2 tapes are associated with what tasks, display the various host MCR records using the FIXCDS command. If they are old-technology cartridges, or recorded in old technology not being written anymore, you should use the DELVOL MARKFULL command so they can be recycled when they meet that criteria.

One approach for determining a unique setting for your installation is to mark the existing ML2 partial tapes as full. Then set ML2PARTIALSNOTASSOCIATEDGOAL to NOLIMIT for a while, and issue the LIST TTOC command with SELECT(ASSOCIATED) and SELECT(NOTASSOCIATED) every few days. When the sum of these two categories settles down or reaches a maximum, your migration workload indicates that you can set ML2PARTIALSNOTASSOCIATEDGOAL to or slightly below the number of not-associated partials indicated by the LIST TTOC command.

SDSP data set contention

Because SDSP data sets reside on ML1 volumes, they can be involved in various ways with DFSMSHsm processing of level 0 volumes and ML2 volumes. For example, an SDSP data set can be a target for automatic primary space management and, at the same time, the SDSP can be a source for a user's recall

of a small data set from an SDSP data set. SDSP data sets can be included in aggregate backup and SDSP data sets require cleanup after a user recalls a migrated data set. Additionally, the AUDIT and FREEVOL functions can be run against volumes on which SDSP data sets reside.

Because SDSP data sets are potentially involved in various DFSMSHsm processes, there are times when concurrent DFSMSHsm processing activities cause contention for SDSP data sets. [Figure 20 on page 144](#) shows that an SDSP data set can be effected by various DFSMSHsm processes. [Table 15 on page 145](#) shows the usage priorities for SDSP data sets and describes how DFSMSHsm resolves contention for SDSP data sets.

Figure 20. SDSP Contention Environment

ARC1SG24

Table 15. SDSP Contention in Single and Multiple DFSMSHsm-Host Environments

Function That Has SDSP	Function That Needs SDSP	Result
Migration (L1 to L2) Recall FREEVOL (source) AUDIT MEDIACONTROLS (source) Aggregate backup	Migration (L0 to L1)	<p>If all other SDSP data sets are presently in use, this small user data set is skipped and, most likely, can migrate to an SDSP during your next migration window.</p>
Migration cleanup or migration (L1 to L2)	Migration (L0 to L1)	<p>Migration cleanup and level 1 to level 2 migration are functions of automatic secondary space management. Because SDSP data sets can be open for a long time during migration cleanup or during level 1 to level 2 migration, it is likely that they will be in use. If all SDSP data sets are presently in use, this small user data set is skipped and, most likely, can migrate during your next migration window.</p> <p>Note: Do not run automatic primary space management and automatic secondary space management concurrently.</p>
Migration (L0 to L1)	Recall	Migration processing gives up its use of this SDSP data set to the recall function that requests the SDSP data set. If all SDSP data sets are presently in use, the migration of this small user data set is skipped and, most likely, can migrate during your next migration window.
Recall	Recall	The first recall request to access the SDSP data set completes its processing. Other recall requests retry the SDSP data set request and, most likely, will be successful.
FREEVOL (source) AUDIT MEDIACONTROLS	Recall	Because FREEVOL and AUDIT MEDIACONTROLS are relatively long-running processes, the recall request will either retry until successful or retry until timing out and failing.
Migration cleanup	Recall	Migration cleanup gives up its use of this SDSP data set to the recall function that requests the SDSP data set. Migration cleanup skips its processing of the SDSP data set.
Aggregate backup	Recall	Recall processing retries the recall request and, most likely, will be successful after the aggregate backup has finished.
Migration (L0 to L1) Recall AUDIT MEDIACONTROLS Migration cleanup Aggregate backup	FREEVOL (source)	FREEVOL processing fails.

Table 15. SDSP Contention in Single and Multiple DFSMSHsm-Host Environments (continued)

Function That Has SDSP	Function That Needs SDSP	Result
Migration (L0 to L1) Recall AUDIT MEDIACONTROLS Migration cleanup Aggregate backup	FREEVOL (target)	If the target SDSP data set cannot be made available to FREEVOL processing, this small data set is skipped and cannot be moved from the source SDSP data set.
Migration (L0 to L1) Recall FREEVOL AUDIT MEDIACONTROLS Migration cleanup Aggregate backup	AUDIT MEDIACONTROLS	If this SDSP data set is in use by other functions, the AUDIT request for the SDSP data set fails.
Migration (L0 to L1) Recall FREEVOL AUDIT MEDIACONTROLS Aggregate backup	Migration cleanup	If the SDSP that is needed by migration cleanup is in use, this small user data set is skipped and it is deleted the next time automatic secondary space management is run.
Migration (L0 to L1)	Aggregate backup	Migration processing gives up its use of the SDSP data set. If all SDSP data sets are presently in use, this small user data set is skipped and, most likely, can migrate during your next migration window.
Recall	Aggregate backup	Aggregate backup will retry its request for the SDSP and will eventually be granted access.
FREEVOL (source)	Aggregate backup	Aggregate backup fails.
FREEVOL (target)	Aggregate backup	FREEVOL processing gives up its use of this SDSP data set to the aggregate backup request. If no other SDSP data sets are available, FREEVOL processing skips the data sets.
AUDIT MEDIACONTROLS	Aggregate backup	Aggregate backup fails.
Migration cleanup	Aggregate backup	The SDSP data sets are released from migration cleanup. Migration cleanup skips processing from this SDSP data set.
Aggregate backup	Aggregate backup	The first aggregate backup request to reach the SDSP gets access to the SDSP. Other aggregate backup requests will retry until successful.

The functions of aggregate backup, aggregate recover, FREEVOL, and AUDIT should be run at times when they will not be contending for the use of the same SDSPs.

Multitasking considerations for SDSP data sets

It is important to plan the number of SDSP data sets in relation to the number of concurrent migration tasks and the amount of processing done by functions with a higher usage priority for the SDSP data sets.

It seems obvious that one SDSP data set is required for each concurrent migration task. However, there are some DFSMSHsm activities that have a higher usage priority for SDSP data sets. These processing activities are:

- Recall
- Aggregate backup
- FREEVOL
- AUDIT MEDIACONTROLS
- Automatic secondary space management

Any of these activities can gain control of your SDSP data sets and leave you with fewer than the expected number of SDSP data sets for migration.

When an activity with a higher usage priority for SDSP data sets has or requests an SDSP data set, that SDSP data set is no longer a candidate for migration. The small data set that is in need of migration must find a different, available SDSP data set or it is skipped and left unprocessed until your next migration window.

Additionally, if all SDSP data sets should become full (as a result of migrations to them) the filled SDSP data sets are not candidates for further migration. Full SDSP data sets are not seen by migration processing and, as a result, any small user data sets are migrated as large data sets to ML1 volumes.

Example: The following three-part example (see Figures Figure 21 on page 147, Figure 22 on page 148, and Figure 23 on page 148) shows how SDSP data sets can become unavailable for use as level 0 to level 1 migration targets. In Part 1, three concurrent migration tasks are moving three small user data sets from level 0 user volumes to ML1 volumes (with SDSP data sets defined on the ML1 volumes).

Figure 21. Part 1—Ideal Multitasking Migration

In Part 2, a recall of a small user data set from an SDSP data set during level 0 to level 1 migration has effectively eliminated one concurrent migration task. The small-user data set, whose migration was preempted by a recall, is skipped and will not be migrated until the next migration window.

Figure 22. Part 2—Recall Processing Has a Higher Priority than Migration

In Part 3, all SDSP data sets have become full. They are no longer seen as candidates for level 0 to level 1 migration destinations and the small-user data sets migrate as large data sets.

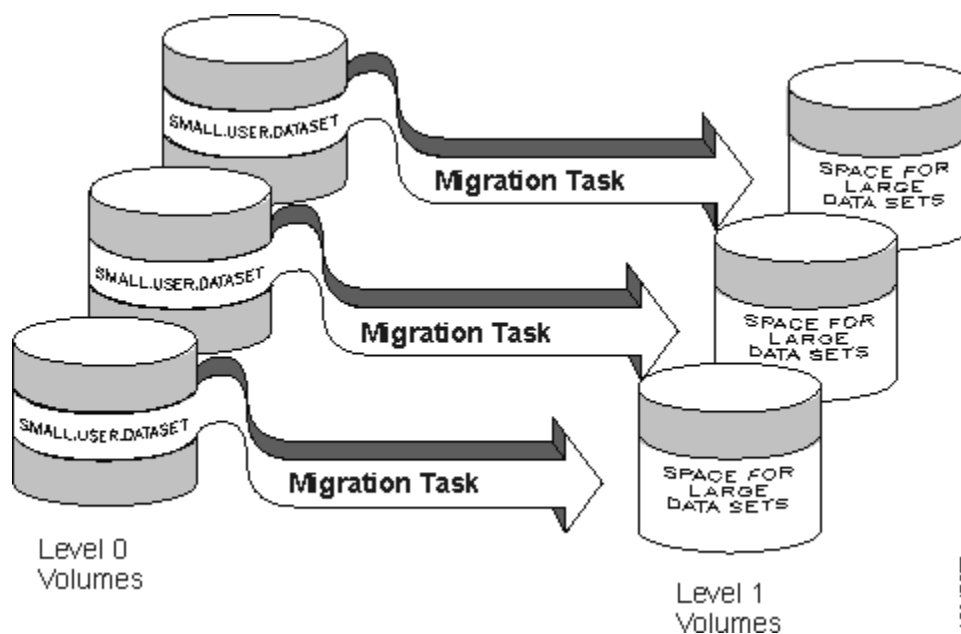

Figure 23. Part 3—All SDSP Data Sets Are Full

In addition to planning the timing of activities whose SDSP usage priority is high, you must ensure that you do not allow automatic secondary space management to run at the same time that automatic primary space management is running. If SDSP data sets are opened and allocated for automatic secondary space management, they cannot concurrently be targets for primary space management processing.

The point here is that other activity can affect your migrations and you need to plan and monitor those activities that can cause your small user data set migrations to be skipped. Therefore, you should define ample SDSP data sets to handle your worst case scenario (remember that one ML1 volume can have at most a single SDSP data set) and run automatic secondary space management at a different time than you run automatic primary space management.

Related reading

For more information about the SDSP parameter of the SETSYS command, see [Chapter 65, “SETSYS command: Establishing or changing the values of DFSMSShsm control parameters,” on page 1057.](#)

Preventing the processing of data sets during space management

Any of the following parameters or values specified with the following commands can prevent an otherwise eligible volume or data set from being processed by space management:

- The DEBUG parameter of the SETSYS command.
- The NOMIGRATION parameter of the SETMIG command.
- The EXITON and EXITOFF parameters of the SETSYS command, which specify the data set migration installation exit or the data set deletion installation exit. DFSMSShsm supplies sample exits that you can tailor to fit your needs.

Any of the following parameters or values specified with the following parameters can cause space management to stop processing or to fail to start processing:

- The MIGRATION(AUTO) parameter of the HOLD command. This stops or prevents automatic volume space management and automatic secondary space management from starting.
- The MIGRATION parameter of the HOLD command. This stops or prevents automatic and command volume space management, automatic secondary space management, and command data set migration from starting.
- The PRIMARYSPMGMTSTART parameter of the SETSYS command when it does not have a starting time specified. The ending time can also prevent space management from processing additional volumes.
- The SECONDARYSPMGMTSTART parameter of the SETSYS command when it does not have a starting time specified. The ending time can also prevent space management from processing additional data sets.
- The EMERGENCY parameter of the SETSYS command. This specifies that an emergency mode is in effect, and no DFSMSShsm processing related to moving user data is performed.

Note: This parameter does not affect the placement of recall requests onto the common recall queue. This enables this host to continue to place recalls onto the common recall queue that are eligible to be processed by other active hosts.

- The STOP command. This causes an orderly shutdown of DFSMSShsm.
- The REQUEST parameter of the SETSYS command. The operator can deny permission to start or restart automatic space management.

Deferred generation data sets

Deferred generation data sets are generation data sets (GDSs) for which a failure occurred before the data set was properly associated with the generation data group (GDG). These data sets are temporary in the sense that at some time they may become associated with the GDG. DFSMSShsm treats deferred generation data sets as permanent non-GDS data sets.

Security considerations for automatic space management

DFSMSShsm bypasses data set security checking during automatic space management, except after automatic recall. After automatic recall, security checking is performed by OPEN. This is to ensure that the user opening the recalled data set is authorized to use the data set.

DFSMSShsm also bypasses security checking when it processes operator commands entered at the system console or commands issued by a DFSMSShsm-authorized user.

DFSMSShsm checks authority for a requester to access data sets when a requester who is not DFSMSShsm-authorized issues an HMIGRATE, HDELETE, or HRECALL command. Security checking is not done when DFSMSShsm-authorized users issue the user commands. If users are not authorized to manipulate data,

DFSMSHsm does not permit them to migrate data sets, delete migrated data sets, or explicitly recall data sets. DFSMSHsm always does security checking for the scratch intercept when deleting migrated data sets. [Table 16 on page 150](#) shows the RACF authority required to perform each space management function.

Table 16. RACF Authority Required for Space Management Functions

DFSMSHsm Function	RACF Resource Access Authority Required
Migrate a data set	Update
Recall a data set using HRECALL (TSO users only)	Execute
Delete a migrated data set	Alter

Space management of data sets with discrete data set profiles

Discrete data set profiles provide a one-to-one relationship between a specific data set on a specific volume and its security authorization requirement. When you use only discrete data set profiles, you should use the RACFIND parameter of the SETSYS command. For a description of discrete data set profiles, see [“Discrete data set profiles” on page 618](#).

Note: Supported multivolume non-VSAM data sets cannot be protected by discrete profiles. Use generic profile protection for these data sets.

Migrating RACF-protected data sets

When an existing data set migrates to a DASD migration volume, the RACF indicator in the data set VTOC entry of the migration copy is set if the RACFIND parameter of the SETSYS command is in effect.

Note:

1. To maintain data set integrity on your system's small data set packing data sets, protect them with a discrete or generic profile.
2. When you migrate a data set, the *volser* in the discrete profile is not updated. Attempts to access the data set without recalling it may cause the ICH408I INSUFFICIENT ACCESS AUTHORITY message to be issued, depending on access intent and access allowed. The message will contain the user, group, data set name, volume(MIGRAT), access intent, and access allowed.

This message is issued because the catalog lookup before the RACHECK returns a volume serial number of MIGRAT. Therefore, MIGRAT is specified as the volume in the RACHECK. If RACF cannot find a discrete profile for the data set on *volser* MIGRAT, then a check is made for a generic profile. If a generic profile does not exist or does not give the requested access, the error message is issued.

This error message will not be issued if specific generic profiles are used as opposed to discrete profiles.

Deleting RACF-indicated migrated data sets

When DFSMSHsm deletes a migrated data set, it deletes the RACF discrete data set profile for the following components:

- Non-VSAM data sets.
- VSAM clusters eligible for volume migration. These clusters can contain up to eight specific components:
 - Base cluster
 - Base data object
 - Base index object
 - One base path
 - One alternate index (AIX)

- AIX data object
- AIX index object
- One AIX path
- VSAM clusters with RACF discrete profile protection only on the base cluster.

If you want to delete migrated VSAM clusters that are not eligible for level migration and whose RACF protection is not on the base cluster, perform the following actions:

1. Recall the data set.
2. Use an Access Method Services command to delete the cluster and any associated RACF profiles.

Recalling RACF-indicated data sets

If the RACF indicator was on when DFSMSHsm migrated the data set, the RACF indicator is set on when DFSMSHsm recalls the data set. When DFSMSHsm recalls a non-VSAM data set, DFSMSHsm changes the volume serial number and device type information, if necessary, in the RACF discrete data set profile to indicate the volume where DFSMSHsm has recalled the data set. When DFSMSHsm recalls a VSAM data set, it does not update the RACF discrete data set profile, because the profile contains the volume serial number of the catalog, which cannot change during recall or recovery.

To recall a RACF-indicated data set that has no RACF profile, perform the following actions:

1. Create a generic profile or recreate the RACF discrete profile. To create the discrete profile, use the RACF ADDSD command and specify the NOSET parameter.
2. Recall the data set without specifying where the data set should reside.

Password protection of data sets on DASD

First, you must remember that password protection applies only to non-SMS-managed data sets.

Password protection in MVS is implemented differently for non-VSAM and VSAM data sets. The passwords for all non-VSAM data sets are stored in one system password data set. The password for each VSAM data set is stored in a catalog record for the specific VSAM data set. Therefore, VSAM passwords are maintained during DFSMSHsm processing as a part of regular catalog record creation and updating.

If you are recalling a non-VSAM data set, the required password is the read-level password currently in the system password data set. If you are recalling a VSAM data set, the password is the one that existed when DFSMSHsm migrated the data set. If you are deleting a migrated non-VSAM data set, the current password is the write-level password.

Be aware of the following conditions when you attempt to change password protection while data sets are migrated or backed up:

- You cannot completely remove password protection from a migrated non-VSAM data set because the password-protection indicator is stored in control information in the migrated data. Also, the data set name of the migrated data set is not the user data set name. Therefore, DFSMSHsm cannot remove a password for a migrated non-VSAM data set from the system password data set because no password exists. Even if the password were deleted while the data set was migrated, the VTOC entry after recall would indicate that your data set is password-protected. You would need to add a password to the system password data set before you access the recalled, non-VSAM data set.
- You can change the password of a migrated non-VSAM data set by using the IEHPROGM utility. However, to change the password of a migrated VSAM data set, you must use Access Method Services. If you use Access Method Services, a migrated VSAM data set is recalled.
- If you delete a password-protected VSAM data set while it is migrated, all password protection is deleted. If you delete a password-protected non-VSAM data set while it is migrated, DFSMSHsm scratches the data set and deletes the catalog entry. However, the password still exists in the system password data set, and you should delete it.

- If you try to add password protection to a migrated non-VSAM data set, the password is added to the system password data set. However, the migrated data set does not have protection, and when DFSMSHsm recalls the data set, the VTOC entry does not indicate password protection.
- If you try to add password protection to a migrated VSAM data set, you must use Access Method Services. For a migrated VSAM data set, DFSMSHsm recalls the data set.

Note: If DFSMSHsm tries to create a catalog entry in a catalog having update protection, the operator receives a password prompt for an unauthorized DFSMSHsm function from an unauthorized DFSMSHsm user.

Access method services considerations

Access Method Services commands allow you to specify either FILE or INFILE to refer to DD statements that specify a data set name, a volume serial, or both, to be used for processing the commands. If a DD statement referred to by either FILE or INFILE specifies both a data set name and a non-SMS-managed volume, and if the data set has been migrated by DFSMSHsm, the Access Method Services command might not be performed successfully. If an error occurs for this condition, perform one of the following two actions before you reissue the Access Method Services command:

- If you need not specify the volume serial number on the DD statement, specify the DD statement without specifying the volume serial number and unit name. This specification causes the data set to be allocated when the job step is initiated, and the migrated data set is recalled for the allocation request.
- If you *must* specify the volume serial number on the DD statement [such as when you specify AMP = (AMORG) for VSAM data sets], recall the data set either:
 - Explicitly by issuing a DFSMSHsm RECALL or HRECALL command
 - Implicitly by referring to the data set without specifying the volume serial number in a step that precedes the step where the Access Method Services command is being requested

GUARANTEED SPACE attribute considerations

The storage class attribute of GUARANTEED SPACE allows the volumes on which a data set resides to be chosen explicitly when that data set is created. If GUARANTEED SPACE is used and any of the volumes specified are not part of one of the storage groups to which the storage class maps, the creation of the data set fails. The use of GUARANTEED SPACE requires some special considerations if DFSMSHsm is to manage data sets that are assigned to such a storage class.

When DFSMSHsm is the data mover, it uses the Access Method Services functions of EXPORT and IMPORT to migrate and recall VSAM data sets. The IMPORT function redefines a VSAM data set by using a copy of the catalog information saved in the EXPORT copy of the data set. This define request explicitly specifies the volumes from which the data set was exported. The explicit specification of the volume affects the way data sets are imported with the GUARANTEED SPACE attribute. Likewise, for non-VSAM data sets, VTOC data set services uses the volume serial number passed by DFSMSHsm if the storage class is GUARANTEED SPACE.

Results of recalling GUARANTEED SPACE VSAM data sets

When DFSMSHsm is the data mover, data sets recalled with the GUARANTEED SPACE attribute are normally placed on the volume from which they migrated. Consider the effects on a migrated, multiple-volume VSAM data set. A subsequent recall preserves the volume-to-component relationship that originally existed as long as the data set remains SMS-managed. For a data set in a GUARANTEED SPACE storage class, the relationship includes returning the data set to the same volumes from which it migrated. Thus, if a data set was originally defined with the data component on one volume and the index component on another, a migrate/recall sequence preserves the relationship between the components and the volumes. Similarly, if a key range data set has three key ranges on three separate volumes, the relationship is preserved.

If a volume is specified on the RECALL command, that volume is passed to IMPORT. When the IMPORT function redefines the VSAM data set, the specified volume overrides the volume or volumes from which

the data set has been exported. If the specified volume is eligible, the data set is imported to that single volume. If there is not enough space, the recall fails. If the volume is not eligible, another volume may be selected. If the data set resides on multiple volumes when it is migrated, it is recalled to a single volume.

Possible problems

In an environment in which the storage groups and storage classes do not change, the preceding results are acceptable for DFSMSHsm to manage the data sets. However, you can expect problems in an environment that is subject to storage group reconfiguration or to changes in the mapping of data sets to storage classes. These problems may discourage the use of DFSMSHsm space management for these data sets and may require special contingency procedures for availability management. The problems that occur relate to the following conditions:

- Changes in the storage group
- Changes in the storage class to data set mapping
- Conversions of data sets to GUARANTEED SPACE

Note: Use of extended address volumes in mixed environment where the volume cannot be brought online to all systems can also result in problems recalling and recovering data sets that belong to a Storage Class having the Guaranteed Space attribute.

Changes in the storage group

Consider the consequence of making a specific volume request in a storage group configuration that has changed. Assume that a data set with a GUARANTEED SPACE request has migrated. Some time later, one or more of the volumes on which the data set resided are removed from the storage groups that contain GUARANTEED SPACE data sets. A subsequent recall of the data set fails because at least one of the requested volumes is no longer part of a storage group for a GUARANTEED SPACE request. The result is the same for both single-volume data sets and multiple-volume VSAM data sets if the specific volume required is unavailable in the necessary storage group. Use of EAVs in mixed environments where the volume cannot be brought online to all systems can also result in problems recalling/recovering data sets that belong to a Storage Class having the Guaranteed Space attribute.

If a storage group is changed to remove volumes that data sets migrated from, you must perform one of the following actions:

- Change the ACS storage class routine so that a storage class with GUARANTEED SPACE is not assigned to the data set.
- Change the volume configuration again so that the storage group contains the volumes from which the data set migrated.
- Change the set of storage groups to which the GUARANTEED SPACE storage class maps to include one that already has the necessary volumes defined. This is applicable only if the volumes are already SMS-managed.
- Use the RECALL command with the FORCENONSMS and the VOLUME parameters. This RECALL command causes the data set to be recalled to a non-SMS-managed volume as a non-SMS-managed data set. You can then move, copy, or convert the data set as necessary.

Note: If the data set was multiple-volume when it migrated, it is recalled to a single volume.

Changes in the storage-class-to-data set mapping

Consider the consequence of making a specific volume request in a storage class mapping that has changed. Assume that a data set is defined and the ACS routines have assigned it to a storage class that does not have the GUARANTEED SPACE attribute or does not assign it to any storage class. The ACS routine is then changed to assign the data set to a storage class with the GUARANTEED SPACE attribute. Also, the original storage class is changed to include the GUARANTEED SPACE attribute. Therefore, the recall might fail because the requested volumes are not in the storage groups that receive GUARANTEED SPACE requests.

If an SMS-managed data set's original storage class is changed to specify the GUARANTEED SPACE attribute before the data set is recalled, you must perform one of the following actions:

- Change the ACS storage class routine so that a storage class without GUARANTEED SPACE is assigned to the data set.
- Change the storage class of the data set to a storage class without GUARANTEED SPACE, without recalling the data set, by using the IDCAMS ALTER command.
- Change the volume configuration in the appropriate storage groups to contain the volumes from which the data set migrated. The volumes may need to be converted to SMS management first. It may be difficult to determine all of the volumes involved. DFSMSHsm does not save all of the original volume serial numbers, only that of the volume on which the base data component resided.
- Change the set of storage groups to which the GUARANTEED SPACE storage class maps to include one that already has the necessary volumes defined. This is applicable only if the volumes are already SMS-managed.
- Use the RECALL command with the FORCENONSMS and the VOLUME parameters. This RECALL command causes the data set to be recalled to a non-SMS-managed volume as a non-SMS-managed data set. You can then move, copy, or convert the data set as necessary.

Note: If the data set was multiple-volume when it migrated, it is recalled to a single volume.

Conversions of data sets to GUARANTEED SPACE

If the data set was non-SMS-managed when it migrated and is assigned a storage class with GUARANTEED SPACE during recall, it is assigned to a volume in a storage group that contains GUARANTEED SPACE data sets.

If the data set was SMS-managed when it migrated but did not have GUARANTEED SPACE, the volumes from which it migrated might not be in a storage group that receives GUARANTEED SPACE requests. To avoid errors, you must perform one of the following actions before the recall:

- Change the target storage class with GUARANTEED SPACE to map to a storage group that contains the original volumes.
- Add the original volumes to a storage group mapped to by the target storage class with GUARANTEED SPACE.

DFSMSHsm retrieval of management classes and storage groups

If you are changing the definitions of management classes, you should know when the new definitions will take effect. DFSMSHsm retrieves a list of all currently defined management classes before the following functions begin:

- Automatic volume space management, which includes primary space management and interval migration
- Automatic secondary space management
- Command volume space management

If one of the volume functions is in progress or has just completed, and another volume function is about to begin, DFSMSHsm uses the list of management classes that exists from the prior processing. When secondary space management begins, a list of management classes is retrieved from the active SMS configuration and is not shared with the other functions in the preceding list.

When DFSMSHsm begins automatic volume space management, it retrieves the storage group definitions to determine which SMS-managed volumes are eligible for space management.

A storage group must meet the following criteria for DFSMSHsm to consider it for processing:

- It must be type POOL.
- It must have a status of either ENABLED, QUIESCED NEW, or DISABLED NEW.
- It must have AM=Y, AM=I, or AM=P.

Deletion of dynamic I/O device considerations

Because DFSMSHsm serializes the UCB of each ML1 volume as soon as the volume is selected for use, you will not be able to delete the device the ML1 volume resides on until processing is complete. The serialization of the UCBs occurs during:

- Automatic volume space management
- Automatic secondary space management
- Command volume migration
- Command level 1 to level 2 migration

Space management considerations for sequential extended-format data sets

DFSMSHsm does migration and recall processing of single-stripe and multiple-stripe sequential extended-format data sets, using DFSMSdss as the data mover. The data sets must be SMS-managed.

Volume space management processing

Because sequential extended-format data sets span volumes, DFSMSHsm migrates a data set only when the volume that contains the first stripe is processed. Migration is skipped for this data set when volumes that contain subsequent stripes are processed.

DFSMSHsm expires an sequential extended-format data set only when the first stripe (volume) is being processed, regardless of whether the data mover is DFSMSdss or DFSMSHsm. Expiration is skipped when subsequent stripes (volumes) are being processed.

You can command migrate single-stripe or multiple-stripe sequential extended-format data sets.

Automatic primary space management processing

DFSMSHsm releases any allocated unused space only for a single-stripe sequential extended-format data set; allocated unused space will not be released for a multiple-stripe sequential extended-format data set.

Extent reduction will not be performed on either single-stripe or multiple-stripe sequential extended-format data sets.

If a sequential extended-format data set is small enough and meets all criteria—regardless of whether it is single-stripe or multiple-stripe—it can be migrated to a small-data-set-packing (SDSP) data set.

DFSMSHsm space management for sequential extended-format data sets will not occur for any of the following reasons:

- A sequential extended-format data set is not migrated if it is larger than the available free space on one DASD migration volume. Ensure that there is a DASD migration volume large enough to fit the entire data set or else migrate it directly to an ML2 tape volume or volumes.
- A multistripe sequential extended-format data set is not migrated if SETSYS USERDATASETSERIALIZATION is not specified for DFSMSHsm.
- A multistripe sequential extended-format data set is not migrated if it is protected by a RACF discrete profile.

Recall processing

DFSMSHsm recalls a sequential extended-format data set (indicated in the MCD record) using DFSMSdss as the data mover.

DFSMSdss recalls a sequential extended-format data set in the following ways:

- A sequential extended-format data set that was multiple-stripe when it was migrated could be recalled as a multiple-stripe or single-stripe sequential extended-format data set, depending on the storage class SUSTAINED DATA RATE value and the availability of the required volumes.
- Conversely, a sequential extended-format data set that was single-stripe when it was migrated could be recalled as a multiple-stripe or single-stripe sequential extended-format data set, depending on the storage class SUSTAINED DATA RATE value and the availability of the required volumes.
- A data set that was not sequential extended-format when it was migrated is always recalled as a data set that is not sequential extended-format. DFSMSHsm does not convert a data set that is not sequential extended-format to a sequential extended-format data set through recall processing.
- A sequential extended-format data set can be recalled as a data set that is not sequential extended-format on a non-SMS-managed volume by specifying FORCENONSMS on the RECALL command.
- A data set that was sequential extended-format when migrated is recalled as a non sequential extended-format but still SMS-managed data set if no SMS volumes supporting sequential extended-format data sets are available.

Recall fails if the ACS filter routines are modified to direct a data set that was sequential extended-format when it was migrated to a non-SMS-managed volume.

Note: If reblocking is required for a sequential extended-format data set, the reblocking is performed.

Object storage in the cloud

DFSMSHsm can use object storage in the cloud as a destination for migrated data set images. When data movement is offloaded to the storage controller, other management functions are performed directly using the z/OS Client Web Enablement Toolkit or the z/OS DFSMSdfp Cloud Data Access (CDA) services.. Using object storage in the cloud allows DFSMSHsm to avoid extra processing such as RECYCLE.

System set up to use the cloud

For DFSMSHsm to use the cloud, you must first set up your system. You can find a full list of the requirements and configuration options in the [*z/OS DFSMSHsm Implementation and Customization Guide*](#).

- For transparent cloud tiering (TCT), DASD volumes in a DS8700 or higher with transparent cloud tiering need to be attached to the system. Only data sets that reside on a device with transparent cloud tiering can be migrated to the cloud through DFSMSHsm.

Note: When configuring DFSMSHsm in a Plex environment, it is highly advised that all DFSMSHsm's running in the Plex are cloud enabled. Doing so allows any DFSMSHsm instance within the Plex to run without error DFSMSHsm functions such as: AUDIT, Secondary Space Management, old cloud migration copy scratch, etc.

DASD volumes

For TCT, ensure that the first volume in an LSS that other volumes are attached from is attached to the system. Failure to do this can lead to attention messages from the DS8000 being missed.

SETSYS

When DFSMSHsm is enabled, it reconnects eligible data sets without performing data movement. If SETSYS CLOUDMIGRATION(RECONNECT(NONE)) is in effect, a subsequent migration of a data set that was otherwise eligible to be reconnected, causes the previous migration copy to be deleted and a new migration copy created.

Cloud password

With an SMS cloud configuration, DFSMSHsm supports CDACREDENTIALS or CLOUDCREDENTIALS option to manage passwords.

- **CDACREDENTIALS** – DFSMSHsm obtains the password for the cloud construct from CDA where the password has been entered by the security administrator. DFSMSHsm will store the encrypted password for future cloud requests. IBM recommends the CDACREDS option when using an SMS cloud configuration.
- **CLOUDCREDENTIALS** – When the CLOUDCREDENTIALS option is specified on the SETSYS CLOUD command to provide DFSMSHsm with cloud password for the user ID that is defined in the SMS network connection construct to DFSMSHsm. Great care needs to be taken with this password. DFSMSHsm keeps the password in encrypted form for later use. Anyone with access to this password can access the cloud directly and delete the migration copies, thus making DFSMSHsm unable to recall those data sets. It is recommended that the security administrator issue this command to protect the access to the cloud.

With a CDA provider configuration, DFSMSHsm does not store the credentials for traditional cloud providers. DFSMSHsm will store the password obtained from CDA for a TS7700 cloud provider in the same way as the CDACREDENTIALS option.

Using the Cloud

Workload distribution with TCT

Currently, the disk subsystem has a maximum of twelve threads per CEC for processing data to or from the cloud. The workload of migrate and recall processing must be evenly distributed. If the workload is not evenly distributed, queuing will occur within the storage controller.

During automatic space management and MIGRATE STORAGEGROUP processing, DFSMSHsm selects volumes for processing such that no more than twelve requests are issued for any volume within the same CEC. Once twelve volumes within the same CEC are being processed, no more volumes within that CEC are selected for processing until one of those volumes completes processing. Additionally, only two large data sets (greater than 5 GB) are migrated per CEC at any one time. These large data sets are revisited later if there are currently two being migrated.

The twelve concurrent request values can be changed via PATCH of MCVT.+494 X'nnnn'. For more information, see [Setting the maximum number of CEC volumes to be migrated to Cloud simultaneously in z/OS DFSMSHsm Implementation and Customization Guide](#).

MIGRATE DATASET and MIGRATE VOLUME processing do not participate in the distribution of work, so care must be taken when issuing these commands during Automatic Space Management and MIGRATE STORAGEGROUP processing, as queuing may still occur.

Migration

Retaining certain types of data on ML1 DASD or ML2 tape is undesirable. Migrating those data sets to the cloud can be desirable when the data sets are large, and not expected to be referenced for a long time.

When you migrate a data set to the cloud, it uses offboard data movement that is provided by the hardware. The elapsed time for data set migrations and recalls to and from cloud storage are longer than the time for migrations and recall functions on FICON attached storage. With cloud storage, data transfer is performed with TCP/IP across Ethernet connections. IBM recommends that installations perform tests to determine the expected elapsed time degradation unique for their environment. You can use DFSMSHsm FSR records to determine both elapsed time and CPU consumption for these functions. Based on the expected degradation, migrate to cloud storage only those data sets for which the degradation is acceptable. For example, migrated data sets that must be recalled within a specific time frame to achieve an application SLA, should be migrated to cloud storage only when the expected degradation is acceptable. Data set types that are both large in size, rarely or never recalled, are recommended for migration.

Because the backup format is different between an ML1/ML2 migration copy and a cloud migration copy, a data set cannot be moved from ML1/ML2 directly to the cloud. First, recall the data set to L0 DASD, then remigrate the data set to the cloud.

Note: When the catalog entry for the data set is migrated to the cloud, it has a *volser* of MIGRAT, like other migrations. However, the device type field in the catalog entry is x'00018000'. The third byte x'80' indicates that it is a tape, and the second byte x'01' indicates it is a cloud type.

If a data set was previously migrated to the cloud and has since been recalled, but is being remigrated back to the cloud, if it is not re-connectable DFSMSHsm will scratch the old cloud migration copy, depending on configuration, in one of three ways:

1. DFSMSHsm will scratch the old migration copy synchronously, before remigrating the data set.
2. DFSMSHsm will scratch the old migration copy asynchronously in conjunction with remigrating the data set, if asynchronous deletion of old migration copies from cloud is enabled.
3. DFSMSHsm will defer scratching of the old migration copy to when Secondary Space Management runs and the SETSYS MIGRATIONCLOUDDAYS *cloud_days* sub-parameter has been satisfied.

Recall

Recall of data sets from the cloud will be performed by the RECALL or HRECALL commands, or when the data set is referenced. No change to the command syntax is necessary. After a Recall, the migration copy of the data set will not be deleted. This enables subsequent reconnection if desired. When Secondary Space Management is performed, the Migration Control Data Set records will be cleaned up and the migration copies in the cloud will be deleted if the RETAIN DAYS number has been exceeded. DFSMSHsm will not delete empty containers, however. If empty containers are an issue, they can be deleted using a cloud management tool.

Delete

When you delete a migrated data set with the DELETE or HDELETE command, the migration copy in the cloud is also deleted.

Listing information

You can use the DFSMSHsm LIST command to get more information about data sets that have been migrated to the cloud. The LIST DATASETNAME MCDS command will show where the migration copy is stored in the cloud. Details such as the *cloud_network_connection_name* representing the cloud, the container name, and object pre fix are included in the output.

The LIST CLOUD command allows you to get successively more detailed views on the contents of the cloud. One way to use it would be to first get a view of what DFSMSHsm created containers are in the cloud through issuing the LIST CLOUD(*cloud_network_connection_name*) TERM command. Next, a more detailed view of one of the containers could be obtained through issuing LIST CLOUD(*cloud_network_connection_name*) CONTAINER(*container_name*) TERM. This will return a list of all the pseudo-directories within that container. Each pseudo-directory is a single migration copy of a data set.

A migration copy of a single data set is made up of many objects. They are grouped together in a pseudo-directory. DFSMSHsm object names use forward slash characters to delineate different levels. DFSMSHsm Storage Administrators may be familiar with the DFSMSHsm migration copy data set names. DFSMSHsm uses this same naming convention in the pseudo-directory name or object pre fix. If details are wanted about the objects that make up a particular migration copy, the LIST CLOUD(*cloud_network_connection_name*) CONTAINER(*container_name*) PREFIX(*pseudo-directory_name*) TERM command can be issued.

Auditing information

The AUDIT DATASETCONTROLS(MIGRATION) command has been updated to include migration copies in the cloud. While examining these records, if the record indicates the data set was migrated to the cloud, DFSMSHsm will check the cloud storage to verify that the expected number of objects for that prefix exist in the cloud. If the expected number of objects does not match what is found in the cloud it is likely that the migration copy has been corrupted.

Additionally, you can use the new `AUDIT MEDIACONTROLS(CLOUD(cloud_network_connection_name))` command to request DFSMShsm examine the DFSMShsm containers found in the cloud. DFSMShsm will examine each container in turn, comparing what is found in the container with the DFSMShsm migration control data set records. The `FIX` parameter will cause DFSMShsm to repair many of the errors it finds.

Chapter 5. Space management procedures

This topic contains information about:

- Interrupting and restarting primary space management, secondary space management, or event-driven migration.
- Defining new primary space management or secondary space management process windows.
- Allowing another host to take over secondary space management functions.

Interrupting and restarting primary space management, secondary space management, or event-driven migration

Primary space management, secondary space management, or event-driven migration can be interrupted during the course of their processing either intentionally or inadvertently. If you are not using the secondary host promotion function, when DFSMSHsm restarts, it resumes its work near the point where it left off.

If you are in a multiple DFSMSHsm-host environment, and are using the secondary host promotion function, a secondary host can take over the unique functions that were being performed by a primary host that has failed. Secondary host promotion also allows another host to take over the secondary space management functions from either a primary or secondary host that has failed.

This topic describes:

- When primary space management, secondary space management, or event-driven migration needs to be restarted.
- Automatic restart of primary space management or secondary space management.
- Automatic restart of event-driven migration.
- Manual restart of primary space management or secondary space management.
- How to define a new primary space management or secondary space management processing window.

When primary space management, secondary space management, or event-driven migration needs to be restarted

Table 17 on page 161 lists causes of interruptions to primary space management, secondary space management, and event-driven migration. It also lists how to restart these functions.

Table 17. Restarting primary space management, secondary space management, or event-driven migration

Cause of Interruption	How to Restart
System outage	IPL system, then start DFSMSHsm (S DFSMSHSM)
Stop DFSMSHsm (F DFSMSHSM,STOP)	Restart DFSMSHsm (S DFSMSHSM)
Hold automatic volume space management HOLD MIGRATION[(AUTO)]	Release automatic volume space management RELEASE MIGRATION[(AUTO)]
Hold automatic secondary space management HOLD MIGRATION[(AUTO)]	Release automatic secondary space management RELEASE MIGRATION[(AUTO)]
Cancel DFSMSHsm	Start (S DFSMSHSM)
SETSYS EMERGENCY	SETSYS NOEMERGENCY

Table 17. Restarting primary space management, secondary space management, or event-driven migration (continued)

Cause of Interruption	How to Restart
Migration held because output media is not available	ADDVOL, then RELEASE MIGRATION[(AUTO)]

Automatic restart of primary space management or secondary space management

If you are not using secondary host promotion, and there is an interruption caused by a system outage, a cancel of DFSMSHsm, or a stop of DFSMSHsm, the start of DFSMSHsm causes DFSMSHsm to attempt to restart primary space management or secondary space management. Primary space management or secondary space management automatically restarts if all of the following conditions exist:

- The time of the DFSMSHsm restart is in the primary space management or secondary space management processing window and the planned start time has not been changed.
- Primary space management or secondary space management is not held.
- DFSMSHsm is not in EMERGENCY mode.
- The operator gives permission if the SETSYS REQUEST command asks permission to restart.

Otherwise, if the planned start times have not been changed, you can manually restart primary space management or secondary space management.

If you are in a multiple DFSMSHsm-host environment and are using secondary host promotion, and the primary DFSMSHsm host or the DFSMSHsm host that runs secondary space management fails or goes into emergency mode, another DFSMSHsm host is promoted to take over the unique functions of the failed DFSMSHsm host. The unique functions performed by the primary DFSMSHsm host include:

- Space check needed for event-driven migration and recall placement of non-SMS data for interval migration.
- Automatic CDS backup.
- Automatic movement of backup versions from ML1 to tape.
- Automatic backup of migrated data sets.
- Expiration of dump copies.
- Deletion of excess dump VTOC copy data sets.

When the original primary DFSMSHsm host or secondary space management DFSMSHsm host restarts, and is not in emergency mode, it takes over those unique functions once more. However, if the promoted host is in the process of performing some of the functions it took over for the original host, the promoted host continues with those functions to completion. The original host does not attempt to perform its unique functions until the beginning of the next window.

By default, if you manually shut down the primary DFSMSHsm host or secondary space management DFSMSHsm host, secondary host promotion is not invoked, with the exception of the STOP DUMP command. You can override the default and cause secondary host promotion to be invoked when you manually shut down a primary DFSMSHsm host or secondary space management DFSMSHsm host by using the STOP PROMOTE command.

Automatic restart of event-driven migration

If the interruption was a system outage, a cancel of DFSMSHsm, or a stop of DFSMSHsm, the start of DFSMSHsm causes DFSMSHsm to check space on primary volumes eligible for automatic space management. If any such volume is over its threshold, DFSMSHsm then restarts event-driven migration if all of the following conditions exist:

- Primary space management or secondary space management is not held.

- DFSMShsm is not in emergency mode.
- The operator gives permission if the SETSYS REQUEST command asks permission to restart.

Manual restart of primary space management or secondary space management

You can restart primary space management or secondary space management from where it was interrupted if it did not complete and if the current time is still within the processing window. The planned start time is when primary space management or secondary space management last planned to start from the beginning.

When the current time is in the processing window

If primary space management or secondary space management does not restart automatically and the current time is still in the processing window, use one of the following commands to restart primary space management or secondary space management:

- If primary space management or secondary space management was held, issue the RELEASE MIGRATION(AUTO) command.
- If DFSMShsm was in emergency mode, issue the SETSYS NOEMERGENCY command.

When the current time is not in the processing window

- Primary space management:

If the current time is after the ending time, redefine an expanded processing window using the SETSYS PRIMARYSPMGMTSTART(*old-planned,new-end*) command. In the command, *old-planned* is the previous planned start time; *new-end* is a value greater than the current time. This command causes primary space management to restart. If you enter a value for a planned start time that is earlier than the previous planned start time, DFSMShsm also considers the request to be for an expansion of the existing processing window.

If you enter a value for the planned start time that is later than the previous planned start time, DFSMShsm considers the request to be for a new processing window, and the restart is not possible. When primary space management next runs, it will start from the beginning.

- Secondary space management:

If the current time is after the ending time, redefine an expanded processing window using the SETSYS SECONDARYSPMGMTSTART(*old-planned,new-end*) command. In the command, *old-planned* is the previous planned start time; *new-end* is a value greater than the current time. This command causes secondary space management to restart.

If you enter a value for the planned start time that is different than the previous planned start time, DFSMShsm considers the request to be for a new processing window, and a resumption from the point of interruption is not done. When secondary space management next runs, it will start from the beginning.

Where primary space management or secondary space management restarts

- Primary space management:

DFSMShsm records which volumes were processed during primary space management, so it will not attempt to process them again when it is restarted.

- Secondary space management:

If your installation is not using secondary host promotion, and secondary space management functions restart (without changing the *planned-start time*), they resume their work at approximately the point of interruption. They complete the work that would have run if the interruption had not occurred, or they continue until the ending time has been reached. If your installation is using secondary host promotion,

and the promotion occurs during a secondary space management window, and the window is not past the latest time to start (as defined on the primary host), then the promoted host takes over from approximately where the original host left off.

Note: Secondary space management consists of two level functions, migration level cleanup and level 1 to level 2 migration. A restart occurs in whichever was interrupted.

Defining a new primary space management or secondary space management processing window

As you increase the number of volumes that DFSMSHsm space manages, you might want to change the primary space management or secondary space management processing window, or you might want to add more tasks. This topic describes how to define a new processing window. For more information about adding more tasks, see [“Specifying the maximum automatic volume space management tasks and subtasks” on page 49](#) and [“Specifying the maximum automatic secondary space management tasks” on page 50](#).

You can define a new processing window whether primary space management or secondary space management is running or not.

When primary space management or secondary space management is running

You can change the primary space management or secondary space management processing window at any time, even when primary space management or secondary space management is currently running on a particular DFSMSHsm host. Primary space management or secondary space management will run when the new planned start time occurs if the currently running primary space management or secondary space management completes before the planned start time of your newly defined processing window. If the currently running primary space management or secondary space management runs past the new planned start time, primary space management or secondary space management will not start automatically until the next time the planned start time occurs.

When primary space management or secondary space management is not running

If you define a planned start time that is later than the time that primary space management or secondary space management last completed, primary space management or secondary space management starts at the planned start time.

If you define a planned start time that is earlier than the time that primary space management or secondary space management last completed, primary space management or secondary space management does not start until the next time the planned start time occurs on a scheduled day.

Allowing another host to take over secondary space management functions

In a sysplex, you can enable another host to take over secondary space management functions for either a primary or a secondary host that has failed. This function, called secondary host promotion, ensures continuous availability of DFSMSHsm functions.

Chapter 6. Availability management of SMS-managed storage

As described in [“Overview of DFSMSHsm functions”](#) on page 9, DFSMSHsm manages SMS-managed storage on a data set basis. That is, the specification for how to treat each data set on a volume is contained in the management class for that data set. The ACS routine can determine the storage group to which a data set is recovered.

This topic contains the following information:

- What the example system shows
- The tasks necessary to do availability management for SMS-managed storage
- Dump and recover tasks

What the example system shows

In the example system (see [Figure 4](#) on page 21) all of the availability management functions are demonstrated. The automatic and command functions described in this topic are also performed for non-SMS-managed storage. The example system shows the following three functions:

Automatic incremental backup

Every day except Sunday in the example system, all changed data sets except those in certain management classes are backed up. Backup starts between 3 a.m. and 4 a.m. with no new volumes started after 5 a.m. Backup is to tape. See [Figure 32](#) on page 193 for the complete set of commands that DFSMSHsm uses to process the incremental backup.

Host 1 backs up the control data sets at the beginning of backup (see Chapter 12, [“Maintaining DFSMSHsm control data sets,”](#) on page 493). It also moves data sets that have been backed up by command from ML1 volumes to backup volumes and backs up migrated data sets that are in need of backup (see [“Determining eligible data sets for backup”](#) on page 68).

Automatic full-volume dump

In the example system a full-volume dump is performed once a week on Sunday, starting between 3 a.m. and 4 a.m. and starting no new volumes after 5 a.m. All DFSMSHsm-managed volumes are dumped every week. In addition, volumes in storage groups 1 and 2 are dumped to an extra copy for off-site storage every 14 days; volumes in storage groups 3 and 4 are dumped to an extra copy for off-site storage every 28 days. See [Figure 26](#) on page 177 for the complete set of commands that DFSMSHsm uses to process a full-volume dump.

Command availability management

In the example system, commands cause availability management functions to occur creating the following conditions:

- One data set to be backed up.
- All the changed data sets on a volume to be backed up.
- A volume to be dumped.
- A backed-up data set to be recovered.
- A volume to be restored from a dump and forward recovered from later incremental backup versions. *Forward recovery* is a process of updating a restored volume by applying later changes as indicated by the catalog and the incremental backup versions.

- A volume to be restored from a dump copy.
- A volume to be recovered from backup versions.
- A specific data set to be restored from a dump volume.
- All expired backup versions to be deleted.
- A fast replication backup version to be recovered from a copy pool.

Tasks for automatic availability management

Now that the functions that the example system can accomplish have been described, the means to make the example system accomplish these functions are described. The tasks for controlling automatic availability management of SMS-managed storage require adding DFSMSHsm commands to the ARCCMDxx member and specifying attributes in the SMS storage classes and management classes. It is assumed that the storage classes and management classes have already been defined. The attribute descriptions explain the attributes to be added to the previously defined storage groups and management classes. Similarly, the descriptions of DFSMSHsm commands relate to commands to be added to the ARCCMDxx member of SYS1.PARMLIB.

Two groups of tasks are performed for availability management: dump tasks and backup tasks. Each of these groups of tasks is described separately.

Dump tasks

The dump tasks that are described consist of:

- Specifying which volumes to dump and the dump classes to use
- Specifying when automatic dump processing starts
- Specifying the DFSMSdss DASD I/O buffering technique to use for dump
- Specifying the maximum number of dump tasks
- Specifying the days on which dump occurs
- Specifying the characteristics of dump classes
- Defining dump volumes to DFSMSHsm

Specifying which volumes to dump and the dump classes to use

DFSMSHsm must be told what volumes to dump and what dump classes to use for the volumes to be dumped. This specification comes from the storage group or copy pool.

Storage group

The AUTO DUMP attribute specifies whether DFSMSHsm is to perform automatic dumps on the volumes assigned to the storage group. In the example system, the AUTO DUMP attribute for all storage groups is AUTO DUMP = Y.

The DUMP CLASS attribute determines two controls for DFSMSHsm: (1) the dump classes to which the volumes associated with the storage group are dumped and (2) how many dump copies are made when the dump occurs. The number of dump classes specified for any storage group determines the *maximum* number of copies that are made for any one dump. You can specify up to five dump classes for each storage group. Parameters in the dump class determine whether a dump copy is made for that particular dump class on that particular day.

The space management example (Figure 5 on page 34) shows how host 1 can be limited to doing space management only for storage group 1. Dump for any of the storage groups is not being limited to a single host. However, should you want to limit the processing to a single host, you can use the DUMP SYSTEM/SYSPLEX NAME attributes in the same way as the MIGRATE SYSTEM/SYSPLEX NAME attribute. Figure 24 on page 167 shows the dump management attributes that have been added to the storage groups in the example system.

```

NAME ==> SG1
  AUTO DUMP    ==> Y
  DUMP CLASS   ==> ONEWEEK
  DUMP CLASS   ==> TWOWEEK
  DUMP SYSTEM/SYSPLEX NAME ==>

Copy pool

The following fields in the COPY POOL DEFINE and COPY POOL ATLER panels provide DFSMSHsm with the required information to know what volumes to dump and what dump classes to use for the volumes to be dumped.

Field

Description and use

Auto Dump

The **Auto Dump** field specifies whether to do automatic dump processing for volumes in the copy pool. Type Y to enable automatic dump processing for the copy pool. If a generation 0 DASD version exists and the dump state of that version is either PARTIAL, FAILED, or NONE, automatic dump processes the version.

Dump Class

The **Dump Class** fields define the dump class name for fast replication dump to use. These fields are used by the DFSMSHsm dump function to know how to manage both automatic dump and FRBACKUP dumps of the copy pool. Up to 5 dump classes can be specified for the copy pool; therefore, up to 5 copies can be created per dump version.

Dump Sys/Sys Group Name

The **Dump Sys/Sys Group Name** field specifies the system to which this copy pool has affinity.

Number of DASD Fast Replication Backup Versions with Background Copy

The **Number of DASD Fast Replication Backup Versions with Background Copy** field specifies the number of backup version (0 to 85, or blank). Up to 85 DASD versions can be specified with a default of 2. If 0 is specified, it implies a NOCOPY environment. In a NOCOPY environment, unless the copy pool is defined with fast reverse restore capability, you cannot recover the backup version from DASD – the only purpose of the backup version is to be available as a source for dump processing.

Note: Expiration is performed at the dump class level for copy pool volumes. The last dump copy is never deleted during expiration processing or version roll-off. It is deleted only when specifically done so by command. Expiration processing of copy pool dump versions might extend the overall automatic dump window because of the additional CDS records that need to be accessed and any overlap with existing non-copy pool dump expiration.

For more information about the copy pool construct, see [“Using the copy pool construct for fast replication setup”](#) on page 257.

Specifying when automatic dump processing starts

In the example system, automatic dump processing is started between 3 a.m. and 4 a.m. and no new volumes start after 5 a.m. The AUTODUMPSTART parameter of the SETSYS command controls the start of automatic dump processing. In the example system, the following SETSYS command is added to the ARCCMDxx member in each of the hosts:

```
SETSYS AUTODUMPSTART(0300 0400 0500)
```

Before automatic dump can start, you must have specified that backup be enabled in that particular host.

Related reading

For more information about how and when to run automatic backup, see [“Specifying whether to perform volume backup and the kind of device to use”](#) on page 189.

Specifying the DFSMSdss DASD I/O buffering technique to use for dump

With a single START I/O instruction, DFSMSdss can read 1, 2, or 5 tracks at a time, or a complete cylinder from the DASD being dumped. The DUMPIO parameter of the SETSYS command identifies which DFSMSdss DASD I/O buffering technique to use and the number of tracks to read.

The command is:

```
SETSYS DUMPIO(n,m)
```

where *n* indicates the DFSMSdss DASD I/O buffering technique for physical volume dump (using the BACKVOL command with the DUMP parameter or during automatic dump), and *m* indicates the value used for DFSMSdss logical dump (DFSMSdss specified as data mover on the SETSYS command).

The values used for n and m are:

- 1** DFSMSDss reads 1 track at a time
- 2** DFSMSDss reads 2 tracks at a time
- 3** DFSMSDss reads 5 tracks at a time
- 4** DFSMSDss reads 1 cylinder at a time

Note: If you specify DUMPIO without a value for m , then m defaults to the value specified for n .

If you do not specify the DUMPIO parameter on any SETSYS command, the DFSMSHsm default for n is 1 and for m is 4.

In the example system, a buffer of 5 tracks is used, so the SETSYS command that is added to the ARCCMDxx member in each of the hosts is:

```
SETSYS DUMPIO(3,1)
```

Specifying concurrent copy for volume dumps

By default, concurrent copy for volume dumps is disabled. To enable concurrent copy for volumes dumps, DFSMSHsm will request that DFSMSDss use concurrent copy, use the VOLUMEDUMP parameter of the SETSYS command.

If you are using concurrent copy for volume dumps and want to disable it, issue the following command:

```
SETSYS VOLUMEDUMP(NOCC)
```

Note: You can use STANDARD in place of NOCC as they are aliases.

For more information about using the VOLUMEDUMP parameter of the SETSYS command, see Chapter 65, “SETSYS command: Establishing or changing the values of DFSMSHsm control parameters,” on page 1057.

Specifying the maximum number of dump tasks

DFSMSHsm can run up to 64 dump tasks concurrently in each host. Because DFSMSHsm can make up to five dump copies concurrently for each dump task, the number of dump tasks does not limit the number of dump copies. In deciding how many dump tasks to specify, consider how many tape units are available to receive the dump copies.

The MAXDUMPTASKS parameter of the SETSYS command controls how many dump tasks run concurrently. In the example system, the use of three concurrent dump tasks is demonstrated. The following SETSYS command is added to the ARCCMDxx member in each host in the example system:

```
SETSYS MAXDUMPTASKS(3)
```

Because it is specified that each storage group have two dump classes, six tape units must be available for each host on the days when both dump classes are scheduled.

If any dump class involved specifies a STACK value of more than one, DFSMSHsm writes multiple dump copies sequentially as each tape is mounted for that dump class. That can reduce the number of tape drives (the number of dump tasks) needed concurrently, but the reduced parallelism can lengthen the total time needed for the automatic dump window specified by SETSYS AUTODUMPSTART.

The STACK value on the dump class (or BACKVOL command) might end up overriding the available MAXDUMPTASKS. Thus, available dump tasks to process dump copies might be under-utilized when the number dump copies from a dump operation divided by the STACK value is less than MAXDUMPTASKS.

The MINSTACK value in the dump class or the value on the BACKVOL command is used to determine how many dump tasks are to be utilized. In some cases, by specifying the minimum stack value, more available MAXDUMPTASKS is utilized as compared to specifying just the maximum stack value, STACK, but might also end up having fewer dump copies on the tape volume. When the dump tasks are selected, they are assigned the number of volumes specified with the MINSTACK keyword. When the maximum number of dump tasks are started, each dump task is then assigned additional volumes in sets equal to the MINSTACK value until the MAXSTACK value are reached.

See Table 18 on page 170 for an illustration about how tasks are selected and assigned volumes.

Table 18. Example of Selecting Tasks and Assigning Volumes

Scenario	Without MINSTACK	With MINSTACK(20)
<ul style="list-style-type: none"> • Volumes to be dumped: 300 • Dump tasks: 5 • MAXSTACK(100) specified for the dump class 	300 volumes are stacked onto 3 tapes (100 volumes on each tape), using 3 dump tasks.	<p>300 volumes are stacked onto 5 tapes (60 volumes on each tape), using 5 dump tasks.</p> <ol style="list-style-type: none"> 1. First 100 volumes are dumped. <ul style="list-style-type: none"> • 20 volumes are stacked onto 5 tapes, using all 5 dump tasks. 2. As the MAXSTACK value (100) is not reached, each of the dump tasks requests more volumes. Processing continues with sets of 20 volumes (the MINSTACK value), until the 300 volumes is processed.

When the SETSYS COMMONQUEUE(DUMP(CONNECT(*basename*))) command is issued, the preference by the system is to fully utilize the available dump tasks, as defined by MAXDUMPTASKS, on all the dump group members in the HSMplex. Tuning the MINSTACK and STACK values might increase dump task parallelism, and might shorten the total time needed for the dump operations to complete. Note that if this command is *not* specified, only local dump tasks where the command was issued are utilized.

Specifying the day on which a dump occurs

The DUMPCYCLE parameter of the DEFINE command specifies when the host does dump processing. You can also specify the day to start the cycle so that the cycle does not change with each reinitialization of DFSMSHsm. In the example system, the following command is added to the ARCCMDxx member in each host:

```
DEFINE DUMPCYCLE(NNNNNNYNNNNNNYNNNNNNYNNNNNNY -  
CYCLESTARTDATE(06/01/03))
```

The command establishes a 28-day cycle that begins on a Monday. Automatic dump processing occurs on Sunday. DFSMSHsm uses the dump cycle to determine the days on which automatic dump occurs. DFSMSHsm performs automatic dump only on days designated with a Y in the dump cycle. The dump cycle that you define applies to *all dump classes that you define*. Thus, the preceding example dump cycle applies to all of the dump classes that are defined in the following examples.

DFSMSHsm stores the date you specify with `CYCLESTARTDATE` as the date the dump cycle began. If you do not specify a `CYCLESTARTDATE` parameter with the `DEFINE` command but a cycle start date is already stored and the dump cycle length has not changed, DFSMSHsm uses the cycle start date that is already stored. If no cycle start date is stored and you do not specify one, DFSMSHsm uses the day that the `DEFINE DUMPCYCLE` command is issued as the cycle start date.

Rule: The date that is specified for the cycle start date cannot be a date in the future. The date must always fall on or before the date that the DEFINE command is issued.

Note:

1. When you redefine the dump class, be careful if you use the DAY parameter to define the days that a given dump class is active. The day that is specified with the DAY parameter should be a Y day in the DUMPCYCLE. If the day that is specified is an N day in the DUMPCYCLE, automatic dump processing does not target the dump class.
2. Dump cleanups run on N days in the dump cycle. Cleanup functions include expiration of expired dump copies and deletion of excess dump VTOC copy data sets and inactive empty containers. Expiration of expired dump copies and deletion of excess dump VTOC copy data sets occur on both 'Y' and 'N' days of the dump cycle. Empty dump container deletion only occurs on an 'N' day in the dump cycle.

Specifying the characteristics of dump classes

The dump classes to which a volume is dumped determine how the particular dump copies are made and used. You can control the following factors with the dump class:

- Whether the dump tapes are automatically reused when the dumped data is no longer valid
- Whether the dump tapes can be used to restore individual data sets
- The day of the dump cycle on which data will be dumped to the dump class
- What to do with the newly created dump tapes
- How often to dump data to the dump class
- Whether to reset the data-set-changed indicator
- When the data on the dump volumes becomes invalid
- The kind of tape unit to use for the dump tapes
- The number of generations for which copies of the VTOC of dumped volumes will be kept
- The expiration date to use in the tape header label
- The maximum number of dump copies to be stacked on a dump tape assigned to this dump class
- Whether to compress and encrypt the dump data
- Whether the dump class is required or optional

The DUMPCLASS parameter of the DEFINE command provides the control for the dump class.

There are three dump classes in the example system: ONEWEEK, TWOWEEK, and FOURWEEK. The copies in the ONEWEEK class are kept at the computer site and are used to restore complete volumes or individual data sets as necessary. The copies in the TWOWEEK and FOURWEEK classes are sent to another site to be available for returning the business to production should a disaster occur at the computer site. Because the DUMPCLASS parameter has many subparameters, the effect of each subparameter is described and the DUMPCLASS parameter is built as you proceed.

Controlling automatic reuse of dump tapes

The AUTOREUSE subparameter of the DUMPCLASS parameter controls whether dump tapes that have a retention period specified for them in the dump class are reused when the data expires. AUTOREUSE specifies that the tapes are returned to the DFSMSHsm tape pool when the dump copy is invalidated. NOAUTOREUSE specifies that the tapes are marked as unavailable for selection by DFSMSHsm when the dump copy is invalidated.

Because the volumes in dump class ONEWEEK are retained at the computer site, they can be reused when the data on them is invalidated. Therefore, begin building the DEFINE DUMPCLASS command to be added to the ARCCMDxx member in each host for this dump class as:

```
DEFINE DUMPCLASS(ONEWEEK AUTOREUSE)
```

Because the volumes in dump classes TWOWEEK and FOURWEEK are sent to another site, they cannot be automatically returned to use by the system. Therefore, add the following DEFINE DUMPCLASS commands to the ARCCMDxx member in each host for these dump classes:

```
DEFINE DUMPCLASS(TWOWEEK NOAUTOREUSE)  
DEFINE DUMPCLASS(FOURWEEK NOAUTOREUSE)
```

The AUTOREUSE subparameter is really of use only when you specify that empty tapes be returned to a DFSMSHsm pool of empty tapes that are known to DFSMSHsm. If tapes are returned to the scratch pool and if you are not selecting specific tapes for subsequent output tape selection, this subparameter is of no use because it makes tapes reusable only if they are known to DFSMSHsm.

In the example system, scratch tapes are used and empty tapes are released to the scratch pool. Therefore, although the specification of AUTOREUSE for dump class ONEWEEK was shown, it has no effect because volumes are not being defined to DFSMSHsm. However, the reason for specifying NOAUTOREUSE in dump classes TWOWEEK and FOURWEEK is valid. NOAUTOREUSE must be specified for tapes that are taken away from the computer system site.

Controlling restoring of individual data sets from dump tapes

You can control whether DFSMSHsm can use copies of data sets on dump tapes to recover individual data sets. If you allow restoring of individual data sets from dump copies in a particular dump class, DFSMSHsm selects the latest copy of the data set, whether it resides on a dump volume or a backup volume. If you do not allow restoring of individual data sets from dump copies in a particular dump class, DFSMSHsm cannot select the data set from a dump copy in that class.

Because it is intended to use the later of the copies on either the dump volumes in dump class ONEWEEK or the backup volumes, change the DUMPCLASS parameter to the following in the ARCCMDxx member in each host:

```
DEFINE DUMPCLASS(ONEWEEK AUTOREUSE DATASETRESTORE)
```

Because the volumes in dump classes TWOWEEK and FOURWEEK will be sent to another site, you do not want to choose them for restoring data sets. Therefore, change the DUMPCLASS parameter for these two classes in the ARCCMDxx member in each host by issuing the following commands:

```
DEFINE DUMPCLASS(TWOWEEK NOAUTOREUSE -  
NODATASETRESTORE)  
DEFINE DUMPCLASS(FOURWEEK NOAUTOREUSE -  
NODATASETRESTORE)
```

Note: The DATASETRESTORE keyword is not applicable to copy pool processing.

Specifying the day to dump data to this dump class

You can specify that you want data dumped to a particular dump class on a particular day in the dump cycle with the DAY subparameter. If you specify the DAY subparameter, the dump class is used only on that day. The day specified with the DAY subparameter must be a Y day in the dump cycle that you have defined with the DEFINE DUMPCYCLE command.

Because you want dump class ONEWEEK to be used four times during the dump cycle and you want dump class TWOWEEK to be used two times, do not specify the DAY subparameter for these two classes. The DAY subparameter does not allow you to use a dump class more than one time in a dump cycle. However, as dump class FOURWEEK is used once every 28 days, you can change its DEFINE DUMPCLASS command as follows:

```
DEFINE DUMPCLASS(FOURWEEK NOAUTOREUSE -  
NODATASETRESTORE DAY(28))
```

Specifying how often to dump data to the dump classes

You can control how often volumes are dumped to a dump class by using the FREQUENCY subparameter. This subparameter of the DUMPCLASS parameter works with the DUMPCYCLE parameter to determine when volumes are dumped. For a volume to be dumped, the dump must occur on a Y day in the dump

cycle and the number of days specified with the FREQUENCY subparameter must have passed. Use the FREQUENCY subparameter, rather than the DAY subparameter, when you want to use the dump class more than one time in the dump cycle.

In the example system, you want the volumes being dumped in dump class ONEWEEK to be dumped every seven days and the volumes in dump class TWOWEEK to be dumped every 14 days. (You also want the volumes being dumped to dump class FOURWEEK to be dumped every 28 days, but have taken care of this requirement with the DAYS subparameter.) To control dumping to dump classes ONEWEEK and TWOWEEK, you can change the DEFINE DUMPCLASS commands as follows:

```
DEFINE DUMPCLASS(ONEWEEK AUTOREUSE -
DATASETRESTORE FREQUENCY(7))
DEFINE DUMPCLASS(TWOWEEK NOAUTOREUSE -
NODATASETRESTORE FREQUENCY(14))
```

Specifying what to do with the dump volumes

As each DASD volume is dumped, DFSMSHsm notifies the operator that the volume is dumped and to which tape volumes that it is dumped. By using the DISPOSITION subparameter of the DUMPCLASS parameter, you can add to this message instructions about what to do with the dump volumes.

Because you are using the volumes from dump class ONEWEEK at the computer site, you have no particular instructions for the operator concerning these volumes. Therefore, do not add the DISPOSITION subparameter to the DEFINE DUMPCLASS command for this dump class. However, because you are sending the volumes from dump classes TWOWEEK and FOURWEEK to another site, you can change the DEFINE DUMPCLASS command for these dump classes as follows:

```
DEFINE DUMPCLASS(TWOWEEK NOAUTOREUSE -
NODATASETRESTORE FREQUENCY(14) -
DISPOSITION('SEND OFFSITE BIWEEKLY'))
DEFINE DUMPCLASS(FOURWEEK NOAUTOREUSE -
NODATASETRESTORE DAY(28) -
DISPOSITION('SEND OFFSITE MONTHLY'))
```

Specifying whether to reset the data-set-changed indicator

You can specify whether to reset the data-set-changed indicator on changed data sets when dump processing is performed to a specific dump class. If the dump operation resets the data-set-changed indicator, the data sets are not backed up by the next incremental backup operation unless the data set is changed after the dump occurs. If volumes are being dumped to multiple dump classes and you indicate in any of the dump classes that the indicator is to be reset, the indicator is reset whenever volumes are dumped to that dump class. If the dump copy is the most-recent backup copy of a data set and the data-set-changed indicator is reset, the most-recent backup copy can be lost if the dump copy expires automatically.

The RESET subparameter of the DUMPCLASS parameter controls whether the data-set-changed indicator is reset. If you intend to use incremental backup copies to update volumes restored from dump copies, you should use the NORESET option of this subparameter. You are going to use the incremental backup copies to update restored volumes; therefore, you can change the DEFINE DUMPCLASS command as follows:

```
DEFINE DUMPCLASS(ONEWEEK AUTOREUSE -
DATASETRESTORE FREQUENCY(7) NORESET)
DEFINE DUMPCLASS(TWOWEEK NOAUTOREUSE -
NODATASETRESTORE FREQUENCY(14) -
DISPOSITION('SEND OFFSITE BIWEEKLY') -
NORESET)
DEFINE DUMPCLASS(FOURWEEK NOAUTOREUSE -
NODATASETRESTORE DAY(28) -
DISPOSITION('SEND OFFSITE MONTHLY') -
NORESET)
```

Note: You cannot specify RESET if the dump class is used for copy pool processing.

You can specify whether the data-set-changed indicator in the VTOC entry, DS1DSCHA, is reset for all data sets that are restored during full volume recover processing, using the RECOVERRESET subparameter of the DUMPCLASS parameter. The data-set-changed indicator indicates whether or not the data set has changed since its last backup. RECOVERRESET(YES), the default, species that the data-set-changed indicator is reset (set to OFF) for all data sets on the volume being recovered. RECOVERRESET(NO) species that the data-set-changed indicator is not reset. This option indicates that the data-set-changed indicator setting retains the value the data sets had when dumped. RECOVERRESET(DUMP) specifies that if the RESET keyword was specified in the dump class at the time the dump was created, the data-set-changed indicator is reset for all data on the volume being recovered, unless RESET was not specified, NORESET was specified, or the dump copy was created prior to z/OS V2R1 DFSMSHsm. Note that DUMP is not applicable for fast replication recovery because RESET cannot be specified in dump classes associated with the FRBACKUP function. For dump classes used during fast replication recovery processing, specify either YES or NO.

Specifying when the data on dump volumes becomes invalid

The data on dump volumes is of value until the data on the original volume has changed significantly. In the meantime, you are making new dump copies periodically. After some period, you want to indicate to DFSMSHsm that the old dump copies are no longer of value. You can do this with the RETENTIONPERIOD subparameter of the DUMPCLASS parameter.

Use the RETENTIONPERIOD subparameter to specify a number of days for which DFSMSHsm considers data on the dump volumes as valid. After the period specified by RETENTIONPERIOD has elapsed, the volumes become eligible to be reused, either automatically or manually.

Because you are making dump copies weekly for use at your site, consider all data on volumes dumped to dump class ONEWEEK to be invalid after three weeks. Similarly, consider data on volumes dumped to dump classes TWOWEEK and FOURWEEK to be invalid after three cycles. If you want to retain the dump copies until the full 100 generations have been made, you can specify NOLIMIT as the value for the retention period. Change the DEFINE DUMPCLASS commands as follows:

```
DEFINE DUMPCLASS(ONEWEEK AUTOREUSE -  
  DATASETRESTORE FREQUENCY(7) NORESET -  
  RETENTIONPERIOD(21))  
DEFINE DUMPCLASS(TWOWEEK NOAUTOREUSE -  
  NODATASETRESTORE FREQUENCY(14) -  
  DISPOSITION('SEND OFFSITE BIWEEKLY') -  
  NORESET RETENTIONPERIOD(42))  
DEFINE DUMPCLASS(FOURWEEK NOAUTOREUSE -  
  NODATASETRESTORE DAY(28) -  
  DISPOSITION('SEND OFFSITE MONTHLY') -  
  NORESET RETENTIONPERIOD(84))
```

Specifying a tape expiration date

Some tape management programs require a tape expiration date in the tape header label. If you specify EXPIRATION or EXPIRATIONINCLUDE as tape security parameters, DFSMSHsm places a tape expiration date of 99365 in the tape header label. You use the TAPEEXPIRATIONDATE subparameter to cause DFSMSHsm to use a unique expiration date for the volumes rather than 99365. The example system does not use a tape expiration date.

Specifying the kind of tape units to use for dump volumes

The UNIT subparameter of the DUMPCLASS parameter limits the kind of tape unit to use for dump volumes when the dump function is not using a system-managed library.

Related reading

For more information about the UNIT subparameter of the DUMPCLASS parameter, see [Chapter 40, “DEFINE command: Defining control structures for use by DFSMSHsm,”](#) on page 809.

Specifying the maximum number of dump copies to stack on a dump volume

The STACK subparameter of the DUMPCLASS parameter directs DFSMSHsm to store one or more dump copies (each in its own file) on a dump tape, while that tape is initially mounted after selection during automatic dump.

Although the STACK value is intended to help you make better use of the newer, higher-capacity tape cartridges, DFSMSHsm does not limit its use to certain unit types, and does not reduce the amount of stacking to prevent dump copies from spanning to additional dump tapes. However, if a dump class specifies a STACK value of more than one, and that value results in a given sequence of dump copies spanning to one or more additional dump tapes, DFSMSHsm writes a message alerting you to that fact; you may want to reduce the STACK value.

Since the number of volumes to be dumped is not likely to be an integral multiple of the STACK value, the last dump tape assigned to a dump class with STACK value of M is likely to contain fewer than M dump copies.

DFSMSHsm does not try to extend existing dump volumes during initial selection, but selects only empty volumes as targets of full-volume dumps. Therefore, after a dump tape is dismounted, it can be taken offsite or whatever action is specified by the dump class DISPOSITION parameter.

All the dump copies stacked on a dump tape expire on the same day, but some copies may become invalid (rolled off) before that time.

Specifying the number of VTOC copies to keep

As DFSMSHsm makes a generation of dump copies, it makes a copy of the VTOC of the level 0 volume being dumped for that generation and associates it with the dump copies that are made. DFSMSHsm uses the VTOC copy when a dump copy is used to restore a data set. You can specify how many copies of the VTOC are kept. DFSMSHsm does not create a VTOC copy when an ML1 volume is dumped.

The example system demonstrates how VTOC copies are kept. It has been stated that storage groups 1 and 2 are using dump classes ONEWEEK and TWOWEEK and that storage groups 3 and 4 are using ONEWEEK and FOURWEEK. Every seven days a new generation is made for all volumes with a copy for dump class ONEWEEK. In addition, every 14 days the volumes in storage groups 1 and 2 are dumped to dump class TWOWEEK so that for those generations, two copies of the volumes in storage groups 1 and 2 are made. However, only one VTOC copy is made for each source volume in a generation even though two copies of the volume are made. [Table 19 on page 175](#) shows the copies in the various generations for one dump cycle.

In this example, the generation-numbering scheme is not the one used by DFSMSHsm but is a simplified scheme for instructional purposes.

Table 19. Generations of Example Dumps

Day	Generation	ONEWEEK	TWOWEEK	Discard VTOC Copy
7	1	X		None
14	2	X	X	None
21	3	X		1
28	4	X	X	None

Now, assuming that you have specified that you want two copies of the VTOC saved for each of dump classes ONEWEEK and TWOWEEK, complete the following actions:

1. When generation 1 is made, save one VTOC copy for dump class ONEWEEK.
2. When generation 2 is made, save one VTOC copy for both dump classes ONEWEEK and TWOWEEK.
3. When generation 3 is made, save one VTOC copy for dump class ONEWEEK and discard the VTOC copy from generation 1 because it exceeds the two VTOCs specified for dump class ONEWEEK.

4. When generation 4 is made, make one VTOC copy for dump classes ONEWEEK, TWOWEEK, and FOURWEEK; however, the VTOC copy from generation 2 cannot be deleted even though it exceeds the two VTOCs specified for dump class ONEWEEK, because it is still needed to satisfy the two VTOCs specified for dump class TWOWEEK. At this time, you have VTOC copies from generations 2, 3, and 4. The copies for generations 3 and 4 satisfy the two generations for dump class ONEWEEK. The copies for generations 2 and 4 satisfy the two generations for dump class TWOWEEK.

The VTOCCOPIES subparameter of the DUMPCLASS parameter controls the number of VTOC copies kept for the dump class. The dump VTOC copy data sets are written to ML1 volumes. The space required for these data sets varies with the size of the original VTOC, but it is less than that of the original VTOC because only part of each data set VTOC entry is written in the dump VTOC copy.

When no VTOC copy exists for a particular set of dump copies, DFSMSHsm can no longer use its automatic search capability to restore data sets from that dump (although it can restore entire volumes). Lack of a VTOC copy also prevents DFSMSHsm from providing listings of the data sets contained in that dump. *Authorized users* can restore data sets from a specified dump volume even though the VTOC copy does not exist.

In the example system, save two VTOC copies for dump classes ONEWEEK and TWOWEEK and no VTOC copy for dump class FOURWEEK. The DUMPCLASS parameters for the DEFINE commands are completed as follows:

```
DEFINE DUMPCLASS(ONEWEEK AUTOREUSE -  
  DATASETRESTORE FREQUENCY(7) NORESET -  
  RETENTIONPERIOD(21) UNIT(ACL) -  
  VTOCCOPIES(2))  
DEFINE DUMPCLASS(TWOWEEK NOAUTOREUSE -  
  NODATASETRESTORE FREQUENCY(14) -  
  DISPOSITION('SEND OFFSITE BIWEEKLY') -  
  NORESET RETENTIONPERIOD(42) -  
  UNIT(ACL) VTOCCOPIES(2))  
DEFINE DUMPCLASS(FOURWEEK NOAUTOREUSE -  
  NODATASETRESTORE DAY(28) -  
  DISPOSITION('SEND OFFSITE MONTHLY') -  
  NORESET RETENTIONPERIOD(84) -  
  UNIT(ACL) VTOCCOPIES(0))
```

Specifying whether to compress and encrypt the dump data

The ENCRYPT subparameter of the DUMPCLASS parameter directs DFSMSHsm to encrypt data dumped to the dump class. DFSMSHsm invokes DFSMSdss during the dump process with the encryption settings specified in the dump classes. For information about how to determine which encryption options to set in the dump class, see Chapter 6, "Managing Availability with DFSMSdss" in *z/OS DFSMSdss Storage Administration*.

The HWCOMPRESS subparameter of the DUMPCLASS parameter indicates whether DFSMSdss is to use hardware assisted compression for dump data before it is encrypted. Because encrypted data cannot be compressed, specify HWCOMPRESS(YES) to prevent a significant increase in the number of tapes required for the dump copies. HWCOMPRESS(YES) increases the CPU time consumed for the dump function.

The set of dump classes that constitute a dump generation (that is, the set of dump classes specified on the BACKVOL command or in the storage group definition) must have the same encryption and HWCOMPRESS settings, or the dump operation fails.

Specifying whether the dump class is required or optional

Using REQUIRED for a dump class ensures that dump class will be dumped to. Copy pools with dump classes that are defined with FASTREPLICATIONDUMP(REQUIRED) must have all REQUIRED dump classes successfully completed in order for the dump version to be considered successful. If an attempt to delete or roll off the DASD version of which a REQUIRED dump class has not been completed, the command fails. You can complete an incomplete dump copy by using the FRBACKUP DUMPPONLY function to retry the volumes that failed. To force a new DASD copy to be created to replace the existing

There is also a discussion of the example system management classes in [“Example management classes”](#) on page 186.

Specifying which storage group has automatic backup performed

The AUTO BACKUP attribute of the storage group specifies whether DFSMSHsm performs automatic incremental backup on the volumes assigned to the storage group. For the example system, the AUTO BACKUP attribute for all storage groups is AUTO BACKUP = Y.

As with the space management example, backup for any of the storage groups is not limited to a single host. However, should you want to limit the processing to a single host, you can use the BACKUP SYSTEM/SYSPLEX NAME attribute in the same way as the MIGRATE SYSTEM/SYSPLEX NAME attribute was used. A sysplex name can also be used as the BACKUP SYSTEM/SYSPLEX NAME.

[Figure 27 on page 178](#) shows the backup attributes added to the storage groups for the example system.

```
NAME ==> SG1
  AUTO BACKUP ==> Y

```

Figure 27. Storage Group Attributes for Backup

Specifying how to manage groups of data sets

During backup processing, DFSMSHsm processes individual SMS-managed data sets to comply with the attributes specified in the management classes to which the data sets are associated. Management class backup attributes let you specify:

- Whether to use concurrent copy

- How often the data sets can be backed up
- How to guarantee frequency of backup
- How many backup versions (maximum) to keep
- How long to keep backup versions
- Who can back up data sets by command
- Whether to perform automatic backup

Related reading

For more information about management classes and their function in SMS, see [z/OS DFSMSdss Storage Administration](#).

Specifying a storage group priority for autobackup processing

The storage group processing priority of the volumes assigned to an SMS storage group may be specified within the storage group definition. The default value is 50. DFSMSHsm will process all of the SMS volumes in the order of the processing priority, with 100 being the highest and 1 being the lowest. This processing priority can help ensure that storage groups that need to be processed first during automatic backup are done so in order.

Specifying whether to use concurrent copy

Concurrent copy is a system-managed backup process. DFSMS provides a BACKUP COPY TECHNIQUE attribute for the SMS management class that informs DFSMSHsm whether to use the concurrent copy facility when backing up data sets during automatic, volume, or command data set backup processing. The BACKUP COPY TECHNIQUE attribute has seven parameters:

- CONCURRENT PREFERRED
- CONCURRENT REQUIRED
- STANDARD
- VIRTUAL PREFERRED
- VIRTUAL REQUIRED
- CACHE PREFERRED
- CACHE REQUIRED

These parameters function as follows:

- CONCURRENT PREFERRED (P) - specifies that the concurrent copy facility is preferred. If a concurrent copy session can be established, the data sets are backed up using the concurrent copy facility. Otherwise, the data sets are backed up by DFSMSdss logical dump without concurrent copy.
- CONCURRENT REQUIRED (R) - specifies that the concurrent copy facility is required. If a concurrent copy session cannot be established, the data sets will not be backed up.
- STANDARD (S) - specifies that the concurrent copy facility is not to be used, even though it may be available for the data sets. Normal DFSMSdss logical dump backup processing is used without concurrent copy.
- VIRTUAL PREFERRED (VP) - specifies that the virtual concurrent copy is preferred. If a virtual concurrent copy session cannot be established, the data sets are backed up by DFSMSdss logical dump without concurrent copy.
- VIRTUAL REQUIRED (VR) - specifies that the virtual concurrent copy is required. If a virtual concurrent copy session cannot be established, the data sets will not be backed up.
- CACHE PREFERRED (CP) - specifies that the cache-based concurrent copy is preferred. If a cache-based concurrent copy session cannot be established, the data sets are backed up by DFSMSdss logical dump without concurrent copy.

- CACHE REQUIRED (CR) - specifies that the cache-based concurrent copy is required. If a cache-based concurrent session cannot be established, the data sets will not be backed up.

When DFSMSHsm is performing either automatic, volume, or command data set backup processing, the management class associated with a data set specifies that a concurrent copy BACKUP COPY TECHNIQUE is to be used, and DFSMSdss is the data mover, then DFSMSHsm invokes DFSMSdss using the appropriate CONCURRENT parameter.

Note:

1. BACKUP COPY TECHNIQUE applies only to data sets residing on level 0 volumes. Migrated data sets are backed up using DFSMSdss logic dump.
2. Concurrent copy does not apply to catalogs and partitioned data sets.

Specifying frequency of backup

The backup attribute BACKUP FREQUENCY governs how frequently the data sets can be backed up automatically. Backup frequency is a management class attribute. This attribute specifies the number of days that must have elapsed since the last backup before the data set can be backed up again automatically, even though the data set may have changed and the volume it resides on is undergoing backup processing. For example, the data set will not be backed up because the frequency specification has not been met if the following conditions are true:

- The management class has a backup frequency of 2
- The data set was backed up yesterday
- The data set has been changed
- The volume is being processed for backup

However, if the backup frequency is 1 or if the data set had been backed up the day before yesterday, the data set is backed up.

The default for BACKUP FREQUENCY is 1.

Note: Normally, DFSMSHsm processes volumes only if they were not already processed within the previous 14 hours. A nightly backup starts over at the beginning. To have DFSMSHsm start the backup with volumes that were not backed up in the previous cycle, set the backup to a larger number of hours. For a patch command example, refer to a discussion on the patches to be added to the ARCCMDxx parmlib member in the [z/OS DFSMSHsm Diagnosis](#).

Guaranteeing frequency of backup

The maximum number of days between backups can be guaranteed by the storage group attribute GUARANTEED BACKUP FREQUENCY. This attribute provides an additional criterion to create a backup version and guarantees that a backup version of the data set is created after the specified number of days has elapsed, whether the data set has been changed. The backup version is created either during DFSMSHsm's automatic backup or command volume backup incremental processing.

Note: There is no interaction between GUARANTEED BACKUP FREQUENCY and command backup of a single data set or of a total volume.

If the data set has not changed and the backup version is created because the GUARANTEED BACKUP FREQUENCY has been met, then that backup version replaces the most recent backup version (replacement will not be performed for (H)BACKDS and BACKVOL TOTAL commands). If the data set has changed, backup versions are kept as described in the [“Specifying the maximum number of backup versions to keep”](#) on page 181 topic that follows.

GUARANTEED BACKUP FREQUENCY (which is a maximum) takes precedence over the management class attribute BACKUP FREQUENCY (which is a minimum), such as in the following: If the BACKUP FREQUENCY is set to six days and GUARANTEED BACKUP FREQUENCY is set to four days, the data set is backed up after four days, whether the data set has been changed. If the attribute values are reversed, the data set is backed up after four days, if changed, or after six days if not changed.

GUARANTEED BACKUP FREQUENCY provides a way to reduce the number of tape mounts needed to recover a volume when a few data sets are not being changed. Volume dumps copy all data, even if nearly all of it is already backed up by incremental backup. Having all the data needed for a recovery on a small number of tapes can reduce the number of tape mounts needed to recover a volume entirely from incremental backups.

If the data set's storage group attribute of AUTO BACKUP is NO, then no data sets are backed up by the automatic backup process, regardless of the setting of GUARANTEED BACKUP FREQUENCY. However, if an SMS volume is backed up by the BACKVOL command, GUARANTEED BACKUP FREQUENCY is honored for data sets that have not been changed.

Specifying the maximum number of backup versions to keep

Each time that DFSMSHsm makes a backup of a data set, the copy is known as a version. (Depending on the record length that is used to define the BCDS, DFSMSHsm can keep up to 29, or up to 100, versions of any data set.) The number of backup versions determines how far back you can go to recover a data set. You can specify the number of backup versions to keep by using the two NUMBER OF BACKUP VERSIONS attributes in the management class.

The NUMBER OF BACKUP VERSIONS (DATA SET EXISTS) attribute controls the maximum number of backup versions you accumulate for data sets that are currently on either a level 0 volume or a migration volume. You will most likely want to keep multiple backup versions of these data sets. After you have as many versions of a data set as you specify with this attribute, each new backup version that is made of that data set causes the oldest backup version that exists to be discarded. The default for NUMBER OF BACKUP VERSIONS (DATA SET EXISTS) is 2.

The NUMBER OF BACKUP VERSIONS (DATA SET DELETED) attribute controls the maximum number of backup versions you keep for a data set that has been deleted. DFSMSHsm does not automatically delete excess backup versions for deleted data sets at the time the data set is deleted. You must issue a DFSMSHsm EXPIREBV command that finds and deletes the excess backup versions of deleted data sets. The default for NUMBER OF BACKUP VERSIONS (DATA SET DELETED) is 1.

Note: When you delete a data set, control of the number of backup versions to be kept changes from the NUMBER OF BACKUP VERSIONS (DATA SET EXISTS) attribute to the NUMBER OF BACKUP VERSIONS (DATA SET DELETED) attribute.

Related reading

For more information about how record length affects the number of backup versions, see [z/OS DFSMSHsm Implementation and Customization Guide](#).

Relationship of frequency and maximum number of backup versions

Proper use of the FREQUENCY and NUMBER OF BACKUP VERSIONS (DATA SET EXISTS) attributes can give added assurance that data sets can be recovered. Assume that you specify a frequency of one day and a maximum number of versions of three. If the data set changes daily, the user has only two days to detect any errors that occur in the data set before the oldest backup version contains the error. If the error is not detected in two days, the user cannot use a backup version to recover the data set.

Now assume that you specify a frequency of two days and a maximum number of versions of three. If the data set changes daily, the user has six days to detect the error before the last backup version contains the error. However, each successive backup version will contain two days' worth of daily changes, and this may not provide enough granularity for your needs.

You can also control the number of days that a user has in which to detect errors by increasing the number of backup versions retained.

Specifying how long to keep backup versions

You can control how long to keep extra backup versions for data sets, how long to keep the only backup version of data sets that have been deleted, and how long to keep specific backup versions. (DFSMSHsm

does not delete the only backup version of a data set that exists unless you specifically delete the backup version.) The attributes that control the number of days to keep extra backup versions are overridden by the attributes that control the number of versions to keep. That is, if you have more backup versions than are specified by the appropriate NUMBER OF BACKUP VERSIONS attribute, the excess versions are deleted by the EXPIREBV command even though they may not have reached the age specified by the RETAIN DAYS attributes. The retention period for a specific backup version can be specified with the RETAIN DAYS keyword on the data set backup command. The value specified on the RETAIN DAYS keyword overrides all other retention values.

The RETAIN DAYS EXTRA BACKUP VERSIONS attribute controls the number of days that you keep backup versions that are older than the most recent one. You can specify values from 1 to 9999 or NOLIMIT for this attribute. If you use the NOLIMIT value, you can delete extra backup versions based on the following criteria:

- The value you assign to the NUMBER OF BACKUP VERSIONS attribute.
- The issuance of a DFSMSHsm command to delete specific backup versions.
- The value assigned to the RETAIN DAYS ONLY BACKUP VERSION attribute.

Note: All remaining backup versions are deleted after the retention period specified if you assign a value other than NOLIMIT.

The RETAIN DAYS ONLY BACKUP VERSION (DATA SET DELETED) attribute controls how long the last backup version is retained after the data set has been deleted. You can specify values from 1 to 9999 or NOLIMIT. If you use the NOLIMIT value, the last remaining backup version can be deleted only by the value of the NUMBER OF BACKUP VERSIONS attribute being zero, or by a DFSMSHsm command to delete the specific backup version. The default for RETAIN DAYS ONLY BACKUP VERSION (DATA SET DELETED) is 60. The number of days is counted from the time that DFSMSHsm detects that the data set has been deleted. DFSMSHsm detects that the data set has been deleted when the EXPIREBV command is processed.

When RETAIN DAYS ONLY BACKUP VERSION is set to other than NOLIMIT (1 to 9999), and the RETAIN DAYS EXTRA BACKUP VERSION is set to NOLIMIT, the resulting effect is to keep the number of backup versions specified by the NUMBER OF BACKUP VERSIONS (DATA SET DELETE) attribute for the amount of time specified by the RETAIN DAYS ONLY BACKUP VERSION attribute. After the retention period, all remaining backup versions are deleted. If NOLIMIT is specified for both RETAIN DAYS EXTRA BACKUP VERSION and RETAIN DAYS ONLY BACKUP VERSION, the backup versions are not deleted by EXPIREBV.

Relationship of the NUMBER OF BACKUP VERSIONS and RETAIN DAYS attributes

Consider a management class that specifies:

NUMBER OF BACKUP VERSIONS (DATA SET EXISTS)	= 4
NUMBER OF BACKUP VERSIONS (DATA SET DELETED)	= 2
RETAIN DAYS EXTRA BACKUP VERSIONS	= 20
RETAIN DAYS ONLY BACKUP VERSION (DATA SET DELETED)	= 60

Now consider a single data set associated with this management class:

- As long as no backup version becomes more than 20 days old and the data set exists, no more than four backup versions are retained because of the action of NUMBER OF BACKUP VERSIONS (DATA SET EXISTS). Backup versions in excess of four are deleted even though they may not yet be 20 days old.
- If backup versions are no longer made (for example, because the data set is not being changed), the next processing of the EXPIREBV command deletes any backup version that is more than 20 days old except for the most recent backup version. (Remember, DFSMSHsm *always* requires you to take specific action to delete the last backup version of an existing data set.) The deletion of the oldest backup version is controlled by RETAIN DAYS EXTRA BACKUP VERSIONS. EXPIREBV treats the newest EXTRA backup copy as if it had been created on the same day as the newest BACKUP VERSION. Therefore, the newest EXTRA backup copy is not deleted until the number of days specified in RETAIN DAYS EXTRA BACKUP VERSIONS has passed, starting from the creation date of the newest backup copy.

Assume that the data set is deleted while four backup versions exist that are less than 20 days old:

- The next processing of the EXPIREBV command deletes the two oldest backup versions because of the action of NUMBER OF BACKUP VERSIONS (DATA SET DELETED). Deleting the data set caused a change in the controlling attribute.
- Since there are only two backup versions left, the oldest backup version is also the newest EXTRA backup version. EXPIREBV treats the newest EXTRA backup copy as if it had been created on the same day as the newest BACKUP VERSION. Therefore, the newest EXTRA backup copy is not deleted until the number of days specified in RETAIN DAYS EXTRA BACKUP VERSIONS has passed, starting from the creation date of the newest backup copy.
- When 60 days have passed since a DFSMSHsm EXPIREBV command has detected that the data set was deleted, the next processing of the EXPIREBV command deletes the last backup version through the action of RETAIN DAYS ONLY BACKUP VERSION (DATA SET DELETED).

Specifying the number of days to retain a backup copy of a data set

You can keep an individual backup copy for either shorter or longer than the normal period of time by specifying the RETAIN DAYS keyword on the BACKDS command or specifying a RETAIN DAYS value in the backup exit (ARCBDEXT). RETAIN DAYS controls the minimum number of days that a backup copy of a data set is maintained. DFSMSHsm uses the RETAIN DAYS value to determine when a backup copy is to be rolled-off and during EXPIREBV processing.

The value of RETAIN DAYS can be in the range of 0–50000, which corresponds to the maximum of 136 years. If you specify 99999, the data set backup version is treated as never expire. For command processing, any value greater than 50000 (and other than 99999) causes a failure with an error message ARC1605I. When a value is specified via the ARCBDEXT exit, any value greater than 50000 (other than 99999) will be changed to 50000. A decimal value of 99999 will indicate that the backup copy should never expire. Any value less than 0 will be changed to 0. A retain days value of 0 indicates that:

- the backup version expires when the next backup copy is created,
- the backup version might expire within the same day that it was created if EXPIREBV processing takes place,
- the backup version is kept as an active copy before roll-off occurs,
- the backup version is not managed as a retained copy.

Note: You can use the RETAIN DAYS keyword only with cataloged data sets. If you specify RETAIN DAYS with an uncataloged data set, BACKDS processing fails with ARC1378I error message.

When you enter the EXPIREBV command, DFSMSHsm checks the retention days for each active backup copy for each data set, starting with the oldest backup version and ending with the third newest version. If the version has a specified retention days value, DFSMSHsm calculates the age of the version, compares the age to the value of the retention days, and expires the version if it has met its RETAIN DAYS. The second-newest version is treated as if it had been created on the same day as the newest backup version, and is not expired unless the number of retention days specified by RETAIN DAYS have passed since the creation of the newest backup version. EXPIREBV does not process the newest backup version until it meets both the management class retention values, and the RETAIN DAYS value.

Note: For non-SMS-managed data sets, the RETAIN DAYS value takes precedence over any of the EXPIREBV parameters.

During the EXPIREBV processing, DFSMSHsm checks the retention days for each retained backup copy. The retained copy is identified as an expired version if it has met its retention period. The EXPIREBV DISPLAY command displays the backup versions that have met their RETAIN DAYS value. The EXPIREBV EXECUTE command deletes the backup versions that have met their RETAIN DAYS value.

Related reading

For more information about active and retained backup copies, see [“Creating retained backup copies” on page 184](#).

Creating retained backup copies

DFSMSHsm maintains backup copies as active backup copies and retained backup copies. Active copies are the backup copies that have not yet rolled off. Retained copies are the backup copies that have rolled off from the active copies, but have not yet reached their retention periods. DFSMSHsm can maintain a maximum of 100 active copies. DFSMSHsm can maintain more than enough retained copies for each data set to meet all expected requirements.

Roll-off processing occurs when the number of existing active copies exceeds the maximum number of active backup versions, as defined by the management class attribute Number of backup versions (data exists) for SMS-managed data sets, and the value of the SETSYS VERSIONS command, for non SMS-managed data sets. When a new backup version causes the maximum number of active copies to be exceeded, DFSMSHsm checks all of the active copies to see if any active copy has retained days specified, and if the retained days value is met. The active backup copies are then rolled off in the following order:

1. Roll-off processing removes all backup versions that have expired RETAIN DAYS values.
2. If at least one active backup copy has retain days specified, but none of the active backup copies have met their retain days:
 - a. The oldest active backup copy is rolled-off if it does not have a RETAIN DAYS value specified.
 - b. If the oldest active backup copy has RETAIN DAYS value specified, then the oldest copy is replaced by the new backup copy, and the replaced active copy is maintained as a retained backup copy.
3. If none of the active backup copies have RETAIN DAYS values specified, the excess versions are deleted, starting with the oldest version. The maximum number of active backup copies is 100.

When an active backup copy is rolled off from the active copies, but has not yet reached its retention period, DFSMSHsm maintains it as a retained backup copy. DFSMSHsm can maintain more than enough retained copies for each data set to meet all expected requirements. Generation and version numbers are not associated with retained copies and cannot be used to recover them. You can recover retained copies only by specifying the date, and optionally time, that the version was created.

Example 1

The following example illustrates roll-off processing when several backup versions of a data set have met their retention periods. Assume, that:

1. the maximum number of active backup versions is 3,
2. the data set is cataloged,
3. 3 data set backup versions are already created.

Table 20. The state of the data set backup versions just before the fourth data set backup version is created on October 31st.

Version number	Date created	RETAIN DAYS value	RETAIN DAYS specified at backup time	RETAIN DAYS met indicator on Oct 31st
Version 3	Oct 30th	1	Yes	Met
Version 2	Oct 29th	2	Yes	Met
Version 1	Oct 28th	0	No	N/A

Table 21. The state of data set backup versions after roll-off processing completes. The second and the third versions rolled off

Version number	Date created	RETAIN DAYS value	RETAIN DAYS specified at backup time	RETAIN DAYS met indicator on Oct 31st
Version 4	Oct 31st	31	Yes	Not met

Table 21. The state of data set backup versions after roll-off processing completes. The second and the third versions rolled off (continued)

Version number	Date created	RETAIN DAYS value	RETAIN DAYS specified at backup time	RETAIN DAYS met indicator on Oct 31st
Version 1	Oct 28th	0	No	N/A

Example 2

The following example illustrates roll-off processing for active copies with retention periods that have not been met. Assume that:

- the maximum number of active backup versions is 3,
- the data set is cataloged,
- 3 data set backup versions are already created.

Table 22. The state of data set backup versions just before the fourth data set backup version is created on October 31st.

Version number	Date created	RETAIN DAYS value	RETAIN DAYS specified at backup time	RETAIN DAYS met indicator on Oct 31st
Version 3	Oct 30th	400	Yes	Not met
Version 2	Oct 29th	400	Yes	Not met
Version 1	Oct 28th	400	Yes	Not met

Table 23. The state of data sets after roll-off processing is complete. The oldest version rolled-off and became a retained backup copy.

Version number	Date created	RETAIN DAYS value	RETAIN DAYS specified at backup time	RETAIN DAYS met indicator on Oct 31st
Version 4	Oct 31st	400	Yes	Not met
Version 3	Oct 30th	400	Yes	Not met
Version 2	Oct 29th	400	Yes	Not met

Table 24. Retained backup copies after roll-off processing completes.

Version number	Date created	RETAIN DAYS value	RETAIN DAYS specified at backup time	RETAIN DAYS met indicator on Oct 31st
N/A	Oct 28th	400	Yes	Not met

Specifying who can back up data sets by command

The ADMIN OR USER COMMAND BACKUP attribute controls who can issue commands to back up data sets associated with the management class. You can specify values of BOTH, ADMIN, or NONE. If you specify BOTH, both DFSMSHsm-authorized and non-DFSMSHsm-authorized users can issue commands to back up data sets associated with the management class. If you specify ADMIN, only DFSMSHsm-authorized users can issue commands to back up data sets associated with the management class. If you specify NONE, data sets associated with that management class cannot be backed up either automatically or by command. The default for the ADMIN OR USER COMMAND BACKUP attribute is BOTH.

Specifying whether to perform automatic backup

The AUTO BACKUP attribute controls whether data sets that belong to the management class can be backed up by automatic backup processing. The values you can specify are Y (yes) and N (no). The default for AUTO BACKUP is Y. However, if the ADMIN OR USER COMMAND BACKUP attribute has the value of NONE, data sets associated with that management class are not backed up regardless of the value of the AUTO BACKUP attribute.

Example management classes

In the example system there are four management classes: standard, GDS, large, and no migration.

Standard management class

For data sets using the standard management class (STANDMC), the following actions occur:

- The data sets are automatically backed up no more frequently than every three days.
- Three versions of the data sets are retained while the data set exists.
- One version of the data set is retained for 60 days after the data set is deleted.
- Extra versions are retained for 20 days after they are created.
- Any users can issue commands to back up data sets.
- Automatic backup processing backs up the data sets.
- Concurrent copy is not used.

Figure 28 on page 186 shows the management class attributes for STANDMC.

GDS management class

Data sets in generation data groups use the GDS management class (GDSMC) for the following results:

- Changed data sets are automatically backed up every day.
- One backup version is retained while the data set exists.
- One backup version is retained for 14 days after the data set is deleted.
- No extra backup versions ever exist.
- Only DFSMSHsm-authorized users can issue commands to back up data sets.
- Automatic backup processing backs up data sets.
- Concurrent copy is not used.

Figure 29 on page 187 shows the management class attributes for GDSMC.

Large management class

Data sets that use this management class (LARGEMC) receive the following processing:

- The data sets are automatically backed up every other day (except Sunday).
- Four backup versions are retained while the data set exists.
- One version is retained for 60 days after the data set is deleted.
- Backup versions other than the most current are retained for 20 days after they are created.
- Only DFSMSshm-authorized users can issue commands to back up the data sets.
- Automatic backup processing backs up the data sets.
- Concurrent copy is not used.

Figure 30 on page 187 shows the management class attributes for LARGEMC.

No migration management class

For data sets that have value as long as they are used but lose value quickly when they are not used, the no migration (NOMIGMC) management class has been defined. Data sets that use this management class receive the following processing:

- The data sets are not backed up automatically.

- Both DFSMSHsm-authorized and non-DFSMSHsm-authorized users can issue commands to back up data sets.
- If a data set is backed up by command, one backup version is retained for 30 days after the data set is deleted.
- Concurrent copy is not used.

Figure 31 on page 188 shows the attributes for NOMIGMC.

Specifying the start time for automatic backup

In the example system automatic backup processing starts at 3 a.m., and no later than 4 a.m.. New volumes are not started after 5 a.m. However, at the beginning of automatic backup, the primary host backs up the control data sets. The enqueue on the control data sets and reserve of volumes prevents automatic space management, automatic backup, and automatic dump from running simultaneously while the control data sets are being backed up. Whichever process starts first (space management, dump, or backup) delays the others from starting.

The AUTOBACKUPSTART parameter of the SETSYS command controls the time of day to start automatic backup processing. The SETSYS command that is added to the ARCCMDxx member in hosts 1, 2, and 3 for the example system is:

```
SETSYS AUTOBACKUPSTART(0300 0400 0500)
```

When DFSMSHsm backs up the control data sets, it issues an exclusive enqueue on the control data sets and, in a multiple DFSMS-host environment, reserves the volumes that contain the journal and the control data sets. The enqueue on data sets and reserve of volumes prevents automatic space management, automatic backup, and automatic dump from running simultaneously while the control data sets are being backed up. Whichever process starts first (space management, dump, or backup) delays the other from starting. You should consider this delay when you plan the start of automatic space management, the start of automatic backup, and the start of automatic dump.

The use of the concurrent copy function with DFSMSdss will significantly reduce the duration of complex-wide serialization of the DFSMSHsm CDS resources when performing CDS version backup. This reduction increases the availability of DFSMSHsm functions. To achieve maximum DFSMSHsm availability, you should place the CDS data sets on SMS-managed devices that support the concurrent copy function, and you should use DFSMSdss to back up the CDSs. If DFSMSdss backs up to tape, each CDS resource data set is copied to an individual tape drive (in parallel).

Specifying whether to perform volume backup and the kind of device to use

DFSMSHsm can use either tape or DASD as target volumes for backup. In the example system, all backup is to tape outside of a system-managed tape library. The BACKUP parameter of the SETSYS command controls whether a host is allowed to do backup and dump processing and limits the kind of device to use as target volumes. In the example system, the following SETSYS command is added to the ARCCMDxx member in each host:

```
SETSYS BACKUP(TAPE(ACL))
```

The BACKUP parameter specifies to DFSMSHsm that the host is allowed to perform backup and dump processing. The TAPE(ACL) subparameter specifies that backup versions are to be written to tapes mounted on the devices associated with the ACL esoteric name.

The SETSYS command has a DENSITY parameter that is related to mounting a scratch backup tape for the backup unit. However, when the tape unit specified is a cartridge-type device, DFSMSHsm ignores the DENSITY parameter.

To prevent the host from performing backup, you would use the NOBACKUP parameter, which prevents both automatic and command backup processing from occurring. The NOBACKUP parameter also prevents automatic and command dump from occurring.

For information about how to direct volume backup to a tape library, see [z/OS DFSMSHsm Implementation and Customization Guide](#).

Specifying the first qualifier for names of backup versions

The backup prefix is used in the ACS filters that prevent DFSMSHsm-owned data sets from being allocated on SMS-managed volumes. In addition, the use of the prefix allows you to use RACF generic profile protection for all your backup versions.

When DFSMSHsm backs up data sets, it leaves the original data set name in the catalog. For use in its own records of the data sets, DFSMSHsm generates its own names for the backup versions. The data set name that DFSMSHsm generates is of the form:

```
prefix.BACK.Tssmmhh.user1.user2.Xydd
```

If patch-enabled, the following dataset name will be generated:

```
prefix.BACK.Tcccchh.user1.user2.Xydd
```

For more information, refer to [Changing DFSMSHsm backup and migration generated data set names to reduce contention for similar names and eliminating a possible performance degradation in z/OS DFSMSHsm Implementation and Customization Guide](#).

The BACKUPPREFIX parameter of the SETSYS command specifies the *prefix* (high-level qualifier) of the generated name. If you do not specify a backup prefix, DFSMSHsm uses the UID you specified in the startup procedure. In the example system the following command is added to the ARCCMDxx member in each host:

```
SETSYS BACKUPPREFIX(HSM)
```

Specifying the maximum number of volume backup tasks in each host

DFSMSHsm can have up to 15 volume backup tasks running concurrently in each host. The MAXBACKUPTASKS parameter of the SETSYS command controls the number of concurrent volume backup tasks that will run. To decide how many concurrent volume backup tasks DFSMSHsm should run, consider how many tape units are available if you use tape backup volumes or how many backup DASD units are available. If you are using the duplex tape option for backups, you will need two tape units for every backup task. Also, consider the system work load when volume backup is running. The default for this parameter is 2.

Note: In a multiple DFSMSHsm-host environment with concurrent multitasking, it is beneficial to run all tasks on a single host. For example, having eight tasks running automatic backup from one host gives you better performance than splitting the tasks and running four on one host and four on another host.

In the example system, the maximum backup tasks are specified as:

```
SETSYS MAXBACKUPTASKS(3)
```

Specifying the data set backup by command environment

The data set backup by command function has a number of options that can control your data set backup operation. These options include the number of tasks, the output device type, and tape management.

Related reading

For more information about how to tailor the command data set backup environment, see [“Using the data set or UNIX file backup by command capabilities” on page 224.](#)

Specifying whether to back up RACF discrete data set profiles

If you are using RACF discrete profiles rather than generic profiles, you can have DFSMSHsm back up the profile when it backs up the data set. The PROFILEBACKUP parameter of the SETSYS command controls whether discrete profiles are backed up. Because the example system is in a RACF always-call environment and uses generic profiles, choose the NOPROFILEBACKUP option of this parameter. In the example system, the following command is added to the ARCCMDxx member in each host:

```
SETSYS NOPROFILEBACKUP
```

Specifying whether DFSMSHsm performs spill processing

When DFSMSHsm performs backup to DASD volumes, the DASD volumes can become full. If this occurs, DFSMSHsm can perform the spill process, which moves older backup versions of data sets to other volumes, known as *spill volumes*. Spill volumes are typically tape volumes.

Because the example system uses tape for backup volumes, no spill processing is possible. Therefore, the following command is added to the ARCCMDxx member in each host:

```
SETSYS NOSPILL
```

Specifying whether to back up only changed data sets

When DFSMSHsm is first installed, you might have many data sets on your volumes with the data-set-changed indicator in the data set VTOC entry off (such as data sets for which the bit has been turned off by some other program product). Because DFSMSHsm uses the data-set-changed indicator to decide if a data set needs to be backed up for incremental backup, these data sets would not be backed

up. DFSMSHsm provides an INCREMENTALBACKUP parameter for the SETSYS command that allows you to specify whether to back up such data sets. If you specify the ORIGINAL subparameter of the INCREMENTALBACKUP parameter, DFSMSHsm searches its records for each data set that does not have the data-set-changed indicator turned on. If DFSMSHsm has a backup copy of the data set, the data set is not backed up again. If DFSMSHsm does not have a backup copy of the data set, a backup version is made.

Of course, searching the records each time a data set is found with the data-set-changed indicator turned off takes a lot of time. You may want to use the ORIGINAL subparameter for the first few backup cycles, then change to the CHANGEDONLY subparameter. When you use the CHANGEDONLY subparameter, DFSMSHsm backs up only those data sets that have the data-set-changed indicator turned on.

In the example system, it is presumed that all old data sets have been backed up or have their data-set-changed indicators set to on, so the following command is added to the ARCCMDxx member in each host:

```
SETSYS INCREMENTALBACKUP(CHANGEDONLY)
```

Specifying how DFSMSHsm should respond to a data set in use

To ensure integrity and consistency of the data in a backup version, DFSMSHsm tries to serialize on system resources to indicate whether a data set is in use. This prevents the data set from changing while DFSMSHsm is backing it up. However, accepting the philosophy that something is better than nothing, you may still want backup copies of data sets that are in use at the time of backup, so long as you can identify (if you should need to recover from such a backup) that a given backup was created while the data set was possibly being changed.

If DFSMSHsm makes an unserialized backup, after first trying and failing to serialize on system resources, the data-set-changed indicator remains on; the data set is still eligible to be backed up. If DFSMSHsm is configured *not* to serialize on system resources on the first attempt to back up a data set, the data-set-changed indicator is turned off. The instruction for no serialization is an option of the ARCHBACK user macro and the ARCBDEXT installation exit. However, the ARCINBAK inline backup program always specifies this option, because it expects the JCL to perform its own serialization.

DFSMSHsm recognizes two situations involving backup and a data set being in use. First, there are data sets that you do not expect to be open for update, but that may be in use when backup is attempted. For this situation, the SETSYS BACKUP parameter has an INUSE subparameter to control how DFSMSHsm can try a second time, after a specified delay, to serialize on a data set before backing it up, and whether successful serialization for such a retry is required or merely preferable. The backups that the INUSE subparameter allows may be placed temporarily on ML1 DASD.

In the example system it is presumed that you want DFSMSHsm to attempt such a retry if needed, after a delay of 10 minutes, and to back up the data set even if it is still (or again) in use on the second try. The following command is added to the example system:

```
SETSYS BACKUP(INUSE(RETRY(Y) DELAY(10) +  
SERIALIZATION(PREFERRED)))
```

For the second situation, there are data sets (typically a database) that you expect to be open for update most of the time. You can use the data set backup installation exit ARCBDEXT for additional control, to direct DFSMSHsm either not to serialize before making a backup or to back up the data set even if serialization fails. The SETSYS INUSE subparameters can also apply in this situation, but the exit can override them for a given data set.

Related reading

For more information about the installation exit, see [z/OS DFSMS Installation Exits](#).

Specifying the days on which automatic backup occurs

The BACKUP parameter of the DEFINE command specifies a backup cycle that specifies the days on which the host does automatic backup processing. You can also specify the day to start the cycle so that the cycle does not change with each re-initialization of DFSMSHsm. In the example system, the following command is added to the ARCCMDxx member in each host:

```
DEFINE BACKUP(YYYYYYN CYCLESTARTDATE(1995/01/06))
```

The command establishes a 7-day cycle that begins on a Monday. Backup processing is done on every day except Sunday.

DFSMSHsm stores the date you specify with CYCLESTARTDATE as the date the backup cycle began. If you do not specify a CYCLESTARTDATE parameter with the DEFINE command but a cycle start date is already stored and the backup cycle length has not changed, DFSMSHsm uses the cycle start date that is already stored. If no cycle start date is stored and you do not specify one, DFSMSHsm uses the day that the DEFINE BACKUP command is issued as the cycle start date.

If you are backing up only to DASD, you should also specify how many DASD backup volumes you want DFSMSHsm to use for each day in the backup cycle.

Rule: The date specified for the cycle start date cannot be a date in the future. The date must always fall on or before the date that the DEFINE command is issued.

Related reading

For more information about defining the desired number of DASD backup volumes, see [“BACKUP: Specifying the backup cycle”](#) on page 814.

Defining backup volumes to DFSMSHsm

If you are using SELECTVOLUME(SPECIFIC) and TAPEDELETION(HSMTAPE), you may want to identify your backup volumes to DFSMSHsm. Use the ADDVOL command to identify the volume as a backup volume and to specify the following:

- The kind of unit for the volume
- Whether the volume is a daily backup volume or a spill volume

The following provides a sample ADDVOL command for adding a DASD daily backup volume on a unit 3390:

```
ADDVOL BAK001 UNIT(3390) BACKUP(DAILY(5))
```

This command makes BAK001 a daily backup volume that is used on day five of the backup cycle.

Figure 32 on page 193 shows the complete set of DFSMSHsm commands that the example system uses to control automatic backup processing for SMS-managed storage.

```

/* SPECIFYING THE TIME AUTOMATIC BACKUP IS TO START */
/* (PROCESSING UNITS 1, 2, AND 3) */
SETSYS AUTOBACKUPSTART(0300 0400 0500)
/* SPECIFYING THE TIME AUTOMATIC BACKUP IS TO START */

/* SPECIFYING TO DIRECT BACKUP TO TAPE, AND TO RETRY */
/* BACKUP WHEN A DATA SET IS IN USE. */

DEFINE BACKUP(YYYYYYN CYCLESTARTDATE(1995/01/06))

```

Figure 32. DFSMShsm Automatic Backup Commands for SMS-Managed Storage

Specifying duplexing for backup tapes

The duplex tape option creates two identical tapes in parallel, with one tape designated as the original and one the alternate. To create duplex backup tapes, specify:

```
SETSYS DUPLEX(BACKUP(Y))
```

If duplexing is not desired for your backup tapes, specify:

```
SETSYS DUPLEX(BACKUP(N))
```

The DFSMShsm default is no duplexing.

Automatic availability management operation

Previously, it has been pointed out how the commands to control DFSMShsm are structured for the example system. In the text that follows, the example system is used to describe what DFSMShsm does in the process of automatic availability management. Dump and backup are shown as two separate processes that contribute to total availability management.

The example system uses cartridge-type tape units in single-file mode for backup volumes. Also, the example system always selects scratch volumes because there are no volumes identified to DFSMShsm as dump or backup tape volumes and all partial tapes are marked full when they are demounted. The example system defers requests for tape mounts until OPEN processing for the data set occurs. These parameter selections minimize interference with other DFSMShsm functions when a tape mount is requested.

Dump processing

Figure 2 on page 17 shows the example system for dump processing. For this process, the dump volumes are mounted on the cartridge-type devices that are designated as 3490 with the automatic cartridge loader feature. Because dump processing moves all of the data sets on the volumes that are processed, any data set names on the volumes in each group are not shown.

Assume that it is 3 AM on 2003/02/02. This is day 28 of the dump cycle that was established with the DEFINE command. Unless a specific action is taken to prevent it, all hosts that are active begin automatic dump processing for the following reasons:

- BACKUP in the SETSYS command is specified.
- AUTODUMPSTART(0300 0400 0500) in the SETSYS command is specified.
- It is a Y day in the dump cycle.
- NOREQUEST in the SETSYS command is specified.

For SMS active hosts, at the beginning of automatic dump, DFSMSHsm obtains volume lists from storage groups that are defined to automatic dump enabled copy pools and storage groups that are pool type, automatic dump enabled, and have a status of ENABLED, QUIESCED NEW, or DISABLED NEW. If a storage group is both automatic dump enabled and defined in an automatic dump enabled copy pool, it is processed twice. If a storage group is in more than one copy pool, it can be processed multiple times. Volume priority for dump processing is determined by copy pool association, dump class stacking settings, system affinity, and SMS association. If SMS is not installed or not active, DFSMSHsm processes only non-SMS managed DASD volumes.

When DFSMSHsm is processing copy pools, volumes are considered candidates if the frequency requirement for the dump class to which the volume belongs has been met.

When DFSMSHsm processes volumes within automatic dump enabled storage groups, those volumes are only considered candidates if:

- The volume has not been processed in any host by automatic dump in the last 14 hours. Any dump that is created during copy pool processing does not apply to this 14 hour window.
- The frequency requirement that is specified for the dump class to which the volume belongs has been met.

A copy pool can be dumped at automatically scheduled intervals with Automatic Dump function. If Auto Dump = Y is specified in the copy pool construct, automatic dump checks generation 0 in the copy pool. If a DASD copy generation 0 exists and has not been previously successfully dumped, automatic dump dumps it. Automatic dump uses the Dump Class specified in the copy pool construct. If the GEN(0) version is partially complete, the failed volumes in the dump classes previously attempted are retried. The automatic dump Y|N settings of the source volumes' storage groups are ignored by automatic dump when it is processing a copy pool. The 14- hours-between-dumps limitation is also ignored by automatic dump when it is processing a copy pool.

DFSMSHsm first determines whether there are volumes with dumps that can be stacked. Those volumes associated with the same set of eligible dump classes, of which at least one has a STACK value of more than one, are considered "stackable" together. Within those volumes, the order is:

1. Affinity copy pool volumes
2. Non-affinity copy pool volumes
3. Affinity SMS volumes
4. Non-affinity SMS volumes
5. Non-SMS volumes

Volumes associated with copy pools are not stacked with non-copy pool volumes. Outside of copy pool associated volumes, dumps of SMS-managed and non-SMS-managed volumes can exist on the same dump tape. Affinity and non-affinity volumes cannot be stacked on the same tape. For more information about dump stacking, see [“DUMPCCLASS\(STACK/MAXSTACK\) and DUMPCCLASS\(MINSTACK\): Specifying the maximum and minimum number of dump copies that are stacked for this dump class” on page 825.](#)

After all volumes eligible for stacking have been dumped, the remaining volumes are dumped, with DFSMSHsm selecting the order of processing as listed above.

After DFSMSHsm has attempted to process all the candidate volumes eligible for automatic dump, it retries the selection of any of these volumes found in use by another DFSMSHsm function.

Dump processing is performed in four phases in the primary host and in one phase in the non-primary hosts. These phases are:

- Delete expired dump copies (primary host only).
- Dump DFSMSHsm-managed volumes for which automatic dump is requested.
- Delete and uncatalog excess dump VTOC copy data sets (primary host only).
- Delete DFSMSHsm inactive empty dump containers (primary host only).

Note: Empty dump container deletion occurs only on an 'N' day in the dump cycle, as specified in the [“DUMPCYCLE: Specifying the automatic dump cycle”](#) on page 829 command.

If a secondary host is made eligible to take over for a primary host that has failed, it can perform the expiration of dump copies, and deletion of excess dump VTOC copy data sets.

Deleting expired dump copies

In the first phase of automatic dump on the primary host, the expired dump copies are deleted. Dump copies become eligible to be automatically deleted when they expire or when the maximum number of dump generations is reached and a new generation of dump copies is to be made. Dump copies are automatically deleted after the number of days that are specified in the RETENTIONPERIOD subparameter of the DUMPCLASS parameter of the DEFINE command elapsed. This phase of automatic dump causes the status of the dump tapes containing the deleted copies to be changed from expired to available if they remain under DFSMSHsm control.

Automatic dump expiration is performed at the dump class level for both copy pool volumes and noncopy pool volumes residing on tape and in cloud storage. DFSMSHsm does not automatically delete the last and only remaining copy of a source volume. The dump volumes that make up this dump copy remain in EXPIRED status. To determine which dump tapes are currently in EXPIRED status, issue the LIST DUMPVOLUME command with the SELECT(EXPIRED) option. To delete the dump volumes in this copy, issue the DELVOL command with the LASTCOPY option for one of the dump volumes. The COPYPOOLCOPY keyword must also be specified if the dump volumes belong to a copy pool version. All volumes in the copy are then deleted. You can delete the last dump class for a copy pool version using the FRDELETE command. Automatic dump expiration of copy pool copies might extend the automatic dump window because of the additional CDS records that need to be accessed and any overlap with existing non-copy pool dump expiration.

To list cloud dump copies with creation and expiration information, issue the LIST PRIMARYOVLUME(*srcvol*) ALLDUMPS BCDS command. To delete the last non-copy pool dump copy residing in cloud storage, issue DDELETE VOLUME(*srcvol*) LASTCOPY DATE(*yyyy/mm/dd*) TIME(*hhmmss*) command.

Deleting empty dump containers

Auto dump processing on a primary host scans for inactive empty DFSMSHsm dump containers and deletes them. A dump container within the current creation period is considered active and, therefore, is not deleted.

Defining what to do with tapes marked unavailable during DUMP processing

When dump processing encounters an I/O error on the output tape, DFSMSHsm marks the tape unavailable. The tape is left under DFSMSHsm's control to prevent re-release of the unavailable tape. This prevents DFSMSHsm from selecting the tape for scratch, and prevents other system functions from encountering the unavailable tape before reinitialization.

Use the following procedure to remove the tape from DFSMSHsm's control:

- Issue the LIST DUMPVOLUME SELECT(UNAVAILABLE) command to get a list of the tapes marked unavailable.
- Run the relabel utility that is provided by your tape management system, such as EDGINERS from DFSMSrmm. If no tape management system is available, use the IEHINITT utility.

- Issue DELVOL *volser* DUMP(PURGE) for each volume.

Dumping DFSMSHsm-managed volumes

Before beginning this phase, each host obtains from SMS a list of the volumes in copy pools and storage groups that have the AUTODUMP attribute = Y. It also obtains a list of the dump classes to which the volumes in each copy pool and storage group are to be dumped. DFSMSHsm then starts automatic dump tasks in each host, until each host has as many dump tasks as are specified by the MAXDUMPTASKS parameter of the SETSYS command. Volumes in copy pools are processed first.

The following process is followed first for volumes with dumps that can be stacked, then for the remaining volumes: If the maximum number of dump tasks is reached and there are still more volumes to process, DFSMSHsm waits for any already-active volume dump task to complete dumping its current volume. When a volume dump task completes dumping its current volume, it begins dumping the next DFSMSHsm-managed volume with the automatic dump attribute. This process continues until all DFSMSHsm-managed volumes have been dumped, or the quiesce time is passed.

When processing each volume, DFSMSHsm checks the FREQUENCY and DAY subparameters specified in the dump classes to which the volume is assigned. If the DAY corresponds with the day of the dump cycle, and the time since the volume was last dumped is not less than the FREQUENCY specified, the volume is dumped to that dump class. The determination of frequency of dumps includes dumps made by command as well as automatic dumps.

As an example of the effect of the DAY and FREQUENCY subparameters, it has been stated that you are beginning this description of processing for day 28 in a specific dump cycle. Consider volume SG2002 in [Figure 2 on page 17](#). Storage Group 2 specifies that the volumes be dumped to dump classes ONEWEEK and TWOWEEK. Now assume that someone had issued a command to dump SG2002 to dump class ONEWEEK on day 16 of the dump cycle. SG2002 would not have been dumped on day 21, as was specified by ONEWEEK for that day, because less than seven days had elapsed since it was last dumped. It is now day 28. Dump class ONEWEEK specifies that you can dump the volume to it every seven days, so that SG2002 is dumped to dump class ONEWEEK.

Now consider volume SG4001. Storage Group 4 is dumped to dump classes ONEWEEK and FOURWEEK. Dump class FOURWEEK specifies that volumes can be dumped to it only on day 28 in the dump cycle. Therefore, SG4001 is dumped to dump class FOURWEEK because it is day 28 in the dump cycle.

If the maximum number of dump generations has been reached and another dump is to be performed, the oldest generation is deleted. If the RETENTIONPERIOD has the attribute of NOLIMIT, a dump copy is automatically deleted only when it is a member of a dump generation that exceeds the maximum of 100.

Copy pool dump processing is given priority in this phase. Dump processing proceeds as follows:

- Copy pool volumes with affinity to the processing host that are to be stacked
- Copy pool volumes with no affinity that are to be stacked
- Non-copy pool volumes with affinity to the processing host that are to be stacked
- Non-copy pool volumes with no affinity that are to be stacked
- Copy pool volumes with affinity that are not to be stacked
- Copy pool volumes with no affinity that are not to be stacked
- Non-copy pool volumes with affinity that are not to be stacked
- Non-copy pool volumes with no affinity that are not to be stacked
- Non-SMS volumes

During dump processing, if a dump class is not eligible because of FREQUENCY, it is not dumped regardless of its REQUIRED/OPTIONAL status. When a copy pool dump is being resumed, FREQUENCY is *not* considered. When a dump class is not added to a copy pool version because it has not met the FREQUENCY criteria, it can be added outside of the automatic dump window with the FRBACKUP DUMPONLY command

Automatic dump attempts to dump every volume in a copy pool. If any of the volumes fail, the dump version is marked as a partial success. If automatic dump terminates early, it issues message ARC1818I indicating '*n* volumes of copy pool *cpname* did not complete the dump process.' This message is issued once for each copy pool that has not completed automatic dump processing. Automatic dump continues to check for the end of the automatic dump window between each volume.

Since a copy pool is composed of one or more storage groups each having their own Auto Dump Y|N settings, it is suggested that these individual storage groups all have Auto Dump=N defined, unless there is a specific need for dumping volumes at both the copy pool and the storage group levels.

Volume serialization

DFSMSHsm always allocates the source and dump volumes for the full-volume dump before it invokes DFSMSdss. DFSMSdss performs only volume level serialization during full-volume dump processing. Because DFSMSHsm does not perform any data set serialization during full-volume dump processing, activity against a volume being dumped should be kept at an absolute minimum during the full-volume dump process, or errors will occur.

For more information about DFSMSdss full-volume dump, see [z/OS DFSMSdss Storage Administration](#).

Names of dump copy data sets

When DFSMSHsm initially allocates a dump volume for output during a volume dump operation, it generates a unique data set name and supplies this name on the dynamic allocation request. (If dump copies are being stacked on a dump volume, each dump copy is in its own file and has its own unique data set name. For each dump copy, DFSMSHsm stores the file sequence number and beginning file block ID in the BCDS records for use during restore.) Because DFSMSdss writes a full-volume dump copy as one data set, this data set name is the same for all tape volumes that are a part of the same dump copy. This name is supplied by DFSMSHsm on the dynamic allocation of a dump copy during a restore operation.

The format of the dump copy data set name is:

```
prefix.DMP.dclass.Vvolser.Dyyddd.Tssmmhh
```

where:

prefix

Prefix you specify with the SETSYS BACKUPPREFIX command.

DMP

V

D

T

Constants.

dclass

Dump class name.

volser

Source volume serial number.

yy

Last two digits of the year of the dump date stamp.

ddd

Julian day of the dump date stamp.

ssmmhh

Time in seconds, minutes, and hours.

Related reading

For more information about how the DFSMSHsm unique data set name is used, see [“Determining the dump copy data set name” on page 458](#).

Write dump VTOC copy data set

If you request it, DFSMSHsm makes a dump VTOC copy data set for each dump generation that is made for a volume. When DFSMSHsm makes a dump VTOC copy data set, it also catalogs the data set. Only a single dump VTOC copy is made for each generation, no matter how many copies are in the generation.

The dump VTOC copy data sets are physical sequential data sets written on ML1 volumes. They contain an entry for each data set VTOC entry that is in the source volume's VTOC when the volume is dumped. These data sets are created just before DFSMSHsm invokes DFSMSdss. VTOC copy data sets are not made when DFSMSHsm dumps a DFSMSHsm-owned volume.

The data set name of the dump VTOC copy is:

```
prefix.DUMPVTOC.Tssmmhh.Vvolser.Dydddd
```

where:

prefix

Prefix you specified with the BACKUPPREFIX parameter of the SETSYS command.

DUMPVTOC

T

V

D

Constants.

ssmmhh

Time in seconds, minutes, and hours.

volser

Source volume serial number.

yyddd

Year and day.

With the following sample job, you can selectively copy all dump VTOC copy data sets to tape. These tapes can be taken off site as a group for use during the recovery and restore process.

```
//DFDSSDUMP JOB 'ACCOUNT #' , 'NAME' , MSGLEVEL=(1,1)
//          EXEC PGM=ADRDSSU
//SYSPRINT DD SYSOUT=A
//TAPE2    DD UNIT=3490 , VOL=SER=DPVTOC , LABEL=( , BLP)
//SYSIN     DD *
            DUMP DATASET (INCLUDE(prefix.DUMPVTOC.**))
            OUTDDNAME (TAPE2)
/*
```

Selecting tape dump volumes

For information about selecting tape dump volumes, see [z/OS DFSMSHsm Implementation and Customization Guide](#).

Deleting and uncataloging excess dump VTOC copy data sets

When a volume dump of a level 0 volume is directed to a dump class that has a VTOCCOPIES value greater than zero, a VTOC copy data set is created. Only one VTOC copy data set is created for each dump generation. If more dump copies of a given volume associated with the same dump class are kept than the specified limit of VTOCCOPIES, the VTOC copies created for the older dumps are excess. If the VTOC copy is in excess for all other dump copies in the same generation, the VTOC copy is deleted and uncataloged during this phase of automatic dump.

Automatic backup processing

Assume that it is 3 a.m. in the morning. Because this is a Monday, it is a Y day in the backup cycle. The combination of the Y day in the backup cycle, the BACKUP parameter of the SETSYS command, and the AUTOBACKUPSTART parameter of the SETSYS command cause automatic backup to start in host 1.

Automatic backup is performed in four phases:

1. Backing up the control data sets
2. Moving backup versions
3. Backing up migrated data sets
4. Backing up DFSMSHsm-managed volumes

In multiple DFSMSHsm-host configurations, only the primary host performs the first three phases. The first three phases are performed as successive phases of a single task.

If the primary host fails in a multiple DFSMSHsm-host environment where the secondary host promotion function is being used, the promoted host can take over the first three phases for the failed primary host.

At the beginning of backup in each of the hosts, DFSMSHsm requests a list of all defined management classes. If SMS does not return the list, DFSMSHsm considers SMS inactive and issues a message that backup cannot be performed for SMS-managed volumes. If SMS is active, DFSMSHsm obtains a list of the volumes associated with storage groups that the host is allowed to process, and that have the following characteristics: the AUTO BACKUP ==> Y attribute, are type POOL, and have a status of ENABLED, QUIESCED NEW, or DISABLED NEW. Volumes in storage groups that have a host specified by the BACKUP SYSTEM/SYSPLEX NAME have a host affinity. If SMS is not installed and active, DFSMSHsm processes only non-SMS-managed DASD volumes. For purposes of the illustration, it is assumed that SMS is installed and active.

DFSMSHsm selects the following order of processing as a method of controlling input path contention, subject to prioritization for SMS volumes restricted to processing by one host:

1. Affinity SMS volumes
2. Retry of in-use affinity SMS volumes
3. Non-SMS and nonaffinity SMS volumes

After DFSMSHsm has attempted to process all candidate volumes eligible for automatic backup, DFSMSHsm retries the selection of any of these volumes found in-use by another DFSMSHsm function.

Related reading

- For more information about secondary host promotion, see [z/OS DFSMSHsm Implementation and Customization Guide](#).
- For more information about retrieving a list of management classes and a list exception, see [“DFSMSHsm retrieval of management classes” on page 464](#).

Phase 1: Backing up the control data sets

The first phase of automatic backup is the backing up of the DFSMSHsm control data sets (CDS). This process is called CDS version backup, and it is controlled by the CDSVERSIONBACKUP parameter of the SETSYS command.

Before backing up the control data sets and the journal data set, DFSMSHsm issues an exclusive enqueue against the control data sets. In a multiple DFSMSHsm-host environment, if the control data sets are *not* being accessed with RLS, DFSMSHsm reserves the volumes containing the journal and the control data sets. If the control data sets *are* being accessed using RLS, DFSMSHsm does an exclusive enqueue. If XCF is available in the multi-host environment, the CDS backup host will notify other hosts through XCF that the enqueue is needed.

The use of the concurrent copy function will reduce the duration of complex-wide serialization of the DFSMSHsm CDS resources when performing CDS version backup and, when SETSYS JOURNAL(RECOVERY) is specified, non-intrusive journal backup is used to further reduce the duration (see [“Using non-intrusive journal backup”](#) on page 496). This time reduction increases the availability of DFSMSHsm functions and non-intrusive journal backup allows DFSMSHsm activity to continue during the journal backup. To achieve the highest level of DFSMSHsm availability, you should place the control data sets on SMS-managed devices that support the concurrent copy function, and you should use DFSMSdss to back up the control data sets. If DFSMSdss backs up to tape, each CDS (or each cluster if multi-cluster control data sets are used) is copied to an individual tape drive (in parallel). Use of concurrent copy is required in order to use non-intrusive journal backup.

If CDS backup is invoked while the control data sets are accessed in RLS mode, DFSMSdss must be the datamover. If the backup is directed to tape, the PARALLEL parameter of the SETSYS CDSVERSIONBACKUP(BACKUPDEVICECATEGORY) must be specified. Automatic backup overrides the settings if they are not correct and issues error message ARC0793I. CDS backup fails.

Using the CDSVERSIONBACKUP parameter, you can specify how many versions of the CDS backups be kept active. Each time CDS version backup runs, DFSMSHsm assigns a new version number to the newly-created backup data sets and uses that version number as the final qualifier of the CDS backup data set names.

When backing up control data sets to tape, DFSMSHsm always creates and catalogs the new version and expires the oldest version, so that only the latest versions are available. When backing up the control data sets to DASD, the oldest existing version is reused to record the new backup, and when the backup is complete, that oldest version is renamed and recataloged as the newest version.

DFSMSHsm optionally invokes the CDS backup installation exit (ARCCBEXT) that allows you to access or validate the backup versions after DFSMSHsm creates them.

When the CDS backup is complete, DFSMSHsm releases the volumes containing the journal data set and each control data set, and removes the exclusive enqueue against the control data sets, allowing other DFSMSHsm functions to proceed.

Related reading

- For more information about non-intrusive journal backup, see [“Using non-intrusive journal backup”](#) on page 496.
- For more information about the ARCCBEXT installation exit, see [z/OS DFSMS Installation Exits](#).

Phase 2: Moving backup versions

Before moving backup versions, DFSMSHsm checks to see if any internal TAPECOPY processing is needed for backup volumes, and if so, schedules internal TAPECOPY MWEs. TAPECOPY processing could be needed because of duplexing errors.

Backup versions that are created by data set backup commands may be stored temporarily on ML1 volumes. After DFSMSHsm backs up the control data sets, the primary host moves any backup versions created by data set backup commands that are temporarily residing on ML1 volumes to daily backup volumes.

The primary host is the only host that moves backup versions. Backup versions are moved only once a day and normally during automatic backup. However, if automatic backup is not scheduled to run on a particular day, you can use the ML1BACKUPVERSIONS parameter of the FREEVOL command to move backup versions. Automatic backup is not scheduled to run if you have specified SETSYS AUTOBACKUPSTART(0) or have specified N for this day in the backup cycle.

Phase 3: Backing up migrated data sets

A migrated data set might not have a backup version because it has migrated after it was created or changed but before it was backed up. Such a condition could occur if a MIGRATE command were issued

for the data set shortly after it was created or changed. The migration could be to either an ML1 volume or a DASD ML2 volume.

A data set needs to be backed up when all of the following apply:

- The data-set-changed indicator is on.
- The value of the AUTO BACKUP attribute in the management class is Y.
- The value of the ADMIN OR USER COMMAND BACKUP attribute in the management class is not NONE.
- The value of the AUTO BACKUP attribute in the storage group is Y.

If DFSMSHsm recalls the data set before it is backed up, DFSMSHsm does not back up the data set from the migration volume. Instead, DFSMSHsm backs up the data set when it backs up the DFSMSHsm-managed volume that now contains the data set.

If you specify the BACKDS command to back up a migrated data set, DFSMSHsm does not back up the data set again during this phase.

The primary host is the only host that backs up migrated data sets. Migrated data sets are backed up once a day and normally during automatic backup. However, if automatic backup is not scheduled to run on a particular day, you can use the BACKUP parameter of the RELEASE command to back up migrated data sets.

In backing up migrated data sets, DFSMSHsm reads the required records in the BCDS. As each record is read, DFSMSHsm passes control to the data set backup installation exit (ARCBDEXT) if the installation exit is enabled. If ARCBDEXT does not prevent backup, DFSMSHsm checks (1) the BACKUP FREQUENCY attribute from the management class associated with the data set when the data set migrated, and (2) the recorded last backup date. If the number of days since the last backup date equals or exceeds the BACKUP FREQUENCY attribute value, DFSMSHsm backs up the data set. If DFSMSHsm cannot determine a last backup date and no backup version exists, it backs up the data set. If the number of days since the last backup date is less than the BACKUP FREQUENCY attribute value, DFSMSHsm retains the information in the BCDS and does not back up the data set. If the exit returns a RETAINDAYS value for the data set, it is stored in the MCC and the MCB records.

Related reading

For more information about the ARCBDEXT installation exit, see *z/OS DFSMS Installation Exits*.

Phase 4: Backing up SMS-managed volumes from storage groups with the automatic backup attribute

Before backup processing begins for SMS-managed volumes, DFSMSHsm requests from SMS a list of management classes defined to the configuration in which DFSMSHsm is running. Successful return of the list of management classes indicates that SMS is installed and active. If DFSMSHsm does not receive the list of management classes, it issues a message to indicate that backup cannot be performed for SMS-managed volumes.

If SMS is active, DFSMSHsm retrieves the list of volumes associated with storage groups that have the AUTO BACKUP attribute value of Y. After it retrieves the list of volumes, DFSMSHsm starts the backup tasks up to the maximum specified by the MAXBACKUPTASKS parameter of the SETSYS command in the particular host. If the maximum number of backup tasks is reached and still more volumes must be processed, DFSMSHsm waits for any already-active volume backup task to complete backing up its current volume. When a volume backup task completes backing up its current volume, it begins backing up the next SMS-managed volume with the automatic backup attribute. This process continues until all SMS-managed volumes have been backed up or the quiesce time has passed.

Backup processing examines each data set on the volume individually. Backup processing for each data set:

- Checks for unmatched data sets and issues a message
- Deletes temporary data sets

- Creates a VTOC copy data set entry for the volume
- Backs up the eligible data sets
- Resets the data-set-changed indicator and the last backup date

Processing unmatched data sets

If the catalog entry, the data set VTOC entry, or both, are missing, the data set is an unmatched data set. For an unmatched data set, the space management and backup exit (ARCSAEXT) is invoked if the exit is enabled. If the exit indicates that further eligibility testing be performed for this data set, DFSMSHsm issues a message that this data set is unmatched. If the exit indicates that further eligibility testing not be performed, DFSMSHsm issues no message. In either case, processing continues on the next data set.

Deleting temporary data sets

If for some reason (such as a system outage) SMS-managed temporary data sets are not deleted at end of job, DFSMSHsm attempts to delete them during backup. In a JES3 environment, an SMS-managed temporary data set must be two days old before it can be deleted. These data sets must be as old or older than the integrity age, which is normally zero days, but can be one or two days.

Related reading

For more information about data set integrity age, see [“Integrity age for space management”](#) on page 56.

Create a VTOC copy data set entry for the volume

As DFSMSHsm examines each data set, it creates a VTOC copy data set entry from the information contained in the data set’s VTOC entry. The VTOC copy data set is used in recovering a complete volume. The VTOC copy data set is stored on an ML1 volume.

For SMS-managed volumes, DFSMSHsm records all the data sets on the volume except unmatched data sets and temporary data sets.

DFSMSHsm keeps the two most recent versions of the VTOC copy data sets for the volumes it backs up. If an excess VTOC copy results when DFSMSHsm backs up a volume, it deletes the oldest VTOC copy data set.

The VTOC copy data set is used to guide volume recovery. When a VTOC copy data set is written, DFSMSHsm catalogs the data set.

For each volume that is backed up, DFSMSHsm generates a unique name for the backup VTOC copy data set. The data set name of the VTOC copy is:

```
prefix.VTOC.Tssmmhh.Vvolser.Dyyddd
```

where:

prefix

Prefix you specified with the BACKUPPREFIX parameter of the SETSYS command, if entered.
Otherwise, the DFSMSHsm default UID.

VTOC

T
V
D

Constants.

ssmmhh

Time in seconds, minutes, and hours.

volser

Source volume serial number.

yyddd

Year and day.

With the following sample job, you can selectively copy all backup VTOC copy data sets to tape. These tapes can be taken off site as a group for use during the recovery/restore process.

```
//DFDSSDMP  JOB 'ACCOUT #', 'NAME', MSGLEVEL=(1,1)
//          EXEC PGM=ADRDSSU
//SYSPRINT  DD SYSOUT=A
//TAPE1     DD UNIT=3490, VOL=SER=BUVTOC, LABEL=(, BLP)
//SYSIN     DD *
            DUMP DATASET (INCLUDE(prefix.VTOC.**)) OUTDDNAME (TAPE1)
/*
```

Backing up eligible data sets

DFSMSHsm loops through the entries for the data sets on the volume and backs up all those data sets that are eligible. An eligible data set is one that:

- Has the management class ADMIN OR USER COMMAND BACKUP attribute value of ADMIN or BOTH
- Has the management class AUTO BACKUP attribute value of Y
- Has eligibility, as determined by the data-set-changed indicator, as follows:
 - If the data-set-changed indicator is off and SETSYS INCREMENTALBACKUP(ORIGINAL) is specified, DFSMSHsm backs up the data set if no prior backup version exists.
 - If the data-set-changed indicator is on and DFSMSHsm can determine a last backup date, DFSMSHsm backs up the data set if the number of days since the last backup date equals or exceeds the value specified with the management class BACKUP FREQUENCY attribute.
 - If the data-set-changed indicator is on but DFSMSHsm cannot determine a last backup date (indicating a new data set), DFSMSHsm backs up the data set.
 - If the data-set-changed indicator is on and the data set resides on a volume in a storage group that is defined with the GUARANTEED BACKUP FREQUENCY attribute, DFSMSHsm backs up the data set if the number of days since the last backup date equals or exceeds the value that is specified by GUARANTEED BACKUP FREQUENCY days.

If the data set is eligible for backup and the exit is enabled, DFSMSHsm passes control to the data set backup exit (ARCBDEXT).

For those data sets that are backed up, DFSMSHsm invalidates the oldest excess versions that exceed the limit specified with the NUMBER OF BACKUP VERSIONS (DATA SET EXISTS) management class attribute.

Related reading

- For more information about the ARCBDEXT installation exit, see [z/OS DFSMS Installation Exits](#).
- For more information about data mover support for DFSMSHsm availability management for backup data sets, see the table about availability management and data mover support in [z/OS DFSMSHsm Implementation and Customization Guide](#).

Resetting the data-set-changed indicator and last backup date

After each data set is backed up, if the backup was serialized, the data-set-changed indicator is turned off in the data set's VTOC entry on the source volume. The data-set-changed indicator is also turned off for data sets that are not serialized, if DFSMSHsm has been configured not to serialize on the first attempt to back up.

Note: For non-VSAM multivolume data sets, the data-set-changed indicator is reset on each volume that the data set is cataloged to.

No serialization is an option of the ARCHBACK user macro and the ARCBDEXT installation exit. However, the ARCINBAK inline backup program always specifies this option, because it expects the JCL to perform

its own serialization. In addition, the current date is written in the catalog entry and in the last backup date field in its own MCB record.

Backing up VSAM data sets

DFSMSHsm backup functions that exist for non-VSAM data sets also exist for VSAM data sets cataloged in the integrated catalog facility catalog. DFSMSHsm backs up VSAM data sets on level 0 volumes by using the Access Method Services EXPORT command or DFSMSdss as a data mover.

The backup of a VSAM data set is performed only on a complete VSAM sphere. The base cluster and all alternate index clusters defined on the base cluster are backed up as part of the data set and are not specified separately. Paths are included automatically in the data set backup.

Note: When a VSAM compressed data set is backed up, DFSMSHsm suspends any software compaction requested and records in the BCDS that the data set is striped, compressed, or both.

DFSMSHsm can back up multiple-volume, SMS-managed, VSAM data sets when it processes the first volume of the base data component. Normally, DFSMSHsm prevents update access to any VSAM data set that is currently being backed up. This is done to prevent possible inconsistency of the backup copy.

Tip: You can override this protection for VSAM data sets with the SETSYS INUSE RETRY command or the ARCBDEX exit.

Some installations, however, would prefer that their jobs not fail when they attempt to open a VSAM data set that is currently being backed up. There are two methods to accomplish this, one which includes the risk of having a corrupted backup copy, and one which excludes that risk:

- One method is to use the DFSMSHsm data set backup installation exit, ARCBDEX. This exit can be coded to change the way DFSMSHsm performs serialization on VSAM data sets, allowing batch jobs to open the data sets while the data sets are being backed up. This technique, however, exposes installations to the possibility of creating unserialized backup copies.
- The other method is to add an IEFBR14 step to any batch job that accesses any VSAM data set for updating. The only function of the added step is to access the data set with a DISP of MOD or OLD. This step should be placed immediately before the step that accesses the data set for updating. The IEFBR14 step attempts to get an exclusive ENQ on the data set, which causes the job to wait until DFSMSHsm has finished processing the data set before the subsequent step accesses the data set. This method may require more time to implement than the ARCBDEX solution, but it does eliminate the possibility of having corrupted backup copies.

Related reading

- For more information about the ARCBDEX installation exit, see [z/OS DFSMS Installation Exits](#).
- For more information and an example of how to use the ARCBDEX installation exit in the SYS1.SAMPLIB file, see [z/OS DFSMSHsm Implementation and Customization Guide](#).

Generating names of backup versions of data sets

For each data set that is backed up, DFSMSHsm generates a name for the backup version. The name also applies to the name of the backup version of the integrated catalog facility catalog and to DFSMSHsm backup profiles. The name is in the form:

```
prefix.BACK.Tssmmhh.user1.user2.Xydd
```

If patch-enabled, the following dataset name will be generated:

```
prefix.BACK.Tcccchh.user1.user2.Xydd
```

where:

prefix

Prefix you specify with the SETSYS BACKUPPREFIX command.

BACK**T**

Constants.

Note: If two data sets with the same first two high-level qualifiers are backed up at the same second on the same day, DFSMSHsm assigns a letter other than T to one of these data sets.

ssmmhh

Time in seconds, minutes, and hours.

If the format is Tcccchh, then cccchh is the time in hundredths of seconds from the beginning of the hour converted to four alphabetic characters, and hh is hours.

The four characters cccc may be converted to time as follows:

1. Create a variable for each character of the string cccc, using *p1* through *p4*, from left to right. Then assign a value 0 thru 24 for each character A thru Y in the sequence. (Note that 25 characters are used, for A through Y, but not Z.)
2. Find the total hundredths of seconds from the beginning of the hour using this formula:

```
hunds_seconds_begin_hour = p1+(p2*25)+(p3*625)+(p4*625*25)
```

3. Find the minutes, seconds, and hundredths using these formulae (% = integer division):

```
minutes = hunds_seconds_begin_hour%(60*100)
seconds = (hunds_seconds_begin_hour-minutes*60*100)%100
hundredths = hunds_seconds_begin_hour-minutes*60*100-seconds*100
```

cccchh

The time in hundredths of seconds from the beginning of the hour converted to four alphabetic characters (cccc) and hours (hh).

The four characters cccc may be converted to time as follows:

1. Create a variable for each character of the string cccc. Assume these variables are *p1* thru *p4*, from left to right. Assign a value 0 thru 24 for each character A thru Y, in sequence (25 characters are used A - Y, but not Z).
2. Find the total seconds from the beginning of the hour:

```
hunds_seconds_begin_hour = p1+(p2*25)+(p3*625)+(p4*625*25)
```

3. Find minutes, seconds, and hundredths (% = integer division):

```
minutes = hunds_seconds_begin_hour%(60*100)
seconds = (hunds_seconds_begin_hour-minutes*60*100)%100
hundredths = hunds_seconds_begin_hour-minutes*60*100-seconds*100
```

For more information, refer to [Changing DFSMSHsm backup and migration generated data set names to reduce contention for similar names and eliminating a possible performance degradation in z/OS DFSMSHsm Implementation and Customization Guide](#).

user1**user2**

First two qualifiers of the data set name.

Xydd

Decade, year, and day of the year. Valid character values for X are:

G

1970

H

1980

I

1990

J	2000
A	2010
B	2020
C	2030
D	2040
E	2050
F	2060

For example, J3032 represents February 1, 2003.

If you need to access a single-file format tape, you must specify a valid data set name for the single file that comprises up to 254 tape volumes. The backed up data set name for each set of cartridge-type tape volumes in single-file format is:

```
prefix.BACKTAPE.DATASET
```

The tape data set name for each copy of a cartridge-type tape volume created by the TAPECOPY command or the duplex tape option is:

```
prefix.COPY.BACKTAPE.DATASET
```

Only the last 17 characters (.BACKTAPE.DATASET) are recorded in the tape label. To access the single-file format data set, you must supply any valid first qualifier along with the .BACKTAPE.DATASET qualifiers.

Backing up RACF discrete profiles for cataloged data sets

When DFSMSHsm backs up a cataloged RACF-indicated data set, it optionally creates a RACF profile, called the backup profile. The original data set's profile is a model for the backup profile, but the volume serial number is MIGRAT, which means the backup profile does not correspond to an existing data set. This eliminates the need for further updates to the backup profile when DFSMSHsm moves the backup versions from an ML1 volume or backup volume to a daily or spill backup volume. After the backup profile is created, it does not have to be changed. DFSMSHsm uses the backup profile for authorization checking during recovery if the discrete profile for the original data set no longer exists or if the authorization check against the original profile fails.

DFSMSHsm also uses the backup profile for authorization checking during HALTERDS and HBDELETE processing if the authorization check against the original profile fails.

You use the PROFILEBACKUP or NOPROFILEBACKUP parameter of the SETSYS command to specify whether DFSMSHsm creates backup profiles. If you specify PROFILEBACKUP, the backup prefix defined to DFSMSHsm or the default backup prefix of HSM must be a user ID or group defined to RACF.

DFSMSHsm maintains only one backup profile for each cataloged, RACF-indicated, VSAM or non-VSAM data set, no matter how many backup versions of the data set are maintained. The backup profile is always associated with the latest backup version of a data set that was RACF-indicated and cataloged at the time of backup. If you delete the latest backup version of a cataloged, RACF-indicated data set through the BDELETE or HBDELETE command, the backup profile is transferred to the next latest backup version of the data set that was made from a RACF-indicated, cataloged data set. DFSMSHsm does not create backup profiles when it backs up uncataloged data sets.

If the DFSMSHsm-started procedure is not associated with a RACF user ID, the user and group names in the backup profile will be “*”.

DFSMSHsm backs up cataloged, RACF-indicated data sets even if a backup profile is not created or transferred.

Profile backup for migrated data sets

If a migrated data set is being backed up, DFSMSHsm uses the RACF profile of the data set as a model for creating the backup profile.

Deleting backup profiles

When DFSMSHsm creates a new backup profile for a data set, it deletes all previously created backup profiles for the data set.

When backup versions of cataloged, RACF-indicated data sets become obsolete, DFSMSHsm deletes their associated backup profiles even if you specified the NOPROFILEBACKUP parameter of the SETSYS command after the backup profiles were created.

Note: Depending on the release of RACF you are using, you can distribute the location of backed up RACF profiles throughout the RACF data set.

Related reading

For more information about distributing the location of backed up RACF profiles, see [z/OS DFSMSHsm Implementation and Customization Guide](#).

Parameters used in creating backup profiles

DFSMSHsm's access control environment element (ACEE) is used when backup profiles are created. If the user ID associated with the DFSMSHsm startup procedure has profile modeling active or is in a group for which profile modeling is active, any access list associated with the model profile is added to the backup profiles. If a profile is recovered that uses the backup profile as a model, the additional user IDs in the access list are attached to the recovered profile.

Selecting daily backup volumes

When DFSMSHsm selects a backup volume, it considers whether this is initial volume selection or subsequent volume selection.

If an error occurs during the selection process for a tape and the error is associated with a particular volume, DFSMSHsm considers the tape backup volume unavailable for backup processing and selects another backup volume. Each time DFSMSHsm is started, all nonfull backup volumes are considered available for backup processing.

The error handling and tape selection process differs when using the duplex tape option for your backup tapes.

Unless they are superseded by the BACKUPDEVICECATEGORY parameter of the BACKVOL or ADDVOL commands, the subparameters of the BACKUP parameter of the SETSYS command control the type of backup volume selected for output during backup processing:

- SETSYS BACKUP(ANY) specifies that any type of backup volume (DASD) or TAPE) defined to DFSMSHsm with the ADVOL command can be selected for output during backup processing. The backup volume has to be nonfull, unallocated, daily backup assigned to the current day in the backup cycle. You must ADDVOL DASD or TAPE volumes to DFSMSHsm for volume selection. If none are defined or available, DFSMSHsm fails the request.
- SETSYS BACKUP(DASD) specifies that only DASD backup volumes are selected for output during backup processing.
- SETSYS BACKUP(TAPE) specifies that only tape backup volumes are selected for output during backup processing. The automatic class selection (ACS) routines determine whether the backup function is directed to a system-managed tape library.

- SETSYS BACKUP(TAPE(*unittype*)) specifies that only tape backup volumes are selected for output during backup processing. The ACS routines determine whether the backup function is directed to a system-managed tape library.

When the backup function is not using a system-managed tape library, UNITTYPE specifies that only tape backup volumes capable of being mounted and written to on the specified type of unit are selected for output during backup processing.

DFSMSHsm backs up users' data sets to daily backup volumes during volume backup. Daily backup volumes either are assigned by the storage administrator to a day in the backup cycle before DFSMSHsm uses them or are assigned when DFSMSHsm selects a volume added as a backup volume.

During backup of a level 0 volume, backup of migrated data sets, or movement of backup versions, DFSMSHsm searches for a target volume as follows:

- It finds a volume already associated with the current day in the backup cycle that is neither full nor in use.
- It reuses a previously full volume.
- It assigns an additional volume.
- It waits for another task to finish using an acceptable volume.

DFSMSHsm stops the search as soon as it finds an acceptable volume. If it does not find an acceptable volume, DFSMSHsm stops processing the requested backup function.

DFSMSHsm determines which daily backup volume to use by considering:

- The status of volumes previously used on this day in the backup cycle. This includes whether this is initial volume selection or subsequent volume selection.
- The backup attributes of the volume being backed up.
- The directions the storage administrator gives to DFSMSHsm.

If an error occurs during the selection process and the error is associated with a particular volume, DFSMSHsm considers the volume unavailable for backup processing and selects another daily backup volume. Each time DFSMSHsm is started, the target volumes previously considered unavailable for backup processing are reinstated as available volumes.

When DFSMSHsm initially selects a daily backup volume, it tries to find one that meets the following characteristics:

- The volume is already assigned to the current day in the backup cycle.
- The volume has the appropriate backup device category.
- The volume is not full.
- The volume is not being used by another task in this or another host.

After a volume backup task has obtained a daily backup volume, it continues to use that volume until the volume is no longer needed, the volume becomes full, or certain error conditions occur.

Now consider the processing that occurs when you specify the backup device categories of DASD, TAPE, or NONE.

Selecting DASD daily backup volumes

For SMS-managed volumes, you specify a backup device category for the entire system with the BACKUP parameter of the SETSYS command. Suppose that you specified SETSYS BACKUP(DASD). In this environment, DFSMSHsm uses DASD unless a command backup for a volume specifies another device category. DFSMSHsm uses DASD daily backup volumes even if the storage administrator has specified the ADDVOL command to add tape daily backup volumes.

Selection of DASD daily backup volumes depends on the daily limit you specify for the backup cycle. The daily limit determines at what point volume backup stops assigning more DASD daily backup volumes to this day in the backup cycle and instead tries to reuse the full DASD daily backup volumes already assigned to this day in the backup cycle. The daily limit has little or no value when backup output is to tape.

Until the daily limit is reached, DFSMSHsm attempts to associate another backup volume with the day in the cycle. DFSMSHsm then reuses as many of these daily backup volumes as necessary during this day in the backup cycle as long as enough space is available on the DASD daily backup volumes. You use the BACKUP parameter of the DEFINE command to define the daily limit.

If you choose a daily limit that is too small, your system will have poorer performance because it spends too much time doing cleanup for the amount of space made usable. The daily limit is too small if cleanup does not make the daily backup volumes reusable.

If you choose a daily limit that is too large, too many volumes can be assigned to a particular day in the backup cycle; therefore, available space cannot be used because it is restricted to certain days in the backup cycle. The daily limit is too large if DFSMSHsm uses only a small percentage of the daily backup volumes assigned to the day in the backup cycle on a day when a normal amount of data is backed up.

To reuse DASD daily backup volumes that were previously full, DFSMSHsm uses spill processing or cleanup processing. You specify spill processing with the SPILL parameter of the SETSYS command; only cleanup processing is done if you specify the NOSPILL parameter.

DFSMSHsm reuses DASD daily backup volumes when the following conditions occur:

- Another volume is needed.
- The number of volumes assigned to this day in the backup cycle has already reached the daily limit or there were no unassigned DASD daily backup volumes to assign to this day in the backup cycle.
- All volumes assigned to this day in the backup cycle are either being used or were marked full after being used earlier during this day in the backup cycle.

If the reuse process has tried today to use all volumes not currently in use, an additional volume is assigned from the set of unassigned DASD backup volumes, even though the number of assigned volumes exceeds the daily limit. If no unassigned DASD backup volume exists but at least one acceptable volume is being used, DFSMSHsm waits for the task to finish using the acceptable volume.

Selecting initial DASD daily backup volumes

The processing that occurs during initial selection of the DASD daily backup volumes depends on whether the daily limit has not been reached or the daily limit has been reached or exceeded.

Daily limit not reached

If all DASD daily backup volumes are full or in use before the daily limit is reached, DFSMSHsm does the following processing:

1. It assigns another DASD daily backup volume. When DFSMSHsm assigns another DASD daily backup volume, it tries to select volumes in the following order:

- a. Unassigned DASD daily backup volume. DFSMSHsm then assigns it to the current day in the backup cycle.
- b. Unassigned DASD backup volume. DFSMSHsm then assigns it as a daily backup volume and to the current day in the backup cycle.
2. It reuses a full DASD daily backup volume. When no unassigned DASD backup volumes are available, DFSMSHsm either spills or cleans up the full, unallocated, DASD daily backup volumes. DFSMSHsm uses the first volume that falls below the threshold of occupancy that you specified with the THRESHOLD parameter of the ADDVOL command.
3. It waits for a DASD daily backup volume that is in use to become available. If the spill or cleanup process does not result in a usable DASD daily backup volume and another volume backup task is currently using a DASD daily backup volume, this volume backup task waits for a DASD daily backup volume to become available.

In a multiple DFSMSHsm-host environment, before a volume backup task enters the wait state, a five-minute timer is set. When the timer expires, the volume backup task is dispatched, and DFSMSHsm tries to select another DASD daily backup volume. If the DASD daily backup volume is still not available, the volume backup task resets the timer and reenters a wait state. If another volume backup task dispatches the volume backup task in the same host before the timer expires, the timer is canceled, and DFSMSHsm tries to select the DASD daily backup volume again.

4. It stops backup processing. If DFSMSHsm cannot find a DASD daily backup volume and no other volume backup task is using a DASD daily backup volume, the current volume backup task ends because no DASD daily backup volume is available.

Daily limit reached or exceeded

If no daily backup volume is available and the number of daily backup volumes assigned to the current day in the backup cycle is greater than or equal to the daily limit, DFSMSHsm does the following processing:

1. It reuses a full DASD daily backup volume. When the daily limit has been reached or exceeded, DFSMSHsm either spills or cleans up the full, unallocated, DASD daily backup volumes. DFSMSHsm uses the first volume that falls below the threshold of occupancy that you specified with the THRESHOLD parameter of the ADDVOL command.
2. It assigns another DASD daily backup volume. If the spill or cleanup process does not result in a usable DASD daily backup volume, DFSMSHsm assigns another daily backup volume. A DASD daily backup volume is not usable if all volumes currently assigned to this day in the backup cycle are being used or have been cleaned up today. DFSMSHsm tries to select volumes in the following order:
 - a. Unassigned DASD daily backup volume. DFSMSHsm then assigns it to the current day in the backup cycle.
 - b. Unassigned DASD backup volume. DFSMSHsm then assigns it as a daily backup volume and to the current day in the backup cycle.
3. It waits for a DASD daily backup volume that is in use to become available. If the spill or cleanup process does not result in a usable DASD daily backup volume and another volume backup task is currently using a DASD daily backup volume, this volume backup task waits for a DASD daily backup volume to become available.

In a multiple DFSMSHsm-host environment, before a volume backup task enters the wait state, a five-minute timer is set. When the timer expires, the volume backup task is dispatched, and DFSMSHsm tries to select another DASD daily backup volume. If the DASD daily backup volume is still not available, the volume backup task resets the timer and reenters a wait state. If another volume backup task dispatches the volume backup task in the same host before the timer expires, the timer is canceled, and DFSMSHsm tries to select the DASD daily backup volume again.

4. It stops backup processing. If DFSMSHsm cannot find a DASD daily backup volume and no other volume backup task is using a DASD daily backup volume, the current volume backup task ends because no DASD daily backup volume is available.

Selecting subsequent DASD daily backup volumes

DFSMSHsm uses the same procedures during subsequent DASD daily backup volume selection as are described in [“Selecting initial DASD daily backup volumes”](#) on page 209. However, after a volume backup task has obtained a daily backup volume, it continues to use that volume until the volume is no longer needed, the volume becomes full, or certain error conditions occur.

If a DASD daily backup volume does not contain enough available space for the backup version of the data set DFSMSHsm is backing up or contains enough total available space but the space is too fragmented, DFSMSHsm does not back up the data set. The space is too fragmented if DFSMSHsm cannot allocate the backup version in five or fewer extents. When the allocation of the backup copy of a data set fails because the DASD daily backup volume does not have enough space for the backup version, DFSMSHsm does one of the following:

- If the percent of occupied space on the DASD daily backup volume is less than the specified threshold of occupancy, DFSMSHsm fails backup of the data set. Volume processing continues with the next eligible data set on the source volume.
- If the percent of occupied space on the DASD daily backup volume is greater than or equal to the specified threshold of occupancy, DFSMSHsm considers the DASD daily backup volume to be full. When the current DASD daily backup volume becomes full, DFSMSHsm releases it, selects another daily backup volume, and tries to back up the data set again. If DFSMSHsm cannot back up the data set a second time because the second daily backup volume does not have enough space, DFSMSHsm fails backup of the data set. However, DFSMSHsm does not consider the second DASD daily backup volume to be full. Volume backup processing continues with the next eligible data set on the source volume.

Selecting tape daily backup volumes

In the example system, the SETSYS BACKUP(TAPE) command was used to specify that all backups are to tape. In this environment, DFSMSHsm uses only tape daily backup volumes unless a volume backup command specifies backup to DASD.

If you want DFSMSHsm to use tape as a daily backup volume and you have not specified restrictions limiting selection to tape, you must define at least one tape for each of the appropriate days in the backup cycle by using the ADDVOL command. You do not have to define tapes as daily backup volumes with the ADDVOL command if you have restricted daily backup volumes to tape by:

- Specifying BDC(TAPE) on a BACKVOL command
- Specifying BACKUP(TAPE) on a SETSYS command

If you use cartridge-type tape backup volumes, DFSMSHsm writes data on the tape in a single-file format.

DFSMSHsm considers the following factors when it selects a tape backup volume:

- Whether this is initial or subsequent volume selection
- For subsequent volume selection, the type of volume selection you specified with the SELECTVOLUME parameter of the SETSYS command: specific or scratch.

Related reading

For more information about the selection of tape volumes that are in a system-managed tape library, refer to the [z/OS DFSMSHsm Implementation and Customization Guide](#).

Selecting initial tape daily backup volumes

If you have no partially filled or empty tape daily backup volumes already assigned to the day in the backup cycle, DFSMSHsm does the following processing:

1. DFSMSHsm assigns another tape daily backup volume. When these volumes are assigned, DFSMSHsm tries to select volumes in the following order:
 - a. Unassigned tape daily backup volume. DFSMSHsm then assigns it to the current day in the backup cycle.

- b. Unassigned tape backup volume. DFSMSHsm then assigns it as a daily backup volume and to the current day in the backup cycle.

If no unassigned backup volumes are available, DFSMSHsm requests a scratch tape.

2. DFSMSHsm waits for a tape daily backup volume that is in use to become available. If no scratch tape is available and another volume backup task is currently using a tape daily backup volume, this volume backup task waits for a tape daily backup volume to become available.

In a multiple DFSMSHsm-host environment, before a volume backup task enters the wait state, a five-minute timer is set. When the timer expires, the volume backup task is dispatched, and DFSMSHsm tries to select another tape daily backup volume. If the tape daily backup volume is still not available, the volume backup task resets the timer and reenters a wait state. If another volume backup task dispatches the volume backup task in the same host before the timer expires, the timer is canceled, and DFSMSHsm tries to select the tape daily backup volume again.

3. DFSMSHsm stops backup processing. If DFSMSHsm cannot find a tape daily backup volume and no other volume backup task is using a tape daily backup volume, the current volume backup task ends because no tape daily backup volume is available.

Selecting subsequent tape daily backup volumes

After a volume backup task has obtained a tape daily backup volume, it continues to use that volume until the volume is no longer needed, the volume becomes full, or certain error conditions occur.

If end-of-volume is reached while DFSMSHsm is writing on a tape daily backup volume, DFSMSHsm considers the currently mounted tape daily backup volume to be full and selects another tape volume.

A backup version of a data set can span more than one tape backup volume. DFSMSHsm fails the backup of a data set if the data set spans more than 254 tape backup volumes.

When DFSMSHsm reaches end-of-volume while writing on a tape daily backup volume, the processing that occurs depends on whether you want DFSMSHsm to select a volume from tapes already known to it, or to select a scratch tape volume.

If you specified the `SELECTVOLUME(SPECIFIC)` or `SELECTVOLUME(BACKUP(SPECIFIC))` parameter of the `SETSYS` command, DFSMSHsm selects a tape backup volume that meets the following conditions:

- The volume is added to DFSMSHsm as a tape backup volume. Use the `ADDVOL` command to add the volume to DFSMSHsm.
- The volume is empty.
- The volume is not currently being used.
- The volume has the same device type and density as the previous volume.

If DFSMSHsm cannot find a volume that meets the criteria just specified or if you specified `SETSYS SELECTVOLUME(SCRATCH)` or `SELECTVOLUME(BACKUP(SCRATCH))`, DFSMSHsm requests that a scratch tape be mounted on the already allocated unit. When the operator mounts a scratch tape, DFSMSHsm assigns it as a tape daily backup volume and assigns it to the current day in the backup cycle.

After the operator mounts the volume, DFSMSHsm continues backing up the current data set to that volume.

Certain error conditions, such as an error in writing on the tape, cause DFSMSHsm to switch tape daily backup volumes. If an error occurs, DFSMSHsm performs the following actions:

- Marks the tape daily backup volume as full
- Releases the tape volume and deallocates the unit
- Performs initial selection to select another tape daily backup volume

Selecting DASD and tape daily backup volumes

If you specify `BACKUP(ANY)` on the `SETSYS` command, you must `ADDVOL DASD` or `Tape` daily backup volumes to DFSMSHsm for daily backup selection. DFSMSHsm selects the first non-full, unallocated, daily

backup volume assigned to the current day in the backup cycle, regardless of its device category. If you want DFSMSHsm to use tape as a daily backup volume and you do not specify restrictions limiting selection to tape, you must define at least one tape for each of the appropriate days in the backup cycle by using the ADDVOL command. DFSMSHsm does not select a scratch tape if no daily or unassigned, nonfull backup volumes are found already defined to DFSMSHsm. If DASD daily backup volumes are not being used in your environment, specify SETSYS BACKUP (TAPE) rather than SETSYS BACKUP (ANY). This allows flexibility of backing up to a scratch tape if an eligible daily backup volume is not found. You do not have to define tapes as daily backup volumes with the ADDVOL command if you restrict daily backup volumes to a tape by:

- Specifying BACKUP (TAPE) on a SETSYS command.
- Specifying BACKUPDEVICECATEGORY (TAPE) on a BACKVOL command.
- Specifying BACKUPDEVICECATEGORY (TAPE) on the ADDVOL command of the nonSMS volume being backed up. When daily backup volumes are restricted to tape in one of these ways, DFSMSHsm selects a scratch tape if an eligible daily backup volume is not found.

Note: If you specify BACKUP(ANY) on the SETSYS command, DFSMSHsm selects the first nonfull, unallocated, daily backup volume assigned to the current day in the backup cycle. If you want DFSMSHsm to use tape as a daily backup volume and you do not specify BACKUP(TAPE), you must define at least one tape for each of the appropriate days in the backup cycle by using the ADDVOL command. DFSMSHsm does not select a scratch tape if no daily or unassigned nonfull backup volumes are found already defined to DFSMSHsm. However, if you restrict daily backup volumes to tape by specifying BACKUP(TAPE) on a SETSYS command, you do not have to define tapes as daily backup volumes with the ADDVOL command. DFSMSHsm selects the first nonfull, unallocated, daily backup assigned to the current day in the backup cycle. If none are available, DFSMSHsm selects a scratch tape.

Selecting initial daily backup volumes (DASD or tape)

DFSMSHsm can select either DASD or tape as a daily backup volume. The process that occurs during initial DASD or tape daily backup volume selection depends on whether the daily limit has been reached or exceeded or has not been reached.

Daily limit reached or exceeded

If no daily backup volume is available and the number of daily backup volumes assigned to the current day in the backup cycle is greater than or equal to the daily limit, DFSMSHsm does the following processing:

1. It reuses a full DASD daily backup volume. When no unassigned backup volumes are available, DFSMSHsm either spills or cleans up the full, unallocated, DASD daily backup volumes. If you specified SETSYS SPILL, DFSMSHsm spills the volumes. If you specified SETSYS NOSPILL, DFSMSHsm only cleans up the volumes. DFSMSHsm uses the first volume that falls below the threshold of occupancy (which you specified with the THRESHOLD parameter of the ADDVOL command). A DASD daily backup volume is not usable if all volumes currently assigned to this day in the backup cycle are either being used or are full and have been cleaned up today.

If the spill or cleanup process does not result in a usable DASD daily backup volume, DFSMSHsm requests a scratch tape. After a scratch tape is mounted, DFSMSHsm obtains the volume serial number and internally adds the volume as a daily backup volume assigned to the current day in the backup cycle.
2. It assigns another daily backup volume. If the spill or cleanup process does not result in a usable DASD daily backup volume, DFSMSHsm assigns another daily backup volume. When DFSMSHsm assigns another daily backup volume, it tries to select volumes in the following order:
 - a. Unassigned daily backup volume. DFSMSHsm then assigns it to the current day in the backup cycle. This daily backup volume can be tape or DASD.
 - b. Unassigned backup volume. DFSMSHsm then assigns it as a daily backup volume and to the current day in the backup cycle. This backup volume can be tape or DASD.

If no unassigned backup volume exists, DFSMSHsm requests a scratch tape. When no unassigned backup volumes are available, DFSMSHsm either spills or cleans up the full, unallocated, DASD daily backup volumes. If you specified SETSYS SPILL, DFSMSHsm spills the volumes. If you specified SETSYS NOSPILL, DFSMSHsm only cleans up the volumes. DFSMSHsm uses the first volume that falls below the threshold of occupancy (which you specified with the THRESHOLD parameter of the ADDVOL command). A DASD daily backup volume is not usable if all volumes currently assigned to this day in the backup cycle are either being used or are full and have been cleaned up today.

If the spill or cleanup process does not result in a usable DASD daily backup volume, DFSMSHsm requests a scratch tape. After a scratch tape is mounted, DFSMSHsm obtains the volume serial number and internally adds the volume as a daily backup volume assigned to the current day in the backup cycle.

3. It waits for a daily backup volume that is in use to become available. If DFSMSHsm cannot find a daily backup volume to use and another volume backup task is currently using an acceptable daily backup volume, this volume backup task waits for any type of daily backup volume to become available.
4. It stops backup processing. If DFSMSHsm cannot find the type of daily backup volume it needs and no other volume backup task is using that type of backup volume, the current volume backup task ends because no daily backup volume is available.

Daily limit not reached

If all daily backup volumes are full or in use before the daily limit for daily backup volumes is reached, DFSMSHsm does the following:

1. It assigns another daily backup volume. When DFSMSHsm assigns another daily backup volume, it tries to select volumes in the following order:
 - a. Unassigned daily backup volume. DFSMSHsm then assigns it to the current day in the backup cycle. This daily backup volume can be tape or DASD.
 - b. Unassigned backup volume. DFSMSHsm then assigns it as a daily backup volume and to the current day in the backup cycle. This backup volume can be tape or DASD.
2. It reuses a full DASD daily backup volume or requests a scratch tape. When no unassigned backup volumes are available, DFSMSHsm either spills or cleans up the full, unallocated, DASD daily backup volumes. If you specified SETSYS SPILL, DFSMSHsm spills the volumes. If you specified SETSYS NOSPILL, DFSMSHsm only cleans up the volumes. DFSMSHsm uses the first volume that falls below the threshold of occupancy (which you specified with the THRESHOLD parameter of the ADDVOL command). A DASD daily backup volume is not usable if all volumes currently assigned to this day in the backup cycle are either being used or are full and have been cleaned up today.

If the spill or cleanup process does not result in a usable DASD daily backup volume, DFSMSHsm requests a scratch tape. After a scratch tape is mounted, DFSMSHsm obtains the volume serial number and internally adds the volume as a daily backup volume assigned to the current day in the backup cycle.

3. It waits for a daily backup volume that is in use to become available. If DFSMSHsm cannot find a daily backup volume to use and another volume backup task is currently using an acceptable daily backup volume, this volume backup task waits for any type of daily backup volume to become available.

In a multiple DFSMSHsm-host environment, before a volume backup task enters a wait state, a five-minute timer is set. When the timer expires, the volume backup task is dispatched and DFSMSHsm tries to select another daily backup volume. If the daily backup volume is still not available, the volume backup task resets the timer and reenters a wait state. If another volume backup task dispatches the volume backup task in the same host before the timer expires, the timer is canceled, and DFSMSHsm tries to select the daily backup volume again.

4. It stops backup processing. If DFSMSHsm cannot find the type of daily backup volume it needs and no other volume backup task is using that type of backup volume, the current volume backup task ends because no daily backup volume is available.

Selecting subsequent daily backup volumes (DASD or tape)

DFSMSHsm uses the same procedures during subsequent daily backup volume selection as those described in [“Selecting initial daily backup volumes \(DASD or tape\)”](#) on page 213. However, after a volume backup task has obtained a daily backup volume, it continues to use that volume until the volume is no longer needed or becomes full, or until certain error conditions occur.

Selecting subsequent DASD daily backup volumes

If a DASD daily backup volume does not contain enough available space for the backup version of the data set DFSMSHsm is backing up, or contains enough total available space for the backup version but the space is too fragmented, DFSMSHsm follows the procedures described in [“Selecting subsequent DASD daily backup volumes”](#) on page 211.

If you use both DASD and tape backup volumes, DFSMSHsm can start backing up a volume to a DASD daily backup volume and continue with a tape daily backup volume. However, after DFSMSHsm has selected a tape daily backup volume to back up a volume, it uses only tape backup volumes when additional backup volumes are required for the backup of the current volume.

Selecting subsequent tape daily backup volumes

If end-of-volume is reached while DFSMSHsm is writing on a tape daily backup volume, DFSMSHsm follows the procedures described in [“Selecting subsequent tape daily backup volumes”](#) on page 212.

Backup volume spill process

Moving backup versions from DASD backup volumes to spill volumes is called *spill*. Spill is a process that applies *only* if you are using DASD devices to store your backup versions. If you use DASD as your daily backup volumes, your daily backup volumes eventually become filled with recent backup versions and older backup versions of the same data sets. The DASD daily backup volumes can also contain backup versions of deleted data sets and retired backup versions.

Note: Although both the spill and recycle process output to spill backup tapes, the spill process occurs only from DASD. Moving backup versions from tape backup volumes is part of recycle.

When adding DASD backup volumes to DFSMSHsm with an ADDVOL command, you can specify a maximum percentage of the capacity of the volume above which the volume is considered to be full after spill or cleanup processing. This percentage is called the threshold of occupancy. When a DASD daily backup volume becomes full (an allocation has been failed for lack of space), it is *spilled* by the spill process. If the spill process does not reduce the occupancy of the volume below the threshold of occupancy, the volume is still considered to be full.

The spill process moves all but the latest backup version of a data set from a DASD daily backup volume to a spill backup volume. DFSMSHsm owns the spill backup volume. During daily backup volume selection when all DASD daily backup volumes are full, DFSMSHsm uses the spill process to make space available on the full DASD daily backup volumes. The spill process produces a DASD daily backup volume usable during volume backup processing. The spill process moves the following from daily backup volumes to spill backup volumes:

- All but the latest backup version of each data set
- All retired backup versions (see [“Data set retirement”](#) on page 114)
- All backup versions of a deleted data set

If a backup version is not valid, DFSMSHsm does not move it. Instead, DFSMSHsm scratches the invalid backup version.

DFSMSHsm spills the full, unallocated, DASD daily backup volume that is assigned to the current day in the backup cycle and that has not been spilled in the longest period of time. If the volume spill process is successful, the DASD daily backup volume is used for the backup of the DFSMSHsm-managed volumes.

Otherwise, DFSMSHsm spills the full, unallocated, DASD daily backup volume that has not been spilled in the next longest period of time. This process is repeated until a usable DASD daily backup volume is produced or until every full, unallocated, DASD daily backup volume assigned to the current day in the backup cycle has been spilled on that day.

If cataloged and uncataloged data sets have the same name and each has backup versions, DFSMSHsm does not move either the latest backup version of the cataloged data set or the latest backup version of the uncataloged data set.

When a DASD daily backup volume is spilled, it is also cleaned up. [“Backup volume cleanup process” on page 219](#) contains detailed information about cleanup processing. When the full DASD daily backup volume to be spilled has been allocated, DFSMSHsm:

- Reads the volume table of contents (VTOC) of the DASD daily backup volume. As each data set VTOC entry is encountered, the name is checked to see if it is a backup version created by DFSMSHsm. If it is, a check is made to see if this backup version is the latest backup version for the cataloged or uncataloged data set. If it is not the latest backup version, is a retired version, or is a version of a deleted data set and it is a valid backup version, DFSMSHsm records that the backup version needs to be moved to a spill backup volume. If the data set on the backup volume either was not created by DFSMSHsm or is a VTOC or VCAT copy, it is not processed.
- Selects a spill backup volume if any backup versions exist that should be moved. After DFSMSHsm selects a spill backup volume, it begins to move the backup versions.
- Determines the percentage of allocated space on the daily backup volume after all the backup versions are moved to the spill backup volume. If the percentage of allocated space is less than or equal to the user-specified threshold of occupancy, the daily backup volume is no longer considered full and is used for the backup of the DFSMSHsm-managed volumes. If the percentage of allocated space is not less than or equal to the threshold of occupancy, the daily backup volume is considered to still be full and is not selected as a target for backup versions. You can specify the threshold of occupancy by using the THRESHOLD parameter of the ADDVOL command.

Selecting spill backup volumes

When DFSMSHsm selects a spill backup volume, it considers whether this is the initial spill volume selection or a subsequent spill volume selection.

If an error occurs during the selection process for a tape and the error is associated with a particular volume, DFSMSHsm considers the tape spill backup volume unavailable for spill backup processing and selects another spill backup volume. Each time DFSMSHsm is started, all non-full backup volumes are considered available for backup processing.

The subparameters of the SPILL parameter of the SETSYS command control the type of spill backup volume selected for output during spill processing. DFSMSHsm ignores the device category specified for backup when it performs spill processing:

- SETSYS SPILL(ANY) specifies that any type of spill backup volume can be selected for output during spill processing.
- SETSYS SPILL(DASD) specifies that only DASD spill backup volumes are selected for output during spill processing.
- SETSYS SPILL(TAPE) specifies that only tape spill volumes are selected for output during spill processing. The automatic class selection (ACS) routines determine whether the spill function is directed to a system-managed tape library.
- SETSYS SPILL(TAPE(*unittype*)) specifies that only tape spill volumes are selected for output during spill processing. The ACS routines determine whether the spill function is directed to a system-managed tape library.

When the spill function is not using a system-managed tape library, UNITTYPE specifies that only tape spill volumes capable of being mounted and written to on the specified type of unit are selected for output during spill processing.

Initial spill backup volume selection (DASD and tape)

For each full, DASD daily backup volume being spilled, DFSMSHsm selects a spill backup volume to contain the backup versions to be moved. If you want DFSMSHsm to use tape as spill backup volumes and you have not specified restrictions limiting selection to tape, you must define at least one tape as a spill volume by using the ADDVOL command. You need not define a tape as a spill volume if you restrict spill backup volumes to tape by specifying SPILL(TAPE) on a SETSYS command.

DFSMSHsm selects the first non-full, unallocated spill backup volume to contain the backup versions to be moved. If a spill backup volume is not available, DFSMSHsm selects an unassigned backup volume and assigns it as a spill backup volume.

Unassigned backup volume exists

The type of unassigned backup volume selected depends on the type of volumes already assigned as spill backup volumes:

- If both tape and DASD spill backup volumes are defined, DFSMSHsm selects any type of unassigned backup volume
- If only DASD spill backup volumes are defined, DFSMSHsm selects only a DASD unassigned backup volume
- If only tape spill backup volumes are defined, DFSMSHsm selects only a tape unassigned backup volume

No unassigned backup volume exists

If no unassigned backup volume exists, the actions taken depend on the type of spill backup volumes already defined:

- If both tape and DASD spill backup volumes are defined, DFSMSHsm also uses the cleanup process in an attempt to produce a usable spill backup volume. However, if the cleanup process does not produce a usable spill backup volume, DFSMSHsm requests a scratch tape. If a scratch tape is not available and another volume backup task is using a tape spill backup volume, this volume backup task waits for any spill backup volume to become available.
- If only DASD spill backup volumes are defined, DFSMSHsm uses the cleanup process in an attempt to produce a usable spill backup volume. If the cleanup process is unsuccessful and another volume backup task is using a DASD spill backup volume, this volume backup task waits for a DASD spill backup volume to become available.
- If only tape spill backup volumes are defined, DFSMSHsm requests a scratch tape. If a scratch tape is not available and another volume backup task is using a spill backup volume, this volume backup task waits for a tape spill backup volume to become available.

Wait for a spill backup volume

In a multiple DFSMSHsm-host environment, before a volume backup task enters a wait state, a five-minute timer is set. When the timer expires, the volume backup task is dispatched, and DFSMSHsm tries to select another spill backup volume. If the spill backup volume is still not available, the volume backup task resets the timer and reenters a wait state. If another volume backup task dispatches the volume backup task in the same host before the timer expires, the timer is canceled, and DFSMSHsm tries to select the spill backup volume again.

No spill backup volume available

If no spill backup volume is available and another volume backup task is not using a spill backup volume, this backup volume spill operation ends because no spill backup volumes are available.

Subsequent spill backup volume selection (DASD and tape)

After a volume backup task has obtained a spill backup volume, the task continues to use that volume until the volume becomes full, the spill of the full DASD daily backup volume completes, or certain error conditions occur.

Subsequent DASD spill backup volume selection

If a DASD spill backup volume is being used and does not contain enough available space for the backup version currently being moved or contains enough total available space for the backup version but the space is too fragmented, DFSMSHsm fails the movement of the backup version. DFSMSHsm considers the space too fragmented if the allocation of the backup version cannot be done in five or fewer extents. When the new allocation for the backup version fails because of insufficient space for the backup version, DFSMSHsm performs the procedures described in [“Selecting subsequent DASD daily backup volumes” on page 211](#).

Note: In reading the procedures just referred to, substitute the term “spill” for the term “daily”.

Subsequent tape spill backup volume selection

If end-of-volume is reached while DFSMSHsm is writing on a tape spill backup volume, DFSMSHsm performs the procedures described in [“Selecting subsequent tape daily backup volumes” on page 212](#).

Note: In reading the procedures just referred to, substitute the term “spill” for the term “daily”.

If DFSMSHsm cannot find a tape volume meeting the preceding criteria or if you specified SETSYS SELECTVOLUME(SCRATCH), DFSMSHsm requests that a scratch tape be mounted on the already allocated unit. When the operator mounts a scratch tape, DFSMSHsm assigns it as a tape spill backup volume.

After the operator mounts the volume, DFSMSHsm continues moving backup versions to that volume.

Certain error conditions, such as an error in writing on the tape, cause DFSMSHsm to switch tape spill backup volumes. If an error occurs, DFSMSHsm considers the tape spill backup volume to be full, releases the volume, and selects another tape spill backup volume as described in [“Initial spill backup volume selection \(DASD and tape\)” on page 217](#), but only a tape volume is selected. After DFSMSHsm selects a tape spill backup volume for the spilling of a full DASD daily backup volume, it uses only tape spill backup volumes when additional spill backup volumes are required during the current spilling of the full DASD daily backup volume.

Cleanup processing

Cleanup processing is a subset of spill processing. When DFSMSHsm does spill processing, it also does cleanup processing. DFSMSHsm also does cleanup processing even when spill processing is not enabled.

DFSMSHsm uses the cleanup process to scratch unwanted data sets on the DASD backup volumes. These data sets are:

- Out-of-date VTOC copy data sets created by DFSMSHsm releases before Version 2 Release 3.0 and out-of-date VCAT copy data sets
- Unwanted backup versions

When DFSMSHsm scratches a VTOC copy data set, it also uncatalogs the data set.

During volume backup processing, DFSMSHsm creates a data set (the VTOC copy data set) that contains selected information from the VTOC of the volume that DFSMSHsm is backing up. This data set drives the recovery of the volume. DFSMSHsm maintains two copies of the VTOC copy data set. When DFSMSHsm backs up a volume, the newly created VTOC copy data set becomes the latest VTOC copy data set, and the data set that was previously the latest VTOC copy data set becomes the next latest VTOC copy data set. As a result, these data sets become continually out of date as DFSMSHsm keeps backing up the

volume. If DFSMSHsm encounters any of these out-of-date VTOC or VCAT copy data sets during volume cleanup processing, DFSMSHsm scratches them and uncatalogs the VTOC copy data set.

Unwanted backup versions are those whose backup version record (MCC) has been deleted from the BCDS. The following are processes that can cause these unwanted backup versions:

- New backup versions are created and the MCC record for an old backup version is deleted, but the old version is not scratched.
- Use of the BDELETE command. The MCC record for the old backup version is deleted, but the old version is not scratched.

DFSMSHsm does cleanup processing under three conditions:

- DFSMSHsm selects a DASD daily or spill backup volume.
- No daily backup volume is available. That is, all daily backup volumes assigned to that day in the backup cycle are full, in use, or unavailable.
- No spill backup volume is available. That is, all spill backup volumes are full, in use, or unavailable.

DFSMSHsm selects a DASD backup volume

When DFSMSHsm selects a non-full, unallocated, DASD daily or spill backup volume, DFSMSHsm cleans it up if the volume has not been cleaned up on that day. DFSMSHsm cleans up the volume even if the volume is not full.

No daily backup volume available

If you specified SETSYS NOSPILL, DFSMSHsm cleans up the full, unallocated, DASD daily backup volumes. DFSMSHsm starts with the full, unallocated, DASD daily backup volume that has not been cleaned up in the longest period of time. If the cleaned up DASD daily backup volume is usable, DFSMSHsm backs up the level 0 volume to this DASD daily backup volume. Otherwise, DFSMSHsm cleans up the full, unallocated, DASD daily backup volume that has not been cleaned up in the next longest period of time. This process continues until a usable DASD daily backup volume is produced or until every full, DASD daily backup volume has been cleaned up on that day. DFSMSHsm does not clean up a DASD backup volume more than once a day.

No spill backup volume available

DFSMSHsm cleans up the full, unallocated, DASD spill backup volume that has not been cleaned up in the longest period of time. If the cleaned up DASD spill backup volume is usable, DFSMSHsm spills the full, DASD daily backup volume to this DASD spill backup volume. Otherwise, DFSMSHsm cleans up the full, unallocated, DASD spill backup volume that has not been cleaned up in the next longest period of time. This process continues until a usable DASD spill backup volume is produced or until every full DASD spill backup volume has been cleaned up on that day. DFSMSHsm does not clean up a DASD spill backup volume more than once a day.

Backup volume cleanup process

After the DASD backup volume to be cleaned up is allocated, the following is performed:

1. The VTOC is read.
 - A check is performed to determine if the data set name corresponds to a VTOC or VCAT copy data set.
 - If the data set name corresponds to a VTOC or VCAT copy data set, a check is performed to determine if the data set is a current version on any volume. If the data set is a current version, the data set is scratched.
 - If the data set name does not correspond to a VTOC or VCAT copy data set, a check is performed to determine if the data set name corresponds to a DFSMSHsm created backup version.

- If the data set name corresponds to a DFSMSHsm created backup version, the backup version record (MCC) from the BCDS is read. If no backup version record exists, the backup version is scratched.
 - If the data set name does not correspond to a DFSMSHsm created backup version, the data is not processed.
2. After the VTOC is read and all unnecessary backup versions, VTOC copy data sets and VCAT copy data sets are scratched, and the percentage of allocated space on the DASD backup volume is determined.
- If a full DASD daily backup volume was cleaned up, and the allocated space is less than or equal to the user-specified allocated space threshold, the volume is no longer considered full and is used to back up DFSMSHsm-managed volumes.
 - If a full DASD spill backup volume was cleaned up, and the allocated space is less than or equal to the user-specified allocated space threshold, the volume is no longer considered full and is used to spill a full DASD daily backup volume.

Tip: The allocated space threshold can be specified using the THRESHOLD parameter of the ADDVOL command.

Note: When cleanup is performed, the backup volume record (BVR) for the volume is held with an exclusive enqueue while the cleanup process is performed. This enqueue can cause message ARC0712I to be issued during the cleanup process.

Releasing a backup volume

When a backup volume task finishes using a backup volume, it releases the backup volume by deallocating it. If the backup volume being released is not full and another volume backup task in the same host is waiting for the type of backup volume being released, the other volume backup task is notified that the backup volume is available. DFSMSHsm determines the amount of unallocated space remaining on the volume if the backup volume is a DASD volume. If the released backup volume is a virtual volume and you have specified the UNLOAD parameter of the SETSYS command, DFSMSHsm issues the MVS UNLOAD command to unload this volume.

Automatic backup example

Table 25 on page 220 shows the conditions that pertain to a group of data sets at the beginning of automatic backup. See “[Example management classes](#)” on page 186 for a description of the management classes for these data sets. The names of the data sets are not precisely as the system would generate them. They have been shortened and modified for convenience in using them for illustrations.

Note: The management class name has been used as the high-order qualifier for the data set names for your convenience in comparing the conditions of the data sets with the attributes specified in the management classes. This is purely for educational purposes. You are not required to use the management class name as any qualifier in the data set name for SMS-managed data sets.

Table 25. Data Set Characteristics for Availability Management Example

Data set name	Number of existing backups	Last backup (days)	Data set changed indicator	Data set was backed up
GDSMC.G3.V1	0	0	Yes	Yes
GDSMC.G3.V2	1	1	Yes	Yes
LARGMC.G4.E1	4	3	Yes	Yes
LARGMC.G4.E2	4	2	No	No
NOMIGMC.G4.G1	0	4	Yes	No
STANDMC.G4.H1	3	2	Yes	No

As DFSMSHsm processes each of the data sets, the following occurs:

- Data set GDSCMC.G3.V1 is backed up because the data-set-changed indicator is on and no backup version exists.
- Data set GDSCMC.G3.V2 is backed up because the data-set-changed indicator is on and the data set has met the BACKUP FREQUENCY specified in management class GDSCMC. However, because a backup version of the data set already exists and the new backup copy exceeds NUMBER OF BACKUPS (DATA SET EXISTS) specified in management class GDSCMC, DFSMSHsm invalidates the old backup version.
- Data set LARGEMC.G4.E1 is backed up for the same reason as for GDSCMC.G3.V2. Note, however, that the days since last backup exceeds the value specified for BACKUP FREQUENCY in management class LARGEMC. This happened because the data set was last backed up on Friday. (Remember, the example system is running on a Monday.) Whether the data set changed on Friday (after backup ran), Saturday, Sunday, or Monday, it could not be backed up until Monday. This data set also causes a roll-off of the existing backup version.
- Data set LARGEMC.G4.E2 is not backed up because the data-set-changed indicator is set off.
- Data set NOMIGMC.G4.G1 is not backed up even though the data-set-changed indicator is on and the last backup meets the BACKUP FREQUENCY attribute in management class NOMIGMC. The data set is not backed up because the AUTO BACKUP attribute value is N in management class NOMIGMC.
- Data set STANDMC.G4.H1 is not backed up because, even though the data-set-changed indicator is on, the last backup days value does not meet the BACKUP FREQUENCY specified in management class STANDMC.

Command availability management

Previous topics have described how you can automatically cause DFSMSHsm to dump and back up your data sets. However, you may want to dump a volume or back up data sets or volumes at a time other than when automatic availability management would cause the backup or dump. Also, when a data set or volume is damaged, either physically or logically, you want to access the dumped or backed up versions to replace the damaged data. Command availability management allows you to accomplish these functions. You can perform the following tasks using availability management commands:

- Dump a volume to either the dump classes specified in the command or the dump classes that are specified in the storage group.
- Dump the volumes in one or more storage groups.
- Back up an individual data set.
- Use the data set backup by command capabilities.
- Use the UNIX file backup by command capabilities.
- Back up all eligible changed data sets on a volume.
- Back up all eligible changed data sets in one or more storage groups.
- Back up all eligible changed UNIX files in a directory subtree.
- Back up all supported data sets on a volume.
- Back up all supported data sets in one or more storage groups.
- Back up all supported UNIX files in a directory subtree.
- Delete expired backup versions from the backup volumes.
- Delete specific backup versions from the backup volumes.
- Recover an individual data set from either a dump copy or an incremental backup version, whichever is the more recent.
- Recover an individual data set from an incremental backup version.
- Recover an individual data set from a dump copy.
- Recover an individual UNIX file.

- Restore a complete volume from a dump copy and update the data sets from the latest incremental backup versions.
- Restore a complete volume from a dump copy.
- Recover a volume by using only incremental backup versions.
- Recover all UNIX files in a directory subtree.

Dumping a volume

Issue one of the following commands to cause a command dump of one or more volumes:

```
BACKVOL VOLUMES(volser,...,volser) DUMP
BACKVOL VOLUMES(volser,...,volser) -
DUMP(DUMPCCLASS(class,class,class,class,class))
BACKVOL VOLUMES(volser,...,volser) -
DUMP(DUMPCCLASS(class, . . . ,class) -
RETENTIONPERIOD(days|*|NOLIMIT, . . . ,days|*|NOLIMIT))
```

For all of the commands, DFSMSHsm checks to ensure that SMS is installed and active in the system. If SMS is installed and active:

- For the first form of the command, the dump operates as explained in [“Dump processing” on page 193](#).
- For the second form of the command, dump processing is the same as is described in [“Dump processing” on page 193](#) except that the dump classes specified by the command are used instead of the dump classes specified by the storage group.
- For the third form of the command, dump processing is the same as is described in [“Dump processing” on page 193](#) except that the dump classes specified by the command are used instead of the dump classes specified by the storage group, and the retention periods specified in the command are used instead of the retention periods specified by the dump classes.

Dumping the volumes in one or more storage groups

To dump all the volumes in one or more storage groups, use the command:

```
BACKVOL STORAGEGROUP(sgm) DUMP
```

The processing for dumping each volume in a specified storage group is the same as explained in [“Dumping a volume” on page 222](#). As in that case, there is an additional available option for stacking dump copies as shown in the following example:

```
BACKVOL STORAGEGROUP(sgn) -
DUMP(DUMPCCLASS(class,class,...,class) STACK(nn,nn,...,nn))
```

You can specify a stacking value, as follows:

- In the STACK parameter on the BACKVOL command
- If the STACK parameter is not specified on the BACKVOL command, in the definition of the dump class specified on the BACKVOL
- If the DUMPCCLASS parameter is not specified, in the definition of a dump class associated with a specified storage group

If the stacking value is greater than 1, DFSMSHsm stacks up to *nn* dump copies on the dump volumes of the dump classes used.

Backing up an individual data set or UNIX file

You can use one of the following data set backup commands to back up a single data set or UNIX file:

BACKDS *dsname* | 'UNIX_filename' | 'UNIX_path+pattern'

HBACKDS *dsname/dsn_filter_name* | 'UNIX_filename' | 'UNIX_path+pattern'

hbackup UNIX_filename | UNIX_path | "UNIX_path+pattern"

Note: You can also use the ARCINBAK program and the ARCHBACK macro to submit data set or UNIX file backup requests. DFSMSHsm processes these requests according to descriptions in this topic.

In processing these commands, DFSMSHsm first checks the management class for the data set or the zFS data set containing the UNIX file, to determine the value of the ADMIN OR USER COMMAND BACKUP attribute. If the value of the attribute is BOTH, a DFSMSHsm-authorized user can use either of the commands, and a non-DFSMSHsm-authorized user can use the HBACKDS command to back up the data set or UNIX file, or the UNIX **hbackup** command to back up the UNIX file. If the value of the attribute is ADMIN, a DFSMSHsm-authorized user can use either of the commands to back up the data set or UNIX file, but a non-DFSMSHsm-authorized user cannot back up the data set. If the value of the attribute is NONE, the command backup cannot be done.

The following process occurs when an individual data set or UNIX file is backed up to DASD:

1. DFSMSHsm can create backup copies to either ML1 backup OVERFLOW volumes or NOOVERFLOW volumes. Use the SETSYS ML1OVERFLOW(DATASETSIZE(*dssize*)) command to specify the minimum size in K bytes (where K=1024) of the data set or UNIX file for which an ML1 OVERFLOW volume is preferred for the migration or backup copy.
2. For data sets, or UNIX files, smaller than 58K tracks (3,365,388,288 bytes for a UNIX file), DFSMSHsm allocates a basic sequential format data set for the backup copy.
3. For data sets larger than 58K tracks (3,365,388,288 bytes for a UNIX file), DFSMSHsm allocates a large format sequential data set for the backup copy. Basic or large format sequential data sets will prefer OVERFLOW or NOOVERFLOW volumes based on the SETSYS ML1OVERFLOW(DATASETSIZE(*dssize*)) value. If there is not enough free space on the NOOVERFLOW or OVERFLOW volume for a particular backup copy, DFSMSHsm tries to create the backup on an OVERFLOW or NOOVERFLOW volume respectively. If the data set, or UNIX file, is too large to fit on a single ML1 volume (OVERFLOW or NOOVERFLOW), then the migration or backup fails.
4. Build an MCM record in the BCDS to indicate that the backup copy must be moved to a backup volume.
5. Build a UFN record in the BCDS for the absolute path of the file. Additionally build UFN records for each parent directory that does not already have a UFN record in the BCDS. The first backup of a file can result in a significant amount of I/O to the BCDS, and thus take longer.
6. Set the data-set-changed indicator to off and update the last backup date fields in the catalog entry and the BCDS MCB record. For UNIX files, the **Last Reftime** field in the file stat area for the UNIX file is updated to the current date or time. (In the past, this field has held the last backup date.) It is used in a manner similar to the data-set-changed indicator so that DFSMSHsm can determine whether it needs to take another backup of the file.
7. Invalidate the oldest versions if the number of backup versions exceeds the value that is specified by the NUMBER OF BACKUPS (DATA SET EXISTS) management class attribute.

If the backup to DASD is unsuccessful, a message is issued.

The following process occurs when an individual data set or UNIX file is backed up to tape:

8. Copy the data set or UNIX file to a backup tape volume.
9. Set the data-set-changed indicator to off and update the last backup date fields in the catalog entry and the BCDS MCB record. For UNIX files, the **Last Reftime** field in the file stat area for the UNIX file is updated to the current date or time. (In the past, this field has held the last backup date.) It is used in a manner similar to the data-set-changed indicator so that DFSMSHsm can determine whether it needs to take another backup of the file.
10. Build a UFN record in the BCDS for the absolute path of the file. Additionally build UFN records for each parent directory that does not already have a UFN record in the BCDS. The first backup of a file can result in a significant amount of I/O to the BCDS, and thus take longer.

11. Invalidate the oldest versions if the number of backup versions exceeds the value that is specified by the NUMBER OF BACKUPS (DATA SET EXISTS) management class attribute.

If the backup to tape is unsuccessful, a message is issued.

DFSMSHsm does not back up an SMS-managed data set or UNIX file that is contained in an SMS-managed zFS if SMS is not installed and active in the system.

Note: Any files in an encrypted zFS are decrypted as they are written to the backup.

Using the data set or UNIX file backup by command capabilities

The data set back up by command function provides the following capabilities:

- Up to 64 data sets or UNIX files per host can be backed up at one time.
- Data sets or UNIX files can be backed up directly to DASD or to tape.
- If concurrent copy is specified, users are notified when the data set or UNIX file backup is either logically or physically complete. Concurrent copy supports non-SMS data sets or UNIX files contained in a non-SMS managed zFS, or if specified on the command, concurrent copy overrides the management class for an SMS data set or UNIX files contained in a non-SMS managed zFS.
- Users can unmount continuously mounted backup tapes.
- Users can tailor the times when DFSMSHsm unmounts a tape.
- Users can specify the number of days to retain a specific backup copy of a data set or UNIX file. See [“Specifying the number of days to retain a backup copy of a data set” on page 183.](#)
- Users can create a data set backup copy and store it under a different, specified data set name. See [“Data set backup using NEWNAME” on page 454.](#)
- Users can create a UNIX file backup copy as if it was originally backed up from a subset of the current path.
- Users can request removal of the UNIX file after a successful backup.
- Users can tailor how backup copies of in-use UNIX files are made using the INUSE keyword or -I option. See [“Backing up UNIX files in use at time of backup” on page 224.](#)

Because the data set or UNIX file backup function allows users to target their backups directly to tape, this might increase the number of required tape drives and mounts. The SETSYS DSBACKUP and the HOLD BACKUP(DSCOMMAND) commands manage the task levels of both tape and ML1 DASD.

Backing up UNIX files in use at time of backup

The INUSE keyword and -I option allows users to tailor how backup copies of in-use UNIX files are made. When the INUSE keyword or -I option is used, UNIX files that are in use at the time of backup will have the backup retried until exclusive serialization can be obtained or the max number of retries has been made. If after the max number of retries has been made and exclusive serialization cannot be obtained the request will either fail or a backup will be taken anyway (a fuzzy backup), depending on what was specified on the command. The INUSE keyword and -I option have subkeyword and suboptions that specify the number of retries, the amount of time to delay in between retries, and whether serialization is required (backup request will fail if exclusive serialization cannot be obtained) or preferred (a fuzzy backup will be taken if exclusive serialization cannot be obtained). The user will be notified if a fuzzy backup of the UNIX file was made.

Specifying data set backup tasks

The data set and UNIX file backup commands allow a user to target a specific output device type. However, if an output device type is not specified, the SETSYS DSBACKUP command controls whether individual backup requests go to DASD or tape. It also allows you to define the number of tasks that are available, up to 64 tasks, to the data set and UNIX file backup function. The SETSYS DSBACKUP command has three parameters: DASDSELECTIONSIZE, DASD, and TAPE.

The DASDSELECTIONSIZE parameter allows you to balance the workload between DASD and tape tasks for all WAIT requests that do not target an output device. This parameter is applicable if both tape and ML1 DASD are used for data set and UNIX file backup requests. Defaults for this parameter are 3000 KB for the *maximum* size and 250 KB for the *standard* size. For a discussion about assigning values for *maximum* and *standard* sizes, see [“Assigning DASDSELECTIONSIZE values”](#) on page 226.

The DASD parameter allows you to specify the number of concurrent data set or UNIX file backup tasks that can direct backups to ML1 DASD. The value *nn* for the TASKS subparameter ranges from 0 to 64 tasks. The command can take the following form:

```
SETSYS DSBACKUP(DASD(TASKS(nn)))
```

The TAPE parameter allows you to specify the maximum number of concurrent data set or UNIX file backup tasks that can direct backups to tape. The value *nn* for the TASKS subparameter ranges from 0 to 64 tasks. The command can take the following form:

```
SETSYS DSBACKUP(TAPE(TASKS(nn)))
```

Note:

1. The DASDSELECTIONSIZE parameter allows you to balance the workload between DASD and TAPE tasks for all WAIT requests that do not specify output media. By setting appropriate values, you ensure that a sufficient number of backups go to each media type to keep them busy. Ultimately, you must weigh the efficient use of data set or UNIX file backup tasks against media use and the need to perform a second movement of backup versions from ML1 DASD to backup tapes during automatic backup processing.
2. The sum of both DASD and tape tasks may not exceed 64.
3. If your installation directs a large amount of individual data set or UNIX file backups to tape, you may want to reassess the number of ML1 OVERFLOW volumes that you have defined to DFSMSHsm.
4. A backup to tape is a one-time process, but a backup to DASD means that the data first goes to DASD before it moves to tape. To avoid this additional data movement, it is almost always more efficient to back up to tape. (An environment with small data sets or UNIX files that arrive infrequently may be the exception.)

Additional TAPE subparameters are MAXIDLETASKS and DEMOUNTDELAY. The MAXIDLETASKS option allows you to tell DFSMSHsm the maximum number of idle tape tasks (0 to 64) that you will accept for each delay. The DEMOUNTDELAY option allows you to tell DFSMSHsm how much time to wait before it deallocates idle tape drives.

Related reading

For more information about the relationship between maximum and standard values associated with the DASDSELECTIONSIZE keyword and the SETSYS DSBACKUP command, see Chapter 65, [“SETSYS command: Establishing or changing the values of DFSMSHsm control parameters,”](#) on page 1057.

Controlling target devices that are used by data set backup

Because DFSMSHsm can use both tape and DASD media types for data set or UNIX file backup requests, there is a need to balance existing workloads against available or allowed resources. In general, tapes take longer from initial selection to first write than DASD does, but tape may be faster in terms of data throughput. By tailoring the SETSYS DSBACKUP command to define the number of tasks that are available to the data set or UNIX file backup function, you can ensure that DFSMSHsm efficiently directs your backup to either tape or DASD, depending on the workload.

The DASDSELECTIONSIZE (*maximum standard*) parameter on the SETSYS DSBACKUP command allows DFSMSHsm to balance the workload between DASD and tape tasks for all WAIT requests that do not target a device type. DFSMSHsm uses a selection process that is based on data set or UNIX file sizes and the availability of tasks. If the data set or UNIX file size is greater than a specified threshold *maximum*,

then the data set or UNIX file is directed to tape. Any data set or UNIX file that is less than or equal to a specified threshold *standard* is directed to the first available task, either DASD or tape.

Note: If you specify the subparameter TASKS(0) for either DASD or tape, DFSMSHsm never directs nontargeted requests to that media.

There are three distinct data set or UNIX file size ranges:

- A small data set or UNIX file is any data set with a size less than the value of *standard* in DASDSELECTIONSIZE(*maximum standard*).
- A medium data set or UNIX file is any data set larger than a small data set but less than the value of *maximum* in DASDSELECTIONSIZE(*maximum standard*).
- A large data set or UNIX file is any data set that is greater than a medium data set.

Note:

1. There is a direct correlation between the number of defined tasks (tape and DASD) and the size of data sets or UNIX files that are directed to DASD. This correlation can result in double data movement during the automatic backup function. (See “Assigning DASDSELECTIONSIZE values” on page 226 for help with assigning size values to *maximum* and *standard*.) The automatic backup function can delay the start of the multitasked volume backup function; that is, volume backup will not begin until all backup versions on ML1 have been moved to tape. You can use the FREEVOL ML1BACKUPVERSIONS command to initiate movement of all backup versions off all ML1 volumes to daily backup volumes.
2. DFSMSHsm starts tape tasks immediately on receipt of WAIT requests (medium and large) and NOWAIT requests, up to the TAPE (DEMOUNTDELAY(MAXIDLETASKS)) value.
3. When both tape and DASD tasks are allowed, NOWAIT requests are only processed by tape tasks.
4. DFSMSHsm starts DASD tasks and tape tasks up to the allowable value when there is enough work for the tasks to do. New tasks are started that are based on the number of requests not currently being processed.

Assigning DASDSELECTIONSIZE values

Small, medium, and large data set or UNIX file sizes are established when you specify the SETSYS DSBACKUP DASDSELECTIONSIZE(*maximum standard*) command. The values assigned to *maximum* and *standard* essentially help balance the workload between DASD and tape tasks. Default sizes for this parameter are 3000 KB for *maximum* and 250 KB for *standard* sizes.

The following considerations might help you decide what to specify for the *maximum* and *standard* values that are associated with the DASDSELECTIONSIZE parameter:

- Increasing either the *maximum* or *standard* value:
 - Increases the number of data sets or UNIX files that may be directed to DASD and decreases the number of data sets or UNIX files that may be directed to tape
 - Uses more ML1 DASD space
 - Increases the workload for autobackup because more backup versions must be moved from ML1 DASD to tape
- Decreasing the *maximum* or *standard* value:
 - Decreases the number of data sets or UNIX files that can be directed to DASD and increases the number of data sets or UNIX file that can be directed to tape
 - Uses less ML1 DASD space
 - Reduces the workload for autobackup since less backup versions must be moved from ML1 DASD to tape

Note: The default is DASDSELECTIONSIZE(3000 250), where 3000 is the maximum in KB, and 250 is the standard in KB. The categories in the table are based on these default values. If the you change the DASDSELECTIONSIZE(maximum standard) settings, then these categories change.

Table 26. Determining Data Set Sizes and Their Task Targets

Default Criteria	Large	Medium	Small
Data Set Size	3001 KB and up	251 – 3000 KB	0 – 250 KB
WAIT Requests	Favor tape	First available	Favor disk
NOWAIT Requests	Favor tape	Favor tape	Favor tape

Related reading

For more information about how to determine the size of a data set and whether it will use tape or disk, see Chapter 65, “[SETSYS command: Establishing or changing the values of DFSMSHsm control parameters](#),” on page 1057.

Switching data set or UNIX file backup tapes

When you specify a value other than zero for SETSYS DSBACKUP(TAPE(DEMOUNTDELAY(MAXIDLETASKS(*n*)))), the data set or UNIX file backup function may allow output tapes to be continuously mounted for an indefinite amount of time. There may be times when you want or need to demount the tapes. You can use the SWITCHTAPES keyword and parameters to demount a continuously mounted tape. You may want to do so, for example, so that it or an alternate can be taken to another site for disaster backup, or so that you can install new tape devices. The SWITCHTAPES keyword is available on both the DEFINE and HOLD commands.

Note: If you specify the MARKFULL parameter of the DEFINE SWITCHTAPES(DSBACKUP) command, the tapes that are released from command data set or UNIX file backup are marked full. However, other partial tapes in the data set or UNIX file backup inventory (previous partial tapes) remain as selection candidates. These partial tapes may be immediately selected and mounted for output processing.

DEFINE SWITCHTAPES tells DFSMSHsm that, at specific times or events, you want the data set or UNIX file backup function to automatically demount and deallocate all currently mounted tapes and allocated drives. HOLD(BACKUP(DSCOMMAND)) tells DFSMSHsm that you want to immediately quiesce data set or UNIX file backup activity to tape, demount all mounted tapes, and deallocate all tape devices. Therefore, if you plan ahead, you can use the DEFINE command to switch tapes. For unplanned activity, use the HOLD command to switch tapes.

Note: A tape can remain continuously mounted for a long period of time because both new tape technologies and a steady stream of data set backup requests allow an increased amount of data on the tape. It can also be mounted for a long time because the MAXIDLETASKS and DEMOUNTDELAY parameters on the SETSYS DSBACKUP command specify that tapes can be continuously mounted while inactive.

The DEFINE SWITCHTAPES(DSBACKUP) command allows you to choose among the following parameters:

TIME

Indicates that you want to define a time when DFSMSHsm initiates the demount and deallocation of all mounted tapes, performed at a certain time of day.

AUTOBACKUPEND

Indicates that you want DFSMSHsm to initiate the demount and deallocation of all mounted tapes at the end of the autobackup cycle.

PARTIALTAPE

Indicates the method that DFSMSHsm uses to mark an output tape as full. This is an optional keyword. MARKFULL, REUSE, and SETSYS are all valid options. SETSYS indicates that you want DFSMSHsm to use the SETSYS PARTIALTAPE value.

The HOLD BACKUP(DSCOMMAND(SWITCHTAPES)) command tells DFSMSHsm to perform SWITCHTAPES processing now; that is, to demount and to deallocate drives. DFSMSHsm demounts active tapes at the end of the current data set, but immediately demounts idle tapes. The demounted tapes are marked

full or not, according to the existing PARTIALTAPE parameter of the DEFINE SWITCHTAPES command. No subsequent RELEASE command is necessary. After these tapes are demounted and the drives are deallocated, data set backup continues with newly selected tapes, if requests are present.

Related reading

For more information about the exact syntax of the DEFINE and HOLD commands, see [Chapter 40, “DEFINE command: Defining control structures for use by DFSMSHsm,”](#) on page 809 and the [Chapter 50, “HOLD command: Preventing DFSMSHsm functions from running,”](#) on page 895.

Taking a backup tape away from a data set backup task

Depending on how you have defined your data set or UNIX file backup by command environment and the arrival rates of data set or UNIX file backup requests, backup output tapes may be mounted for extended periods of time. Consequently, DFSMSHsm has a recover tape takeaway function. This function allows, for instance, the timely recovery of a data set or UNIX file when its backup was made in a previous job step.

For an explanation of backup tape contention possibilities and the scope of the recover tape-takeaway function, see [Chapter 10, “Other availability management considerations,”](#) on page 445.

Targeting data set backups to required device types

To target data set or UNIX file backups to a required target output device type, such as ML1 DASD or backup tape, use the following commands:

```
BACKDS dsname|'UNIX_filename' TARGET(DASD)
```

```
BACKDS dsname|'UNIX_filename' TARGET(TAPE)
```

TARGET DASD specifies that you want to back up the data set or UNIX file initially to ML1 DASD. TARGET TAPE specifies that you want to back up the data set or UNIX file directly to tape.

Users can specify the TARGET keyword on any of the data set backup commands. For example, the BACKDS *dsname* TARGET(DASD) NOWAIT command forces the backup copy to DASD. The TARGET keyword may override any device output or task that DFSMSHsm might have selected on its own.

Using concurrent copy for data set or Clone for UNIX file backup

The BACKDS command has the optional CC keyword, which allows you to specify concurrent copy for both SMS and non-SMS data sets, or UNIX File Snapshot for UNIX files.

```
BACKDS dsname CC(PREFERRED)
```

```
BACKDS dsname CC(REQUIRED)
```

```
BACKDS dsname CC(VIRTUALPREFERRED)
```

```
BACKDS dsname CC(VIRTUALREQUIRED)
```

```
BACKDS dsname CC(CACHEREQUIRED)
```

```
BACKDS dsname CC(CACHEPREFERRED)
```

REQUIRED indicates that concurrent copy must be used as the backup method. If virtual concurrent copy is unavailable cache-based concurrent copy is used. The data set backup should fail if both types of concurrent copy are not available. When processing a UNIX file, REQUIRED indicates that UNIX File SnapShot must be used as the backup method.

PREFERRED indicates that you want to use concurrent copy as the backup method, if it is available. If virtual concurrent copy is not available, cache-based concurrent copy is used. If both types of concurrent

copy are not available, the data set will be backed up as if this keyword were not specified. . When processing a UNIX file, PREFERRED indicates that you want to use UNIX File SnapShot as the backup method, if it is available. If UNIX File SnapShot is unable to be used, the file will be backed up as if this keyword were not specified.

VIRTUALREQUIRED indicates that virtual concurrent copy must be used as the backup method. The data set backup should fail if virtual concurrent copy is not available. When processing a UNIX file, this keyword is treated as if REQUIRED were specified.

VIRTUALPREFERRED indicates that you want to use virtual concurrent copy as the backup method, if it is available. If virtual concurrent copy is not available, the data set will be backed up as if this keyword were not specified. When processing a UNIX file, this keyword is treated as if PREFERRED were specified.

CACHEREQUIRED indicates that cache-based concurrent copy must be used as the backup method. The data set backup should fail if cache-based concurrent copy is not available. When processing a UNIX file, this keyword is treated as if REQUIRED were specified.

CACHEPREFERRED indicates that you want to use cache-based concurrent copy as the backup method, if it is available. If cache-based concurrent copy is not available, the data set will be backed up as if this keyword were not specified. When processing a UNIX file, this keyword is treated as if PREFERRED were specified.

You can also specify the STANDARD keyword, which indicates that you want to use a standard backup method (without using concurrent copy). The standard backup method may possibly override a management class option to use concurrent copy.

Note: For SMS data sets or UNIX files, DFSMSHsm uses the management class values if you do not specify the CC parameter. (For UNIX files, the management class value is inherited from the value of the zFS data set that contains the UNIX file.) For non-SMS data sets or UNIX files, DFSMSHsm does not use concurrent copy if you do not specify the CC parameter.

There are two additional options: PHYSICALEND (PE) and LOGICALEND (LE).

- PHYSICALEND (the default) indicates that control returns to the application only after the backup has physically completed.
- LOGICALEND indicates that control returns to the application when the concurrent copy initialization completes. If PREFERRED was specified and concurrent copy is unavailable for the data set or UNIX file, the backup continues as if this keyword had not been specified. The BACKDS command fails if you specify both STANDARD and LOGICALEND keywords.

DFSMSHsm uses the STGADMIN.ADR.DUMP.CNCURRNT facility class resource to limit concurrent copy use to those users who are authorized to use the CC option.

Authorizing the use of concurrent copy: By default, all users can use the CC option. However, if RACF indicates a lack of authority, DFSMSHsm fails the data set or UNIX file backup request if the concurrent copy request is specified as REQUIRED, VIRTUALREQUIRED or CACHEREQUIRED. If the concurrent copy request is not specified as REQUIRED, VIRTUALREQUIRED or CACHEREQUIRED and RACF indicates a lack of authority, DFSMSHsm continues to back up the data set or UNIX file as if the concurrent copy keyword were not specified on the backup command.

Note: UNIX File Snapshot can only be initiated from the owning system for files located in a zFS that is mounted NORWSHARE. If the zFS is mounted RWSHARE, UNIX file Snapshot can be used from any system in the sysplex.

Authorizing the use of concurrent copy

By default, all users can use the CC option. However, if RACF indicates a lack of authority, DFSMSHsm fails the data set backup request if the concurrent copy request is specified as REQUIRED, VIRTUALREQUIRED or CACHEREQUIRED. If the concurrent copy request is not specified as REQUIRED, VIRTUALREQUIRED or CACHEREQUIRED and RACF indicates a lack of authority, DFSMSHsm continues to back up the data set as if the concurrent copy keyword were not specified on the backup command.

Inline backup of an individual data set or UNIX file

Use the ARCINBAK program to back up individual data sets or UNIX files in a batch environment and to support the JCL back reference of data set or UNIX file names and relative GDG data set names. The processing for backing up individual data sets or UNIX files with ARCINBAK is the same as explained in [“Backing up an individual data set or UNIX file” on page 222](#).

For information about how to use inline backup, see [“Inline backup” on page 447](#).

Backing up all data sets on one or more volumes

To back up all the data sets on a volume, use the command:

BACKVOL VOLUMES(*volser*,...,*volser*) TOTAL

The processing for backing up all the data sets on a volume by command is the same as that explained in [“Phase 4: Backing up SMS-managed volumes from storage groups with the automatic backup attribute” on page 201](#) except:

- DFSMSHsm does not retrieve a list of volumes to be backed up.
- DFSMSHsm checks only the ADMIN OR USER COMMAND BACKUP attribute from the management class for each data set. The SMS-managed data set is eligible to be backed up unless the ADMIN or USER = NONE. All other values for this attribute and all other attributes in the management class are ignored.
- Non-SMS-managed data sets excluded by the ALTERDS or HALTERDS VERSIONS(0) command are not backed up.
- If you specify the BACKUPDEVICECATEGORY parameter of the BACKVOL command, the data sets are backed up to the device type you specify.

When the BACKVOL VOLUME command is issued for an SMS-managed volume, that volume is considered to be DFSMSHsm-managed. DFSMSHsm will maintain control records for the volume until the DELVOL command is issued against it.

Backing up all data sets in one or more storage groups

To back up all the data sets in a storage group, use the command:

BACKVOL STORAGEGROUP(*sgn*,...,*sgn*) TOTAL

The processing for backing up all the data sets in a storage group by command is the same as is explained in [“Phase 4: Backing up SMS-managed volumes from storage groups with the automatic backup attribute” on page 201](#), except for the following difference:

- DFSMSHsm checks the AUTO BACKUP attribute from the management class for each data set. The SMS-managed data set is eligible to be backed up if AUTO BACKUP=YES. All other values for the command backup attribute and all other attributes in the management class are ignored.
- If you specify the BACKUPDEVICECATEGORY parameter of the BACKVOL command, the data sets are backed up to the device type you specify.
- When the BACKVOL STORAGEGROUP command is issued, the volumes processed are considered to be SMS-managed.

Backing up all UNIX files in a directory

To back up all the UNIX files within a directory, use the command:

```
BACKDS '/directory/directory/'
```

```
BACKDS '/directory/directory/*'
```

DFSMSHsm looks for the last forward slash character in the requested name. The name ending in a forward slash indicates to DFSMSHsm that the entire directory should be backed up. Additionally, if the

requested name ends with only an asterisk character, this also indicates that the entire directory should be processed. See the “UNIX file wildcard processing” on page 231 section for more discussion.

DFSMSHsm then reads the directory contents to find the individual file and directory names that may be processed. An internal request for each supported file and empty directory is created and added to the DFSMSHsm backup queue to be processed in parallel according to the definitions of the SETSYS DSBACKUP setting. See “Specifying data set backup tasks” on page 224 for more information on that setting.

To back up files within subdirectories, specify the RECURSE keyword.

```
BACKDS '/directory/directory/' RECURSE(CROSSMOUNTS)
```

The RECURSE keyword indicates that DFSMSHsm should also look at the contents of directories that it finds for files and directories to process. The directory is read at the time DFSMSHsm begins to process that internal request, which could be different from the time of the original request.

The sub-parameter, CROSSMOUNTS, indicates that DFSMSHsm can back up files that are contained in a different filesystem compared to where the original request began. DFSMSHsm will continue to examine sub-directories until no more directories are found. The default processing of NOCROSSMOUNTS can be used to limit the processing to files that are contained within a single zFS data set.

Note: The initial backup of each UNIX file can take longer due to the additional Backup Control Data Set record creation that must be done. This can cause a large growth in the size of the BCDS and should be considered when sizing the BCDS.

UNIX file wildcard processing

The UNIX path name you pass to DFSMSHsm can include wildcard characters to request selection of filenames that match a pattern. This can be used to back up all the log files, or specific subsets of files within a directory.

The UNIX path name passed to DFSMSHsm is made up of two parts: a directory path, and a filename pattern.

```
/dir1/dir2/dir3/file_pattern
```

The directory path ends with the last forward slash character and represents a specific nested set of directories beginning with root (/). Any asterisk (*), question mark (?), or backslash (\) characters in the directory path are treated as simple characters in the directory names and are not used in wildcard matching.

The filename pattern can contain an asterisk anywhere within the pattern to indicate that 0 or more characters can be used to match, question marks to indicate that any single character can match that position. If the pattern should contain an asterisk or question mark character, the backslash character must be used to indicate that the following asterisk or question mark is not a wildcard. Additionally, the pattern may end in an asterisk to indicate that all following characters are acceptable. The pattern is used to compare against file names in a directory. If the RECURSE keyword is specified, then the pattern is used to compare against file names in the sub-directories as well.

Some examples of patterns are:

- BACKDS '/dir1/subdir1/*.txt' RECURSE - Start in the /dir1/subdir1/ directory, and back up all files that end in .txt. Additionally, if there are sub-directories, any files that end in .txt should also be processed. Processing of a sub-directory tree will stop when a different zFS filesystem is encountered.
- BACKDS '/dir1/subdir1/abc*.log' - Back up all files in /dir1/subdir1/ that start with abc and end with .log. Do not examine sub-directories because the RECURSE keyword is not specified.
- BACKDS '/dir1/subdir1/app-12???.log' - Back up all files in /dir1/subdir1 that start with app-12, followed by any two characters, ending with .log.
- BACKDS '/dir1/subdir1/comment\?*out*' - Back up all files in /dir1/subdir1 that start with comment?, and contain .out afterward.

Note: The initial backup of each UNIX file can take longer due to the additional Backup Control Data Set record creation that must be done. This can cause a large growth in the size of the BCDS and should be considered when sizing the BCDS.

Backing up all eligible changed data sets on one or more volumes

You can back up all the eligible changed data sets on one or more volumes by issuing either of the following commands:

BACKVOL VOLUMES(*volser*,...,*volser*)

BACKVOL VOLUMES(*volser*,...,*volser*) INCREMENTAL

Processing for either of these commands is the same as that explained in [“Phase 4: Backing up SMS-managed volumes from storage groups with the automatic backup attribute”](#) on page 201, except:

- No list of volumes to process is retrieved
- If you specify the BACKUPDEVICECATEGORY parameter of the BACKVOL command, DFSMSHsm backs up the data sets to the volume type you specify

Backing up all eligible changed data sets in one or more storage groups

You can back up all of the eligible changed data sets in one or more storage groups by entering either of the following commands:

BACKVOL STORAGEGROUP(*sgn*,...,*sgn*)

BACKVOL STORAGEGROUP(*sgn*,...,*sgn*) INCREMENTAL

Processing for either of these commands is the same as explained in [“Backing up all eligible changed data sets on one or more volumes”](#) on page 232, in which DFSMSHsm determines each volume involved from the definitions of the specified storage groups.

When you use the **STORAGEGROUP** parameter, DFSMSHsm checks the AUTO BACKUP attribute of the management class for each changed data set, and does the following:

AUTO BACKUP=YES...

DFSMSHsm performs the remainder of eligibility processing for the data set.

AUTO BACKUP=NO...

DFSMSHsm does not process the data set.

Backing up all eligible changed UNIX files in a directory

You can back up all of the eligible changed data sets in one or more storage groups by entering either of the following commands:

BACKDS '*dir1/dir2*' CHANGEDONLY

BACKDS '*dir1/dir2/subdir/' RECURSE CHANGEDONLY**

Processing for either of these commands is the same as explained in [“Backing up all UNIX files in a directory”](#) on page 230. Before creating the internal request to process a file, the Last Reference date field, which holds the date of its last backup, in the file metadata is examined. If the Modification date or Metadata Modification date is newer than the value in the Last Reference date, or if DFSMSHsm does not have a backup of the file, the internal request for that file is created. If the UNIX file resides in a file system that is mounted in Read-Only mode, then the Last Reference date is not examined. Instead, the timestamp of the most recent backup in the DFSMSHsm inventory is used to determine if the file has changed since its last backup was taken. DFSMSHsm does not attempt to update the reftime field for the UNIX file to set the last backup date.

Additionally, if you want DFSMSHsm to look in subdirectories for eligible files, the RECURSE keyword might be specified along with the CHANGEDONLY keyword. This might be used to schedule backups of the same directory on a recurring basis, but not take up unnecessary space with duplicate backups.

Note: The CHANGEDONLY parameter is defaulted for UNIX files. If a new backup should be taken, even though the UNIX file has not changed since its last backup, the TOTAL keyword must be specified.

Deleting expired backup versions from the backup volumes

Availability management does not delete data set or UNIX file backup versions when a data set or UNIX file is deleted. Doing so defeats the purpose of availability management. Also, retained backup versions that have met their retention period are not automatically deleted. Therefore, over time, unneeded backup versions can accumulate on your backup volumes. You can use the EXPIREBV EXECUTE command to find and delete these unneeded backup versions.

The EXPIREBV command initiates a search of the BCDS for old, unwanted backup versions and deletes them. The old and unwanted backup versions are deleted based on the BACKDS command retention days value that is specified during data set or UNIX file backup and attributes in the management class for each data set or UNIX file. The EXECUTE parameter causes the BCDS records to be deleted. Each time the EXPIREBV command is issued, all versions that have met their retention duration will expire, except for the most recent version.

Note: While data sets and UNIX files are being changed, new backup versions are created and excess backup versions are deleted or retained. Backup versions are retained if they were created with a BACKDS command retention days value and have not exceeded the retention duration. The EXPIREBV command provides a capability to apply expiration criteria without creating a new backup version. However, if you modify only the maximum backup version limits and data sets or UNIX files are not backed up. Only by issuing the EXPIREBV command (or the BDELETE command) will the new expiration criteria be applied and expired backup versions deleted.

The EXPIREBV command must be issued twice to delete backup versions that were created without a BACKDS command retention days value. The first execution determines that the data set was scratched or UNIX file was deleted and stores the date the EXPIREBV command was issued as the scratch date in the control data set MCB record. The second execution deletes the backup versions when the requested time has passed. The requested time is specified in the management class for SMS data sets or using the EXPIREBV command for non-SMS data sets.

If you want to see a list of backup versions that will be deleted when the EXECUTE parameter is used, use the DISPLAY parameter instead. The output of the DISPLAY parameter can be sent to an output data set or SYSOUT, using the OUTDATASET or SYSOUT parameters. When the EXECUTE parameter is specified, the list is written to the backup activity log.

- For information about how the EXPIREBV command works with ABARS, see [“DFSMSHsm coexistence considerations for aggregate groups and management classes”](#) on page 339 and [“Expiring ABR records in the BCDS”](#) on page 354.
- For more information about the parameters of the EXPIREBV command, see Chapter 44, [“EXPIREBV command: Deleting unwanted backup versions of data sets and UNIX files,”](#) on page 851.

EXPIREBV processing

The following terms are referred to in the following description: *date of scratch* or *scratch date*, *cataloged version*, *uncataloged version*, *active copies*, and *retained copies*:

- The date of scratch or scratch date refers to the date on which the EXPIREBV command determines that a data set or UNIX file for which a backup version exists has been deleted. The scratch date is generally not the date on which the data set or UNIX file was actually scratched. Instead, it is the date that EXPIREBV was next run after the data set was scratched or UNIX file was deleted. The date is stored in the BCDS MCB record in the 4-byte field MCBSCRD (offset X'48', packed decimal). It can be displayed using the FIXCDS command.

Note: DFSMSHsm honors a scratch date stored by the DFSMSHsm space maintenance and recovery utilities if the date is newer than the most recent backup date for the data set or UNIX file and if EXPIREBV has not already stored the scratch date itself.

- A cataloged version refers to a backup version of a data set that was cataloged when the backup version was made; that is, the data set was cataloged when it was backed up.
- An uncataloged version is a version of a data set that was not cataloged when the version was made; that is, the data set was uncataloged when it was backed up.
- UNIX files are always considered to be cataloged.
- Active copies are the set of backup copies created that have not yet rolled off.
- Retained copies are the set of backup copies that have rolled off from the active copies and have not yet reached their retention periods.

Expire backup versions (EXPIREBV) processing is performed in eight steps. DFSMSHsm:

1. Issues a starting message.
2. Sets up the output destination.
3. Retrieves a list of management class definitions.
4. Determines the starting point for the scan of the BCDS.
5. Determines the ending point for the scan of the BCDS.
6. Processes each data set or UNIX file record in the BCDS between the starting and ending points.
7. Ends the scan of the BCDS.
8. Issues an ending message.

Issue a starting message

If you specified DISPLAY in the EXPIREBV command, DFSMSHsm sends a message to the user ID that issued the command. If you specified EXECUTE, DFSMSHsm sends the starting message to the user and to the backup activity log.

Set up the output destination

If you specified DISPLAY in the EXPIREBV command, DFSMSHsm allocates and opens the output data set for the expire backup listing. DFSMSHsm uses the OUTDATASET | SYSOUT parameter that you specified in the EXPIREBV command to allocate the data set. If an error occurs in allocating or opening the output data set, DFSMSHsm issues a message, and EXPIREBV processing ends.

Retrieve a list of management class definitions

The management classes for the SMS-managed data sets contain the attributes that determine whether any particular backup version should be deleted. At the start of EXPIREBV processing, DFSMSHsm requests from SMS a list of the management classes that are defined to the configuration in which DFSMSHsm is running. Successful return of the list of management class definitions indicates that SMS is installed and active. If SMS is not installed and active, DFSMSHsm issues a message to indicate that EXPIREBV processing could not be done for SMS-managed data sets or UNIX files in an SMS-managed zFS data set.

Determine the starting point for the BCDS scan

The starting point for the scan of the BCDS depends on:

- Whether STARTKEY is specified in the command
- Whether RESUME is specified in the command
- Whether the key of the last data set processed (last-processed key) was saved at the end of the last EXPIREBV processing in this host

If STARTKEY is specified in the command, DFSMSHsm starts with the BCDS record that the command specifies.

If RESUME is specified in the command and the saved last-processed key is not blank, DFSMSHsm starts with the saved last-processed key.

If neither STARTKEY nor RESUME is specified in the command or if RESUME is specified but the saved last-processed key is blank, DFSMSHsm starts with the first record in the BCDS.

Determine the ending point for the BCDS scan

The ending point for the scan of the BCDS depends on:

- Whether ENDKEY is specified in the command.
- Whether RESUME is specified in the command.
- Whether a saved planned ending key exists from the previous EXPIREBV processing in this host. The planned ending key is saved at the beginning of EXPIREBV processing.

If ENDKEY is specified in the command, DFSMSHsm ends when the next record to be processed has a higher key value than that specified with ENDKEY.

If neither ENDKEY nor RESUME is specified in the command or if RESUME is specified without ENDKEY and the saved ending key is blank, DFSMSHsm ends EXPIREBV processing after the last BCDS record is processed.

If the saved planned ending key is not blank and RESUME is specified without ENDKEY in the command, DFSMSHsm ends EXPIREBV when the next record to be processed has a higher value than the saved planned ending key.

Process each data set record in the BCDS

For each data set or UNIX file record in the BCDS, DFSMSHsm performs the following processing:

- It determines whether the version is a retired version. See [“Data set retirement” on page 114](#) for a description of “delete if backed up”. If the version is a retired version, DFSMSHsm knows that it is not an SMS-managed data set or UNIX file and processes it according to rules for processing non-SMS-managed data sets or UNIX files. EXPIREBV processing for non-SMS-managed data sets is described in [Chapter 7, “Availability management of non-SMS-managed storage,” on page 303](#).

If the version is not a retired version, DFSMSHsm continues processing.

- It determines whether the data set exists and is SMS-managed. Or it determines that the zFS containing the UNIX file is SMS-managed.

For each data set that does not have a retired version and does not indicate that all backup versions are for an uncataloged data set and that does not have a scratch date that is recorded by prior EXPIREBV processing, DFSMSHsm determines the names of the storage class, management class, and data class for the data set or UNIX file.

If a catalog entry exists for the data set, the data set has not been scratched.

If the data set is not cataloged and the MCB record does not contain a scratch date, DFSMSHsm assumes that the data set has been scratched, and it records the current date in the scratch date field of the MCB record in the BCDS. DFSMSHsm resets an existing scratch date to the current date if the date of the most recent backup version is the same or later than the existing scratch date. Because DFSMSHsm cannot be sure, it assumes that the old scratch date is invalid. This is because the data set may have been re-created and backed up after prior EXPIREBV processing found that the data set had been scratched. This creates the possibility that more than one EXPIREBV command will need to be run to remove the backup versions, but it also prevents DFSMSHsm from deleting valid backup versions. The scratch date is stored when either DISPLAY or EXECUTE is specified on the EXPIREBV command.

DFSMSHsm then checks the MCB record to determine whether the data set or UNIX file was SMS-managed when it was last backed up. If the data set or UNIX file was SMS-managed when it was backed up, DFSMSHsm processes all of its cataloged backup versions as described here. If it was not SMS-managed, DFSMSHsm processes it as described in [“Processing for expired backup versions of non-SMS-managed data sets” on page 310](#).

If any error occurs, other than being unable to find the data set, DFSMSHsm assumes that the data set still exists and processes only the uncataloged versions of the data set as described in [“Processing for expired backup versions of non-SMS-managed data sets”](#) on page 310.

If the MCB record already contains a scratch date, DFSMSHsm assumes that the data set or UNIX file has been scratched and determines from the MCB if the data set or UNIX file was SMS-managed when it was last backed up.

- It identifies expired backup versions.

Each SMS-managed data set's or UNIX file's backup versions are processed based on the RETAIN DAYS value and the attributes that are specified in the management class associated with the data set or UNIX file (or in the default management class if the data set or UNIX file is not associated with a management class). If a management class name is found but there is no definition for the management class, DFSMSHsm issues a message and does not process the cataloged backup versions of that data set or UNIX file.

After the management class has been established, processing depends on whether the data set exists:

- If the data set or zFS exists, the management class used is the one associated with the existing data set or zFS.
 1. DFSMSHsm compares the number of backup versions that exist with the value of the NUMBER OF BACKUPS (DATA SET EXISTS) attribute in the management class. If there are more versions than requested, the excess versions are deleted if the versions do not have a RETAIN DAYS value or the RETAIN DAYS value has been met, starting with the oldest. The excess versions are kept as excess active versions if they have an un-met RETAIN DAYS value. These excess versions will then be changed to retained backup versions when a new version is created.
 2. Starting with the now-oldest backup version and ending with the *third-newest* version, DFSMSHsm calculates the age of the version to determine if the version should be expired. If a RETAIN DAYS value was specified when the version was created, then the age is compared to the retain days value. If RETAIN DAYS was not specified, then the age is compared to the value of the RETAIN DAYS EXTRA BACKUPS attribute in the management class. If the age of the version meets the expiration criteria, then the version is expired.

The *second-newest* version is treated as if it had been created on the same day as the newest backup version. Therefore, the second-newest version (newest EXTRA backup copy) is not expired until the number of retention days specified by the RETAIN DAYS value or the number of days specified in RETAIN DAYS EXTRA BACKUPS attribute in the management class have passed since the creation of the newest backup version. (The management class value is only used if RETAIN DAYS was not specified for the version).

If only one backup version exists for the data set or UNIX file, it is not deleted by the EXPIREBV.

- If the data set or zFS is deleted, the management class used is the one (if any) that was associated with the data set or zFS when the last backup version was made.

If this is the first time EXPIREBV has found this data set or zFS to be deleted:

1. DFSMSHsm compares the number of backup versions that exist with the value of the NUMBER OF BACKUPS (DATA SET DELETED) attribute in the management class. If there are more versions than requested, the excess versions are deleted if the versions do not have a RETAIN DAYS value or the RETAIN DAYS value has been met, starting with the oldest. The excess versions are kept as excess active versions if they have an unmet RETAIN DAYS value. These excess versions will then be changed to retained backup versions when a new version is created.
2. Starting with the now-oldest backup version and ending with the *third-newest version*, DFSMSHsm calculates the age of each cataloged version to determine if the version should be expired. If a RETAIN DAYS value was specified when the version was created, then the age is compared to the retain days value. If RETAIN DAYS was not specified, then the age is compared to the value of the RETAIN DAYS EXTRA BACKUPS attribute in the management class. If the age of the version meets the expiration criteria, then the version is deleted.

The *second-newest* version is treated as if it had been created on the same day as the newest backup version. Therefore, the second-newest version (newest EXTRA backup copy) will not be expired until the retention days specified by the RETAINDAYS value or the number of days specified in RETAIN DAYS EXTRA BACKUPS attribute have passed since the creation of the newest backup version. (The management class value is only used if RETAINDAYS was not specified for the version).

If the scratch date has been set by prior EXPIREBV processing:

1. DFSMSHsm compares the number of backup versions to the value of the NUMBER OF BACKUPS (DATA SET DELETED) attribute in the management class. If there are more versions than requested, the excess versions are deleted if the versions do not have a RETAINDAYS value or the RETAINDAYS value has been met, starting with the oldest. The excess versions are kept as excess active versions if they have an unmet RETAINDAYS value. These excess versions will then be changed to retained backup versions when a new version is created.
2. Starting with the now-oldest backup version and ending with the third-newest version, DFSMSHsm calculates the age of each cataloged version to determine if the version should be expired. If a RETAINDAYS value was specified when the version was created, then the age is compared to the retain days value. If RETAINDAYS was not specified, then the age is compared to the value of the RETAINDAYS EXTRA BACKUPS attribute in the management class. If the age of the version meets the expiration criteria, then the version is deleted.

The *second-newest* version is treated as if it had been created on the same day as the newest backup version. Therefore, the second-newest version (newest EXTRA backup copy) will not be expired until the retention days specified by the RETAINDAYS value or the number of days specified in RETAINDAYS EXTRA BACKUPS attribute have passed since the creation of the newest backup version. (The management class value is used only if RETAINDAYS was not specified for the version).

3. If the RETAINDAYS EXTRA BACKUP attribute is NOLIMIT and the RETAINDAYS ONLY BACKUP attribute is other than NOLIMIT, DFSMSHsm calculates the difference between the current date and the scratch date, then compares the result to the value of the RETAINDAYS ONLY BACKUP (DATA SET DELETED) attribute. If the difference between the current date and the scratch date is greater than the specified value for the attribute, DFSMSHsm deletes all of the remaining backup versions that do not have an unmet RETAINDAYS value.
 4. If all of the extra backups are deleted, DFSMSHsm calculates the difference between the current date and the scratch date and compares the result to the value of the RETAINDAYS ONLY BACKUP (DATA SET DELETED) attribute. If the difference between the current date and the scratch date is greater than the specified value for the attribute, DFSMSHsm deletes the single remaining backup version if it does not have an unmet RETAINDAYS value.
- It determines the disposition of the MCB record and the MCBR record.

If you specified the EXECUTE parameter in the EXPIREBV command, DFSMSHsm can change the MCB record in the BCDS as follows:

- If all backup versions are being deleted or no backup version existed when the EXPIREBV command first read the MCB record, DFSMSHsm deletes the MCB record (only for SMS-managed data sets).
- DFSMSHsm updates the MCB record if either of the following is true:
 - The scratch date field has been changed.
 - One or more backup versions, but not all versions, are being deleted.

If all active copies have been deleted and there are one or more retained copies, then the most recent retained copy will be moved from the MCBR record to the MCB record so that the MCB record has at least one valid backup version.

If you specified the EXECUTE parameter in the EXPIREBV command, DFSMSHsm can change or delete the MCBR record in the BCDS as follows:

- If all backup versions are being deleted or no backup version existed when the EXPIREBV command first read the MCBR record, DFSMSHsm deletes the MCBR record.

- DFSMShsm updates the MCBR record for the following:
 - One or more backup versions, but not all versions, are being deleted
 - A version is moved from the MCBR record to the MCB record.

If you specified the DISPLAY parameter for EXPIREBV, DFSMShsm updates the MCB record only if the scratch date field has been changed (updates only that field in the record).

- It deletes the eligible backup versions.

If you specified the EXECUTE parameter in the EXPIREBV command, DFSMShsm deletes a backup version as follows:

- If the backup version resides on an ML1 volume, the version is scratched (with the appropriate erase-on-scratch indication) and the MCM, MCC, and applicable UFN records are deleted. In addition, if a discrete backup profile is associated with a deleted version, the profile is also deleted.
- If the backup version resides on a non-removable DASD backup volume, the version is scratched (with the appropriate erase-on-scratch indication), and the MCC record is deleted. In addition, if a discrete backup profile is associated with a deleted version, the profile is also deleted.
- If the backup version resides on a removable DASD volume, the backup version is invalidated at this time, but it is not scratched until the backup volume is selected for spill or cleanup processing. If the erase option is in effect for the version, the MCC record is updated to reflect that the data set should be erased when it is scratched. If the erase option is not in effect for the version, the MCC record is deleted.
- If the backup version resides on a tape backup volume, the MCC record is deleted and the TTOC entry for the data set is invalidated.
- It reports on the eligibility of backup versions.

If the DISPLAY parameter was specified in the EXPIREBV command, DFSMShsm creates an output line for every backup version that is eligible to be deleted. The expired retained backup versions are appended to the end of active backup versions. The difference in the output data set between the active backup versions and the retained backup version is that the generation number of retained backup version is displayed as "****" rather than generation number.

If the EXPIREBV command specified EXECUTE, DFSMShsm sends ARC0734I messages to the backup activity log under control of the SETSYS ACTLOGMSGLVL value:

- FULL specifies that an ARC0734I message is sent for each backup version for which deletion is attempted, whether deletion is successful or not.
- EXCEPTIONONLY specifies that an ARC0734I message is sent only when a failure occurs in attempting to delete a backup version.
- REDUCED has the same effect as EXCEPTIONONLY.

If DFSMShsm is running in DEBUG mode when the EXPIREBV command is initiated, the output created is identical to the output when DFSMShsm is not in DEBUG mode, but no backup versions are deleted even if EXECUTE is specified.

Note: During the scan of the BCDS, backup versions associated with a data set name of "*prefix*.BACK" may be skipped and not expired. The prefix qualifier is set based on the BACKUPPREFIX parameter of the SETSYS command or the UID specified in the startup procedure. Because backup versions with high level qualifiers of "*prefix*.BACK" may not be expired and deleted, do not create data sets using this naming convention. Data sets not deleted during EXPIREBV processing are still eligible for deletion during rolloff of backup versions, or when a BDELETE or HBDELETE command is issued.

End the scan of the BCDS

The EXPIREBV command ends as planned when the key of the next record is higher than the planned ending key. Because the planned ending key was reached, a blank key value is saved in the backup control record (BCR) as the last processed key and the planned ending key.

The key of the last MCB record processed is saved periodically in the backup control record for this host when the host is processing an EXPIREBV command. This saved last-processed key is used to enable RESUME processing across system outages. If the EXPIREBV command ends early, the key of the last MCB record processed is saved in the backup control record for the host before processing ends. This allows processing to begin at that key if RESUME is specified on the next EXPIREBV command that is issued in that host. The EXPIREBV command can be caused to end early by:

- A HOLD command with the ALL or EXPIREBV parameters. (A RELEASE EXPIREBV or RELEASE ALL command must be issued before another EXPIREBV command can be issued.)
- A SETSYS command with the NOBACKUP or EMERGENCY parameters.
- The STOP command.

Issue an ending message

If the EXPIREBV command specified DISPLAY, DFSMSHsm sends a message to the user ID that issued the command.

If the EXPIREBV command specified EXECUTE, DFSMSHsm sends a message to the user and to the backup activity log.

Deleting backup versions of specific data sets or UNIX files

The EXPIREBV command allows you to delete all expired backup versions from all of your backup volumes. You can also delete the backup versions of specific data sets or UNIX files. The specified backup versions will be deleted even if their RETAIN DAYS value has not been met. You can delete either specific versions or all versions of the data sets or UNIX files. Use the following commands to delete backup versions:

```
BDELETE ('/filepath') ALL
BDELETE (ddsname...) -
    VERSIONS(backup_version_number)
BDELETE (ddsname...) -
    DATE(date) TIME(time)

HBDELETE (ddsname...) ALL
HBDELETE (ddsname...) -
    VERSIONS(backup_version_number)
HBDELETE (ddsname...) -
    DATE(date) TIME(time)
HBDELETE ('/filepath') ALL

hbdelete -a filename /absolutepath
hbdelete -V backup_version_numbers /absolutepath
hbdelete -d date -t time filename
```

where:

backup_version_number

Is a comma-separated list of backup versions to delete.

date

Is the date when the backup version was created.

time

Is the time when the backup version was created.

DFSMSHsm-authorized users can issue the first group of commands. Any user can issue the second and third groups of commands. The second group of commands can be issued from a TSO session. The third group of commands can be issued from a UNIX shell session.

The first form of the commands deletes all backup versions of the data set. An absolute path for the UNIX file name may be specified with single quotation marks instead of ddsname. The second form of the commands deletes only those backup versions of the data set or UNIX file for which you specify the

version numbers. The third form of the commands deletes a backup version that was taken on a specific date and time.

The last backup date field of the catalog entry is altered to a null value when all of the following apply:

- No backup versions exist.
- The data set is cataloged.
- The data set is SMS-managed.
- The data set is not migrated.

The last backup date of the UNIX file is altered to the most recent backup date in the DFSMSHsm inventory. If no more backup versions exist, then the last backup date is set to January 1, 1970.

Transferring the backup profile from one backup version to another

Discrete backup profiles are associated with only the most recent backup version of a data set. If the backup version being deleted is associated with a backup profile, DFSMSHsm reads BCDS backup version records to determine if any remaining backup versions are of a cataloged, RACF-indicated data set.

If one of the backup versions is of a cataloged, RACF-indicated data set, the backup profile is transferred to the latest backup version of a cataloged, RACF-indicated data set.

Note: Backup profiles are not transferred to a backup version of an uncataloged data set.

Profile creation

If the profile creation fails, message ARC0382I is issued, but the backup version associated with the backup profile is still deleted. If any backup profiles remain, they are not deleted.

Authorization checking during HBDELETE processing

During HBDELETE processing for data sets, DFSMSHsm uses RACF to determine the user's authorization to process the data set. First, DFSMSHsm makes an authorization check against the original data set name. If either a generic profile or a discrete profile cannot be found for a cataloged data set that was RACF-indicated at the time of backup, DFSMSHsm determines whether a backup profile exists. If a backup profile exists, DFSMSHsm makes a second authorization check with the backup profile name. If the second authorization check fails, the HBDELETE processing fails.

During HBDELETE and hbdelete processing for UNIX files, DFSMSHsm uses RACF to determine the user's authorization to the UNIX file. Using the invoker's USERID, GROUP, along with the UID, GID, and file permissions at the time of the last backup, Write Access is checked for the requested file. If the authorization check fails, the processing fails.

Command recovery and restore

You use the recovery and restore process to:

- Recover a data set that has been lost or damaged
- Recover a UNIX file that has been lost or damaged.
- Access an earlier version of the data set without deleting the current version
- Restore a data set from a dump copy
- Restore a volume from a dump copy and update it from incremental backup versions
- Restore a volume from a full-volume dump
- Recover a volume from DFSMSHsm backup versions

The recovered backup version can replace an existing data set or UNIX file, or you can rename the recovered data set copy so it exists in parallel with the current data set. You can recover or restore a data set, UNIX file, or volume only by specifying the RECOVER command.

A backup extended format VSAM data set can be recovered only as an extended format data set.

If the data set was RACF indicated at the time that the dump or backup version was created or is RACF indicated at the time of the recovery or restore, DFSMSHsm recovers a discrete profile for the recovered or restored data set. See [“Recovering or restoring RACF-indicated data sets” on page 461](#) for a discussion of profile recovery.

The permissions and attributes of the UNIX file at the time of backup are recovered

If you want to use DFSMSHsm recovery, you must have specified SETSYS BACKUP.

The recovery process has two restrictions:

- DFSMSHsm cannot recover a data set to a migration volume
- DFSMSHsm cannot recover a data set that is currently marked as migrated in the computing system catalog, *unless* the data set is non-VSAM, a recover data set name is issued with NEWNAME specified, and the NEWNAME data set is not a migrated data set.

Data set recovery and restore

You can use the following commands to recover a data set from a DFSMSHsm backup version or dump copy:

- These two forms of the command recover a specific data set when no data set with the same name is cataloged in the system catalog. If there is a data set with the same name, the recovery fails.

```
HRECOVER dsname
RECOVER dsname
```

- These two forms of the command recover a specific data set but recover it under the fully qualified data set name specified by the NEWNAME parameter that is not currently cataloged in the system catalog. The original data set name may or may not exist in the system catalog.

```
HRECOVER dsname NEWNAME(newdsname)
RECOVER dsname NEWNAME(newdsname)
```

- These two forms of the command recover a specific data set under its original name, even though a data set with the same name is cataloged. The cataloged data set is replaced by the recovered data set.

```
HRECOVER dsname REPLACE
RECOVER dsname REPLACE
```

- These two forms of the command recover a specific data set to a fully qualified data set specified by the NEWNAME parameter, even though a data set is cataloged with the same name as is specified by the NEWNAME parameter. The recovered data set replaces the cataloged NEWNAME data set.

```
HRECOVER dsname NEWNAME(newdsname) -
REPLACE
RECOVER dsname NEWNAME(newdsname) -
REPLACE
```

The HRECOVER command can be used by any user; the RECOVER command can be used by DFSMSHsm-authorized users. Three other parameters—DATE, GENERATION, and VERSION—can be specified that cause DFSMSHsm to select a backup version or dump copy other than the most recent. The GENERATION and VERSION parameters are used to select a specific backup version. The DATE parameter allows the selection of either a dump copy or a backup version.

When the RECOVER or HRECOVER command is issued in any of the shown forms, DFSMSHsm recovers the later of the most recent dump copy or the most recent incremental backup version. For a data set to be restored from a dump copy, the dump copy must have been made from a dump class that allows data set restore, and a VTOC copy must exist for the dump (except when an authorized user explicitly specifies a dump volume).

DFSMSHsm's recovery process involves five steps:

- Determine if the data set being recovered currently exists on a level 0 volume
- Select a target volume
- Determine the storage class, management class, and data class to be associated with the data set
- Determine whether to recover a backup version or a dump copy
- Recover the data set to the target volume

Determining whether the data set exists

DFSMSHsm considers the target data set to exist if the target data set name is cataloged. The target data set and target data set name refer to either the original name of the data set (if you did not specify a new name) or to the new name of the data set that you specified with the NEWNAME parameter of the RECOVER or HRECOVER command.

Selecting the target volume for incremental backup version recovery

When SMS is active, it selects the target volume for the data set to be recovered from an incremental backup version.

Selecting the target volume for physical dump copy restore

Since DFSMSDss does not invoke SMS to select the target SMS volume for a physical data set restore, DFSMSHsm selects the final target volume and passes that volume to DFSMSDss for a data set restore from a physical dump copy. The order of precedence of DFSMSHsm target volume selection is:

1. The source volume serial number of the dump copy, if FROMDUMP(DUMPVOLUME(*volser*)) is specified for a multiple-volume data set
2. The volume serial number to which the target SMS data set is currently cataloged
3. The volume serial number of the TOVOLUME parameter specified on the RECOVER command
4. The volume serial number of the FROMVOLUME parameter specified on the RECOVER command
5. The volume serial number to which the target non-SMS data set is currently cataloged
6. The source volume serial number of the dump copy, if FROMDUMP(DUMPVOLUME(*volser*)) is specified on the RECOVER command
7. The source volume serial number of the incremental backup version
8. The volume serial number to which the original data set is currently cataloged, if the NEWNAME data set is not currently cataloged and an incremental backup version is not available

If the source and selected target device types are not similar, or if the target data set and the target volume are incompatible (that is, one is SMS managed and the other is non-SMS managed), DFSMSHsm fails the restore of the data set from the dump copy. If this happens, you may be required to specify the target volume, either by cataloging the target data set or by using the TOVOLUME parameter of the RECOVER command.

Determining the storage class, management class, and data class

Determination of the SMS classes associated with the data set depends on whether SMS is active, whether the target data set exists, and whether FORCENONSMS is specified.

When SMS is not active

When SMS is not active, any data set that currently exists and is SMS-managed or that was SMS-managed when it was backed up or dumped cannot be processed unless FORCENONSMS is specified on the RECOVER command. For a discussion of using the FORCENONSMS parameter, see [“Recovering specific data sets”](#) on page 311.

When SMS is active and the target data set exists

If the target data set exists, DFSMSHsm uses the storage class, management class, and data class from the catalog entry as the SMS classes to be associated with the recovered data set.

When SMS is active and the target data set does not exist

If the target data set does not exist, DFSMSHsm invokes the ACS services of DFSMSdfp to determine the SMS classes to be associated with the recovered data set. In invoking ACS services, DFSMSHsm passes to the ACS routine of DFSMSdfp any of the following that are available:

- The name of the data set.
- The name of the storage class associated with the data set when the data set was incrementally backed up.

No storage class is passed if one of the following is true:

- The data set was not SMS-managed when it was incrementally backed up.
- A physical dump copy is being explicitly recovered because you specified FROMDUMP or FROMDUMP(DUMPVOLUME(*volser*)).
- The data set does not have an incremental backup version.

Note: If the data set was SMS-managed when it was physically dumped, and your ACS storage class routine expects DFSMSHsm RECOVER to provide the storage class in effect when the data set was dumped, the data set may be filtered as non-SMS-managed, and the recovery may fail with an “unable to recover a non-SMS-managed data set to an SMS-managed volume” error. If this occurs, use FORCENONSMS or TOVOLUME to recover the data set to a non-SMS-managed volume.

- The name of the management class associated with the data set when the data set was incrementally backed up. No management class is passed if one of the following is true:
 - The data set used the default management class when it was incrementally backed up.
 - The data set was not SMS-managed when it was incrementally backed up.
 - A physical dump copy is being explicitly recovered because you specified FROMDUMP or FROMDUMP(DUMPVOLUME(*volser*)).
 - The data set does not have an incremental backup version.
- The name of the data class associated with the data set when the data set was incrementally backed up. No data class name is passed if one of the following is true:
 - The data set had no data class when it was incrementally backed up.
 - The data set was not SMS-managed when it was incrementally backed up.
 - A physical dump copy is being explicitly recovered because you specified FROMDUMP or FROMDUMP(DUMPVOLUME(*volser*)).
 - The data set does not have an incremental backup version.
- The volume serial number specified with the TOVOLUME parameter in the request or the volume serial number and unit type of the volume where the data set originally resided.

Note: If your storage class ACS routine checks for a valid DASD unit name, be sure to include any unit names that may have existed in your installation at one time and are no longer in use, because the data set could have resided on such a unit when it was backed up.

- An environment indicator of RECOVER.
- The RACF user ID and group ID for non-DFSMSHsm-authorized users.
- The data set size in KB.
- The data set expiration date.
- A generation data group indication.
- The data set organization.

- The record organization for VSAM data sets.

ACS services returns the SMS class names to be associated with the recovered data set. If ACS services does not return a storage class name, the data set is not SMS-managed and is recovered as a non-SMS-managed data set.

Determine whether to use backup or dump versions for data set recovery

The non-DFSMSHsm-authorized user has little control over whether a restore or a recover is done. The user's ability to cause a physical data set restore rests with the options set for the dump classes and the dump volumes. Unless the user who issues a RECOVER or HRECOVER command specifies the GENERATION, VERSION, or DATE parameter, DFSMSHsm tries to recover the most recent dump copy or backup version available (based on time of day and date).

The following conditions must exist for a data set restore to be performed instead of a recover of an incremental backup version when a RECOVER or HRECOVER command is issued:

- The data set must be currently cataloged or must have been incrementally backed up by DFSMSHsm at some time. If the data set is currently cataloged and no backup version exists for it, it must have been dumped from the volume it is cataloged on.
- If FROMVOLUME is used to direct DFSMSHsm to restore a data set from a dump copy, the dump copy made from the FROMVOLUME specified is used, regardless of the catalog status of the data set when the dump copy was made. The data set is restored to the FROMVOLUME specified and left uncataloged.
- An eligible dump class must exist that allows individual data set restores (that is, the dump class must have the DATASETRESTORE attribute.)
- The data set to be restored must have resided on a volume dumped to an eligible dump copy. See [“Searching for eligible dump copies” on page 245](#) for detailed information.
- The dump volumes on which the dump copy resides must have a retention period other than NOLIMIT. DFSMSHsm assumes that the dump volumes are physically available to be mounted when the RECOVER command is issued.
- The data set must be listed in the dump VTOC copy data set associated with the dump generation in which the dump copy is contained.
- The eligible dump copy must have been created more recently than the most recent incremental backup version. If a date is specified on the HRECOVER or RECOVER command, the recover is done from the backup version or dump copy that was performed *before or on* the specified date.
- A specific generation or version must not have been requested. A generation for a data set refers only to the DFSMSHsm incremental backup versions of the data set and not to the dump copies of the source volume.
- The volume receiving the data set and the original volume from which the dump copy was made must be of similar device type.
- The volume receiving the data set and the data set being restored must be compatible in terms of being SMS-managed. DFSMSHsm will neither restore an SMS-managed data set to a non-SMS-managed volume, nor restore a non-SMS-managed data set to an SMS-managed volume.
- The version of DFSMSdss installed must be at a sufficient level to support SMS.
- The volume receiving the data set and the data set itself must both be SMS managed or non-SMS managed. DFSMSHsm does not restore an SMS-managed data set to a non-SMS-managed volume, or a non-SMS-managed data set to an SMS-managed volume.

Note:

1. DFSMSHsm always uses the backup version of SMS-managed, multiple-volume data sets unless you specify that the data set is to be restored from a dump copy.
2. See [“Restoring a data set from a DFSMSHsm dump copy” on page 251](#) for a discussion of specifying data set restore from a dump copy.
3. Only an authorized user can specify restore from a dump copy.

If any of the conditions are not met, the HRECOVER or RECOVER process continues by attempting to find a DFSMSHsm backup version to recover. If no DFSMSHsm backup version exists, the HRECOVER or RECOVER request fails.

To further identify the backup version or dump copy you want to recover, specify a date or a relative generation number for the backup version. When you identify a backup or dump version with a date, DFSMSHsm recovers the last version DFSMSHsm created on or before the date you specified. When you identify a backup version with a generation number, the number represents the number of backup versions created before the most recent one. A GENERATION(0) indicates the most recently created backup version. If DFSMSHsm requires access to a level 0 volume, daily backup volume, or spill backup volume during recovery and that volume is not online, DFSMSHsm dynamically allocates the volume. If the backup version is on more than one tape volume, DFSMSHsm allocates each required volume and the operator mounts each required volume.

Searching for eligible dump copies

If an HRECOVER command is not restricted to recovering from incremental backup volumes, or if a RECOVER command is not restricted from recovering backup versions or a specified dump volume, DFSMSHsm must determine the volume from which the data set may have been dumped, in order to find an eligible dump copy. The following conditions narrow the search:

- If the data set is currently cataloged, DFSMSHsm begins with the volume the data set is currently cataloged on as the original source volume. Dump copies of this volume are searched to try to find an eligible copy. If no eligible copy can be found, and this data set also has a valid DFSMSHsm backup version, and if this backup version was created from a different volume from the one on which the data set is currently cataloged, the search continues with dump copies of the volume last backed up from.
- If the data set is not currently cataloged, it must have a valid DFSMSHsm backup version to determine the original source volume. The volume where the data set was located, and where incremental backup last found the data set, is used to locate an eligible dump copy.
- If FROMVOLUME is used to direct DFSMSHsm to restore a data set from a dump copy, the dump copy made from the FROMVOLUME specified is used, regardless of the catalog status of the data set when the dump copy was made. The data set is restored to the FROMVOLUME specified and left uncataloged.

If an eligible dump copy is not found that is more recent than an eligible backup version, the data set is recovered from the backup version.

Recovering the data sets to SMS-managed volumes

The recovery action taken depends on whether a DFSMSHsm backup version or a dump copy is used to recover the data set, and on whether the data set being recovered is a VSAM or non-VSAM data set. If you are recovering an existing data set, you must specify either REPLACE or NEWNAME. If you specify REPLACE, DFSMSHsm replaces the existing data set with the recovered data set. If you specify NEWNAME, DFSMSHsm recovers the data set with the NEWNAME data set name.

If an out-of-space condition causes the recovery of an SMS-managed data set to fail, the RECOVER DFDSSOPTION(VOLCOUNT(N(nn) | ANY)) command can be used to ensure the successful recovery of the data set. The RECOVER DFDSSOPTION(VOLCOUNT(N(nn) | ANY)) command overrides the environment established by the SETSYS VOLCOUNT command. If you do not know what your environment is, use the QUERY SETSYS command to determine the current operating environment.

Recovering a non-VSAM data set from a DFSMSHsm backup version

If the target data set exists, DFSMSHsm deletes the existing data set. DFSMSHsm passes the storage class name associated with the data set to SMS or DFSMSdss. SMS selects the volume and allocates the target data set on that volume. DFSMSHsm or DFSMSdss then copies the backup version into the recovered data set.

The catalog status of a recovered generation data set (GDS) is dependent upon its catalog status before being recovered. If the GDS is not cataloged before recovery, its catalog status after recovery is DEFERRED. If the GDS is cataloged before recovery, its catalog status after recovery remains the same,

with the following exception: when DFSMSHsm is used as a data mover to recover a rolled-off GDS, the cataloged status of the GDS, after it is recovered, is DEFERRED. Use the IDCAMS ALTER ROLLIN command to change the status from DEFERRED to ACTIVE.

If the backup version spans multiple tape volumes, DFSMSHsm issues a message to the operator asking if all necessary tapes are available. If they are not all available, DFSMSHsm cannot recover the data set.

If DFSMSHsm requires access to a level 0 volume, a daily backup volume, or a spill backup volume during recovery and if that volume is not on line, DFSMSHsm dynamically allocates the volume. If the backup version is on more than one tape volume, DFSMSHsm allocates a unit where the operator mounts each required volume.

Recovering a VSAM data set from a DFSMSHsm backup version

If the target data set exists, DFSMSHsm deletes the existing data set, uses the Access Method Services IMPORT command or DFSMSdss as the data mover, and passes the storage class name associated with the data set. Access Method Services or DFSMSdss determines the volume to which the data set is recovered and creates space for the data set.

DFSMSHsm recovers VSAM data sets to a level 0 volume by using the Access Method Services IMPORT command or DFSMSdss as the data mover. However, because the backup version of a VSAM data set contains DFSMSHsm control information, a user-issued IMPORT command or DFSMSdss command cannot be used to recover a backup version.

If DFSMSHsm recovers a VSAM data set to a volume on a type of device that is different from the device from which DFSMSHsm backed up the VSAM data set, the allocation for the buffer that the Access Method Services IMPORT command uses could be too small. If this occurs, you can define the target VSAM data set (base cluster and all alternate indexes) and then reissue the command.

The recovery of an integrated catalog facility catalog is restricted to those users who are recognized as DFSMSHsm-authorized users. If TOVOLUME is specified, the volume specified must have the same volume serial number and device type as the volume from which the catalog was backed up. For more information about recovering the integrated catalog facility catalog, see [“Backing up and recovering a catalog”](#) on page 487.

The NEWNAME parameter limits the recovery of VSAM data sets to spheres that do not have two or more paths defined on the base cluster, and recovers only the base cluster even when alternate indexes exist. After DFSMSHsm recovers the base cluster, you can rebuild any necessary alternate indexes using the Access Method Services BLDINDEX command.

For VSAM data sets not cataloged, if the data set with the new name does not exist, DFSMSHsm generates the new names for the data, index, and path components based on the character length of the new user-supplied cluster name:

New cluster name length	Component naming scheme
1–38 characters	<i>cluster.DATA, cluster.INDEX, cluster.PATH</i>
39–42 characters	<i>cluster.D, cluster.I, cluster.P</i>
43–44 characters	<i>fourqual.Dhhmmss, fourqual.Ihhmmss, fourqual.Phhmmss</i>

Where *cluster* is the new user-supplied cluster name, *fourqual* is the first four qualifiers of the new user-supplied cluster name, and *hhmmss* is a time stamp.

If the data set with the new name already exists and the type (KSDS, ESDS, or RRDS) is the same, DFSMSHsm reuses the entry names of the data component and index component. For information about how DFSMSdss generates new names for the data and index components, refer to the [z/OS DFSMSdss Storage Administration](#).

A message is printed containing the generated or existing name.

If you specified the NEWNAME parameter and the REPLACE parameter and if a data set with the name you specified already exists, DFSMSHsm deletes the existing data set before it recovers the data set you specified with the RECOVER command.

The new data set name and the old data set name can be cataloged in the same or different catalogs when you specify the NEWNAME parameter.

For VSAM data sets not cataloged, if you specify NEWNAME the data and index objects of the data set being recovered must be the same as the object names exported. The object name of the data set being recovered is passed to Access Method Services IMPORT to rename the NEWNAME data set. Access Method Services verifies if the name is the same as the one exported.

Restoring a non-VSAM data set from a dump copy

If the target data set exists, DFSMSHsm deletes the data set. DFSMSHsm invokes DFSMSdss with the storage class name and management class name associated with the data set. DFSMSHsm also passes the target volume serial number selected by the criteria mentioned in “[Selecting the target volume for physical dump copy restore](#)” on page 242. With the information that DFSMSHsm passed to it, DFSMSdss then restores the data set to that volume.

Note: Use the FORCENONSMS keyword to recover the data set to a non-SMS managed volume.

If the target data set does not exist, DFSMSHsm invokes DFSMSdss with the storage class name and management class name associated with the data set when it was incrementally backed up. If the data set does not have an incremental backup version, neither the storage class name nor the management class name is passed to DFSMSdss, and the data set may be restored as non-SMS-managed.

If you specified the NEWNAME parameter in the command and a data set with that name exists, DFSMSHsm deletes the existing data set. DFSMSHsm then invokes DFSMSdss to restore the NEWNAME data set. DFSMSdss restores the data set to the volume passed by DFSMSHsm. If the restore is successful, DFSMSHsm catalogs the restored data set.

Restoring a VSAM data set from a dump copy

If the data set does not exist on a level 0 volume, you can create it. If a backup version of the data set exists, you need not create the data set. DFSMSHsm performs a recovery of the backup version (which creates the data set) then invokes DFSMSdss to restore the data set. If you are a DFSMSHsm-authorized user, DFSMSHsm still attempts to restore the data set even if it is not cataloged and no backup version can be found. The restored data set is not cataloged. In this case, you must use the Access Method Services DEFINE RECATALOG command to catalog the data set again. If a new name was specified, it is passed to DFSMSdss. If you are not a DFSMSHsm-authorized user, the recovery fails and DFSMSHsm issues an error message if the data set is not allocated and no backup version can be found.

If the data set is cataloged, DFSMSHsm invokes DFSMSdss, specifying REPLACE, and passes the management class name and storage class name. DFSMSdss attempts to restore the data set over the top of the existing data set. If the space is too small, DFSMSdss fails the request, and DFSMSHsm writes the DFSMSdss error message in the dump activity log and issues an error message to the user.

If you specify NEWNAME and the NEWNAME data set is cataloged when the original data set is not cataloged, DFSMSHsm first recovers the backup version of the original data set, using the storage class and management class appropriate to the NEWNAME data set. DFSMSHsm then restores the dump copy of the data set over the top of the recovered data set. Finally, DFSMSHsm deletes the cataloged NEWNAME data set and renames the restored data set to the new name.

If you specify NEWNAME and the NEWNAME data set is not cataloged when the original data set is cataloged, DFSMSHsm invokes DFSMSdss to restore the dump copy of the data set passing the NEWNAME. DFSMSHsm then attempts to catalog the restored new target data set name when it is a single-volume data set. In the case when it is part of a multi-volume data set, use the Access Method Services DEFINE RECATALOG command to catalog the data set.

Recovery of direct access data sets

The way to access data after a BDAM data set is recovered is an important consideration when recovering a data set to a volume with a different track length than the level 0 volume from which it was backed up. Using the DAOPTION parameter of the RECOVER command allows you to specify how the recovered data set is to be accessed (relative track or relative block). For instance, using the RELBLK option of DAOPTION allows a data set to be recovered to a device type with a smaller track size than the original level 0 volume. In this case, the data is moved to "fill out the track" rather than a "track to track" image as is the case for the RELTRK and SAMETRK options.

The DAOPTION parameter can only be used when recovering a data set as non-SMS-managed. The FORCENONSMS parameter can be used to recover a data set that would otherwise be returned as SMS managed.

Note: If the BDAM data set is to be recovered from a physical volume dump copy, the device types must be the same. Consequently, DAOPTION (RELBLK) cannot be specified.

Recovery of extended format data sets

DFSMSHsm recovers or restores an extended format data set (as indicated in the MCC record), using DFSMSDss as the data mover, as follows:

- If FROMDUMP(DUMPVOLUME(*volser*)) is not specified, DFSMSHsm always recovers an incremental backup version of a multiple-stripe extended format data set, even if a physical dump copy is more recent than the incremental backup version.
- If FROMDUMP(DUMPVOLUME(*volser*)) is not specified, DFSMSHsm fails the recovery of a multiple-stripe extended format data set if the data set has only been backed up by a physical full-volume dump.
- An extended format data set that had been multiple-stripe when it was backed up or dumped is recovered or restored as a single stripe or multiple-stripe extended format data set, regardless of the existence of the target data set before the RECOVER command is issued. The number of stripes depends on the storage class SUSTAINED DATA RATE value, and the availability of the required volumes.
- An extended format data set that had been single stripe when it was backed up or dumped is recovered or restored as a single stripe or multiple-stripe extended format data set, regardless of the existence of the target data set before the RECOVER command is issued. The number of stripes depends on the storage class SUSTAINED DATA RATE value, and the availability of the required volumes.
- A data set that was extended format when backed up or dumped is recovered or restored as a nonextended format but still SMS-managed data set if no SMS volumes supporting extended format data sets are available.
- If the ACS routine is modified to direct an extended format data set to a non-SMS-managed volume, or if no SMS-managed DASD volumes attached to an ESCON 3990 Model 3 are available, DFSMSHsm fails the recover of the data set.
- A data set that was not extended format when it was backed up is always recovered or restored as a data set that is not extended format. DFSMSHsm never converts a data set that is not extended format to an extended format data set through recover or restore processing, even if the data set is preallocated as an extended format data set before the RECOVER command is issued.
- If FORCENONSMS is specified on the RECOVER command to force an extended format data set to be recovered or restored to a non-SMS-managed volume, DFSMSHsm recovers or restores the data set to a non-SMS-managed volume, but the data set becomes a data set that is not extended format.
- If FROMVOLUME is specified on the RECOVER command to recover an extended format data set, DFSMSHsm fails the recover or restore.
- If reblocking is required for an extended format data set, DFSMSHsm performs the reblocking.

To restore a single stripe extended format data set from a physical dump copy on a specific dump tape, you can issue:

RECOVER *dsname* FROMDUMP(DUMPVOLUME(*volser*))

To restore an existing multiple-stripe extended format data set from a physical dump tape, you must issue the `RECOVER dsname FROMDUMP(DUMPVOLUME(volser))` command for each stripe of the data set. If the extended format data set no longer exists, you must catalog the data set after the restore operations. DFSMSHsm and DFSMSdss do not catalog a multiple-stripe extended format data set during physical data set restore processing.

Last-backup date after recovery

After DFSMSHsm recovers or restores a data set, the settings for the last-backup date are as follows:

- If a new name has been provided for the data set, the last-backup date is set to zero.
- If a new name has not been provided for a non-VSAM data set and the data set was recovered from a backup version, the last-backup date is set to the backup date of the version being recovered.
- If a new name has not been provided for a VSAM data set and the data set was recovered from a backup version, the last-backup date is the value set by `IMPORT` or `DFSMSdss`, whichever recovered the data set.
- If a new name has not been provided and the data set had been restored from a dump copy, the last-backup date is the value restored from the dump copy.

Reblocking during recovery

The purpose of reblocking is to make the most efficient use of available space. If you use DFSMSHsm as the data mover and specify the `CONVERSION` parameter of the `SETSYS` command, DFSMSHsm can reblock some types of record organizations of physical sequential data sets during recovery.

If you use DFSMSdss as the data mover, specify `CONVERSION(REBLOCKTOANY)` to reblock physical sequential and partitioned data sets.

Resetting the date-of-scratch field

During a recovery or restore, DFSMSHsm checks the date-of-scratch field in the MCB record if `NEWNAME` is not specified. If a date-of-scratch exists, DFSMSHsm removes the date.

Tape mount optimization during recovery

The tape mount optimization for data set recoveries is accomplished by recovering all queued or soon arriving data set requests from a single and common backup tape with a single tape mount. For media before 3480s, those requests from a single and common backup tape are processed in ascending file-block ID. For 3480 (single-file-format tape cartridges) and later media, those requests from a single and common backup tape are processed in priority order on the recovery queue. The tape mount optimization is not applied to data set requests from dump tapes or when a data set spans backup tapes.

Processing priority of data set recoveries

Programming Interface Information

All data set recovery requests are queued to and processed from a queue of management work elements called the recovery queue (separate from the volume recovery queue). DFSMSHsm gives all `WAIT` requests a higher priority on the queue than `NOWAIT` requests.

You can change the priorities of these requests as they are put on the queue by using the return-priority installation exit `ARCRPEXT`. `ARCRPEXT` allows you to assign a relative queuing priority such that `WAIT` requests can be prioritized relative to other `WAIT` requests, and `NOWAIT` requests prioritized relative to other `NOWAIT` requests. (In the case of a `NOWAIT` request initiated from a volume recover request, the queuing priority is initialized with the value propagated from the volume recover request passed earlier to the exit.) See *z/OS DFSMS Installation Exits* for a description of `ARCRPEXT`.

End Programming Interface Information

UNIX file recovery

You can use the following commands to recover a UNIX file from a DFSMSHsm backup version:

- These three forms of the command recover a specific UNIX file when no existing file has the same absolute path. If there is a UNIX file with the same absolute path, the recovery fails.

```
HRECOVER 'absolute_pathname'
RECOVER 'absolute_pathname'
hrecover filename absolute_pathname
```

- These three forms of the command recover a specific UNIX file, even though an existing file with the same absolute path exists. The UNIX file is replaced by the recovered UNIX file.

```
HRECOVER 'absolute_pathname' REPLACE
RECOVER 'absolute_pathname' REPLACE
hrecover -f filename absolute_pathname
```

- These three forms of the command recover all files and empty directories within a directory

```
HRECOVER '/directory_path/'
RECOVER '/directory_path/'
hrecover directory/
HRECOVER '/directory_path/*'
RECOVER '/directory_path/*'
hrecover "directory/*"
```

- These three forms of the command recover all files and directories in a sub-tree.

```
HRECOVER '/directory_path/' RECURSE
RECOVER '/directory_path/' RECURSE
hrecover -R directory/
```

The HRECOVER TSO command and hrecover UNIX shell command can be used by any user. The RECOVER command can be used by DFSMSHsm-authorized users. Three other parameters—DATE, GENERATION, and VERSION—can be specified that cause DFSMSHsm to select a backup version or dump copy other than the most recent. The GENERATION, VERSION, and DATE/TIME parameters are used to select a specific backup version. The RECURSE parameter allows sub-directories to be examined for versions to recover. Because other filesystems may be mounted under a directory, the RECURSE parameter allows specification of NOCROSSMOUNTS to indicate that the other filesystem should not be entered when looking for files to recover. The default setting of RECURSE is NOCROSSMOUNTS, which indicates it is not acceptable to enter other filesystems when looking for files to recover.

The commands shown above result in DFSMSHsm recovering the most recent backup version.

DFSMSHsm's recovery process for a single UNIX file involves the following:

- Determine if a UNIX file exists with the same absolute path as the UNIX file being recovered
- Recover the UNIX file, recreating any necessary directories.

UNIX file recovery wildcard processing

To allow recovery of multiple UNIX files in a single request, DFSMSHsm supports the limited use of the wildcards, asterisk (*) and question mark (?). The request pathname passed to DFSMSHsm is considered to be made up of two parts; a directory path from root, and a filename pattern.

- directory path - starting from root (/), a series of directory names separated by forward slash, ending in a forward slash. e.g. /dir/dir2/dir3/
- filename pattern - a series of characters that should be used to match with filenames in the DFSMSHsm inventory under a particular directory. The asterisk (*) character may be used once within the pattern

to indicate 0 or more characters may match, and optionally at the end of the pattern to indicate any number of trailing characters may match. The question mark (?) character may be used multiple times within the pattern to indicate that any single character is acceptable in that place. If the requested filename should include the asterisk, question mark, or backslash character, a preceding backslash character must be used as an escape character. e.g. file?5*.txt , file\?5*.txt

DFSMSHsm's recovery process for multiple files involves the following:

- Examine the request pathname. If it ends in a forward slash (/), or a wildcard is found in the pattern portion, it examines the DFSMSHsm inventory for matching names to recover. Each directory that is encountered, is additionally examined for matching names to recover.
- Create an internal request to process a specific file.
- Because it is possible that an absolute pathname can be for a UNIX file at one backup time, and a directory at other backup times, DFSMSHsm will stop processing that sub-tree of backups as it is unable to determine which version is required (file or directory).

Last-backup date after recovery

After DFSMSHsm recovers a UNIX file, the last-backup date of the file is set to the date of the backup version that was recovered.

Resetting the date-of-scratch field

During a recovery, DFSMSHsm checks the date-of-scratch field in the MCB record. If a date-of-scratch exists, DFSMSHsm removes the date.

Tape mount optimization during recovery

The tape mount optimization for data set recoveries is accomplished by recovering all queued or soon arriving data set requests from a single and common backup tape with a single tape mount. For media before 3480s, those requests from a single and common backup tape are processed in ascending file-block ID. For 3480 (single-file-format tape cartridges) and later media, those requests from a single and common backup tape are processed in priority order on the recovery queue. The tape mount optimization is not applied to data set requests from dump tapes or when a data set or a UNIX file backup spans backup tapes.

Processing priority of UNIX file recoveries

Programming Interface Information

All Unix file recovery requests are queued to and processed from a queue of management work elements called the recovery queue (separate from the volume recovery queue). DFSMSHsm gives all WAIT requests a higher priority on the queue than NOWAIT requests. DFSMSHsm gives all single UNIX file requests a higher priority than the internal requests that are generated from a directory recover request.

You can change the priorities of these requests as they are put on the queue by using the return-priority installation exit ARCRPEXT. ARCRPEXT allows you to assign a relative queuing priority such that WAIT requests can be prioritized relative to other WAIT requests, and NOWAIT requests prioritized relative to other NOWAIT requests. (In the case of a NOWAIT request initiated from a volume recover request, the queuing priority is initialized with the value propagated from the volume recover request passed earlier to the exit.) See z/OS DFSMS Installation Exits for a description of ARCRPEXT.

End Programming Interface Information

Restoring a data set from a DFSMSHsm dump copy

A DFSMSHsm-authorized user can specifically request that a data set be restored from a dump copy rather than recovered from a backup version. The following commands specifically request that a data set be restored from a dump copy:

- RECOVER *dsname* FROMDUMP

This form of the command restores the data set from the most recent dump copy. If a data set is cataloged with the same name as the data set being restored, the restore fails.

- RECOVER *dsname* FROMDUMP(DUMPCLASS(*class*))

This form of the command restores the data set from the most recent dump copy made to the specified dump class. If a data set is cataloged with the same name as the data set being restored, the restore fails.

- RECOVER *dsname* FROMDUMP(DUMPVOLUME(*volser*))

This form of the command restores the data set from a specific dump volume. The volume might not be the most recent dump copy. If a data set is cataloged with the same name as the data set being restored, the restore fails.

- RECOVER *dsname* FROMDUMP(DUMPVOLUME(*volser*)) REPLACE

This form of the command restores the data set from a specific dump volume. The restored data set replaces the cataloged data set having the same name.

- RECOVER *dsname* TOVOLUME(*volser*) UNIT(*unittype*) - FROMDUMP(DUMPGENERATION(*dgennum*))

This form of the command restores the data set to the specified volume from a specified generation of a dump volume.

- RECOVER *dsname* FROMDUMP(DUMPVOLUME(*volser*)) - UNIT(*unittype*) TOVOLUME(*volser*)

This form of the command restores the data set from a specific dump volume. This command must be used to restore a data set from a former device type when a new volume of a similar device type—but having the same volume serial number—resides on the system (for example, a 3380 volume is replaced with a 3390 volume, the same volume serial number is retained, and the 3390 volume is running in a 3380 emulation mode). The recovery is supported only when the target device type is similar to the source device type from which the dump copy was made.

The FROMDUMP parameter of the RECOVER command directs that the data set be restored from a dump copy. If the dump copy starts in file 2 or beyond on a stacked dump tape, DFSMSHsm supplies the file block ID for high-speed positioning to the start of the dump copy.

You can also specify a DATE parameter to direct DFSMSHsm to restore the data set from a dump made on or before the specified day.

Non-VSAM data sets and non-key-range VSAM data sets cataloged in an integrated catalog facility catalog that can be restored within the restrictions of DFSMSdss can be restored by DFSMSHsm. Key-range VSAM data sets can be recovered from backup versions, but cannot be restored from dump volumes. The DFSMSHsm default for a dump class does not allow physical data set restores from dump volumes. You can allow DFSMSHsm to perform restores by specifying the DATASETRESTORE parameter of the DEFINE DUMPCLASS command.

During the data set restore, the dump volumes must be mounted in the same order that they were written during the full-volume dump. The dump volumes are read until the desired data set is found. For a dump copy stacked on a dump tape, with its own unique data set name, the search for the data set starts in the file containing the dump copy. If the dump volume has more than one valid dump copy, the desired data set is not cataloged or is migrated, and the data set has no backup copy, you must use the SOURCEVOLUME(*volser*) parameter of the FROMDUMP parameter to tell DFSMSHsm which dump copy to use.

To restore an SMS-managed, multivolume, non-striped data set from a full-volume dump copy, you must recover each segment of the data set to a non-SMS-managed volume. This is accomplished by issuing the RECOVER command with the FORCENONSMS parameter for each segment of the data set (you can use the TOVOLUME parameter to direct the recovery of the data set to a specific volume). After recovering each segment of the data set, you can catalog the data set as a multivolume, non-SMS data set using IDCAMS. To make the data set SMS-managed, you can copy or move the data set to SMS-managed volumes. The restoration of the data set is complete after the data set is cataloged. The data set is not cataloged by the recovery operation.

You can use the LIST command to ensure that a dump copy contains the data set to be restored. For example, you may need the list if you are not running the incremental backup function and the data set is no longer cataloged.

To request that a data set be *specifically restored* from a dump copy, the following conditions must be satisfied:

- The volume receiving the data set and the original volume from which the dump copy was made must be of similar device type.
- The volume receiving the data set and the data set being restored must be compatible in terms of being SMS-managed. (You can override this restriction by using the FORCENONSMS parameter to restore an SMS-managed data set to a non-SMS-managed volume, and the TOVOLUME parameter to direct recovery to a specific volume.)
- The FROMDUMP parameter must be specified.
- If the DUMPVOLUME subparameter is not specified, the data set must be currently cataloged or must have been incrementally backed up by DFSMSHsm at some point in time. There must also be a dump copy of the original source volume in the specified class.

If the DUMPCLASS subparameter or the DUMPVOLUME subparameter is specified with the RECOVER command, DFSMSHsm does not enforce the DATASETRESTORE subparameter or the permanent retention restrictions of the DEFINE command for the dump class that the dump copy is associated with. Dump volume availability is the responsibility of the authorized user in these cases; therefore, be careful not to request a data set restore from a dump volume that is not in the on-site tape library.

Rules: If neither the DUMPCLASS subparameter nor the DUMPVOLUME subparameter is specified with the FROMDUMP parameter, then the following conditions *must* be met or the command fails:

- The data set must be currently cataloged or must have been incrementally backed up by DFSMSHsm at some time. (This condition is also necessary when DUMPCLASS is specified.)
- An eligible dump class must exist that allows individual data set restores. For example, the dump class must have the DATASETRESTORE attribute defined for the class.
- The data set to be restored must have resided on a volume dumped to an eligible dump copy, as described by [“Searching for eligible dump copies”](#) on page 245.
- The dump volumes on which the dump copy resides must have a retention period other than NOLIMIT. DFSMSHsm assumes the dump volumes are physically available to be mounted when the RECOVER command is issued.
- The data set must be listed in the dump VTOC copy data set associated with the dump generation in which the dump copy is contained. This condition must also be met even if DUMPCLASS is specified.

Restoring VSAM data sets

The restoration of a VSAM data set does not recatalog the data set. However, DFSMSHsm can recatalog a VSAM data set if a backup version of the data set exists. To recatalog the restored data set, DFSMSHsm first recovers the backup copy. The recovery of the backup copy recatalogs the data set. After recovering the backup version of the VSAM data set, DFSMSHsm invokes DFSMSdss to restore the data set by replacing the version just recovered.

If a backup version of the data set does not exist or the attempt to recover the backup version fails, the VSAM data set that is restored to the target volume is uncataloged. A warning message is issued to alert you to your need to recatalog the data set. When a VSAM data set does not have a DFSMSHsm backup version or has not been CATALOGED on the target volume, you must recatalog the data set by using the Access Method Services DEFINE command with the RECATALOG option. DFSMSHsm does not recatalog a VSAM data set after a restore. When a restored VSAM data set replaces an existing data set or a recovered backup version, you should ensure that the catalog records reflect the desired conditions.

If DFSMSHsm successfully recovered a backup version but the restore failed (for example, the allocated space or the control interval was too small), you should delete the recovered data set. After deleting the recovered data set, you should:

1. Predefine the data set on the target volume, using the proper allocation and control interval sizes
2. Reissue the RECOVER command to request the restore

If the VSAM data set exists on the target volume when the recovery request is made, neither DFSMSHsm nor DFSMSdss alters any preexisting catalog information for the data set. You are responsible for ensuring that the catalog information is correct.

No catalog entries are created or modified for these cases. DFSMSdss does restore the VSAM volume data set catalog entry. The data set cannot be an integrated catalog facility catalog. DFSMSHsm processing causes the catalog to be opened if it is not already opened. DFSMSdss does not restore an open integrated catalog facility catalog. If you need to restore the catalog from a dump copy, refer to [“Restoring data sets or volumes directly with DFSMSdss” on page 458](#).

Rule: The original VSAM data set must have been backed up by DFSMSHsm backup for the recover function to operate correctly.

Managing volume backups with fast replication

Fast replication is a function that uses volume-level fast replication to create backup versions for sets of storage groups. You define a set of storage groups with the SMS "copy pool" construct. Fast replication target volumes contain the fast replication backup copies of DFSMSHsm-managed volumes. Fast replication target volumes are defined with the SMS "copy pool backup" storage group type. The fast replication backup versions on DASD can then be dumped to tape using either the FRBACKUP command or with Automatic Dump.

Recovery from the fast replication backup versions can be performed at the data set, volume, or copy pool level. The entire copy pool, individual volumes and data sets within a copy pool, can be recovered from the fast replication backup versions on DASD or tape. Individual data sets are recovered to the volume or volumes that they existed on at the time of backup.

The fast replication function enables the backup and recovery of a large set of volumes to occur within a small time frame. The fast replication function supports the FlashCopy and SnapShot functions.

DFSMSHsm supports the following FlashCopy functions:

COPY and NOCOPY modes

A FlashCopy relationship is established in either COPY or NOCOPY mode. COPY mode results in a background copy which causes all tracks in the FlashCopy relationship to be physically copied from the source volume tracks to the target volume tracks. When the background copy operation completes, the FlashCopy relationship ends. When you define a copy pool with a VERSIONS value of 1 to 85, a COPY mode FlashCopy relationship is established.

NOCOPY mode suppresses the background copy and causes the relationship to be established without immediately initiating a background copy. When the device receives an update to a source track in a FlashCopy relationship, a copy of the point-in-time (pre-update) data is preserved on the target volume. A FlashCopy relationship established in NOCOPY mode remains active until the FlashCopy relationship is withdrawn, or all specified source device tracks or a threshold number of source tracks are updated. When you define a copy pool with a VERSIONS value of 0 (zero), a NOCOPY mode FlashCopy relationship is established.

Incremental FlashCopy

Incremental FlashCopy provides the capability to refresh a volume in a FlashCopy relationship by copying the changed data only. It reduces background copy time when only a subset of data has changed. An incremental FlashCopy relationship persists until it is withdrawn. DFSMSHsm supports incremental FlashCopy in COPY mode.

For more information, see [“Creating a copy pool incremental version” on page 267](#) and [“Recovering from a copy pool incremental version” on page 279](#).

Preserve mirror operation

DFSMSHsm allows the target of the FlashCopy operation to be a Peer-to-Peer Remote Copy (PPRC) primary device. When the tracks associated with the FlashCopy relationship are copied to the PPRC secondary device, the PPRC (Metro Mirror) pair goes into a duplex pending state, to ensure the integrity of the mirror between the local site and the remote site. When the FlashCopy operation completes, the Metro Mirror volume pair returns to full duplex state.

To avoid placing the Metro Mirror pair in an unsynchronized state, IBM Remote Pair FlashCopy, also known as preserve mirror operation, mirrors the FlashCopy command that is issued at the local site, to the remote site, if proper configuration exists. Preserve mirror operation preserves the Metro Mirror duplex state and at the same time ensures that the Metro Mirror remote site is a true mirror of the local site.

For more information, see [“Using Metro Mirror primary volume during fast replication backup” on page 267](#) and [“Using Metro Mirror primary volume during fast replication recovery” on page 279](#).

Space efficient FlashCopy

Space efficient FlashCopy refers to a FlashCopy relationship for which the target volume is a space efficient volume. With space efficient FlashCopy, the amount of physical space consumed by the target volume is limited to the minimum amount of space required to maintain the copy. Space efficient FlashCopy is supported in NOCOPY mode only and cannot be used in combination with preserve mirror operation.

Fast reverse restore

Fast reverse restore provides the capability to reverse the direction of an existing FlashCopy relationship and restore the source volume to the point-in-time state when it was last flashed to the target without waiting for the background copy to complete. Once a fast reverse restore has completed, the contents of the backup volume (the original FlashCopy target) become invalid. When using fast reverse restore, it is best to keep dump tape copies in addition to DASD copies.

DFSMSHsm supports fast reverse restore of a copy pool in both COPY and NOCOPY modes. However, fast reverse restore cannot be used in combination with the preserve mirror operation. When the storage subsystem supports cascaded FlashCopy function, the additional FlashCopy targets will not need to be removed prior to attempting fast reverse restore. Ensure the correct backup version is specified on the command you intend to use for fast reverse restore.

For more information, see [“Recovering a copy pool using fast reverse restore” on page 278](#).

FlashCopy consistency group

When logically related data spans across multiple volumes, FlashCopy consistency group can be used to create consistent copies while minimizing application impact.

To accomplish this, the process consists of freezing the source volumes as each volume pair in the copy pool is copied using FlashCopy, and thawing all the frozen volumes using the Consistency Group Created command after a consistent copy pool backup version has been created. When the FlashCopy freeze option is used, the control unit puts the source volume in an extended long busy (ELB) state causing I/O activities to be held at the host. During the time window starting when the first volume is frozen until the volumes are thawed, no dependent-write updates will take place, which allows a consistent backup version to be created.

The FlashCopy consistency group function can be used in combination with other FlashCopy options.

Combining fast replication options in DFSMSHsm

“Combining fast replication options in DFSMSHsm” on page 256 shows the current allowable fast replication options in the DFSMSHsm environment. Note, however, that IBM System Storage DS8000® series might permit different combinations of FlashCopy options.

Table 27. Allowable combinations of fast replication options

Can FR option → be used with an FR operation or option ↓?	Multiple (up to 12) FlashCopy targets	COPY mode (Copy pool VERSIONS = 1 to 85)	NOCOPY mode (Copy Pool VERSIONS = 0)	Incremental FlashCopy	Preserve Mirror	FlashCopy SE	Fast reverse restore	FlashCopy consistency group
FRBACKUP COPYPOOL	Yes	Yes	Yes	Yes	Yes	Yes	Yes (1)	Yes
FRRECOV COPYPOOL	No	Yes	Yes/No (2)	Yes	Yes	Yes (2)	Yes	No
FRRECOV TOVOLUME	No	Yes	No (4)	Yes	Yes	No (4)	No	No
FRRECOV DSNAME	Yes	Yes	No (4)	No (5)	Yes	No (4)	No	No
Multiple (up to 12) FlashCopy targets	–	Yes	Yes (3)	Yes (6)	Yes	Yes (3)	Yes (7)	Yes
COPY mode	Yes	–	No	Yes	Yes	No	Yes	Yes
NOCOPY mode	Yes (3)	No	–	No	Yes	Yes	Yes	Yes
Incremental FlashCopy	Yes (6)	Yes	No	–	Yes	No	Yes	Yes
Preserve Mirror	Yes	Yes	Yes	Yes	–	No	No	Yes
FlashCopy SE	Yes (3)	No	Yes	No	No	–	Yes	Yes
Fast reverse restore	Yes (7)	Yes	Yes	Yes	No	Yes	–	Yes (8)
FlashCopy consistency group	Yes	Yes	Yes	Yes	Yes	Yes	Yes (8)	–

Notes:

1. When a copy pool is defined to allow for fast reverse restore, its copy pool backup versions will be created with fast reverse restore capability.
2. DFSMSHsm FR copy pool recovery from NOCOPY or space efficient backup volumes can only be used with fast reverse restore. When the NOCOPY version is defined without fast reverse restore capability, the FRRECOV copy pool operation can be performed from dump tapes.
3. A DASD backup version created in NOCOPY mode without fast reverse restore capability is withdrawn when the dump tape has been created. A NOCOPY DASD backup version with fast reverse restore capability can be used for recovery and is kept until it is withdrawn, deleted, or replaced.
4. FRRECOV in VERSIONS=0 environment can be performed FROMDUMP.
5. If there is an existing incremental or persistent relationship, the FRRECOV data set recovery command can be performed using standard I/O. The FASTREPLICATION (PREFERRED | NONE) parameter can be specified to override the SETSYS FASTREPLICATION(DATASETRECOVERY) specification. You can also specify FROMDUMP to recover from dump tapes.
6. When the software and microcode requirements are met, Incremental FlashCopy requests result in Incremental FlashCopy Version 2 (V2), which allows a volume to have more than one incremental relationship. With Incremental FlashCopy Version 1 (V1), a FlashCopy source can have only one incremental target.

7. Multiple backup copies with fast reverse restore capability can be created. When the storage subsystem supports cascaded FlashCopy function, additional FlashCopy targets do not need to be removed before using fast reverse restore. Otherwise, only one relationship can exist when fast reverse restore is used; all additional relationships must be removed before fast reverse restore is initiated or the FRR operation will fail.
8. A copy pool can be defined with either or both the FlashCopy consistency group option and fast reverse restore capability. In the case where both FlashCopy consistency group = Yes and fast reverse restore = Yes are designated, the copy pool will be backed up using the FlashCopy consistency group option; the copy pool backup DASD version will have fast reverse restore capability. When FRRECOV COPYPOOL FROMDASD is performed, fast reverse restore will be used. Consistency groups will not be used in any FRRECOV operation.

Combining copy services operations in DFSMS

Hardware platforms support different copy services combinations. For information about which copy services combinations are allowed on the same device in a DFSMS environment, see [Combining copy services operations in z/OS DFSMS Advanced Copy Services](#).

Using the copy pool construct for fast replication setup

The SMS copy pool construct contains the names of up to 256 storage groups that can be processed collectively for fast replication operations.

When you define a copy pool through ISMF, the individual source pool storage group names are recorded. The actual volumes that are associated with each storage group are retrieved during subsequent processing. Consequently, the volumes that are processed during a function, such as backup, might not be the same volumes that are associated with the storage group at the time that the copy pool was established.

Example: If one or more volumes are added to a storage group within a copy pool, those volumes are automatically processed as part of the next backup. You are not required to update the copy pool definition unless you want to add or remove storage groups from the pool.

Restriction: An individual storage group can be associated with more than one copy pool, but with no more than 50. When using FlashCopy version 1 as the fast replication utility, do not associate a storage group with multiple copy pools. This is because each individual copy pool, with its associated background copies for all the volumes in the common storage group, must process completely before the next copy pool can be processed. This processing can take several hours and prevents the volumes in storage groups associated with a single copy pool from having a timely backup created. FlashCopy version 2 and SnapShot do not have this restriction.

You can maintain as many as 85 backup versions for each copy pool. Each version can have a DASD copy, a dump tape copy, or both. The number of backup versions kept on DASD is specified on the SMS copy pool definition panel. Each DASD maintained copy requires a unique target volume for each source volume. If you specify five dedicated versions, there must be five target volumes that are available for each source volume that is associated with the copy pool. All target volumes must be available when you issue the FRBACKUP COPYPOOL(*cpname*) PREPARE command. If the PREPARE function is not performed, the target volumes need not be available until the actual backup version is created. The number of tape versions that are maintained depends on the expiration settings of the dump classes used to create the individual tape copies.

In the COPY POOL DEFINE and COPY POOL ALTER panels, you can use the **Number of DASD Fast Replication Backup Versions with Background Copy**, **FRBACKUP to PPRC primary Volumes allowed**, **FRRECOV to PPRC primary Volumes allowed**, **Capture Catalog Information for Data Set Recovery**, **Allow Fast Reverse Restore**, and other fields to tailor your copy pool definition.

You can use the **Number of DASD Fast Replication Backup Versions with Background Copy** field to specify the desired number of DASD fast replication backup versions with background copy between 0 and 85. A value of 0 causes DFSMSHsm to use NOCOPY mode when creating the DASD backup copy. When the copy pool is defined with fast reverse restore capability, a DASD backup copy created in

NOCOPY mode can be used for recovery and as a backup copy from which to create a dump tape copy. The DASD backup copy is kept until it is withdrawn or deleted. When the copy pool is defined without fast reverse restore capability, it is only used to create a point-in-time backup copy from which a dump tape copy is created. Once the tape copy is successfully created, the DASD backup copy is deleted. Values between 1 and 85 cause DFSMSHsm to use COPY mode. A COPY mode environment allows recovery of the latest versions from DASD or dump tapes. For example, a COPY mode environment with 2 versions specified and all versions dumped, the latest two versions are on DASD and tape, while the older versions (up to 83) are only available as dump tape copies. When a new DASD version is created, it replaces an existing DASD version. Specifying two copies guarantees that one backup copy is always available on DASD.

You can specify whether DFSMSHsm uses Metro Mirror and Global Mirror primary volumes as targets of the FRBACKUP and the FRRECOV commands in the **FRBACKUP to PPRC primary Volumes allowed** and **FRRECOV to PPRC primary Volumes allowed** fields. The following are valid values and their meaning for the **FRBACKUP to PPRC primary Volumes allowed** and **FRRECOV to PPRC primary Volumes allowed** fields:

NO

Metro Mirror and Global Mirror primary volumes cannot be targets.

PN

Metro Mirror and Global Mirror primary volumes can be used as FlashCopy target volumes. Configuration requirements for preserve mirror operation are not considered.

PP

Metro Mirror and Global Mirror primary volumes can be FlashCopy target volumes. If the target volume is a Metro Mirror primary device, a preserve mirror operation is preferred.

The IBM DS8880 series and newer IBM storage systems do not support the Preserve Mirror Preferred option (PP) for Metro Mirror. If you are using one of those storage systems, and you want to preserve your disk mirror or copy, specify PR.

PR

Metro Mirror and Global Mirror primary volumes can be FlashCopy target volumes. If the FlashCopy target is a Metro Mirror primary volume, a preserve mirror operation is required.

[blank]

None specified. This is the default.

Note: You can use the ALLOWPPRC keyword on the FRRECOV command to override the SMS copy pool PPRC primary volumes allowed settings.

You can specify whether DFSMSHsm uses FlashCopy consistency groups to create consistent copy pool backup copies in the **FlashCopy Consistency Group** field. If you specify Y (yes), the FlashCopy consistency group option will be used and consistent copies are required. If you specify N (no) or leave the field as blank, the FlashCopy consistency group option will not be used.

You can specify whether DFSMSHsm uses FlashCopy consistency group to create consistent copy pool backup copies in the FlashCopy Consistency Group field. If you specify Y (yes), FlashCopy consistency group option will be used and consistent copies are required. If you specify N (no) or leave the field as blank, FlashCopy consistency group will not be used.

You can specify whether catalog information for all catalogs should be collected at time of backup by changing the value in the **Capture Catalog Information for Data Set Recovery** field. If you enter R (required), the fast replication backup request fails if the catalog specified in the copy pool definition cannot be found or if the catalog information cannot be retrieved and captured in its entirety. If you enter P (preferred), under the same conditions, the backup copy pool version is valid, but you might not be able to recover some data sets in the version. Entering N (no) disables the recovery of moved or deleted data sets, this is the default.

Because mature or highly utilized catalogs often contain logical errors, capturing catalog information from a catalog with errors fails and causes the catalog search interface to return an error. When the catalog search interface returns an error, message ARC1812I is issued.

When required is specified, all catalog errors must be corrected to allow fast replication backup to succeed. Alternatively, if preferred is specified, capturing the catalog information will fail, but the fast replication backup request will continue processing.

You can also specify whether fast reverse restore is allowed by changing the value in the **Allow Fast Reverse Restore** field. If you enter Y (yes), recovery of a FlashCopy source from the FlashCopy target can occur without waiting for the background copy to complete. Entering N (no) disables fast reverse restore and requires you to wait for the original FlashCopy operation to complete prior to starting recovery, this is the default. The copy pool fast reverse restore setting is saved at the time of the fast replication backup. During fast replication recovery, the use of fast reverse restore is based on the DASD backup version setting and the state of the current FlashCopy relationships.

The other fields on the COPY POOL DEFINE and COPY POOL ALTER panels allow you to further tailor your copy pool definition.

Note:

1. With FlashCopy version 1, the source and target volumes must be in the same logical subsystem (LSS), which is limited to 256 total volumes. Thus, for three unique versions, you could have up to 64 source volumes, leaving 192 volumes available as target volumes. The source volumes within a storage group can span logical and physical subsystems.
2. When defining a copy pool, consider how many DASD backup versions to keep, whether backup versions should also be kept on tapes, and whether DFSMSHsm automatic dump processing should be used to create the copies on tapes. For tape dumps, your definition of the copy pool through ISMF includes values for the tape related options: Auto Dump, Dump Sys/Sys Group Name, and up to five dump classes.

Using the copy pool backup storage group type for fast replication setup

The SMS copy pool backup storage group type contains the candidate target volumes for DFSMSHsm fast replication requests. The volumes associated with a copy pool backup storage group are for DFSMSHsm use. If you need to restrict use of a volume in a copy pool backup storage group, vary the volume off-line.

The **Copy Pool Backup SG Name** field, in the SMS storage group definition, is provided for you to specify the name of the backup storage group associated with the copy pool. You can associate a backup storage group with a copy pool storage group only. You can define a copy pool storage group with its own backup storage group or to with a backup storage group that is shared by multiple copy pool storage groups.

For each source volume in a storage group to be copied, enough eligible target volumes must exist in the copy pool backup storage group to satisfy the number of volumes required by the number of specified backup versions.

When the space efficient FlashCopy function is enabled, space efficient volumes defined in a copy pool backup storage group are eligible FlashCopy target volumes for a copy pool defined with a VERSIONS value of 0 (NOCOPY mode). Space efficient FlashCopy is supported in NOCOPY mode only. Do not assign space efficient volumes to a copy pool backup storage group associated with a copy pool defined with a VERSIONS value of 1 to 85 (COPY mode).

An eligible target volume must meet the following requirements:

- Have the same track format as the source volume.
- Be the same size as the source volume.
- For FlashCopy:
 - For FlashCopy version 1:
 - Reside in the same LSS as the source volume.
 - Not be in a FlashCopy relationship at the time of backup.
- For SnapShot:
 - Reside in the same RVA or SVA as the source volume.

Related reading

For more information about the copy pool backup storage group type and the pool storage group, see [z/OS DFSMSdfp Storage Administration](#).

Using the extend and overflow storage group types with fast replication

The SMS "extend" and "overflow" storage group types allow you to allocate data sets on volumes, or to extend data sets onto volumes that are not a part of a main source storage group. In most environments, SMS extend or overflow storage groups should *not* be used in a copy pool environment. These storage group types should only be used if all source storage groups utilizing a particular extend or overflow storage group and the extend or overflow storage group itself are all contained within the same copy pools. Extend and overflow storage groups must not be used if the source storage groups that are utilizing them are contained within different copy pools.

Related reading

For more information about the extend and overflow storage group types, see [z/OS DFSMSdfp Storage Administration](#).

Preparing for the fast replication backup

Because the task of establishing a valid DFSMSHsm fast replication environment can be nontrivial, DFSMSHsm provides a PREPARE keyword that you can use with the FRBACKUP command. The PREPARE keyword allows you to validate your fast replication environment for DFSMSHsm. DFSMSHsm preassigns the required number of target volumes to each source volume in each storage group in the specified copy pool.

When you specify the PREPARE keyword, DFSMSHsm verifies that there are sufficient eligible target volumes in the specified copy pool backup storage group. The PREPARE function does not create a backup of the copy pool, but only does initial processing. If VERSIONS=0 is defined for the copy pool, DASD backup volumes are not preassigned to the copy pool source volumes, but PREPARE does check that sufficient target volumes are available. You should only define VERSIONS=0 for a copy pool without fast reverse restore capability when only a tape backup copy is desired. With VERSIONS=0 and Allow Fast Reverse Restore=N specified, you cannot recover from the DASD backup copy.

Example: If you specified in the copy pool definition that DFSMSHsm should keep two backup versions (VERSIONS=2), DFSMSHsm preassigns two target volumes to each source volume in the copy pool.

The PREPARE function supports volume preferencing. DFSMSHsm prefers an eligible copy pool backup storage group volume in the same cluster as the source volume. If such a volume is unavailable, DFSMSHsm selects any fast replication eligible volume.

Use the PREPARE keyword whenever there is a change in the fast replication environment. Changing any of the following definitions will change the fast replication environment:

- The volumes in the pool or copy pool backup storage group are changed or removed.
- The number of backup versions for DFSMSHsm to maintain is changed.

- The storage groups defined to the copy pool have changed.

You can use the PREPARE keyword on the FRBACKUP command to verify whether a Metro Mirror primary volume is allowed to become a target of a FlashCopy operation. For more information about the SMS copy pool settings for allowing Metro Mirror primary volumes to be used during fast replication backup, see [“Using Metro Mirror primary volume during fast replication backup” on page 267](#).

Note:

1. If you specify the PREPARE keyword, DFSMSHsm does not save the catalog information.
2. If the PREPARE function fails, make the necessary corrections and reissue the PREPARE function until it is successful.

Creating a fast replication backup

The FRBACKUP command creates a fast replication backup version for each volume in every storage group defined within a copy pool. You can use the following FRBACKUP command to initiate a fast replication backup for a copy pool:

```
FRBACKUP COPYPOOL(cpname) EXECUTE TOKEN(token)
```

The fast replication backup function is not available as part of automatic backup or dump. You can invoke the FRBACKUP command from a system console, with a TSO command (HSEND CMD), with a batch job, or by using the ARCHSEND macro interface. DFSMSHsm invokes the DFSMSdss COPY FULL function to create a fast replication backup for each volume in the specified copy pool.

The FRBACKUP COPYPOOL command is successful only after DFSMSdss has successfully established a fast replication relationship for each source volume. If one of the volumes fails, the entire backup version is failed with the following results:

- DFSMSHsm continues to process volumes to determine if any remaining volumes will also encounter an error.
- For each volume in error, the target volume is disassociated from the source volume. If there is a problem with the target volume, then it should be removed from the copy pool backup storage group. Otherwise, it may be re-selected during the next FRBACKUP command.
- FlashCopy relationships that are successfully established are withdrawn after all volumes are processed.
- The backup version is marked as invalid after all volumes are processed.

DFSMSHsm skips all volumes whose SMS status has not been defined to the system. DFSMSHsm fails volumes for which it cannot obtain a UCB, such as a volume that is varied offline.

You can use the **FRBACKUP to PPRC Primary Volumes allowed** field in the SMS copy pool definition panel to indicate whether a Metro Mirror primary volume is allowed to become a target of a FlashCopy operation, and whether a preserve mirror operation is required, preferred, or not desired when the target volume is a Metro Mirror primary volume during backup. For more information about the SMS copy pool settings for the **FRBACKUP PPRC Primary Volumes allowed** field and the ALLOWPPRC keyword, see:

- [“Using Metro Mirror primary volume during fast replication backup” on page 267](#).
- [“Syntax of the FRRECOV command” on page 884](#).

Considerations for the FRBACKUP COPYPOOL command

The following topics are related to your use of the FRBACKUP COPYPOOL command:

- **Processing a FRBACKUP COPYPOOL command:** During the processing of a FRBACKUP COPYPOOL command, the new backup version is directed to the target volumes that contain the oldest backup version (after the requested number of versions has been reached). If a FRBACKUP COPYPOOL command fails, there are only $n-1$ valid versions available, where n is the number of requested versions. When a failed version exists, the failed version is the target of the new copy until that copy is successful.

The backup version is not incremented for subsequent backups until a successful version has been created.

- **When FlashCopy is the fast replication technique being used:** DFSMSHsm returns control to the system after a FlashCopy relationship for each volume has been established. However, the background copies for those volumes last from minutes to hours longer, depending on criteria such as:
 - The number of background copies being processed.
 - The amount of other higher priority activity that exists in the storage subsystem.

Notes:

1. When you are using FlashCopy version 1, any subsequent FRBACKUP COPYPOOL command that is issued against the same copy pool or against another copy pool with a common storage group before all the background copies are complete causes the command to fail. This restriction does not exist for FlashCopy version 2 because a source volume can be in multiple concurrent relationships.
 2. If catalog information is saved at the time of backup, you must have sufficient space available on your ML1 volumes to accommodate catalog information data sets. For more information on saving catalog information at time of backup, see [“Saving catalog information at the time of backup” on page 263](#).
 3. Some of the FlashCopy options are incompatible. For example, preserve mirror operation cannot be used in combination with space efficient FlashCopy or fast reverse restore. Consider these restrictions when you define a copy pool.
- **Using the TSO command:** When you use commands that specify WAIT or NOWAIT, the results that are sent back to the user depend on whether the WAIT parameter is specified, and the success or failure of one or more volumes:
 - If WAIT is specified and all volumes process successfully, a return code of zero is returned.
 - If WAIT is specified and one or more volumes fail, a nonzero return code and associated messages are returned.
 - If WAIT is not specified, control is returned to the user after the command has been accepted and verified. All messages continue to be issued, but you are not notified when the command completes.
 - **Using the TOKEN parameter:** The TOKEN parameter accepts a token of up to 40 bytes in length that is associated with that particular version of the copy pool. The token is used to reference a particular backup version. **Tip:** Use unique tokens for each version so that you can easily reference the correct version.

The token is returned as part of the LIST and ARCXTRCT data for a copy pool.

- **Refreshing the UCB on remote systems:** The VTOC and the volume serial on the target volume may have changed as a result of this operation. Before the volume can be accessed on any remote system, the UCB must be refreshed. The refresh occurs automatically if the volume is online and the device manager REFUCB function is enabled. You enable the REFUCB function through PARMLIB member DEVSUPxx or the MODIFY DEVMAN command. For more information, refer to the description of the REFUCB keyword in [z/OS MVS Initialization and Tuning Reference](#) or [z/OS MVS System Commands](#).

Serialization for the fast replication function

Attention: It is the responsibility of the caller of DFSMSHsm to ensure that the source volumes are in a state such that DFSMSHsm can process them for a meaningful recovery. This includes protecting against data set level updates (actual changes to the data) and volume level changes (DADSM functions such as allocations, renames, extends and scratches). By default, DFSMSdss serializes on the VTOC of each volume as it is processed to prevent DADSM functions from occurring against that volume.

If the caller needs to prevent DADSM functions from being performed against the set of volumes in the copy pool during the backup, it is the caller's responsibility to do so. This should be done by serializing on all of the VTOCs before invoking DFSMSHsm. Serializing on the VTOC prevents DADSM functions and also prevents DFSMSdss functions such as DEFRAG, COPY and RESTORE from modifying the VTOCs. When you perform this serialization, use the NOVTOCENQ parameter with the FRBACKUP command to indicate that DFSMSdss should not serialize on the VTOC of each volume.

Saving catalog information at the time of backup

At the time of backup, DFSMSHsm can save the catalog information for the data sets within a copy pool and store it in a DFSMSHsm-managed data set. During fast replication recovery processing, saved catalog information is used to recover and re-catalog data sets that are either deleted or moved.

You can use the COPY POOL DEFINE and COPY POOL ALTER panels to specify up to 10 catalog names. The catalog names can have up to 44 alphanumeric characters, including a delimiter. The catalogs must reside on volumes within the copy pool, collectively represent all data sets in the copy pool, and cannot contain any data sets outside of the copy pool in which they are defined.

You can specify whether catalog information for all catalogs should be collected at time of backup by changing the value in the **Capture Catalog Information for Data Set Recovery** field. If you enter R (required), the fast replication backup request fails if the catalog specified in the copy pool definition cannot be found or if the catalog information cannot be retrieved and captured in its entirety. If you enter P (preferred), under the same conditions, the backup copy pool version is valid, but you might not be able to recover some data sets in the version. Entering N (no) disables the recovery of moved or deleted data sets, this is the default.

Because mature or highly utilized catalogs often contain logical errors, capturing catalog information from a catalog with errors fails and causes the catalog search interface to return an error. When the catalog search interface returns an error, message ARC1812I is issued.

When required is specified, all catalog errors must be corrected to allow fast replication backup to succeed. Alternatively, if preferred is specified, capturing the catalog information will fail, but the fast replication backup request will continue processing.

You can also specify whether fast reverse restore is allowed by changing the value in the **Allow Fast Reverse Restore** field. If you enter Y (yes), recovery of a FlashCopy source from the FlashCopy target can occur without waiting for the background copy to complete. Entering N (no) disables fast reverse restore and requires you to wait for the original FlashCopy operation to complete prior to starting recovery, this is the default.

The following example shows the second page of the COPY POOL DEFINE and COPY POOL ALTER panels:

```

Figure 33. COPY POOL DEFINE/ALTER panel, Page 2.

You can use the FRBACKUP command to create a fast replication backup version for sets of storage groups followed by a memory dump of each fast replication target volume. During FRBACKUP processing, information from the catalogs that are specified in the copy pool definition in SMS is captured and saved to a DFSMSHsm-managed data set, called catalog information data set (CIDS). If preferred is specified and the catalog specified in the copy pool definition cannot be found or the catalog information cannot be

retrieved, a warning message is issued, indicating that only partial catalog information is captured, and all catalog information that can be saved is saved. This allows you to recover the entire copy pool, individual copy pool volumes, cataloged data sets, and moved or deleted data sets for which the catalog information was captured. If required is specified and the catalog specified in the copy pool definition cannot be found or the catalog information cannot be retrieved, the FRBACKUP request is failed and terminates.

During processing of the FRBACKUP command, one CIDS is created for each copy pool version. Because you can specify 10 catalog names in the copy pool definition, each CIDS might contain information from up to 10 catalogs. The size of a CIDS depends on the number and type of catalog entries contained in each of the catalogs specified in the copy pool definition. Each CIDS is allocated on an ML1 volume and is cataloged. The catalog data sets are treated similarly to the way VTOC copy data sets are treated. They are not eligible for SDSPs and cannot be migrated to ML2 volumes. When you enter the FRBACKUP command, you must ensure that you have sufficient space available on ML1 volumes to accommodate the catalog information data sets. Catalog information data sets are deleted when their associated versions are rolled off, deleted, expired, or withdrawn.

Note: Catalog information data sets are allocated on 50 primary and 50 secondary cylinders, unless this setting is modified by patches described in the [Tuning DFSMSHsm](#) topic of *z/OS DFSMSHsm Implementation and Customization Guide*.

To move valid backup versions and migration copies from DFSMSHsm-owned DASD volumes, you can use the FREEVOL command. FREEVOL allows you to move the catalog data sets from a single ML1 volume to other ML1 volumes. Catalog information data sets are moved from the freed volume to other ML1 volumes, regardless of the target level of the FREEVOL command.

The naming convention for a CIDS is as follows:

```
PREFIX.HSMCIDS.Dyyddd.Thhmmss.Cnumseq
```

where:

PREFIX

is the value of the BACKUPPREFIX parameter of the SETSYS command, if specified. Otherwise, PREFIX is the DFSMSHsm default UID.

yddd

is the year and day of the backup.

hhmmss

is the time in hours, minutes, and seconds of when the fast replication backup was created.

numseq

is the qualifier that ensures that the data set name is unique. It is a 3-digit number. A '0' followed by a value derived from the host ID.

Valid host IDs are: 0 - 9, A - Z, \$, #, and @. DFSMSHsm converts the host ID to a value of 1 through 39 in ascending order. If a data set name collision occurs, a '1' is substituted in the '0' position. If another data set name collision occurs, a '2' is substituted in the '0' position. If that fails, creation of the CIDS fails.

Note: HSMCIDS, D, T, and C are constants.

Dumping a fast replication backup to tape

You can dump fast replication DASD backup copies to tape. You can create these dumps on tape through the FRBACKUP command or through an automatic dump processing. For more information on automatic dump processing of copy pools, see [“Dump processing” on page 193](#)

To create a fast replication DASD backup and dump it to tape, you can use the following command:

```
FRBACKUP CP(COPYPOOL1) EXECUTE DUMP RETURNCONTROL(FREND)
```

In this example, DFSMSHsm creates a fast replication backup copy on DASD for each volume of each storage group defined in the COPYPOOL1 copy pool. After the fast replication DASD copy has been

successfully created, DFSMSHsm returns control to the user and then dumps the fast replication DASD copy to tape. The time stamp of all the dump copies reflects the time that the DASD copy is created. If RETURNCONTROL(DUMPEND) is specified, then control is returned to the user after the dump copy has been created. The COPYPOOL keyword and associated parameter indicate the name of a previously defined copy pool which the FRBACKUP command should process.

The copy pool definition specifies how the dump copies are created. Up to five dump classes can be specified for each copy pool. Each dump class correlates to one dump copy. The dump class defines settings such as frequency, expiration and whether the dump class is optional or required. For more details on the REQUIRED or OPTIONAL definition of dump classes, see [“Specifying whether the dump class is required or optional” on page 176](#).

A dump class of a Fast Replication version can have the following states: COMPLETE, PARTIAL, or FAILED. COMPLETE indicates that the volumes are successfully dumped for that dump class. PARTIAL indicates that not all volumes for the dump class are processed. FAILED indicates that *no* volume attempted for the dump class has been dumped successfully.

A Fast Replication dump version can have the following states: ALLCOMPLETE, REQUIRED COMPLETE, PARTIAL, NONE, and FAILED. ALLCOMPLETE indicates that all dump classes specified in the copy pool definition or the FRBACKUP command have completed successfully. REQUIRED COMPLETE indicates that all dump classes marked as REQUIRED are successfully dumped and that one or more dump classes marked as OPTIONAL are incomplete. PARTIAL indicates that one or more dump classes are incomplete. This can be any combination of REQUIRED and OPTIONAL dump classes. FAILED indicates that no attempted volumes have been successfully dumped for any of the specified dump classes. Use the LIST COPYPOOL(*cpname*) command to display the status of the dump classes for each copy pool. The SELECT(DUMPSTATE) option can be used to find incomplete dump copies. NONE indicates that a dump copy has not been created for this version.

Dump copies can only be created from valid DASD copies. DFSMSHsm ensures that once the creation of a dump copy has begun for a DASD copy, that the DASD copy will not roll-off until the dump copy is complete. If an FRBACKUP command is issued that will roll-off a DASD version that has a dump version with a status FAILED or PARTIAL, and one or more dump classes are REQUIRED, then the FRBACKUP command fails. If all of the dump classes are OPTIONAL, then the FRBACKUP command is allowed to continue. Failing the FRBACKUP command ensures that the dump copy can be retried with the FRBACKUP DUMPONLY command before the DASD copy is rolled-off. If it is acceptable to have an incomplete dump copy so that a new DASD backup copy can be created, then use the FORCE keyword on the FRBACKUP command.

You can specify, in the copy pool definition, the number of DASD versions with background copy maintained by DFSMSHsm, from 0 (NOCOPY mode) to 85 (COPY mode). If you specify 0 for a copy pool defined with fast reverse restore capability, it indicates a DASD backup copy created in NOCOPY mode can be used for recovery and as a backup copy from which to create a dump tape copy. The DASD backup copy is kept until it is withdrawn, deleted, or replaced. If you specify 0 for a copy pool defined without fast reverse restore capability, it indicates that you do not require a DASD copy to recover from and DFSMSHsm is to withdraw the DASD version when the dump tape version has been created successfully. The number of tape versions required is independent of the number of DASD versions requested. The number of available tape versions is managed by expiration processing, or by explicit deletion of the dump version using the FRDELETE command. AUTODUMP processing expires the fast replication dumps based on expiration criteria specified in each dump class. Because up to 85 versions of a copy pool can be kept at any time, FRBACKUP DUMP processing also expires the 85th dump when a subsequent dump is requested.

DUMPCCLASS is a keyword for the FRBACKUP command. From 1 to 5 dump classes can be specified, with 1 dump copy of each volume produced for each dump class. If DUMPCCLASS is specified on the FRBACKUP command, dump classes defined to the copy pool are not considered. Since stacking can be specified in the dump class, the FRBACKUP command does not support any separate stacking keyword.

DUMPONLY is used to create one or more dump copies from an existing DASD copy. DUMPONLY can be used to:

- create one or more dump copies when there are no existing dump copies.

- create additional dump copies (up to five) when one or more dump copies already exist.
- attempt to complete existing dump copies that failed.

VERSION, DATE, TOKEN and GENERATION are mutually exclusive keywords describing which DASD version should be dumped. If none of those keywords are specified, then the latest DASD copy is dumped. A DASD copy must be valid in order for it to be dumped. If the DUMPONLY command is issued against a version with an invalid DASD copy, then the command fails.

Only 5 dump classes can be associated with a single dump version, so an FRBACKUP command specifying one or more dump classes fails if *both* the number of existing dump copies for a version and the number of dump classes specified on the FRBACKUP command exceed 5.

If DUMPONLY is issued against a version for which there are no existing dump copies, then the following statements hold true:

- If DUMPCLASS is not specified, then the dump classes from the copy pool definition are used.
- If DUMPCLASS is specified, then the specified dump classes are used.

If DUMPONLY is issued against a version for which there are existing successful dump copies, then the following statements hold true:

- If DUMPCLASS is not specified, then the command fails.
- If DUMPCLASS is specified, then only those dump classes that were not already created are processed. The number of existing dump copies and new dump copies cannot exceed five.

If DUMPONLY is issued against a version that is marked partially successful, then the following statements hold true:

- If DUMPCLASS is not specified, the dump is resumed for any dump classes not previously successfully dumped.
- If DUMPCLASS is specified and the dump class previously failed, then only that dump class is resumed.
- If DUMPCLASS is specified with a dump class that is not previously attempted, and fewer than 5 dump classes have been dumped for the version, a new dump copy of the version is created for the specified dump class.
- If DUMPCLASS is specified with a dump class that is not previously attempted, and 5 dump classes have already been dumped for the version, the command fails.

In a VERSIONS = 0 (NOCOPY) environment, if the DASD version is marked NONE or FAILED, and the dump for the version is marked ALL COMPLETE or REQUIRED COMPLETE, any DUMPONLY request for that version fails.

In the following example, the DATE subparameter is used to dump to tape the backup of COPYPOOL1 that was created on June 2, 2006:

```
FRBACKUP CP(COPYPOOL1) DUMPONLY(DATE(2006/06/02))
```

RETURNCONTROL, a keyword telling DFSMSHsm when to return control for WAIT type user commands. RETURNCONTROL(FASTREPLICATIONEND) tells DFSMSHsm to return control just before dump processing starts. RETURNCONTROL(DUMPEND) tells DFSMSHsm to return control after all volumes have been dumped. The keyword applies to the DUMP keyword but not to the DUMPONLY keyword. DUMPEND is the default. If a user specifies the RETURNCONTROL() keyword with NOWAIT, the command fails. If a user specifies the RETURNCONTROL() keyword without WAIT, the command fails with a syntax error. NOWAIT is the default.

For more information about FRBACKUP and the parameters related to dumping fast replication backups, see Chapter 46, [“FRBACKUP command: Requesting a fast replication backup or dump version,”](#) on page 865.

Creating a copy pool incremental version

DFSMSHsm supports the FlashCopy Incremental function for Fast Replication copy pools. A copy pool can be designated to have an incremental backup version by using the FCINCREMENTAL keyword on the FRBACKUP command. When the software and microcode requirements are met, you can use the FCINCREMENTAL keyword on multiple FRBACKUP commands to specify that those copies are to be incremental, or add the ALL subparameter to specify that all subsequent copy pool backup copies should also be incremental.

Once an incremental version has been established in a copy pool, the copy pool has an incremental version until either it is deleted or the FCINCRREMENTALLAST keyword is used. The volumes in a copy pool incremental version have persistent relationships with the target volumes. When a single disk version is maintained, the FlashCopy Incremental function is used each time a new disk version is created. When multiple disk versions are being maintained, then the FlashCopy Incremental function is used only for the version that was originally identified as the Incremental version by the FCINCREMENTAL keyword. All other versions are full copies. For example, if two disk versions are being maintained, then every other disk version uses the FlashCopy Incremental function.

The FCINCREMENTAL keyword is optional when creating a new incremental version. If the FCINCREMENTAL or FCINCRREMENTALLAST keyword is specified, and the oldest disk generation to be overwritten to create the new version is not an incremental version, the command fails.

When a copy pool incremental version is no longer needed for a copy pool, issue FCINCRREMENTALLAST when you create the next incremental version. After the background copies for the incremental version have completed, the persistent relationship for each volume is withdrawn. The disk version remains recoverable. An alternative method is to delete the incremental version with the FRDELETE command. After using either the FCINCRREMENTALLAST keyword or the FRDELETE command, all future disk versions are full copies until the FCINCREMENTAL keyword is used again. Adding the ALL subparameter to FCINCRREMENTALLAST causes a new incremental of the oldest copy to be taken, the persistent relationships of that copy to be withdrawn, and the relationships of all other backup copies to be withdrawn after the next increment is taken of each of those copies.

The initial establishment of a FlashCopy Incremental version creates a full copy of each volume (0-n tracks). Subsequent copies utilize the FlashCopy Incremental technology only to copy tracks from the source that have changed. This results in the background copy completing in a shorter time period.

Fast Replication incremental copy pool versions are not supported when the copy pool is defined with zero DASD backup versions. If the number of DASD backup versions in the copy pool definition is changed to zero and an incremental version exists, the subsequent FRBACKUP command fails. The incremental version must be removed by the FCINCRREMENTALLAST keyword or deleted by the FRDELETE command.

If the number of versions is reduced so that an incremental version is automatically deleted, the FRBACKUP command fails. The incremental version either has to be deleted or has to be the oldest disk generation for FRBACKUP processing to be successful.

Using Metro Mirror primary volume during fast replication backup

You can use the **FRBACKUP to PPRC Primary Volumes allowed** field in the SMS copy pool definition panel to indicate whether a Metro Mirror or Global Mirror primary volume is an eligible FlashCopy target, and whether a preserve mirror operation is required, preferred, or not desired when the target volume is a Metro Mirror primary volume during backup processing.

If you specify a value in the **FRBACKUP to PPRC Primary Volumes allowed** field, the value specified is considered in selecting FlashCopy target volumes for FRBACKUP processing during volume pairing. Otherwise, if you do not specify a value, DFSMSHsm uses the currently stored preserve mirror indicator for the copy pool. If no preserve mirror indicator is set for the copy pool, the default is NO.

If you specify a value in the **FRRECOV to PPRC Primary Volumes allowed** field in the SMS copy pool definition panel, the L0 volumes are not examined for FlashCopy to Metro Mirror or Global Mirror primary eligibility for FRRECOV processing during volume pairing. If preserve mirror is required during fast replication recovery using FlashCopy, you must ensure that your copy pool environment meets preserve mirror configuration requirements.

If preserve mirror is used in combination with incremental FlashCopy, the use of the PMPREF (preserve mirror preferred) or PMREQ (preserve mirror required) option needs to be consistent with the existing relationship when taking an increment. For example, if the existing incremental relationship was established without preserve mirror, an increment cannot be taken with the PMREQ option because the remote relationship will not exist and, therefore, an increment cannot be taken at the remote site. Do not change your preserve mirror settings between increments.

Note:

1. A Metro Mirror or Global Mirror primary volume is not allowed to be a FlashCopy target volume when:
 - NO is specified in the **FRBACKUP to PPRC Primary Volumes allowed** field
 - the NO option is in effect by default
 - the capability is not supported by the storage controller
2. Specifying PMNO, PMPREF, or PMREQ in the **FRBACKUP to PPRC Primary Volumes allowed** field does not guarantee that a Metro Mirror or Global Mirror primary volume is selected. You can ensure that a Metro Mirror or Global Mirror primary volume is selected by ensuring that only Metro Mirror or Global Mirror primary volumes exist in the copy pool backup storage group to be used.
3. When you specify PMNO or PMPREF in the **FRBACKUP to PPRC Primary Volumes allowed** field, use SETSYS FASTREPLICATION(DATASETRECOVERY(NONE)) to prevent the source (LO) volume from going into a duplex pending state during the recovery of an individual data set from disk.
4. The preserve mirror operation cannot be used in combination with fast reverse restore. Do not specify PMPREF or PMREQ in the **FRBACKUP to PPRC Primary Volumes allowed** or **FRRECOV to PPRC Primary Volumes allowed** fields for a copy pool defined allowing fast reverse restore.
5. The preserve mirror operation cannot be used in combination with space efficient FlashCopy. When you specify PMPREF or PMREQ in the **FRBACKUP to PPRC Primary Volumes allowed** field, space efficient volumes are not eligible FlashCopy targets.
6. When in a mixed release environment, releases prior to z/OS V1R11 specify the ALLOWPPRCP settings on the FRBACKUP command. z/OS V1R11 will always use the SMS values first. If the value has been set in the SMS copy pool definition in z/OS V1R11, the DFSMSShsm setting will be updated and the lower release hosts will use that value.
7. A Global Mirror primary volume is not allowed to be a FlashCopy target volume when:
 - NO is specified in the FRBACKUP to PPRC Primary Volumes Allowed field
 - the NO option is in effect by default
 - the capability is not supported by the storage controller
 - DISABLE(FLASHCOPYTOGM) is specified in your DEVSUPxx parmlib member
 - the DISABLE(FLASHCOPYTOGM) is in effect by default

Using the XRC primary volume during fast replication backup

You can use the FRBACKUP to XRC Primary Volumes allowed field in the SMS copy pool definition panel to indicate whether an XRC primary volume is an eligible FlashCopy target during backup processing.

If you specify a value (YES/NO) in the FRBACKUP to XRC Primary Volumes allowed field, the value specified is considered in selecting FlashCopy target volumes for FRBACKUP processing during volume pairing. If no XRC Primary allowed indicator is set for the copy pool, the default is NO. When you specify a value in the FRRECOV to XRC Primary Volumes allowed field in the SMS copy pool definition panel, the LO

volumes are not examined for FlashCopy XRC primary eligibility for FRRECOV processing during volume pairing. If remote pair FlashCopy to XRC is required during fast replication recovery, you must ensure that your copy pool environment meets remote pair FlashCopy/XRC configuration requirements.

The fast reverse restore option cannot be combined with the FlashCopy to XRC Primary option. Do not specify FRBACKUP to XRC Primary Volumes (YES) or FRRECOV to XRC Primary Volumes (YES) for a copy pool defined allowing fast reverse restore.

In a Metro/zOS GM environment, both XRC Primary YES and the PMREQ option must be set to allow FlashCopy to metro mirror and XRC primary volumes. See *z/OS DFSMS Advanced Copy Services* for more information.

Creating consistent copies using FlashCopy consistency groups

When logically related data spans across multiple volumes, FlashCopy consistency groups can be used to create consistent copies while minimizing application impact. You can indicate consistent backup copies are required for a copy pool by specifying **FlashCopy consistency group** in the SMS copy pool definition.

When this is specified, a consistency group will be formed during FRBACKUP. As each copy pool volume is processed, the FCFREEZE option will be used to specify that the source volume is to be part of a FlashCopy consistency group. The control unit will put the source volume in an extended long busy (ELB) state, causing I/O activities to be held at the host. When all volumes have been processed, DFSMSHsm will issue the DFSMSdss CGCREATED command to thaw all of the frozen volumes and I/O activities will resume on the volumes.

The frozen volumes will remain in extended long busy state until the Consistency Group Created command is received or when the FlashCopy consistency group timer expires. The default timer value is 2 minutes for CKD devices. If the frozen FlashCopy volumes are not already thawed when timer expires, the control unit will reset the extended long busy state and the held I/O activities will resume.

Since it is possible that the FlashCopy consistency group timer might expire before the consistency group has been formed, or that one or more frozen volumes might be thawed unexpectedly by another FlashCopy consistency group operation or by the thaw command, DFSMSHsm will always validate the frozen (ELB) state of the source volumes before thawing the volumes. If DFSMSHsm detects that the copy pool backup version might not be a consistent backup, it will fail the FRBACKUP operation and invalidate the new copy pool backup version.

Note:

1. To ensure a consistent copy can be created within the time window, the DFSMSHsm FlashCopy consistency group function is intended to be used for small LOG copy pools.
2. The thaw command is processed by each LSS receiving the command for all frozen FlashCopy volumes residing in the LSS, regardless of which FRBACKUP command (or job) froze them. Therefore, users should avoid creating multiple FlashCopy consistency groups with volumes in the same LSS at the same time. For example, do not run FRBACKUP of multiple copy pools using the FlashCopy consistency group option from multiple hosts concurrently, where the source volumes residing in the same LSS belong to the different copy pools being backed up.
3. When the FlashCopy consistency group option is used, all volumes are processed under one DFSMSdss server (address space). The total number of source volumes allowed in a consistency group is limited to 252.

Parallelism for fast replication backup copies to DASD

DFSMSHsm processes FRBACKUP COPYPOOL commands serially. To maximize throughput, DFSMSHsm creates the fast replication backup for the volumes in a copy pool in parallel. There are two levels of parallelism. The first level is that DFSMSHsm invokes DFSMSdss with the PARALLEL option and up to 254 volume pairs. The second level of parallelism is the number of DFSMSdss invocations that DFSMSHsm processes concurrently. DFSMSHsm processes between 1 and 64 DFSMSdss invocations concurrently, the default being 15. The number of concurrent DFSMSdss invocations that are processed and the number of parallel volumes passed to DFSMSdss can be modified with the SETSYS MAXCOPYPOOLTASKS(FRBACKUP(*nn*) DSS(*nnn*)) command.

Note: When the FRBACKUP COPYPOOL command uses FlashCopy consistency groups, DFSMSHsm processes all the copy pool volumes in one DFSMSdss invocation, regardless of the SETSYS MAXCOPYPOOLTASKS(FRBACKUP(*nn*) DSS(*nnn*)) setting.

Parallelism for fast replication backup copies to dump tape

DFSMSHsm uses the existing dump processing structure to dump fast replication target volumes to tape. Use the SETSYS MAXDUMPTASKS command to specify the number of concurrent volume dump tasks to use.

Recovering a fast replication backup

You can use the FRRECOV command to recover copy pools, volumes and data sets from the fast replication backup versions on DASD or tape. Prior to the recovery of a copy pool, DFSMSHsm will unallocate the specified catalogs. If DFSMSHsm cannot unallocate any of the catalogs, the FRRECOV operation might fail. Catalog reallocates the catalogs when used.

Examples

- You can use the following command to recover all of the volumes from a copy pool:

```
FRRECOV COPYPOOL(cpname)
```

The COPYPOOL(*cpname*) keyword indicates that all volumes associated with the named copy pool are to be recovered. You can specify the VERIFY keyword to verify that none of the volumes are in an unexpected FlashCopy relationship before starting the recovery. When the copy pool is defined allowing fast reverse restore, VERIFY(Y) indicates DFSMSHsm is to verify that the state of the FlashCopy relationships meet the fast reverse restore requirements. Otherwise, regular FlashCopy can be used for the copy pool or the FRRECOV command will be failed. VERIFY(N) indicates that the user has verified that the recovery can proceed successfully. VERIFY(N) cannot be specified when the copy pool is defined allowing fast reverse restore unless a previous FRRECOV COPYPOOL operation has determined the copy pool backup version is no longer eligible to use fast reverse restore. Regular fast replication recovery can be used instead. If one or more volumes fail, the FRRECOV command ends with a nonzero return code. If the copy pool was recovered without using fast reverse restore, volumes that fail recovery can be tried again using the TOVOLUME keyword. If the copy pool was recovered using fast reverse restore and the recovery was incomplete, volumes that were not recovered can be tried again by issuing the FRRECOV COPYPOOL command again. The RESUME(YES) keyword can also be used to retry recovery of volumes that previously failed to recover.

- You can use the following command to recover individual volumes:

```
FRRECOV TOVOLUME(volser)
```

The TOVOLUME keyword indicates that only 1 volume should be recovered from the copy pool. If the source volume specified by volume serial number is contained within a storage group that is defined within multiple copy pools, you must also specify the optional parameter FROMCOPYPOOL(*cpname*).

FRRECOV recovers the most recent DASD version available if it is not given a more specific source. If GENERATION(0) exists on both DASD and tape, the DASD copy is recovered. If the keyword FROMDUMP is used without any further specification of which dump to recover from, recovery of GENERATION(0) is attempted. If GENERATION(0) does not have a dump, then the command fails.

You can use the following command to retrieve the most recent copy of GENERATION(0) (DASD or DUMP) for the volume in the specified copy pool:

```
FRRECOV TOVOLUME(volser) FROMCOPYPOOL(cpname)
```

You can use the following command to recover the GEN(0) dump version of volume *volser*:

```
FRRECOV TOVOLUME(volser) FROMCOPYPOOL(cpname) FROMDUMP
```

You can specify the FROMDASD keyword to only consider DASD copies.

You can specify the FROMDUMP keyword to consider dump copies only. If two or more dump classes are used for the dump, you can use the DUMPCLASS(*dclass*) keyword to only consider dumps from *dclass*. Specify the DUMPVOLUME(*dvol*) keyword to use tape *volser* as the source.

Note: DUMPCLASS and DUMPVOLUME are mutually exclusive.

If a version other than the most recent must be recovered, you can specify the GENERATION, VERSION, DATE, or TOKEN keyword. Select the appropriate generation or version from the available versions that are returned by the DFSMSHsm LIST command or ARCXTRCT macro.

If DATE is specified, and more than one version exists for that date, then the most recent version from that date is recovered.

Use the TOKEN keyword to recover the unique version that corresponds to that token. If a token of less than 40 characters is passed in, then the token is left justified and padded with binary zeros before a backup version with a matching token is searched for. A hexadecimal token can be specified by using the X'...' Syntax. For example, TOKEN(12345) is equivalent to TOKEN(X'F1F2F3F4F5'). If the token is not unique, the most recent version that corresponds to the token is recovered. If no version exists with the specified token, the recover operation fails.

Results sent back to the user depend on whether the WAIT parameter is specified, and the success or failure of one or more volumes:

- If WAIT is specified by the user and all volumes are successfully processed, a successful return code of zero is returned.
- If WAIT is specified by the user and one or more volumes failed, a non-zero return code, and associated messages, are returned to the caller.
- If WAIT is not specified by the user, control is returned to the caller after the command has been accepted and verified. All messages continue to be issued, but the user is not notified when the command completes.

There is no keyword to perform a recovery at the storage group level.

For more information on using the FRRECOV command, see [Chapter 49, “FRRECOV command: Requesting a fast replication recovery,” on page 883](#)

Recovering a data set from a fast replication backup

You can use the FRRECOV command to recover individual data sets from a copy pool backup. On FRRECOV, specify one or more data set names (fully or partially qualified). If you specify a partially qualified data set name with a filter (wild card), DFSMSHsm processes every cataloged data set in the standard search order that matches your filtering criteria. The FRRECOV command allows you to:

- Specify fully qualified data set names.
- Specify partially qualified data set names.
- Use wild cards for data sets that have been moved and are cataloged. FRRECOV processing will attempt to recover and catalog moved data sets to the volume where they were allocated at the time of backup. If unable to recover the data set to the original volume, the most eligible volume with the most free space within the storage group will be selected.
- Recover an uncataloged data set, if the data set is fully qualified.
- Recover data sets that have been deleted or moved. FRRECOV processing uses the catalog information gathered at the time of backup to recover the data set. If the data set is cataloged at the time of recovery, FRRECOV compares the current catalog information to catalog information gathered at the time of backup to determine if it is a moved data set. If the data set has been deleted, DFSMSHsm

references the catalog information collected at the time of backup to recover the data set. FRRECOV will attempt to recover and catalog moved and deleted data sets to the volumes in which they were allocated at the time of backup. If unable to recover the data set to the original volume, the most eligible volume with the most free space within the storage group will be selected.

- Specify more than one data set and use wild cards in a multi-data set request.

Table 28 on page 272 shows the wildcard support on the FRRECOV command.

<i>Table 28. Wildcard support on the FRRECOV command.</i>			
Type of data sets that are specified with the FRRECOV command	Moved data sets	Deleted data sets	Original allocation
Single fully qualified data set	Process	Process	Process
Multiple fully qualified data sets	Process	Process	Process
Wildcard specified on a single or multiple data sets	Process	Not processed	Process

Note: You cannot use wild cards for deleted data sets.

For a FRRECOV of a data set to be successful, DFSMSHsm must have catalog information from either the catalog information data set captured at backup time or current catalog information at the time of recovery. If the catalog information is not captured, but the data set is cataloged at the time of recovery, the data set recovery is attempted. If the catalog information is not captured and the data set is cataloged at backup time, but it is not cataloged at the time of recovery, the individual data sets cannot be recovered using the DSNAMES() keyword.

If you omit a copy pool catalog name from the copy pool definition, data sets from that catalog are eligible for recovery if they were backed up in the copy pool and if they are currently cataloged to the same volumes in which they were allocated to at the time of backup. If you specify a catalog name that does not belong to the copy pool, DFSMSHsm captures the information for that catalog at the time of backup. During FRRECOV processing, DFSMSHsm uses the irrelevant catalog information to attempt to recover the data set, determines that the data set is not backed up as part of the copy pool, and fails the request. You can identify data sets that are backed up as part of a copy pool version using the DATASETS keyword on the LIST COPYPOOL command.

When you attempt to recover a data set that has changed volumes, the data set might be scratched and re-cataloged or just re-cataloged. If the data set is cataloged at the backup time, but not cataloged at the recovery time, the data set is allocated to the same volume on which the data set was allocated at the time of backup and DFSMSHsm re-catalogs the data set. If a data set is cataloged to different volumes at the recovery time than it was cataloged at the backup time, the data set is scratched, allocated to the volumes on which the data set was allocated at the time of backup, and then DFSMSHsm re-catalogs the data set. If this initial recovery attempt fails, DFSMSHsm will perform SMS volume selection within the primary storage group and retry data set recovery.

If you define a storage group in multiple copy pools, and then create a backup, the data sets in this storage group have multiple copies on the backup volumes. To recover these data sets, use the FROMCOPYPOOL(*cpname*) keyword on FRRECOV command to identify which copy of the data set to recover. You must also specify FROMCOPYPOOL(*cpname*) and a fully qualified data set name to recover a deleted data set. If you do not specify FROMCOPYPOOL for a deleted data set, DFSMSHsm fails.

FRRECOV processes each data set independently. If a data set is not found, FRRECOV continues processing until the other specified data sets are processed. On completion, FRRECOV processing issues messages to indicate which data sets are recovered and which requests fail. For wait-type requests, FRRECOV returns control when all of the data set recoveries have completed.

For a specified data set name, the high-level qualifier can be fully or partially qualified. You cannot specify two asterisks ('**') as the high-level qualifier or as the only qualifier but it can be specified in place of subsequent qualifiers. You can specify '*' within the high-level qualifier as long as it is not the first character specified. The remainder of the data set name can include any arrangement of wildcard characters. These restrictions help to prevent inadvertent requests for large numbers of data sets.

You cannot recover the following types of data sets using fast replication data set recovery:

- User catalog
- VVDS
- VTOC index
- VSAM key-range
- Migrated data sets
- GDG base

In the following example, DFSMSHsm requests a fast replication recovery for two data sets (DSNAME1 and DSNAME2).

```
FRRECOV DSNAME(DSNAME1,DSNAME2) REPLACE
```

You can use the following command to recover individual data sets:

```
FRRECOV DSNAME(USER.DATA.**,USER.LOG.**,USER.JOURNAL) REPLACE
```

The DSNAME keyword is mutually exclusive with the TOVOLUME and COPYPOOL keywords. If GEN, VER, DATE, TOKEN, or FROMDUMP(DVOL) are not specified, then the default is GEN(0).

NEWNAME is an optional keyword that allows you to recover a data set to different name on the same or different system, while preserving the originally-named data set for analysis or other purposes. You must specify the DSNAME keyword if you are also specifying NEWNAME(*newdsname*). If a data set already exists with the same name as the new name you are specifying, the REPLACE keyword must be specified to replace the existing data set.

REPLACE is a required keyword for cataloged data sets. FROMCOPYPOOL is a required keyword for deleted data sets. In order to recover a data set that is uncataloged but exists on a volume, you must specify both REPLACE and FROMCOPYPOOL.

FROMDASD and FROMDUMP are mutually exclusive optional parameters that can be used to indicate the source of the recovery. The default is to recover the data set from DASD. If a DASD copy is not available, then the tape copy is recovered. You cannot specify DVOL(*dvol*) with GEN, VER, DATE, or TOKEN.

FROMCOPYPOOL is an optional keyword, but you must specify this keyword if the volume or volumes that a data set resides on belong to multiple copy pools. FROMCOPYPOOL is only valid with the TOVOLUME and DSNAME keywords. You must specify FROMCOPYPOOL for recovery of deleted data sets. NOCOPYPOOLBACKUP is an optional keyword. When a partially qualified data set name is specified and a copy pool backup version is not found for a data set that matches the filtering criteria, the default return code is 8. When RC4 is specified with this keyword, a return code of 4 is returned instead. This keyword is ignored for fully qualified data set names.

FASTREPLICATION is an optional keyword. It overrides any value specified on the SETSYS FASTREPLICATION command. If not specified, the value of SETSYS FASTREPLICATION is used. This keyword is only valid with DSNAME. The command fails if this keyword is specified with COPYPOOL or TOVOLUME.

You can use the LIST COPYPOOL command to list all data sets that are backed up with a specified version. The list output also contains the data sets that were backed up but have been deleted, and indicates whether a full, partial, or no catalog information is captured for a specific copy pool version. Data sets are listed in alphabetical order by catalog:

```
LIST COPYPOOL(cpname) DATASETS(GENERATION(gen)|TOKEN(token))
```

Considerations for the FRRECOV command

The following topics are related to your use of the FRRECOV command:

- **Before processing an FRRECOV COPYPOOL command:** DFSMSDss restores a volume only if the volume is not allocated to another job. If the volume contains a catalog, the catalog address space in a DFSMSDfp environment may have the catalog (and the volume) allocated. If the copy pool catalog names are specified in the SMS copy pool definition, DFSMSHsm attempts to unallocate the catalogs prior to recovery. If the catalog names are not specified in the copy pool definition or the unallocation fails, follow these steps:
 1. Issue the F CATALOG,OPEN(*volser*) command to determine which catalogs on the target volume are allocated.
 2. For each catalog that is open, issue the F CATALOG,UNALLOCATE (*catalogname*) to cause the catalog address space to close the catalog and deallocate it. When the last catalog on the volume is deallocated, the target volume is also deallocated by the catalog address space.
 3. Issue a D U,,addr,1 command to ensure that the volume is not allocated by another user.
 4. If the volume is not marked as allocated, issue the FRRECOV command to DFSMSHsm.

If the catalogs on copy pool volumes are shared in ECS mode, the following steps must be followed. Otherwise, a catalog might be allocated on a different LPAR than the one doing the restore. This could cause a catalog breakage which might not be detected immediately. .

To avoid this, follow following steps before performing FRRECOV:

1. Remove any catalogs on the volumes to be restored from ECS using F CATALOG,ECSHR(REMOVE,*catalogname*) command.
2. LOCK or SUSPEND all the catalogs on the volumes which will be restored using F CATALOG,RECOVER,LOCK | SUSPEND(*catalogname*). SUSPEND is preferred.
3. UNALLOCATE all the catalogs on the volumes which will be restored from all systems using F CATALOG,UNALLOCATE(*catalogname*).
4. Issue FRRECOV to restore the volumes.
5. .If the backup copy of the catalogs were not LOCKed or SUSPENDed, there is no need to unlock them, but this can be done anyway.
6. Bring back any ECS catalogs that were removed from ECS with F CATALOG,ECSHR(ENABLE,*catalogname*).

Note: You may need to issue F CATALOG,VCLOSE(*volser*) after the full volume restores (Step 4) for each volume restored on each system. Or you could simply restart Catalog afterward to ensure every system is looking at the current VVDSs.

- **Modifying FRRECOV wait time for unallocating catalogs:** In a Common Recover Queue SYSPLEX environment, FRRECOV will issue the catalog unallocate command for each catalog name specified in the copy pool definition at the time of the FRRECOV. Wait time applies to all catalogs in the copy pool definition, it is not per catalog.

The wait time allows users to modify the amount of time FRRECOV will wait for the catalog to be unallocated prior to continuing with the recover process. The wait time is only utilized if operating in a CVQ environment or environment where the FRGCBF_ROUTEALL_UNALLOC bit has been patched on in the FRGCB.

The FRGCBF_ROUTEALL_UNALLOC bit defaults to ON in release V2R3 and later.

The default time is 3 seconds, a wait of 3 seconds = 300 one-hundredths of a second. This wait time can be adjusted with a patch to the FRGCB. For example, to change from 3 seconds to 6 seconds:

```
PATCH .FRGCB.+84 X'00000258' VERIFY(.FRGCB.+84 X'0000012C')
```

The field name being patched is FRGCB_CAT_UNALLOC_WTIME. If you do not want a wait time to be used, then patch the FRGCB_CAT_UNALLOC_WTIME field to X'00000000'.

- **Processing an FRRECOV command:** When SnapShot is used as the fast replication utility, a recovery can be performed immediately after the DFSMSHsm FRBACKUP command completes.

When FlashCopy is used as the fast replication utility, a recovery from a fast replication backup cannot be performed if any of the volumes are in an existing FlashCopy relationship unless fast reverse restore is to be used. If fast reverse restore is not intended, do not attempt to recover the copy pool until all of the background copies have completed from an invocation of the FRBACKUP command. You can use the QUERY COPYPOOL command to determine if any of the source volumes for a copy pool are in a FlashCopy relationship.

When a copy pool is defined without fast reverse restore capability, you can use the FRRECOV command with the VERIFY keyword to prevent the initiation of a recovery of a copy pool for which all of the background copies from the backup have not yet completed. When you specify VERIFY(Y), before initiating any volume recoveries, DFSMSHsm first determines if any of the volumes are in an existing FlashCopy relationship. If so, the recover fails. If you need an immediate recovery, you have two options:

1. Wait until all of the background copies have completed. Then the latest backup version can be used for the recovery.
2. For FlashCopy version 1, withdraw the outstanding FlashCopy relationships using the FRBACKUP COPYPOOL(*cpname*) WITHDRAW command. Doing this invalidates the latest version of the backup and enables an immediate recovery from the prior version. This process only works for FlashCopy version 2 when the generation 1 background copies are complete.

Attention: Use the LIST COPYPOOL command or the ARCXTRCT macro to ensure that you do not invalidate the only valid fast replication backup version.

When a copy pool is defined with fast reverse restore capability, the VERIFY(Y) keyword allows DFSMSHsm to determine whether fast reverse restore or regular FlashCopy can be used. For more information, see [“Recovering a copy pool using fast reverse restore” on page 278](#).

- **TSO usage considerations:** When you use commands that specify WAIT or NOWAIT, the results sent back to the user depend on whether the WAIT parameter is specified and the success or failure of one or more volumes:
 - If WAIT is specified and all volumes process successfully, a return code of zero is returned.
 - If WAIT is specified and one or more volumes fail, a nonzero return code and associated messages are returned.
 - If WAIT is not specified, control is returned to the system after the command has been accepted and verified. All messages continue to be issued, but you are not notified when the command completes.
- **Trying a copy pool recovery again:** During recovery of a copy pool, one or more volumes might fail to be recovered. In order to complete the recovery, you must identify and correct the cause of the failures. After correcting the cause of the failures, your options for completing recovery depend on the source of the recovery (DASD or tape) and if fast reverse restore was used.

- When the copy pool was recovered from DASD without using fast reverse restore (that is, the background copy completed before the recovery began), you can try to recover the individual volumes that failed, or try to recover the entire copy pool again.
 - If a small number of volumes failed recovery, issue a FRRECOV COPYPOOL(*cpname*) TOVOLUME(*volser*) command for each volume to try recovery of that volume again.
 - If FlashCopy version 2 or SnapShot is your fast replication utility, you can immediately try to recover the entire copy pool again.
 - If FlashCopy version 1 is your fast replication utility, you must wait for the FlashCopy relationships that were successfully established during the prior recovery to complete before you can try to recover the copy pool again.
- When the copy pool was recovered from DASD using fast reverse restore or the recovery was from tape, the recovery can be resumed. This is possible because the recovery status of each volume in the copy pool is tracked in the CDS records. The LIST COPYPOOL(*cpname*) command can be used to determine if a copy pool version previously failed recovery. If the recovery of a copy pool version failed, the LIST COPYPOOL output will indicate "RECOVERYINCOMPLETE=Y" and, if fast reverse restore was used, the fast replication state will be FCFRRINCOMPLETE. To resume recovery of the copy pool, issue a FRRECOV COPYPOOL(*cpname*) command specifying the same token, version, date, or generation as the failed command. The volumes that failed during the prior recovery are determined and a recovery is attempted for only those volumes that failed.

Note:

1. If the initial copy pool recovery was from a DASD version using fast reverse restore (the FASTREPLICATIONSTATE is FCFRRINCOMPLETE) and the recovery is resumed from a dump version, the default is to resume recovery of the remaining volumes. You can specify RESUME(NO) to perform a full recovery from tape. The copy pool DASD backup version will be invalidated when the copy pool recovery is completed successfully.
2. If the initial copy pool recovery was from a dump tape version and you are now trying to recover from the DASD version, a full recovery is performed.
3. The VTOC and the volume serial on the target volume may have changed as a result of the command. Before the volume can be accessed on any remote system, the UCB must be refreshed. The refresh occurs automatically if the volume is online and the device manager REFUCB function is enabled. You enable the REFUCB function through PARMLIB member DEVSUPxx or the MODIFY DEVMAN command. For more information, refer to the description of the REFUCB keyword in [z/OS MVS Initialization and Tuning Reference](#) or [z/OS MVS System Commands](#).

Selecting a data set level recovery method

If a backup version resides on disk, DFSMSHsm can perform data set recovery through either fast replication or traditional copy methods. You can use the SETSYS command to select a preferred method for data set recoveries.

To indicate the method in which data set recoveries are to be performed, enter the SETSYS command, as the following example:

```
SETSYS FASTREPLICATION(DATASETRECOVERY(PREFERRED))
```

In this example, PREFERRED is specified to indicate that fast replication should be used whenever possible. For situations in which fast replication cannot be used to recover a data set, recovery is done

through traditional copy methods. You cannot use fast replication for recovery when the backup version's background copy for the volume that the data set resides on, has not yet completed.

To use only fast replication, specify `FASTREPLICATION(DATASETRECOVERY(REQUIRED))`. Here, if fast replication cannot be used, the recovery request fails. To use only traditional copy methods, specify `FASTREPLICATION(DATASETRECOVERY(NONE))`.

Note: The SETSYS setting can be overridden by specifying FASTREPLICATION on the FRRECOV command.

Data set level recovery performance considerations

The elapsed time for data set level recovery varies significantly based on the recovery method that is used.

- **FlashCopy from disk.** When FlashCopy is used to perform the recovery, the recovered data set is available for use in a matter of seconds. Note that FlashCopy is not the default method for performing a recovery, because the recovery creates a FlashCopy relationship between the backup volume and the production volume. This relationship prevents a backup of the copy pool from being created until the background copy has completed and the relationship is terminated. The SETSYS `FASTREPLICATION(DATASETRECOVERY(option))` command can be used to change the default.
- **Standard I/O from disk.** When the recovery is from disk, standard I/O is the default recovery technique. The elapsed time for the recovery varies depending on the size of the data set. Small data sets may complete in seconds, while larger data sets may take minutes to tens of minutes.
- **Standard I/O from tape.** When the recovery is from tape, the elapsed time is significantly longer. The increase in the length of time is due to the time that it takes to find the data set on tape. Since the backup copies are created as a full volume dump, DFSMSHsm does not record the file block ID of each data set. This results in DFSMSHsm having to read through the entire dump volume contents to find the data set before it can begin recovering the data set. The time of the search is longer for larger volumes. This means that Db2 object level recovery from tape takes significantly longer than a recovery from disk. It also takes significantly longer than an object level recovery from a Db2 image copy created on tape.

Making dump classes available for data set level recovery and volume recovery

When multiple dump copies have been created for a fast replication backup version, DFSMSHsm needs to know which dump copy to use during recovery. You can specify this with the optional parameter `FRRECOV(AVAILABLEFORMOUNT(YES|NO))` on the `DEFINE DUMPCLASS` command. The default value, `FRRECOV(AVAILABLEFORMOUNT(YES))`, indicates that dump copies created for the dump class are available for recovery and can be selected during FRRECOV processing. `FRRECOV(AVAILABLEFORMOUNT(NO))` indicates that dump copies created for this dump class are not immediately available for recovery and the dump class name must be specifically specified on the FRRECOV command with the `FROMDUMP(DUMPCLASS(dclass))` keyword to use this dump class. When multiple dump copies are created for a backup version and more than one of the dump classes have `FRRECOV(AVAILABLEFORMOUNT(YES))` specified, the first dump copy found with YES specified is used. If `FRRECOV(AVAILABLEFORMOUNT(NO))` has been specified for all of the dump classes, then the user must specify `DUMPCLASS` or `DUMPVOLUME` on the FRRECOV command, otherwise the command fails. The `DUMPCLASS` and `DUMPVOLUME` keywords of the FRRECOV command always take precedence over the `DUMPCLASS FRRECOV` setting.

This example shows how to use the `FRRECOV(AVAILABLEFORMOUNT)` keyword:

```
DEFINE DUMPCLASS(ONSITE FRRECOV(AVAILABLEFORMOUNT(YES)))
DEFINE DUMPCLASS(OFFSITE FRRECOV(AVAILABLEFORMOUNT(NO)))
```

In this example, dump class `ONSITE` represents a dump class whose copies are kept at the production site. Since these tape copies are immediately available for recovery, the dump class uses the option `AVAILABLEFORMOUNT(YES)`. Dump class `OFFSITE` represents a dump class whose copies are stored offsite. This dump class specifies `AVAILABLEFORMOUNT(NO)` since the tapes are kept offsite and are not immediately available for recovery. When an FRRECOV command is processed, it automatically selects

dump copies associated with dump class ONSITE. To use the dump copies associated with dump class OFFSITE, specify FROMDUMP(DUMPCCLASS(OFFSITE)) on the FRRECOV command.

This FRRECOV dump class setting applies to FRRECOV tape processing at the data set and volume level.

Recovering a copy pool using fast reverse restore

You can use the FRRECOV COPYPOOL(*cpname*) command to recover all volumes associated with the named copy pool defined with fast reverse restore capability. DFSMSHsm saves the copy pool fast reverse restore capability setting at the time of the fast replication backup. There are no additional keywords to specify to recover from a DASD copy pool fast reverse restore eligible version. If the state of the FlashCopy relationships meet the fast reverse restore requirements, DFSMSHsm uses fast reverse restore to recover the copy pool. Otherwise, DFSMSHsm will use regular FlashCopy if the background copy has completed.

Following a successful fast reverse restore, the contents of the DASD backup volume become invalid. DFSMSHsm invalidates and initializes the individual DASD backup volume so it is ready to be reused. When the entire copy pool has been successfully recovered, DFSMSHsm invalidates the DASD copy pool backup version.

If some of the volumes fail to recover, the FASTREPLICATIONSTATE of the DASD version becomes FCFRRINCOMPLETE. You can issue the FRRECOV COPYPOOL(*cpname*) command again after you have addressed the reason for the failure. DFSMSHsm will try to recover the remaining volumes again using fast reverse restore.

Using fast reverse restore does not require the removal of all other FlashCopy targets when cascaded FlashCopy is supported by the storage subsystems. For a successful fast reverse restore when multiple targets are not supported, verify there are not multiple FlashCopy targets before issuing the FRRECOV COPYPOOL(*cpname*) command.

To determine if a copy pool is defined to allow fast reverse restore and select a fast reverse restore eligible backup version, issue LIST COPYPOOL (*cpname*). If the copy pool is defined allowing fast reverse restore at time of backup, the output displays the backup version with: FCFRR=Y. Otherwise, the output contains: FCFRR=N.

Example: LIST COPYPOOL(CP1) will list information about the copy pool named CP1, which is defined to allow fast reverse restore.

```
LIST COPYPOOL(CP1) OUTDATASET
-- DFSMSHsm CONTROL DATASET --COPY POOL--LISTING -- AT 09:25:44 ON 09/03/07 FOR SYSTEM=1234
COPYPOOL=CP1
ALLOWPPRCP FRB=PN FRR=PN
VERSION  VTOCENQ    DATE        TIME        FASTREPLICATIONSTATE  DUMPSTATE
  002      Y      2009/03/06    16:35:24    RECOVERABLE          ALLCOMPLETE
TOKEN(C)=C' '
TOKEN(H)=X' '
TOTAL NUM OF VOLUMES=000002, INCREMENTAL=N, CATINFO=N, FCFRR=Y, RECOVERYINCOMPLETE=N
```

To determine if fast reverse restore can be used for a copy pool version, issue the QUERY COPYPOOL command. When fast reverse restore can be used, the QUERY COPYPOOL command output will display "background copy percent-complete" (PCT-COMP) information other than "***". Percent-complete information (a percentage) is available for full-volume FlashCopy pairs with an incomplete background copy only. A full-volume FlashCopy relationship is established when the FlashCopy technique (such as fast reverse restore or incremental) designates it, or when SETSYS FASTREPLICATION(FCRELATION(FULL)) has been specified.

Because fast reverse restore will invalidate the entire DASD backup version following a successful recovery, you can use the PCT-COMP percentage to determine how far along the background copy is and decide whether fast reverse restore should be used for recovery.

Note:

1. A DASD backup version can be used for fast reverse restore only once because the process invalidates the data on the backup volume. Keep dump tape copies in addition to DASD backup copies when you plan to use the fast reverse restore function.
2. VERIFY(N) cannot be specified when the copy pool is defined allowing fast reverse restore unless a previous FRRECOV COPYPOOL operation has determined the copy pool backup version is no longer eligible to use fast reverse restore. Regular fast replication recovery can be used instead.
3. When a recovery operation such as fast reverse restore from a DASD backup will invalidate an existing DASD copy that has an incomplete dump copy, the recovery operation fails. To force the use of a DASD copy with an incomplete dump copy, specify the FORCE parameter on the FRRECOV command.
4. The preserve mirror operation cannot be used in combination with fast reverse restore. Do not specify PMPREF or PMREQ in the **FRBACKUP to PPRC Primary Volumes allowed** or **FRRECOV to PPRC Primary Volumes allowed** fields for a copy pool defined allowing fast reverse restore.
5. Do not use the TOVOLUME operation to recover individual volumes in a copy pool defined with fast reverse restore capability.

Recovering from a copy pool incremental version

There are no additional keywords to recover from a DASD copy pool incremental version. When a volume from an incremental version or a copy pool incremental version is recovered, only the tracks that have changed since the time the backup version was created are copied back to the source volumes. After the background copy for the recovery is complete, the persistent incremental relationships are withdrawn. The copy pool still remains incremental, and the incremental relationships are re-established once the new incremental version is created. When the new backup copy is created for the incremental version, the FlashCopy incremental relationship is re-established by creating a full copy of each volume.

The following restrictions apply to recovering from an incremental version:

- The FlashCopy incremental relationship must be the only relationship when the storage subsystem does not support cascaded FlashCopy.
- To use reverse restore, the background copy must have completed.
- To use fast reverse restore, the background copy must be in progress.

When recovering from an incremental copy pool version, the FlashCopy incremental relationship must be the only relationship when cascaded FlashCopy is not supported by the storage subsystem. When unsupported, if there are multiple incremental FlashCopy relationships, the unwanted FlashCopy targets (backup versions) must be removed prior to attempting recovery. The FRBACKUP WITHDRAW or FRDELETE commands can be used to remove DFSMSHsm managed backups.

In a configuration where the storage subsystems do not support cascaded FlashCopy, when a non-incremental copy pool version is recovered while an incremental version exists, the FlashCopy incremental volume relationships are withdrawn if the background copies of the incremental volume relationships have completed. The incremental version remains recoverable. If the FlashCopy incremental background copies are still active at the time the non-incremental version recovery is requested, the request fails. If the FlashCopy incremental relationships for the incremental version are persistent, individual volume recovery using the TOVOLUME keyword from a non-incremental copy pool version fails regardless of completion of the background copy.

Using Metro Mirror primary volume during fast replication recovery

The FRRECOV command uses fast replication to recover one or more data sets, a single volume, or a pool of volumes from the managed backup versions. You can use the SMS copy pool field **FRRECOV to PPRC Primary Volumes allowed** to indicate to DFSMSHsm whether a Metro Mirror or Global Mirror primary volume is an eligible FlashCopy target, and whether a preserve mirror operation is required, preferred, or not desired when the target volume is a Metro Mirror primary volume during fast replication recovery. DFSMSHsm indicates this option to DFSMSdss for fast replication recovery.

If you did not specify a value in the **FRRECOV to PPRC Primary Volumes allowed** field in the SMS copy pool definition panel, you can specify the ALLOWPPRCP keyword on the FRRECOV command. Specifying

ALLOWPPRCP on the FRRECOV command overrides the currently stored preserve mirror indicator for the copy pool. The ALLOWPPRCP value specified on the FRRECOV command, however, is used only once during the FRRECOV operation and is not stored in the copy pool record. You can use the LIST COPYPOOL(cpname) command prior to recovery to determine the value of the ALLOWPPRCP indicator.

If Preserve Mirror is used in combination with incremental FlashCopy, the use of the PMPREF or PMREQ option needs to be consistent with the existing relationship when recovering from an incremental version. For example, if the existing incremental relationship was established without Preserve Mirror, it cannot recover with the PMREQ option because the remote relationship will not exist and, therefore, an incremental FlashCopy cannot be done at the remote site. Do not change your Preserve Mirror settings between increments.

Note:

1. If you do not specify ALLOWPPRCP on the FRRECOV command, DFSMSShsm uses the currently stored preserve mirror indicator for the copy pool. If no preserve mirror indicator has been set for the copy pool, the default is NO.
2. ALLOWPPRCP is ignored when recovering from a tape.
3. When you specify a value in the **FRRECOV to PPRC Primary Volumes allowed** field, DFSMSShsm considers the value's setting when selecting FlashCopy target volumes for FRBACKUP processing during volume pairing. DFSMSShsm does not check if the LO volumes are eligible for FlashCopy to Metro Mirror and Global Mirror primary or preserve mirror operation for recovery processing during volume pairing, even if a value is specified in the **FRRECOV to PPRC Primary Volumes allowed** field in the SMS copy pool definition. If preserve mirror is required during fast replication recovery using FlashCopy, you must ensure that your copy pool environment meets preserve mirror configuration requirements.
4. A Metro Mirror or Global Mirror primary volume is not permitted to be a FlashCopy target volume when:
 - NO is specified in the **FRRECOV to PPRC Primary Volumes allowed** field
 - the NO option is in effect by default
 - the capability is not supported by the storage controller
5. When you specify PN or PP in the **FRRECOV to PPRC Primary Volumes allowed** field in the SMS copy pool definition or with the YES, PRESERVEMIRRORNO, or PRESERVEMIRRORPREFERRED parameter of the ALLOWPPRCP parameter on the FRRECOV command, use SETSYS FASTREPLICATION(DATASETRECOVERY(NONE)) to prevent the source (LO) volume from going into a duplex pending state during the recovery of an individual data set from disk.
6. A Global Mirror primary volume is not allowed to be a FlashCopy target volume when:
 - NO is specified in the FRRECOV to PPRC Primary Volumes Allowed field
 - the NO option is in effect by default
 - the capability is not supported by the storage controller
 - DISABLE(FLASHCOPYTOGM) is specified in your DEVSUPxx parmlib member
 - the DISABLE(FLASHCOPYTOGM) is in effect by default

Related reading

- For more information about the IBM Remote Pair FlashCopy, Metro Mirror, also known as synchronous Peer-to-Peer Remote Copy (PPRC), and other copy services functions, see [z/OS DFSMS Advanced Copy Services](#).
- For more information about the ALLOWPPRCP keyword, see [“Syntax of the FRRECOV command” on page 884](#).

Using the XRC primary volume during fast replication recovery

The FRRECOV command uses fast replication to recover one or more data sets, a single volume, or a pool of volumes from the managed backup versions. You can use the SMS copy pool field FRRECOV to

XRC Primary Volumes allowed to indicate to DFSMSHsm whether an XRC primary volume is an eligible FlashCopy target. DFSMSHsm indicates this option to DFSMSdss for fast replication recovery.

If you did not specify a value (YES/NO) in the FRRECOV to XRC Primary Volumes allowed field in the SMS copy pool definition panel, you can specify the ALLOWXRCP keyword on the FRRECOV command. Specifying ALLOWXRCP on the FRRECOV command overrides the currently defined FlashCopy to XRC Primary indicator for the copy pool. The ALLOWXRCP value specified on the FRRECOV command, however, is used only once during the FRRECOV operation and is not stored in the copy pool record. You can determine the value of the current FRRECOV to XRC Primary Allowed indicator for the COPYPOOL using the ISMF COPY POOL panels.

The fast reverse restore option cannot be combined with the FlashCopy to XRC Primary option. Do not specify FRBACKUP to XRC Primary Volumes (YES) or FRRECOV to XRC Primary Volumes (YES) for a copy pool defined allowing fast reverse restore.

In a Metro/zOS GM environment, both XRC Primary YES and the PMREQ option must be set to allow FlashCopy to metro mirror and XRC primary volumes. See [z/OS DFSMS Advanced Copy Services](#) for more information.

Parallelism for fast replication

DFSMSHsm processes the FRRECOV COPYPOOL commands serially. To maximize throughput, DFSMSHsm recovers the fast replication source volumes from the target volumes in parallel. There are two levels of parallelism. The first level is that DFSMSHsm invokes DFSMSdss with the PARALLEL option and up to 254 volume pairs. The second level of parallelism is the number of DFSMSdss invocations that DFSMSHsm processes concurrently. DFSMSHsm processes between 1 and 64 DFSMSdss invocations concurrently, the default being 15. The number of concurrent DFSMSdss invocations that are processed and the number of parallel volumes passed to DFSMSdss can be modified with the SETSYS MAXCOPYPOOLTASKS(FRRECOV(*nn*) DSS(*nnn*)) command.

Parallelism for fast replication data set recovery

The default value for the maximum number of concurrent data set recovery tasks is 2. Two SETSYS keywords are defined to manage the maximum number of tasks for data set recoveries. SETSYS MAXDSRECOVERTASKS is used to specify the maximum number of data set recovery tasks from either DASD or tape. SETSYS MAXDSTAPERECOVERTASKS is used to specify the maximum number of data set recovery tasks specifically from tape. The maximum number of tasks for data set recoveries from tape should be limited to the number of available tape drives.

The following example shows that as many as four tape devices are available to be used for data set recovery.

```
SETSYS MAXDSTAPERECOVERTASKS(4)
```

This value must be less than or equal to the maximum number of allowable tasks for data set recoveries from DASD and tape.

To prevent any data set recoveries from tape, specify:

```
SETSYS MAXDSTAPERECOVERTASKS(0)
```

To enable up to 32 data set recovery tasks from both disk and tape, specify:

```
SETSYS MAXDSRECOVERTASKS(32)
```

Up to 64 tasks can be specified. To maximize throughput for fast replication volume recovery, use the SETSYS DSSXMMODE command to start DFSMSdss in a separate address space to process these requests. For more information about this address space and controlling it, see [Chapter 65, “SETSYS command: Establishing or changing the values of DFSMSHsm control parameters,” on page 1057](#) and [z/OS DFSMSHsm Implementation and Customization Guide](#).

Parallelism for fast replication volume recovery from tape

The default value for the maximum number of concurrent volume recovery from dump tasks is 1. A SETSYS parameter is defined to manage the maximum number of tasks for volume recovery from dump. SETSYS MAXDUMPRECOVERTASKS is used to specify the maximum number of concurrent volume recovery from dump tasks. The maximum level of parallelism for multi-tasked recovery is limited by the number of tape drives available and how volumes are stacked on the dump tapes. If all volumes being recovered are stacked on a single tape, then only a single recovery task can be started.

The following example shows that as many as 32 volume recovery from dump tasks can run concurrently:

```
SETSYS MAXDUMPRECOVERTASKS(32)
```

A maximum of 64 tasks can be specified. To reduce the time required for fast replication volume recoveries from dump, DFSMSHsm scans the dump volume recover queue for other volumes that are on the same tape before requesting the tape be dismounted. For more information about using the MAXDUMPRECOVERTASKS parameter, see [Chapter 65, “SETSYS command: Establishing or changing the values of DFSMSHsm control parameters,” on page 1057.](#)

Withdrawing DFSMSHsm background copies

A FlashCopy relationship between a source volume and a target volume that was established through a FRBACKUP command should never be withdrawn outside of DFSMSHsm control. Doing so will invalidate the backup version, but DFSMSHsm will still manage the version as if it was valid. This may result in a data integrity exposure.

When it is necessary to withdraw one or more relationships established by a FRBACKUP command, you can use the following command:

```
FRBACKUP COPYPOOL(cpname) WITHDRAW
```

This command withdraws all current FlashCopy relationships associated with the volumes in the most recent VALID version for the specified copy pool. The version of the backup is marked as invalid unless it has a dump associated with it. In that case it becomes a dump only version.

If a dump is in progress for the version, then all incomplete dump copies for that version are marked as partial and are to be resumed. Any dumps completed before submission of the WITHDRAW command are kept and marked successful. Any volume that is currently being dumped when the WITHDRAW command is submitted is marked as a failure, though the dump is allowed to finish. Volumes that have yet to begin dumping at the time the command is submitted are marked as failed.

When a copy pool incremental version is withdrawn, the persistent relationships are withdrawn and the version is marked failed if the background copy was in progress. If the background copy is completed, the version remains VALID and recoverable.

If the most recent valid version is not generation zero and any relationships are withdrawn, then the withdrawn version is also deleted because it is no longer usable.

The withdraw can only be performed at the copy pool level. If any part of a copy pool backup version is invalidated, then the entire version is invalidated.

Attention: Use the LIST COPYPOOL command or the ARCXTRCT macro to ensure that you do not withdraw the only valid fast replication backup version. Withdrawing the only valid fast replication backup version will prevent recovery from being performed.

Note:

1. If a volume pair is withdrawn before DFSMSHsm completes the copy of the tracks that the target VTOC resides on, the target volume might become inaccessible. To avoid this, DFSMSHsm checks during WITHDRAW processing if a FlashCopy relationship exists on tracks where the VTOC resides, and invokes ICKDSF to initialize the volume. FlashCopy relationships on FlashCopy version 2 enabled volumes are withdrawn and the VTOC is recreated.

2. When a volume is initialized in a sysplex, only the host on which the volume was initialized is aware of the changes to the VTOC. You should vary off, and then on, the volumes identified in message ARC1838I to allow all hosts that share those volumes to recognize the changes to the VTOC. Message ARC1838I is most often issued when a volume is initialized in a sysplex using a copy pool defined with zero versions (NOCOPY mode).

Holding and releasing the fast replication functions

You can use the HOLD FRBACKUP and HOLD FRRECOV commands to hold and release the FRBACKUP function, as follows:

- **HOLD FRBACKUP.** This command indicates to DFSMSHsm that no new FRBACKUP commands are selected for processing.
- **HOLD FRRECOV.** This command indicates to DFSMSHsm that no new FRRECOV commands are selected for processing.

When you enter the HOLD FRBACKUP or HOLD FRRECOV command, all WAIT requests fail and all NOWAIT requests remain on the respective queue. Requests that have already been selected continue with normal processing.

The HOLD FRBACKUP command has a different effect if the host issuing the command is connected to a common dump queue (CDQ). New dump requests (any type from FRBACKUP, BACKVOL or AUTODUMP) from this host are submitted and processed by the CDQ, but the CDQ does not use the resources on this host to process them. If the host is the master scheduler in the CDQ, it is unable to perform scheduling of CDQ work. Consider using SETSYS MAXDUMPTASKS(0) from the master scheduler instead of this HOLD if you want the master scheduler to schedule CDQ work but not use its resources for CDQ dump processing.

You can use the RELEASE command from a host that is connected to a common dump queue to allow new a dump command, and auto dump volumes, to be selected and processed.

You can use HOLD DUMP and HOLD DUMP(FRBACKUP) commands to prevent any new dumps of FRBACKUP target volumes from being started by the FRBACKUP command.

You can use the HOLD FRRECOV and HOLD FRRECOV(TAPE) commands to prevent any new recoveries from a FRBACKUP generated dump. HOLD FRRECOV(TAPE) command only affects recovery from dump, but not from DASD backups.

You can use the HOLD FRRECOV(DATASET) command to hold data set recoveries from copy pool backup versions. HOLD RECOVER(TAPEDATASET) does not apply to the FRRECOV command.

You can use the RELEASE FRBACKUP and the RELEASE FRRECOV commands to release the holds that were placed on the respective functions.

You can use the RELEASE DUMP and RELEASE DUMP(FRBACKUP) to allow all FRBACKUP dump functions to be processed if no higher level HOLD is in effect.

You can use the RELEASE FRRECOV and RELEASE FRRECOV(TAPE) to allow all FRRECOV dump functions to be processed if no higher level HOLD is in effect.

You can use the RELEASE FRRECOV(DATASET) command to release only data set recoveries if they are not held at a higher level.

Deleting unneeded DFSMSHsm fast replication backup versions

Through normal processing, new backup versions replace older backup versions. There are two instances in which a process other than the normal roll-off case is required to delete an unneeded copy version. The first instance is when the number of versions specified for a copy pool is decreased. The second instance is when a copy pool is renamed or is no longer needed.

When the number of versions for a copy pool is decreased (by modifying the SMS copy pool definition), the next time that the FRBACKUP COPYPOOL command is issued for that copy pool, the unneeded versions are deleted. The target volumes that contained those versions are made available for other use.

When a copy pool is renamed or no longer needed, you must delete the backup versions that relate to that copy pool. You can use the following FRDELETE command to delete the backup and dump versions:

```
FRDELETE COPYPOOL(cpname) BOTH ALL
```

When you specify the VERSIONS keyword, the named backup versions are deleted. If you specify the TOKEN keyword, the version with the specified token is deleted. If you specify the ALL keyword, all backup versions are deleted. Before a version is deleted, any outstanding FlashCopy relationships are withdrawn. When a Fast Replication version is deleted, the associated catalog information data set is also deleted.

To limit your deletions to tape backups only, while preserving any DASD backups, specify the DUMPONLY keyword. The named backup versions are deleted only from tape dumps, but not from DASD backups. For example:

```
FRDELETE CP(COPYPOOL1) TOKEN(FRBACKUP_JUNEDATA) DUMPONLY
```

Here, DFSMSHsm deletes the dump copy of any fast replication backup for copy pool *COPYPOOL1* associated with token *FRBACKUP_JUNEDATA*. Omitting *DUMPONLY* from this command causes both tape and DASD backups associated with this token to be deleted.

You can also specify the DASDONLY keyword of the FRDELETE command to limit your deletions to DASD backups only.

When FRBACKUP fails because of an invalid request for an incremental version, the incremental version might need to be deleted to continue processing:

- Changing to a NOCOPY environment.
- Reduction in the number of copy pool versions necessitates an incremental version deletion.
- Current incremental version is not the oldest disk version and FCINCREMENTAL or FCINCREMENTALLAST is specified.

There are no additional keywords needed to delete an incremental version. Once an incremental version is deleted, the FCINCREMENTAL keyword must be used to re-establish the copy pool as having an incremental version.

When a Fast Replication version is deleted, the associated catalog information data set is also deleted. To limit your deletions to tape backups only, while preserving any DASD backups,

Obtaining DFSMSHsm fast replication backup information

You can use the QUERY command, the LIST command, the REPORT command, and the ARCXTRCT macro to obtain information regarding the fast replication backup versions that DFSMSHsm is managing.

Using the QUERY command to obtain fast replication information

[Table 29 on page 285](#) describes the QUERY command parameters that you can use to obtain information about the fast replication functions.

Table 29. QUERY command parameters used to obtain information about fast replication functions

Parameter	Description of use
COPYPOOL(<i>cpname</i>)	<p>When you use the COPYPOOL(<i>cpname</i>) parameter, DFSMSHsm returns message ARC1820I for each version that has one or more source volumes in a FlashCopy relationship. If there are no outstanding relationships, DFSMSHsm returns the ARC1821I message. For FlashCopy version 2, the source volume can be in more than one relationship. When using FlashCopy version 1, this command can be used to determine if another backup version can be created. This command can also be used to determine when all FlashCopy relationships are complete, so that a recovery can be performed. When you query a copy pool with an incremental version, only the versions with an active background copy are listed.</p> <p>When the FlashCopy technique (such as fast reverse restore or incremental) establishes a full-volume FlashCopy relationship, or when SETSYS FASTREPLICATION(FCRELATION(FULL)) has been specified, message ARC1820I will display "background copy percent-complete information" (PCT-COMP) for each full-volume FlashCopy pair. Three asterisks ("***") indicate percent-complete information is not available. The percent-complete information (the percentage) can be used to determine how far along the background copy is. Depending on the percent-complete information, you can decide whether to use fast reverse restore immediately, and reduce recovery time, or wait for the background copy to complete in order to use regular fast replication recovery and preserve the DASD backup version.</p> <p>If SnapShot is the fast replication utility, then the QUERY COPYPOOL(<i>cpname</i>) command is of no value. If you issue this command, DFSMSHsm will indicate that there are no outstanding FlashCopy relationships.</p>
ACTIVE	<p>When you use the ACTIVE parameter, DFSMSHsm lists two messages that relate to fast replication. Message ARC1822I describes an active FRBACKUP COPYPOOL or FRRECOV COPYPOOL command. Message ARC1826I shows whether FRRECOV is HELD at the level of EOD or EOV, shows whether FRBACKUP DUMP is HELD, ACTIVE, or both, and shows whether FRRECOVER(DATASET) is HELD, ACTIVE, or both. Message ARC0162I reports active fast replication data set recovery tasks.</p> <p>Note: If FRBACKUP DUMP is active, it could indicate that FRBACKUP DUMP command or FRBACKUP DUMPPONLY command is active. FRBACKUP dump could run several hours before it comes to the end. Multiple FRBACKUP DUMP MWEs may still be running after FRBACKUP MWE is purged, therefore, whether FRBACKUP DUMP is active does not necessarily mean that FRBACKUP command is active. If FRRECOVER(DATASET) is active, it indicates that FRRECOV DSNAME(<i>dsname</i>) is being processed.</p>
AUTOPROGRESS	<p>Message ARC1824I shows the number of copy pools that have not been completed by the active automatic function, and the total number of copy pools that are eligible to be processed. This message also shows the affinity and non-affinity copy pool count. Message ARC1828I shows the number of volumes for a specific copy pool that have not been processed, and the total number of volumes for this specific copy pool that are eligible to be processed by the active automatic function. ARC1828I also shows the affinity and non-affinity volumes count for the specific copy pool.</p>

Table 29. QUERY command parameters used to obtain information about fast replication functions (continued)	
Parameter	Description of use
SETSYS	When you use the SETSYS parameter, message ARC1823I indicates the current COPYPOOL settings for backup and recovery, and FASTREPLICATION settings. Message ARC0274I indicates the MAXDSRECOVERTASKS and MAXDSTAPERECOVERTASKS value.
STATISTICS	Individual data set recoveries from FRRECOV commands are reported together with data set restores from RECOVER commands in message ARC0641I. The number of FRRECOV DATASET commands are not recorded.
DATASET, USER, or REQUEST	When you use either the DATASET, USER, or REQUEST parameters, DFSMSHsm lists four messages that relate to fast replication. Messages ARC0162I and ARC0167I report on both the main FRRECOV DSNAME MWE and the individual data set recoveries that are derived from a FRRECOV command. Message ARC0167I displays VOLUME volser, COPY POOL= <i>cpname</i> waiting to be processed, data set name, and the number of MWES ahead of the present one. Message ARC1822I displays FRBACKUP DUMP or DUMPONLY MWE from COPY POOL <i>cpname</i> processed and waiting to be processed. The TOTAL number of MWES indicates the number of volume MWEs within same FRBACKUP command. Message ARC0161I displays the volser, copy pool name, user and request number for a volume being dumped as part of a copy pool.
WAITING	When you use the WAITING parameter, DFSMSHsm issues message ARC0168I to indicate the number of DFSMSHsm commands waiting to be processed. The fast replication backup commands are reported in the FRBACKUP= <i>nfrbackup</i> field. The individual dump commands derived from an FRBACKUP DUMP or FRBACKUP DUMPONLY command are included in the BACKUP= <i>nbackup</i> field. The fast replication recover commands are reported in the FRRECOV= <i>nfrrecov</i> field. The individual data set recover commands derived from an FRRECOV DSNAME command are included in the RECOVER= <i>nrecover</i> field.

Using the LIST command to obtain fast replication information

Table 30 on page 286 describes the LIST command parameters that you can use to obtain information about the fast replication functions.

Table 30. LIST command parameters used to obtain information about fast replication functions	
Parameter	Description of use
COPYPOOL	When you use the COPYPOOL parameter, with no copy pool name, DFSMSHsm returns version information for each copy pool that has at least one attempted backup. This information includes the copy pool name, version number, valid or invalid, VTOCENQ, token, backup date, and time. Source and target volume pairs are not listed. Information about whether a version has a dump, or DASD copy, or both, is also included. The SELECT keyword allows the user to limit the scope of output based on the state of the FRBACKUP or FRDUMP.

Table 30. LIST command parameters used to obtain information about fast replication functions (continued)	
Parameter	Description of use
COPYPOOL(<i>cpname</i>)	<p>When you use the COPYPOOL(<i>cpname</i>) parameter, DFSMSHsm returns detailed version information for each backup version for the specified copy pool. This information includes the copy pool name, version number, valid or invalid, VTOCENQ, token, backup date, and time. Source and target volume pairs are included in this list. (The date and time fields are zero for "Prepare" versions). COPYPOOL(<i>cpname</i>) displays the most recent ALLOWPPRCP settings for the copy pool as follows:</p> <p>NO is displayed for the NO option.</p> <p>PN is displayed for the PRESERVEMIRRORNO or PMNO option.</p> <p>PP is displayed for the PRESERVEMIRRORPREFERRED or PMPREF option.</p> <p>PR is displayed for the PRESERVEMIRRORREQUIRED or PMREQ option.</p>
COPYPOOL(<i>cpname</i>) ALLVOLS(TOKEN(<i>token</i>))	When you use the ALLVOLS(TOKEN(<i>token</i>)) parameter, DFSMSHsm limits the LIST information to the version or versions associated with a specific TOKEN request.
DATASETS GENERATION(<i>gennum</i>)	Specifies that DFSMSHsm is to list data sets associated with a particular generation. The default, DATASETS GENERATION(0), lists only the most recent DASD and dump copies.
DATASETS TOKEN(<i>token</i>)	Specifies that DFSMSHsm is to list data sets associated with the version with the specified token.
DUMPCLASS	When you use the DUMPCLASS parameter, DFSMSHsm returns information regarding whether the dump class associated with the copy pool is required or optional.
DVOL	When you use the DVOL parameter, DFSMSHsm returns information regarding whether the volume resides in a copy pool.
HOST	When you use the HOST parameter, DFSMSHsm lists the host holding a copy pool resource. If subparameter RESET is specified, DFSMSHsm resets associated serialization fields.
PVOL	When you use the PVOL parameter, with either the BCDS or BOTH subparameters, DFSMSHsm returns information about which copy pools the volume is associated with. With ALLDUMPS or BCDS subparameters, should also consider copy pool dumps. Copy pool dumps versions should include the name of the source copy pool. If the volume is in a copy pool, associated information needs to be displayed. Target volumes of a copy pool source/target pair does not display information. To determine which target volumes are associated with a particular source volume, you can use the LIST COPYPOOL(<i>cpname</i>) command.

Using the REPORT command to obtain fast replication information

Table 31 on page 288 describes the REPORT command parameters that you can use to obtain information about the fast replication functions.

Table 31. *REPORT* command parameters used to obtain information about fast replication functions

Parameter	Description of use
DAILY	When you use the DAILY parameter, DFSMSHsm reports the following: <ul style="list-style-type: none"> • The total number of requested fast replication volume backups. • The total number of fast replication volume backups that failed. • The total number of requested fast replication volume recovers. • The total number of fast replication volume recovers that failed.
VOLUMES	When you use the VOLUMES parameter, DFSMSHsm reports the following: <ul style="list-style-type: none"> • The total number of times a fast replication backup was attempted for the volume. • The total number of failed backup attempts for that volume. • The total number of times a fast replication recover was attempted for the volume. • The total number of failed recover attempts for that volume.

Note: Statistics for dump copies created for copy pool backup versions are reported with existing report categories for dump and recovery. Also, statistics for data set recoveries from copy pool backup versions are reported with the existing data set restores from dump copies. Note that bytes/tracks written statistics are not recorded for data set recoveries from copy pool backup versions.

Using the ARCXTRCT macro to obtain fast replication information

You can use the ARCXTRCT macro to obtain information about the fast replication function. When you use the data type of COPYPOOL and the COPYPOOL keyword with its associated subparameter, the ARCXTRCT macro returns information for each version of a specified copy pool. This information includes the version number, generation number, valid or invalid indicator, incremental indicator, date, time, token, dump class name, and other dump class information.

Preventing DFSMSHsm functions from processing target volumes

The DFSMSHsm automatic functions (Primary Space Management, Autobackup, and Interval Migration) only process pool type storage groups. These automatic functions do not process copy pool backup storage group types.

The BACKVOL STORAGEGROUP command only processes pool type storage groups. This BACKVOL command will not process copy pool backup storage groups.

The BACKVOL VOLUME and the MIGRATE VOLUME commands will not process any volumes that reside in a copy pool backup storage group.

Other copy pool considerations

You might encounter the following situations as you use copy pools and fast replication methods.

Migration of data sets within a copy pool

DFSMSHsm *does not* support the migration of data sets within a copy pool, although it is not explicitly prevented. Recovering a copy pool or a volume within a copy pool from which data was migrated will cause data loss.

Data set recovery errors

A data set that fails recovery remains cataloged, but its integrity is unknown. It is your responsibility to ensure that a data set that fails recovery is not used for processing. When one or more pieces of a

multivolume data set fail, the failed pieces are listed as a part of message ARC1861I. The successful pieces are not listed as a part of message ARC1860I.

Maintaining catalogs with fast replication backup

Because a fast replication backup is a physical copy of the data, you should take special care to ensure that the catalogs stay synchronized with the data. Catalogs should be copied with the data that they represent so that both can be recovered to the same point-in-time.

If it becomes necessary for you to recover an individual volume and not the corresponding catalog, you must be aware that the data on the volume will not be synchronized with the catalog and the following may occur:

- Data sets may exist on the volume but not in the catalog.
- The catalog may have entries for data sets on the volume that are not actually present.
- Data set information for existing data sets in the catalog may be inaccurate.

Increasing the number of volumes in a copy pool

When one or more volumes are added to a storage group within a copy pool, DFSMSHsm includes those new volumes with any subsequent backup versions. If you must recover a version that does not contain the new volumes, and data has been placed onto those volumes, after the recovery, those volumes will contain residual data that is unusable and must be cleaned up.

Example: If you have a storage group that has 2 volumes (volumes A and B) and you request a fast replication of those two volumes. Later on, you add a third volume (volume C) to the storage group. New data is then placed onto volume C. You discover that an error has occurred and that you need to recover the last backup version. During the recovery, volumes A and B are recovered to the point of the fast replication. Because volume C was not a part of the original fast replication backup, it is not processed during the recovery. Volume C may contain data that is no longer valid and you will need to review this data on the volume. DFSMSHsm issues message ARC1810I for each volume that fits this scenario.

Decreasing the number of volumes in a copy pool

Removing a volume from a storage group defined to a copy pool Special care must be taken when removing a volume from a storage group that is included in one or more copy pool definitions. When a volume is removed from a storage group, it will no longer be included in subsequent backup copies, but it will still be required to be available for copy pool recovery operations. Copy pool recovery is a volume to volume operation and requires all of the original volumes to be available at the time of the recovery. A volume that is removed from a storage group should not be reused for data set allocations until there are no remaining copy pool backup versions that include that volume. An exception to this rule are copy pools for which only data set level recoveries will be performed. In this case, a volume can be removed and reused immediately elsewhere in the configuration because data set level recovery performs volume selection and can recover a data set to a different volume than the original.

The LIST COPYPOOL(*cpname*) command can be used to determine which volumes are included in each copy pool backup version. When the removed volume is no longer returned in the output of this LIST command, it is no longer included in a backup version and may be used elsewhere in the environment.

When a copy pool recovery is performed, as each volume is recovered, DFSMSHsm will verify that the volume is still defined to the same storage group within the copy pool as it existed at the time of the backup. Any volume that fails this verification will fail to be recovered. This prevents the recovery process from overlaying any data that is written to the volume after it was removed from the copy pool. Any valid data that exists on a volume that failed recovery must be moved to a different volume. Once there is no more valid data on the volume, the volume must be redefined to the original storage group within the copy pool. After this has been completed for each volume that failed, the entire copy pool may be recovered once again, or just the individual volumes that failed may be recovered using the TOVOLUME keyword.

Example: Copy pool CPA is defined with one storage group, SGA. SGA is comprised of 2 volumes, VOLA and VOLB. Copy pool CPA is backed up nightly to disk and tape. After the disk backup completes, the disk

backup is dumped to tape. For this copy pool, one backup copy is maintained on disk and seven backup copies are maintained on tape.

A single, larger volume, VOLC is added to SGA within the copy pool. All of the data is moved from volumes VOLA and VOLB to single volume VOLC. VOLA and VOLB are removed from the storage group definition for SGA.

Before the next backup copy is created, there are 8 backup versions that contain volumes VOLA and VOLB. If one of these versions need to be recovered, then the recovery will require volumes VOLA and VOLB to be returned to storage group SGA.

These are the steps that can be taken:

1. If VOLA and VOLB have not been reused at all, as is recommended, redefine them to storage group SGA before the recovery. The copy pool recovery will be successful.
2. If VOLA and VOLB are not returned to the storage group before the copy pool is recovered, each volume will fail with message ARC1811E. Remove any valid data from the volumes, redefine them to storage group SGA and retry the recovery.
3. In the case of a larger copy pool definition where most volume recoveries are successful and only a small number of volumes fail with the ARC1811E message, each of the failed volumes can be recovered individually after redefining them to the original storage group:

```
FRRECOV TOVOLUME(volser) FROMCOPYPOOL(cpname) VERSION(vernum)
```

FROMCOPYPOOL and VERSION are optional keywords used in this example. (If fast reverse restore was used for the recovery, there is no need to selectively recover just the failed volumes. DFSMSHsm knows which volumes failed and will selectively retry only those volumes if the FRRECOV COPYPOOL command is reissued).

4. In all cases, VOLC should be reinitialized as part of the recovery process since the data on it is no longer valid.

As new backup copies are created, the newer backup copies will contain only volume VOLC. If one of these versions need to be recovered, no additional action is required because the active configuration is what existed at the time of the backup.

After the single disk backup and all seven tape backup copies that contained volumes VOLA and VOLB have been replaced with newer backup copies that contain only VOLC, then volumes VOLA and VOLB can be used elsewhere in the system configuration.

Decreasing the number of volumes in a copy pool backup storage group

You must take special care when removing a volume from a copy pool backup storage group. Before doing so, you **must** ensure that the volume is not the target of a valid DFSMSHsm backup version. You can verify this by examining the output from the DFSMSHsm LIST COPYPOOLBACKUPSTORAGEGROUP command.

If a target volume needs to be removed from a valid source to target pairing, you should use the FRDELETE command to delete the DFSMSHsm backup version that the volume is a part of before you remove the volume.

Defining a storage group to multiple copy pools

Although you may include a storage group in multiple copy pools, IBM recommends against doing this when FlashCopy version 1 is used as your the fast replication utility. If the FRBACKUP COPYPOOL command is issued for a copy pool with a common storage group, other copy pools with that same common storage group cannot be backed up until the background copies for all of the volumes in the common storage group have completed. Even though the first FRBACKUP COPYPOOL command logically completes in a manner of minutes, allowing the subsequent FRBACKUP commands to be issued, the subsequent FRBACKUP commands will fail until all of the background copies are complete, which might take several hours. This prevents the volumes in the noncommon storage groups in those copy pools from having a timely backup created.

FlashCopy version 2 and SnapShot do not have this restriction.

Using multivolume data sets in a fast replication environment

You must give special consideration to multivolume data sets in a fast replication environment. Because VTOC enqueues are obtained as each volume is processed, it is possible for a multivolume data set to be updated on one of its volumes while the other volume is being fast replicated. To prevent this from occurring, you should ensure that data set activity for multivolume data sets is quiesced during the fast replication process.

When recovering multivolume data sets, DFSMSHsm creates individual data set recovery commands to recover each piece of the data set from each volume. After all of the individual pieces have completed processing, DFSMSHsm determines if the multivolume data set has been recovered successfully or not. To determine if a multivolume data set recovered successfully, look for messages ARC1863I, ARC1864I and ARC1865I. It is possible that individual pieces recover successfully, while the data set as a whole fails. It is also possible for individual pieces to fail, while the data set as a whole is successful (This occurs if the data set has extended to one of more volumes that it does not reside on at the time of the backup. DFSMSHsm determines that the data set has grown, scratch the space off of the volumes that the data set extended to after the backup, and recatalog the data set onto only the original volumes).

Multivolume VSAM data sets with AIXs fail with message ARC1866I RC16. In order to recover the VSAM data set, all associated AIXs must be deleted. You can then recover the data set and recreate the AIXs. If a multivolume data set that has changed sizes cannot be recataloged, message ARC1865I lists the volumes to which the user should recatalog the data set.

Using the APPLYINCREMENTAL keyword

The APPLYINCREMENTAL (AINC) keyword of the FRRECOV command is *only* valid with the TOVOLUME keyword. This keyword specifies that an incremental volume recovery process immediately follows after the volume restore, and is part of the single request to recover a specific volume. APPLYINCREMENTAL is supported on eligible dump volumes created by the FRB DUMP command or automatic dump.

Using an alternate copy pool backup storage group

For the FRBACKUP command, you can override the copy pool backup storage group defined in the pool storage groups with an alternate storage group by specifying the BACKUPSTORAGEGROUP(*bsgname*) keyword with a copy pool backup storage group (CPBSG) name. For example:

```
FRBACKUP CP(cpname) BACKUPSTORAGEGROUP(bsgname)
```

When you specify the BSG keyword, there cannot be any existing DASD backup versions for the copy pool.

When the keyword is specified, DFSMSHsm will override the CPBSG defined in the pool storage groups with the alternate CPBSG. Once the override has been established, DFSMSHsm will continue to use the alternate CPBSG for subsequent FRBACKUP commands even if the BSG keyword is not present.

To reset fast replication backup to the original CPBSG, issue the FRBACKUP command with the BSG keyword without specifying a CPBSG name. As with setting up an override, no existing fast replication DASD backup versions for the copy pool are allowed. For example:

```
FRBACKUP CP(cpname) BACKUPSTORAGEGROUP
```

Defining an override copy pool backup storage group

The storage group type should be defined as a COPY POOL BACKUP.

Collecting fast replication messages in message data sets

In order to simplify problem determination in the event of an error, DFSMSHsm can collect all DFSMSHsm and DFSMSdss messages issued for an FRBACKUP and FRRECOV COPYPOOL request, auto dump of a copy pool and FRRECOV TOVOLUME FROMDUMP in a dynamically allocated, unique message data

set. Fast replication messages are additionally written to activity logs. To enable the collection of fast replication messages in message data sets, issue the SETSYS FASTREPLICATION(MESSAGE DATASET(YES HLQ(*hlq*))) command. For more information, refer to Chapter 65, “SETSYS command: Establishing or changing the values of DFSMSHsm control parameters,” on page 1057.

Message data set allocation

Fast replication message data sets must be SMS-managed. DFSMSHsm allocates the physical sequential data sets with these attributes:

Record Format

FBA

LRECL

121

Block size

1210

System defaults for primary and secondary space, as specified in ALLOCxx, will be used. To override this, define a data class that specifies appropriate space attributes and modify the ACS routine to assign the data class to DFSMSHsm message data sets.

Message data set names have the following format:

- For FRBACKUP requests: *msgdsprefix.FB.Ccccccc.ippppppp.Dyyddd.Thhmmss.z*
- For FRRECOV requests: *msgdsprefix.FR.Ccccccc.ippppppp.Dyyddd.Thhmmss.z*
- For FRRECOV TOVOLUME requests: *msgdsprefix.FR.Vvolser.Dyyddd.Thhmmss.z*

where:

msgdsprefix

is the value of the HLQ parameter of the SETSYS FASTREPLICATION(MESSAGE DATASET) command, if specified. If the HLQ parameter is not specified, the default prefix of 'HSMMMSG' is used.

cccccc

is up to 7 characters to identify the copy pool that was processed. For a non-Db2 copy pool, this will be the first 7 characters of the copy pool name. For a Db2 copy pool, this will be the first 7 characters of the location qualifier in the Db2 copy pool name.

Underscore characters in the copy pool name will be replaced with a hyphen to satisfy MVS data set naming convention.

i

is a 1-character identifier, indicating whether the message data set contains messages regarding:

D

Db2 data

L

Db2 log

X

non-Db2 copy pool data

ppppppp

is up to seven characters to identify the copy pool that was processed. For a non-Db2 copy pool, this is the next seven characters of the copy pool name (the characters following ccccccc). For a Db2 copy pool, this is the next seven characters of the location qualifier in the Db2 copy pool name.

volser

is the volser of the volume that was recovered.

yyddd

is the year and day when the FRBACKUP, FRRECOV, or copy pool auto dump operation started.

hhmmss

is the time in hours, minutes, and seconds when the FRBACKUP, FRRECOV, or copy pool auto dump operation started.

z

indicates the status of the FRBACKUP, FRRECOV, or copy pool auto dump operation, and is set to one of the following:

S

Success. The operation completed successfully.

F

Fail. One or more errors occurred while processing the operation.

I

In progress. DFSMSHsm allocates the data set with this final qualifier, and renames the data set with one of the other qualifiers once the operation completes

When DFSMSHsm attempts to allocate a message data set and a data set with the selected name already exists, DFSMSHsm increments the time stamp in the data set name by one second and attempts to allocate with this new name. DFSMSHsm renames the data set up to a maximum of 10 times, and if a unique message data set name is not found, an ARC1873I message is issued and messages are not captured for this request.

You can specify the date and time used in the message data set name with the MESSAGEDATASET parameter of the FRBACKUP command and the FRRECOV COPYPOOL command. Refer to [Chapter 46, “FRBACKUP command: Requesting a fast replication backup or dump version,”](#) on page 865 and [Chapter 49, “FRRECOV command: Requesting a fast replication recovery,”](#) on page 883.

Message data set contents

DFSMSHsm allocates a message data set for a request once the FRBACKUP, FRRECOV or auto dump operation has been verified as eligible for processing. Therefore, messages indicating parse errors or termination prior to the ARC1801I or ARC1841I start message being issued are not placed in a message data set.

DFSMSHsm prefixes each message written to the message data set with the date and time that the message was written to the data set, along with the ID of the host that wrote the message. The following format is used: *yy/mm/dd hh:mm:ss Hx message-text* where *x* is the host ID. Some messages appear multiple times in a message data set.

Message data set example

This command is issued:

```
FRBACKUP COPYPOOL(DSN$PAYROLLA123$DB) DUMP
```

DFSMSHsm performs an FRBACKUP DUMP of Db2 copy pool DSN\$PAYROLLA123\$DB using the common dump queue. Message data set support has been enabled, so DFSMSHsm allocates message data set HSMMSG.FB.CPAYROLL.DA123.D14325.T100910.S.

```
14/11/21 10:09:10 H2 ARC1801I FAST REPLICATION BACKUP DUMP IS STARTING FOR COPY POOL DSN$PAYROLLA123$DB, AT 10:09:10

Volume recovery and restore

Volume recovery refers to the process of recovering a level 0 volume to its original condition as of a specified date. Volume recovery is typically necessary only after a complete volume has been damaged.

Four methods exist for DFSMSHsm volume recovery:

- Full-volume restore with update from incremental backup versions
- Full-volume restore
- Volume recovery from incremental backup versions
- Volume recovery with the fast replication function

Because full-volume restore with update is somewhat a combination of the other two methods, and therefore the most complete, it is discussed first.

When recovering volumes by using backup versions either for update or as the only source, DFSMSHsm provides optimized tape usage. The optimization is accomplished by recovering all required data sets from each individual tape in priority order with a single tape mount.

When recovering volumes by using backup versions either for update (APPLYINCREMENTAL) or as the only source, DFSMSHsm recovers all cataloged non-VSAM data sets—whether they are SMS-managed—and all cataloged VSAM non-SMS-managed data sets to the volume being recovered. DFSMSHsm may recover VSAM SMS-managed data sets to other volumes in the same storage group as the volume being recovered.

The procedures for recovering an ML1 volume differ from those for recovering a level 0 volume. See [“Recovering a migration volume”](#) on page 552 for a discussion of the procedures for ML1 volumes.

Attention: DFSMSHsm incremental recovery and volume restore with APPLYINCREMENTAL does not support a device type change on the volume being recovered. If the device type is changed after the volume is backed up and if the device type in the catalog for all data sets residing on the volume is not changed, all VSAM data sets will fail to be recovered. All non-VSAM data sets may appear to be recovered successfully, but the first allocation after the recovery will fail because of the inconsistent unit name and device type that were created by the recovery.

Specifying the maximum number of data set recovery tasks in each host

In recovering from incremental backup versions (as the only source or during APPLYINCREMENTAL processing after a volume restore), DFSMSHsm can recover multiple data sets in parallel.

The MAXDSRECOVERTASKS parameter of the SETSYS command controls the number of concurrent data set recovery tasks (to a maximum of 64) that should be started for both DASD and tape; and the MAXDSTAPERECOVERTASKS parameter of the SETSYS command specifies the maximum number of concurrent data set recovery tasks that should be started for tape. To decide how many concurrent tasks DFSMSHsm should run, consider how many tape drives are available if you use tape backup volumes.

MAXDSTAPERECOVERTASKS is an optional SETSYS keyword. SETSYS MAXDSTAPERECOVERTASKS(0) should be specified if you do not want any data set recoveries from tape. The default value of MAXDSTAPERECOVERTASKS is the value of MAXDSRECOVERTASKS, and cannot exceed the value specified for MAXDSRECOVERTASKS. This requires you to specify MAXDSRECOVERTASKS before MAXDSTAPERECOVERTASKS, if the value for MAXDSTAPERECOVERTASKS is greater than the default value for MAXDSRECOVERTASKS.

Specifying the maximum number of volume recovery from dump tasks

DFSMSHsm can process up to 64 volume recovery from dump tasks concurrently. The MAXDUMPRECOVERTASKS parameter of the SETSYS command defines the maximum number of volume recovery from dump tasks that can be concurrently processed. The default value is 1. A value greater than 1 must be specified to allow multi-tasked volume recovery from dump tapes. The MAXDUMPRECOVERTASKS value specified becomes the maximum number of simultaneous volume recovery tasks that can be processed using the FRRECOV and RECOVER commands. When recovering

volumes without using fast replication, multiple RECOVER commands must be issued to take advantage of multi-tasked volume recovery from dump.

For example, the following SETSYS command specifies that a maximum of 64 volume recovery from dump tasks can be processed concurrently:

```
SETSYS MAXDUMPRECOVERTASKS(64)
```

In the above example, the maximum number of concurrent volume recovery from dump tasks is 64. This allows you to issue multiple RECOVER commands and that those commands can be processed concurrently (a maximum of 64 concurrent volume recovery tasks). In addition, it also allows a single FRRECOV command to initiate up to 64 concurrent recovery operations from tape.

To decide how many concurrent volume recovery from dump tasks DFSMSHsm should process, consider how many tape drives are available. If any dump class involved is defined with a STACK value of more than 1, DFSMSHsm writes multiple dump copies sequentially as each tape is mounted for that dump class. The maximum level of parallelism for multi-tasked recovery is limited by how volumes are stacked on the dump tapes. If all volumes being recovered are stacked on a single tape, then only a single recovery task will be started for those volumes. The reduced parallelism might lengthen the total time needed for the volume recovery to complete.

When the SETSYS COMMONQUEUE(RECOVER(CONNECT(*basename*))) command is specified, the preference by the system will be to fully utilize the available recover tasks as defined by MAXDUMPRECOVERTASKS on all of the CVQ group members in the HSMplex. Note that when this SETSYS is *not* specified, only local tasks where the command was issued will be utilized. This reduced parallelism might shorten the total time necessary for the recover operations to complete. In either case, the number of concurrent tasks is further limited by the stacking of the volumes on the dump tapes. For example, recovering 100 volumes from a single tape uses only a single recover task.

If you want a common recover host to be able to submit volume restore work, but not process the work, issue the SETSYS MAXDUMPRECOVERTASKS(0) command on that host. This can be either a master scheduler host or a non-master scheduler host. In the case of a master scheduler host, this does not impact the master scheduler duties for the common recover queue.

Full-volume restore with update

Attention: Most of the DASD that is installed today is permanently mounted (for example, the 3380 or 3390 DASD devices). In addition, DASD can be either online or offline. Therefore, when you are recovering a volume with full-volume restore and incremental backup versions, a possibility exists that one of your users could begin using a data set in the interval between the restore and the incremental recovery. This can be avoided by putting the SMS-managed volume in DISALL status. There are two considerations you need to be aware of before placing the volume in DISALL status:

- With DISALL status, some data sets may be recovered (as directed by your ACS routines) to different volumes in the storage group containing the volume being recovered.
- If you are recovering a catalog, or a volume belonging to a storage group using the guaranteed space attribute, the volume must be in enabled (ENABLE) status during the recovery process.

Ensure that the SMS-managed volume is in disabled (DISALL) status before issuing the RECOVER command, unless you are recovering a catalog, or a volume from a storage group using the guaranteed space attribute.

After the recovery process has completed, be sure to review the messages for failures or data sets that were not recovered. For example, if the volume you are recovering contains part of a multivolume data set, that partial data set is not recovered. After the recovery process has completed, the data set is listed as having not been recovered, giving you the opportunity to recover the entire data set, including the parts of the data set that reside on volumes not being recovered. You can issue individual RECOVER *dsn* commands for data sets such as these.

You can use the following commands to combine full-volume restore with full-volume recovery.

```
RECOVER * TOVOLUME(original_volser) UNIT(unittype) -  
FROMDUMP(DUMPVOLUME(tape_volser) APPLYINCREMENTAL)  
  
RECOVER * TOVOLUME(original_volser) UNIT(unittype) -  
FROMDUMP(DUMPCCLASS(class) APPLYINCREMENTAL)  
  
RECOVER * TOVOLUME(original_volser) UNIT(unittype) -  
FROMDUMP(DUMPGENERATION(dgennum) APPLYINCREMENTAL)
```

When APPLYINCREMENTAL is specified on a RECOVER FROMDUMP command, DFSMSHsm first performs a full-volume restore as described in [“Full-volume restore from a dump copy” on page 298](#). After the volume restore has been completed, DFSMSHsm performs the following steps:

1. If integrated catalog facility catalogs reside on the volume, DFSMSHsm recovers any catalog for which a backup version exists that was created following the dump. All such catalogs must be successfully recovered for the APPLYINCREMENTAL process to continue. Recovery of the catalog will fail and the APPLYINCREMENTAL process will not continue for either or both of the following conditions:
 - Any catalog was backed up by DFSMSHsm operating with a version of MVS/DFP earlier than version 2 release 3.0
 - Any catalog was dumped before being exported or backed up by DFSMSHsm, which uses export
2. DFSMSHsm creates a list of candidate data sets from either or both the dump and backup VTOC copy data sets to control the volume recovery process.
3. DFSMSHsm applies incremental data set backups from the list of candidate data sets with the following exceptions:
 - Catalogs.
 - Data sets cataloged as multiple-volume, including multiple-stripe data sets. If the target volume is SMS-managed, the data set is not currently cataloged on the volume being processed, and the data set has been restored to the volume, DFSMSHsm scratches it from the restored volume.
 - VSAM data sets currently cataloged as MIGRAT. Cluster, index, and data components are scratched from the restored volume.
 - Non-VSAM data sets currently cataloged as MIGRAT but the dump VTOC copy data set is more recent than the backup VTOC copy data set. If the data set was restored to the volume, DFSMSHsm scratches it from the restored volume.
 - VSAM volume data sets (VVDS).
 - VTOC index data sets.
 - Data sets that are not on the backup VTOC copy data set but the backup VTOC copy data set is more recent than the dump VTOC copy data set. If the data set was restored to the volume, DFSMSHsm scratches it from the restored volume.

- Currently uncataloged VSAM data sets. If the data set was restored to the volume, DFSMSHsm scratches it from the restored volume.
- Currently uncataloged non-VSAM data sets targeted to an SMS-managed volume. If the data set was restored to the volume, DFSMSHsm scratches it from the restored volume.
- ICF VSAM component data sets.
- Data sets that are currently cataloged as MIGRAT, that were cataloged when backed up, and that are selected for recovery. If the data set was restored to the volume, DFSMSHsm scratches it from the restored volume.
- Data sets that are currently cataloged as MIGRAT, that were uncataloged when backed up, that are selected for recovery, and that were migrated after the backup version of the uncataloged data set was made from the same volume. If the data set was restored to the volume, DFSMSHsm scratches it from the restored volume.
- Data sets that are currently cataloged on another volume but the selected data set was cataloged when backed up. If the data set was restored to the volume, DFSMSHsm scratches it from the restored volume.
- Data sets that were last backed up when they were cataloged, but a backup version of a data set that was uncataloged when it was backed up is selected for recovery. If the data set was restored to the volume, DFSMSHsm scratches it from the restored volume.
- Data sets that are cataloged on the non-SMS-managed target volume but the backup version was made when the data set was uncataloged. (If the data set was uncataloged when backed up from the target volume and is now cataloged on the target volume, and the volume is now SMS-managed, recovery is allowed.) If the data set was restored to the volume, DFSMSHsm scratches it from the restored volume.
- Data sets that are not SMS-managed being recovered to SMS-managed volumes.

Note:

1. If the data set was not on the volume when it was dumped, but was on the volume later in the volume backup (backup VTOC is the latest), the latest backup version is applied regardless of the version date.
2. When you are running full-volume restore with update, there is one instance when DFSMSHsm allows a data set backup version (made while the data set was uncataloged) to be recovered for a data set that is currently cataloged. This occurs when the volume being recovered is SMS-managed, and the backup version of a data set was made from this volume when the data set was uncataloged—the volume was converted to SMS-managed—and the data set is currently cataloged on the volume being recovered.

If a data set is cataloged as a multiple-volume or multiple-striped extended format data set, incremental recovery of the data set fails.

3. If a dump VTOC copy data set does not exist for the volume being restored, some of the cleanup described in the preceding steps may not be performed. The extent of the cleanup activity depends on the candidate data set list that is created from the current backup and dump VTOC copies. If you do not have a dump VTOC copy that corresponds to the dump copy being restored, you should verify that the APPLYINCREMENTAL parameter causes the volume and the catalogs to be synchronized.

It is not necessary for the volume to have been processed by the DFSMSHsm volume backup function if a dump VTOC copy data set exists for the dump generation from which the volume is restored. The VTOC copy data sets are used only to build a candidate list. Rely on the current contents of the catalogs and BCDS to verify any action to be taken during the apply incremental process.

4. During volume restore with update, all non-VSAM SMS data sets are recovered to the volume being restored. VSAM SMS data sets may be recovered to other volumes that are in the same storage group as the volume being restored.

The APPLYINCREMENTAL subparameter has some restrictions: in systems running DFSMSdftp, DFSMSHsm can recover catalogs with the APPLYINCREMENTAL process. To be recoverable, these catalogs must have been backed up with MVS/DFP Version 2 Release 3.0, or later. To recover these catalogs, do the following:

- Start DFSMSHsm under DFSMSdftp
- Use DFSMSHsm to back up all catalogs

- Back up new catalogs before dumping

When the preceding steps are taken, DFSMSHsm can recover the integrated catalog facility catalogs during the APPLYINCREMENTAL process. If any of these steps are omitted, the APPLYINCREMENTAL process stops. For this condition, you may need to update aliases manually or with the recommended integrated catalog Forward Recovery Utility (ICFRU), and restart the incremental recovery process.

If you plan to use ICFRU regularly, you should run it before starting the incremental recovery process. Use the following procedure:

1. Use the DFSMSHsm RECOVER command to recover the catalogs that resided on the volume being restored.
2. Run the ICFRU on each catalog. See the instructions for the ICFRU for details.
3. Use the DFSMSHsm BACKDS command to back up the updated catalogs. This updates the backup versions used during the incremental recovery process.
4. Issue the RECOVER FROMDUMP command with the APPLYINCREMENTAL parameter.

If you do not plan to use ICFRU on the system, you must audit the volumes after the recovery process to either delete data sets or delete catalog entries in order to clean up any discrepancies found. However, if ICFRU is used before the incremental recovery process, no discrepancies occur in the catalogs.

Note:

1. If the data set has been migrated, scratched, or moved since the latest backup version was made, it must be scratched after the recovery process has completed. Because the data set has migrated, was scratched, or was moved, it is not the most current copy, and the catalog has no way to point to it.
2. If the data set was recalled since the backup of the catalog, the catalog entry must be removed by using the DELETE NOSCRATCH command. You can attempt to recover the data set from the latest backup version.
3. If a data set was created since the backup of the catalog, the catalog entry must be removed by using the DELETE NOSCRATCH command.

Full-volume restore from a dump copy

Full-volume restore is the process of recovering the entire physical contents of a volume. Full-volume restore, an alternative to the DFSMSHsm volume recover function, invokes Data Facility Data Set Services (DFSMSDss) to perform full-volume restores. DFSMSHsm uses the dump volumes of a dump copy as input to a DFSMSDss full-volume restore request. If the dump copy starts in file 2 or beyond on a stacked dump tape, DFSMSHsm supplies the file block ID for high-speed positioning to the start of the dump copy. The following commands can be used to request a full-volume restore:

```
RECOVER * TOVOLUME(original_volser) UNIT(unittype) -  
FROMDUMP  
  
RECOVER * TOVOLUME(original_volser) UNIT(unittype) -  
FROMDUMP DATE(date)  
  
RECOVER * TOVOLUME(original_volser) UNIT(unittype) -  
FROMDUMP (DUMPVOLUME(tape_volser))  
  
RECOVER * TOVOLUME(original_volser) UNIT(unittype) -  
FROMDUMP (DUMPCCLASS(class))  
  
RECOVER * TOVOLUME(original_volser) UNIT(unittype) -  
FROMDUMP (DUMPCCLASS(class)) DATE(yyyy/mm/dd) -  
  
RECOVER * TOVOLUME(original_volser) UNIT(unittype) -  
FROMDUMP (DUMPGENERATION(dgennum)) -  
TARGETVOLUME(spare_volser)
```

Note:

1. The TARGETVOLUME(*spare_volser*) parameter can be used to supply the restore with a volume that has a volume serial number different from the one that is being restored. This saves you the step of changing the volume serial number (clipping a volume) to the lost volser.
2. A DFSMSdss restriction is that the original source volume of the full-volume dump must be of the same or similar device type (for example, 3390) as the target volume of the full-volume restore.
3. For more information, see [“TARGETVOLUME: Specifying the volume to receive the restored data sets” on page 1009 and Chapter 60, “RECOVER command: Recovering a backup version or dump copy of a data set, or UNIX file, or a volume,” on page 997.](#)
4. The VTOC and the volume serial on the target volume may have changed as a result of the command. Before the volume can be accessed on any remote system, the UCB must be refreshed. The refresh occurs automatically if the volume is online and the device manager REFUCB function is enabled. You enable the REFUCB function through PARMLIB member DEVSUPxx or the MODIFY DEVMAN command. For more information, refer to the description of the REFUCB keyword in [z/OS MVS Initialization and Tuning Reference](#) or [z/OS MVS System Commands](#).

The first form of the command restores the volume from the most recent dump copy. However, DFSMSShsm must search its records to determine the most recent dump copy for the particular volume. You should not use this form of the command because of the extensive searching required.

The second form of the command narrows the search for the correct dump copy. If you know the date that the volume was dumped to the copy that you want to restore from (either the most recent or some other copy), you can specify the date. Then DFSMSShsm searches only for dump copies made on or before the date you have specified.

Similarly, the other forms of the command allow you to narrow the search by specifying:

- The volumes to which the source volume was dumped
- The dump class from which the dump volumes are to be taken
- The dump generation from which the dump volumes are to be taken

When a full-volume restore is requested, DFSMSShsm verifies with the tape operator that the dump volumes are available for mounting. If any dump volume is unavailable, the restore fails. Dump volumes can be stored at a location other than the data processing location.

If the volume being restored is an SMS-managed volume and the dump copy being used to restore the volume was made when the volume was *not* SMS-managed, DFSMSShsm fails the command and issues an error message. Likewise, if an attempt is made to restore a non-SMS-managed volume from a dump copy of the volume when it was SMS-managed, DFSMSShsm fails the command and issues an error message.

The dump volumes on which the dump copy resides must have a retention period other than NOLIMIT unless the DUMPCLASS or DUMPVOLUME parameter is specified. DFSMSShsm assumes the dump volumes are physically available to be mounted when the RECOVER command is issued. DFSMSShsm considers any volume with a retention period of NOLIMIT to be physically not available.

To restore an SMS-managed volume, you must have DFSMSdftp installed at the correct level to support SMS, and SMS must be active.

DFSMSdss restores a volume only if the volume is not allocated to another job. If the volume contains a catalog, the catalog address space in a DFSMSdftp environment may have the catalog (and the volume) allocated. To free the volume before starting the restore, do the following:

1. Issue the F CATALOG,OPEN(*volser*) command to determine which catalogs on the target volume are allocated.
2. For each catalog that is open, issue the F CATALOG,UNALLOCATE (*catalogname*) to cause the catalog address space to close the catalog and deallocate it. When the last catalog on the volume is deallocated, the target volume is also deallocated by the catalog address space.
3. Issue a D U,,,addr,1 command to ensure that the volume is not allocated by another user.
4. If the volume is not now marked as allocated, issue the RECOVER command to DFSMSShsm.

For more information about a DFSMSdss full-volume restore, see [z/OS DFSMSdss Storage Administration](#).

Volume recovery from incremental backup versions

Normally volume recovery is run when an entire DASD pack has been lost or damaged or a significant amount of the data has become inaccessible. A copy of the VTOC made during the incremental backup of the volume is used to drive the individual incremental recovery of data sets for which DFSMSShsm has backup versions. DFSMSShsm volume recovery is also referred to as incremental volume recovery. After DFSMSShsm successfully recovers a volume, each supported data set on the recovered volume is at the level of its latest backup. This recovers the data set to the most recent level unless someone changed the data set since the last time DFSMSShsm backed it up.

The following commands cause volume recovery from incremental backup copies:

```
RECOVER * TOVOLUME(volser) UNIT(unitttype)
RECOVER * TOVOLUME(volser) UNIT(unitttype) DATE(date)
```

Volume recovery is similar to data set recovery in that DFSMSShsm recovers each data set; DFSMSShsm does not recover data track by track. First, a single task builds the queue of data sets that need to be recovered, then multitasking is used during the actual recovery of the data sets. If recovering multiple volumes, it is most efficient to first put a hold on tape data set recovery, then create the queue of data sets to be recovered, then release the tape data set recovery processing. Since data sets from different volumes may reside on one tape, recovering data sets for multiple volumes at the same time, rather than volume-by-volume, reduces the number of required tape mounts, and thus speeds processing. However, because DFSMSShsm recovers each data set and because the backup operation uses backup volumes from different days, volume recovery can require access to many backup volumes just to recover one level 0 volume. As a result, volume recovery can be very time-consuming. Consider using the DFSMSShsm full-volume dump restore facility (see [“Full-volume restore with update” on page 295](#)) to reduce the time required for recovery.

You can specify that backup versions be at least as recent as a particular date by specifying the DATE parameter of the RECOVER command. You must use the TOVOLUME parameter to identify an entire volume that you want to recover.

DFSMSShsm uses the *latest* VTOC copy data set to recover the volume unless an error occurs in allocating or opening the latest VTOC copy data set. If the error occurs, DFSMSShsm attempts to recover the volume, using the *next latest* copy of the VTOC copy data set. If a similar error occurs again, the volume recovery fails.

When DFSMSShsm recovers a volume, it recovers the following:

1. Any base entries for a generation data group cataloged in the catalog residing on the volume being recovered.
2. Any integrated catalog facility user catalogs that do not already exist on the volume being recovered. For information about recovering an integrated catalog facility catalog, see [“Backing up and recovering a catalog” on page 487](#).
3. All other data sets except the following:
 - Catalogs
 - VSAM data sets currently cataloged as MIGRAT
 - ICF VSAM components
 - Data sets that are cataloged as multiple-volume
 - Non-VSAM data sets that are currently cataloged as MIGRAT but the selected backup version was made when the data set was cataloged
 - Non-VSAM data sets that are currently cataloged as MIGRAT, the selected backup version was made when the data set was uncataloged, but the migration took place after the backup version was made

- Data sets that are cataloged on a volume other than the one being recovered when the backup version of a cataloged data set is selected for recovery
- Data sets that are currently cataloged on the volume being recovered but the backup version selected for recovery was uncataloged when it was backed up
- Data sets that were cataloged when backed up and but not currently cataloged
- Data sets whose creation date is later than the backup date
- Data sets that are not SMS-managed being recovered to a SMS-managed volume

DFSMSHsm considers data sets uncataloged at the time they are backed up to be unique to the volume on which they reside. This is because multiple uncataloged data sets with the same name may exist on different volumes. Backup versions of uncataloged data sets will only be recovered to the volume from which they were backed up.

DFSMSHsm considers a cataloged data set to be the same data set regardless of the volume on which it is currently cataloged. Therefore, DFSMSHsm will recover the most current backup version of a cataloged data set regardless of the volume on which it was cataloged when it was backed up.

Table 32 on page 301 shows the process of backup version data set selection for volume recovery.

Table 32. Backup Version Data Set Selection for Recovery

First Criterion	Second Criterion	Result
If only backup versions of cataloged data sets exist,	and if the data set is currently cataloged on the target volume,	then the cataloged backup copy is recovered.
	and if the data set is not currently cataloged,	then recovery of this data set fails.
	and if the data set is cataloged but not on the target volume,	then recovery is not attempted.
If only backup versions of uncataloged data sets exist,	and if the data set is currently cataloged on the target volume,	then recovery fails.
	and if the data set is not currently cataloged,	then the uncataloged backup version, made from this volume, is recovered.
	and if the data set is cataloged but not on the target volume,	then the uncataloged backup version, made from this volume, is recovered.
If backup versions of cataloged and uncataloged data sets exist,	and if both backup versions are from the target volume,	then DFSMSHsm recovers the most recent backup copy. Recovery continues, depending on whether the data set was cataloged, as previously discussed.
	and if the backup version of a cataloged data set was made from a different volume, and the data set is currently cataloged on a volume other than the target volume,	then DFSMSHsm attempts to recover the uncataloged backup version.
	and if the backup version of a cataloged data set was made from a different volume, but the data set is currently cataloged on the target volume,	then DFSMSHsm attempts to recover the backup version of the cataloged data set.
	and if the backup version of a cataloged data set was made from a different volume, but the data set is not currently cataloged,	then DFSMSHsm attempts to recover the uncataloged backup version.

For SMS-managed volumes, SMS must be active to recover the data sets that were backed up from that volume.

All non-VSAM SMS data sets are recovered to the volume being recovered. VSAM SMS data sets may be recovered to other volumes that are in the same storage group as the volume being recovered.

If DFSMSHsm encounters a cataloged multiple-volume VSAM data set, it issues a message stating that the data set is multiple volume but does not recover the data set. If the multiple-volume data set is not cataloged or is presently cataloged as a single-volume data set, DFSMSHsm recovers the data set if an eligible backup version exists.

Processing priority of volume recoveries

Programming Interface Information

All volume recover requests are queued to and processed from a queue of management work elements called the volume recovery queue (separate from the recovery queue used for data sets). DFSMSHsm gives all WAIT requests a higher priority on the queue than NOWAIT requests.

You can change the priorities of these requests as they are put on the queue by using the return-priority installation exit ARCRPEXT. ARCRPEXT allows you to assign a relative queuing priority to WAIT requests so they can be prioritized relative to other WAIT requests, and NOWAIT requests prioritized relative to other NOWAIT requests. Refer to [z/OS DFSMS Installation Exits](#) for a description of ARCRPEXT.

End Programming Interface Information

If you are using MVS concatenated PARMLIB support, DFSMSHsm uses the PARMLIB data set containing the ARCCMDxx member and the PARMLIB data set containing the ARCSTRxx member indicated in the startup procedure.

Chapter 7. Availability management of non-SMS-managed storage

DFSMSHsm manages non-SMS-managed storage on a system basis. That is, all the data sets on volumes are managed by a system specification, whether for number of days between backups or number of retained versions. Primary differences in processing for SMS-managed storage and non-SMS-managed storage occur in the following processes:

- Uncataloged data sets can be backed up and recovered.
- Users can specify the volume to which a data set is to be recovered.
- Volumes to be dumped or backed up are individually identified to DFSMSHsm.

Unlike space management, availability management of non-SMS-managed storage has no major differences in the processing techniques from those that are used for management of SMS-managed storage. However, there are some additional tasks that must be accounted for when dealing with the availability management of non-SMS-managed storage.

References to the example system in this topic reflect input needed to support the tasks for non-SMS-managed storage.

Tasks for availability management of non-SMS-managed storage

Because storage groups or management classes are not available to define how to manage the volumes and which volumes to manage for non-SMS-managed storage, the following subtasks provide a way to manage non-SMS-managed storage:

- Defining how frequently data sets that are managed by a system be backed up
- Defining how many versions to keep for each backed up data set
- Defining which volumes are backed up automatically
- Defining which volumes are dumped automatically

Specifying how frequently data sets are backed up

For SMS-managed data sets, you can specify a different backup frequency for each management class. This lets you have as many different backup frequencies as you have management classes. For non-SMS-managed storage, you can specify only one backup frequency for all volumes processed by any one DFSMSHsm host. You can, however, change the backup frequency of individual non-SMS-managed data sets with the (H)ALTERDS command. See “Changing the backup conditions for a data set” on page 308 for more information. Both the backup frequency specified for a DFSMSHsm host and the backup frequency specified for a management class indicate the number of days that must pass between backups of any data set.

The FREQUENCY parameter of the SETSYS command controls the backup frequency for the data sets processed by each DFSMSHsm host. For the example, the command that is added to the ARCCMDxx member for each host is:

```
SETSYS FREQUENCY(1)
```

Specifying how many versions to keep for each backed up data set

For non-SMS-managed storage, the number of backup versions to retain is a DFSMSHsm host-wide specification.

Note: You can use the (H)ALTERDS command to specify a different value from the DFSMSHsm host-wide default for individual data sets.

As with SMS-managed storage, depending on the record length that is used to define the BCDS, DFSMSHsm can maintain up to 29, or up to 100, backup versions of any data set. Within that upper limit, the VERSIONS parameter of the SETSYS command controls the number of backup versions to be retained. For the example system, the following command is added to the ARCCMDxx member for each DFSMSHsm host:

```
SETSYS VERSIONS(5)
```

If you use the RETAIN DAYS keyword when you create a data set backup copies, and active backup copies with an unmet RETAIN DAYS values are rolled off, DFSMSHsm maintains them as retained backup copies. DFSMSHsm can maintain more than enough retained copies for each data set to meet all expected requirements.

Specifying which volumes are backed up automatically

For non-SMS-managed storage, you can identify each individual volume that DFSMSHsm backs up automatically. At the same time that you make the volume known to DFSMSHsm, you can specify the kind of unit to back the volume up to.

If multiple DFSMSHsm hosts are requested to process automatic backup, only the first DFSMSHsm host to process a given volume will perform the function. However, should you find it necessary to limit processing of certain volumes to one DFSMSHsm host, you can do so by:

- Specifying the AUTOBACKUP parameter on the ADDVOL command in the DFSMSHsm host you want to perform automatic backup on the volume
- Specifying the NOAUTOBACKUP parameter on the ADDVOL command in the DFSMSHsm hosts you do not want to perform automatic backup on the volume

See [Figure 3 on page 18](#) for the example system to which you will add the volumes. DFSMSHsm host 3 will do the backup processing for the non-SMS-managed volumes, so the following commands are added to the ARCCMDxx member for DFSMSHsm host 3:

```
ADDVOL GP0001 UNIT(3390) PRIMARY(AUTOBACKUP)
ADDVOL GP0002 UNIT(3390) PRIMARY(AUTOBACKUP)
ADDVOL GP0003 UNIT(3390) PRIMARY(AUTOBACKUP)
ADDVOL UG1001 UNIT(3390) PRIMARY(AUTOBACKUP)
ADDVOL UG1002 UNIT(3390) PRIMARY(AUTOBACKUP)
ADDVOL UG1003 UNIT(3390) PRIMARY(AUTOBACKUP)
ADDVOL UG2001 UNIT(3390) PRIMARY(AUTOBACKUP)
ADDVOL UG2002 UNIT(3390) PRIMARY(AUTOBACKUP)
ADDVOL UG2003 UNIT(3390) PRIMARY(AUTOBACKUP)
ADDVOL VP0001 UNIT(3390) PRIMARY(AUTOBACKUP)
ADDVOL VP0002 UNIT(3390) PRIMARY(AUTOBACKUP)
ADDVOL VP0003 UNIT(3390) PRIMARY(AUTOBACKUP)
```

You can add the following commands to the ARCCMDxx member in DFSMSHsm hosts 1 and 2:

```

ADDVOL GP0001 UNIT(3390) PRIMARY(NOAUTOBACKUP)
ADDVOL GP0002 UNIT(3390) PRIMARY(NOAUTOBACKUP)
ADDVOL GP0003 UNIT(3390) PRIMARY(NOAUTOBACKUP)
ADDVOL UG1001 UNIT(3390) PRIMARY(NOAUTOBACKUP)
ADDVOL UG1002 UNIT(3390) PRIMARY(NOAUTOBACKUP)
ADDVOL UG1003 UNIT(3390) PRIMARY(NOAUTOBACKUP)
ADDVOL UG2001 UNIT(3390) PRIMARY(NOAUTOBACKUP)
ADDVOL UG2002 UNIT(3390) PRIMARY(NOAUTOBACKUP)
ADDVOL UG2003 UNIT(3390) PRIMARY(NOAUTOBACKUP)
ADDVOL VP0001 UNIT(3390) PRIMARY(NOAUTOBACKUP)
ADDVOL VP0002 UNIT(3390) PRIMARY(NOAUTOBACKUP)
ADDVOL VP0003 UNIT(3390) PRIMARY(NOAUTOBACKUP)

```

For non-SMS-managed volumes, you can restrict the kind of unit that is used when backing up the volume. The BACKUPDEVICECATEGORY parameter of the ADDVOL command lets you specify whether to back the volume up to either DASD or tape (if you have identified both DASD and tape backup volumes to DFSMSHsm with the ADDVOL command).

Specifying which volumes are dumped automatically

As with volumes to be backed up, you must identify the non-SMS-managed volumes to be dumped automatically. With the same command, you specify the dump classes to which the volume is to be dumped. If multiple DFSMSHsm hosts are requested to process automatic dump, only the first host to process a given volume performs the function. However, should you find it necessary to limit processing of certain volumes to one host, you can do so by:

- Specifying the AUTODUMP parameter on the ADDVOL command in the host you want to perform automatic dump on the volume
- Specifying the NOAUTODUMP parameter on the ADDVOL command in the hosts you do not want to perform automatic dump on the volume

See [Figure 3 on page 18](#) for the example system to which the volumes are added. You can add the following commands to the ARCCMDxx member for DFSMSHsm host 2:

```
ADDVOL GP0001 UNIT(3390) PRIMARY(AUTODUMP -  
  (ONEWEEK,TWOWEEK))  
ADDVOL GP0002 UNIT(3390) PRIMARY(AUTODUMP -  
  (ONEWEEK,TWOWEEK))  
ADDVOL GP0003 UNIT(3390) PRIMARY(AUTODUMP -  
  (ONEWEEK,TWOWEEK))  
ADDVOL UG1001 UNIT(3390) PRIMARY(AUTODUMP -  
  (ONEWEEK,TWOWEEK))  
ADDVOL UG1002 UNIT(3390) PRIMARY(AUTODUMP -  
  (ONEWEEK,TWOWEEK))  
ADDVOL UG1003 UNIT(3390) PRIMARY(AUTODUMP -  
  (ONEWEEK,TWOWEEK))  
ADDVOL UG2001 UNIT(3390) PRIMARY(AUTODUMP -  
  (ONEWEEK,TWOWEEK))  
ADDVOL UG2002 UNIT(3390) PRIMARY(AUTODUMP -  
  (ONEWEEK,TWOWEEK))  
ADDVOL UG2003 UNIT(3390) PRIMARY(AUTODUMP -  
  (ONEWEEK,TWOWEEK))  
ADDVOL VP0001 UNIT(3390) PRIMARY(AUTODUMP -  
  (ONEWEEK,FOURWEEK))  
ADDVOL VP0002 UNIT(3390) PRIMARY(AUTODUMP -  
  (ONEWEEK,FOURWEEK))  
ADDVOL VP0003 UNIT(3390) PRIMARY(AUTODUMP -  
  (ONEWEEK,FOURWEEK))  
ADDVOL ML1001 UNIT(3390) MIGRATION(MIGRATIONLEVEL1 -  
  AUTODUMP(ONEWEEK,TWOWEEK))  
ADDVOL ML1002 UNIT(3390) MIGRATION(MIGRATIONLEVEL1 -  
  AUTODUMP(ONEWEEK,TWOWEEK))  
ADDVOL ML1003 UNIT(3390) MIGRATION(MIGRATIONLEVEL1 -  
  AUTODUMP(ONEWEEK,TWOWEEK))
```

You can add the following commands to the ARCCMDxx member for DFSMSHsm hosts 1 and 3:

```
ADDVOL GP0001 UNIT(3390) PRIMARY(NOAUTODUMP)  
ADDVOL GP0002 UNIT(3390) PRIMARY(NOAUTODUMP)  
ADDVOL GP0003 UNIT(3390) PRIMARY(NOAUTODUMP)  
ADDVOL UG1001 UNIT(3390) PRIMARY(NOAUTODUMP)  
ADDVOL UG1002 UNIT(3390) PRIMARY(NOAUTODUMP)  
ADDVOL UG1003 UNIT(3390) PRIMARY(NOAUTODUMP)  
ADDVOL UG2001 UNIT(3390) PRIMARY(NOAUTODUMP)  
ADDVOL UG2002 UNIT(3390) PRIMARY(NOAUTODUMP)  
ADDVOL UG2003 UNIT(3390) PRIMARY(NOAUTODUMP)  
ADDVOL VP0001 UNIT(3390) PRIMARY(NOAUTODUMP)  
ADDVOL VP0002 UNIT(3390) PRIMARY(NOAUTODUMP)  
ADDVOL VP0003 UNIT(3390) PRIMARY(NOAUTODUMP)  
ADDVOL ML1001 UNIT(3390) MIGRATION(MIGRATIONLEVEL1 NOAUTODUMP)  
ADDVOL ML1002 UNIT(3390) MIGRATION(MIGRATIONLEVEL1 NOAUTODUMP)  
ADDVOL ML1003 UNIT(3390) MIGRATION(MIGRATIONLEVEL1 NOAUTODUMP)
```

All volumes except VP0001, VP0002, and VP0003 are dumped in accordance with the specifications for dump classes ONEWEEK and TWOWEEK. VP0001, VP0002, and VP0003 are dumped in accordance with the specifications for dump classes ONEWEEK and FOURWEEK. Notice that the ML1 volumes ML1001, ML1002, and ML1003 have been added to the list of volumes to be dumped. Although automatic backup cannot be performed for migration volumes, automatic dump can be performed for ML1 volumes.

Automatic availability management of non-SMS-managed volumes

Processing for availability management of non-SMS-managed volumes is the same as that for SMS-managed volumes with the following exceptions:

- No request is sent to DFSMSdftp for the management classes and storage classes.
- The FREQUENCY and VERSION parameters of the SETSYS command control how often data sets are backed up and how many versions are kept for all of the non-SMS-managed data sets.
- A non-SMS-managed volume can contain uncataloged data sets that can be backed up.

Backing up cataloged and uncataloged data sets with the same name

Although DFSMSShsm and DFSMSdss do not migrate uncataloged data sets, DFSMSShsm can back them up, either automatically or by command. Therefore, DFSMSShsm can back up several different uncataloged data sets that have the same data set name but reside on different volumes. Depending on the record length that is used to define the BCDS, DFSMSShsm can maintain up to 29, or up to 100, backup versions for any specific data set name. After the number of backup versions reaches that limit, backup versions of cataloged data sets take precedence over backup versions of uncataloged data sets of the same name. When DFSMSShsm backs up the data set again, DFSMSShsm deletes the backup version of an uncataloged data set first. In the case of data sets that are indirectly cataloged to SYSRES, those on the inactive SYSRES pack are considered uncataloged by backup processing, but are considered cataloged if backed up while running backup from their own system. For this reason, they cannot be protected by incremental backup. The results of a recover command are unpredictable due to the mixture of indirectly cataloged and uncataloged data sets with the same name.

To avoid potential confusion, do not give cataloged and uncataloged data sets the same data set name.

DFSMSShsm keeps backup versions of a data set name in the following order:

1. All backup versions of a cataloged data set, arranged by date. The most recently created backup version is first. The number of backup versions DFSMSShsm keeps is the limit of versions that existed the last time DFSMSShsm backed up the data set.
2. All backup versions of all uncataloged data sets having the same name, arranged by date. The most recently created backup version is first. The number of backup versions DFSMSShsm keeps is the limit of versions that existed the last time DFSMSShsm backed up the data set.

Although the limit specified by the VERSIONS parameter of the SETSYS command applies to cataloged and uncataloged data sets separately, the maximum number of versions (based on the BCDS record size) applies to the sum of the backup versions of both cataloged and uncataloged data sets with the same name. When the sum of the current backup versions is greater than the BCDS-related limit, DFSMSShsm creates a new version and deletes the oldest backup version of the uncataloged data sets. For example, assume the following:

- The maximum BCDS record size allows DFSMSShsm to maintain 29 backup versions for any data set.
- A cataloged data set and several uncataloged data sets have the same data set name.
- The cataloged data set currently has 24 backup versions.
- The uncataloged data sets currently have four backup versions.
- You specified a limit of 24 with the VERSIONS parameter.
- DFSMSShsm backs up one cataloged data set and two uncataloged data sets with the same name.

Because DFSMSShsm (in this example) tracks only 29 backup versions, here are the results:

- Twenty-four backup versions of the cataloged data set.
- Five backup versions of the uncataloged data sets. DFSMSShsm keeps the five most recently created backup versions of these data sets.

You can identify backup versions of an uncataloged data set by associating the data set name with the volume serial number of the source volume for the backup version. DFSMSShsm considers this association of the data set name and the source volume serial number a unique identification.

Command availability management for non-SMS-managed storage

The activities that were specified as being available by command for SMS-managed storage are available for non-SMS-managed storage. Differences for non-SMS-managed storage are:

- A command that allows changing the backup conditions for individual data sets
- The ability to back up uncataloged data sets
- The ability to back up all non-SMS-managed primary volumes
- The ability to delete backup versions of uncataloged data sets
- The ability to specify a frequency value for a volume backed up by command
- The ability to recover uncataloged data sets
- The ability to recover an SMS-managed data set to a non-SMS-managed volume
- Differences in the way that the EXPIREBV command selects backup versions for deletion

This topic describes the differences between the commands for SMS-managed storage and for non-SMS-managed storage. The forms of the commands specified for SMS-managed storage also are used for non-SMS-managed storage. However, when they are used for non-SMS-managed storage, those forms of the commands use the frequency and versions attribute specified with the system SETSYS command.

Dumping a volume

The commands for dumping a volume are the same for non-SMS-managed storage as for SMS-managed storage. However, the dump process for non-SMS-managed volumes does not request the storage group attributes from DFSMSdfp.

Changing the backup conditions for a data set

SMS-managed storage controls the frequency of backup and the number of versions retained for each data set or UNIX file through the management class attributes. For non-SMS-managed storage or UNIX files contained in a non-SMS-managed zFS, frequency and versions are a DFSMSShsm host-wide specification. However, you can control the frequency and versions for individual data sets with the (H)ALTERDS command. You can control the frequency and the versions independently of each other. The forms for the command are:

```
ALTERDS dsname ... FREQUENCY(days)
ALTERDS dsname ... VERSIONS(limit)
ALTERDS 'pathname' ... VERSIONS(limit)

ALTERDS dsname ... FREQUENCY(days) VERSIONS(limit)
HALTERDS dsname ... FREQUENCY(days)
HALTERDS dsname ... VERSIONS(limit)
HALTERDS 'pathname' ... VERSIONS(limit)
HALTERDS dsname ... FREQUENCY(days) VERSIONS(limit)
```

Non-DFSMSShsm-authorized and DFSMSShsm-authorized users can use the HALTERDS form of the command. Only DFSMSShsm-authorized users can use the ALTERDS form of the command.

The command causes the frequency or versions attributes for the data sets that are identified by *dsname* or UNIX files that are identified by *pathname*, to be changed to the values that are specified by the command parameters. The new values are then used for all volume backup functions that are performed on those data sets until a new ALTERDS or HALTERDS command is issued for the data set. For UNIX files, the new VERSIONS value is used for EXPIREBV, and determining roll-off of old backups.

Security checking with discrete profiles

If your data sets are protected with discrete profiles, HALTERDS processing checks the profile of the original data set for authorization to change the backup conditions for the data set. If the original data set has been deleted, DFSMSHsm checks any backed up discrete profile for the data set. If the second authorization check fails, the HALTERDS processing fails.

Backing up an individual data set

Backing up an individual cataloged data set is performed in the same way as for SMS-managed data sets. However, to back up individual *uncataloged* data sets, issue the following command:

```
BACKDS dsname UNIT(unitttype) VOLUME(volser)
HBACKDS dsname UNIT(unitttype) VOLUME(volser)
```

The HBACKDS form of the command can be used by either non-DFSMSHsm-authorized or DFSMSHsm-authorized users. The BACKDS form of the command can be used only by DFSMSHsm-authorized users. The UNIT and VOLUME parameters are required because DFSMSHsm cannot locate an uncataloged data set without being told where it is.

Inline backup of an individual data set

Backing up individual cataloged data sets is performed the same way as for SMS-managed data sets. (See [“Backing up an individual data set or UNIX file” on page 222.](#)) However, the backup of uncataloged data sets is not supported by inline backup.

Related reading

For more information about how to use inline backup, see [“Inline backup” on page 447.](#)

Backing up all primary volumes

Use the following command to back up all non-SMS-managed primary volumes:

```
BACKVOL PRIMARY
```

This command causes DFSMSHsm to back up *every* volume that has been identified to it as a primary volume by the ADDVOL command, not just those volumes with the AUTOBACKUP attribute.

Note: Volumes selected for processing by BACKVOL PRIMARY are not processed by automatic backup the same day and visa versa.

Backing up all changed data sets on volumes

You can back up all eligible changed data sets on non-SMS-managed volumes, whether the volumes are managed by DFSMSHsm or not. Issue the following additional commands to back up non-SMS-managed volumes:

```
BACKVOL VOLUMES(volser,volser,...volser)
BACKVOL VOLUMES(volser,volser,...volser) FREQUENCY(days)
BACKVOL VOLUMES(volser,volser,...volser) UNIT(unitttype) -
    FREQUENCY(days)
BACKVOL PRIMARY INCREMENTAL
BACKVOL PRIMARY INCREMENTAL FREQUENCY(days)
```

The first two forms of the command are used for backing up volumes that are managed by DFSMSHsm. The first form backs up the changed data sets on the volume in accordance with the frequency for the system as specified by the SETSYS command. The next form uses the frequency specified on the command to replace the attribute specified for the system.

The third form of the command backs up a volume that is not managed by DFSMSHsm.

The last two forms of the command use either the frequency attribute specified for the system or the one specified in the command to back up all the non-SMS-managed primary volumes in the system.

Deleting expired backup versions of non-SMS-managed data sets

To delete expired backup versions from the backup volumes, use the EXPIREBV command as you do for deleting expired SMS-managed backup versions. Issue the following command to delete non-SMS-managed backup versions:

```
EXPIREBV NONSMSVERSIONS(DELETEIFBACKEDUP(days))  
EXECUTE
```

```
EXPIREBV NONSMSVERSIONS(CATALOGEDDATA(days))  
EXECUTE
```

```
EXPIREBV NONSMSVERSIONS(UNCATALOGEDDATA(days))  
EXECUTE
```

Processing for expired backup versions of non-SMS-managed data sets

The EXPIREBV command processing for non-SMS-managed data sets is identical to that for SMS-managed data sets up to the point of determining the expired backup versions. EXPIREBV processing for SMS-managed data sets is described in [“Deleting expired backup versions from the backup volumes” on page 233](#).

The EXPIREBV command has an initial process that checks the retention days value for each active backup version for each data set. If you specified a retention days value when the BACKDS command was issued during data set backup, the number of days since the date when the backup version was created is calculated and compared to the retention days value. If the number of days since the backup version was created is greater than the number of retention days, the backup version is deleted. This process includes both the active backup versions and the retained backup versions. If the retention duration has not been exceeded, the backup version is not processed, even if it meets other expiration criteria. If you did not specify a retention days value, the DELETEDIFBACKUP, CATALOGEDDATA, and UNCATALOGEDDATE parameters provided with the NONSMSVERSION parameter of the EXPIREBV command are used to determine which backup versions are deleted.

Note: If there is only one backup version of a data set, EXPIREBV does not delete the backup version. You must use the BDELETE or HBDELETE command to delete the backup version.

If the command includes (DELETEIFBACKEDUP(*days*)), DFSMSHsm deletes any retired version older than the value specified by the *days* subparameter. It also deletes any additional older cataloged backup versions that exist.

If the command includes (CATALOGEDDATA(*days*)), DFSMSHsm processes only data sets that were cataloged when they were backed up. For deleted data sets, if a date of scratch exists in the MCB record, DFSMSHsm calculates the number of days since the date of scratch, and compares the result to the *days* specified in the command, or to the default of 60 days (if *days* was not specified). If the time since the date of scratch is more than the value specified or more than the default, DFSMSHsm deletes all cataloged backup versions of the data set except for the retired version. For existing data sets, the *days* subparameter is ignored, and all excess backup versions (that result from the (H)ALTERDS command) are deleted.

When (CATALOGEDDATA(*days*)) is used, two executions are required to delete unwanted versions. The first execution determines that the data set was scratched and stores the date of the first EXPIREBV

execution as the scratch date in the DFSMSHsm control data set MCB record. A subsequent execution deletes the unwanted backup versions when the requested time has passed. The scratch date is generally not the date that the data set was actually scratched, but is the date EXPIREBV was next run after the data set was scratched.

Programming Interface Information

The scratch date is stored in the BCDS MCB record in the 4-byte field MCBSCRD (offset X'48', packed decimal). It can be displayed using the FIXCDS command.

End Programming Interface Information

Note: DFSMSHsm honors a scratch date stored by the DFSMSHsm space maintenance and recovery utilities if the date is newer than the most recent backup date for the data set and if EXPIREBV has not already stored the scratch date itself.

If the command includes (UNCATALOGEDDATA(*days*)), DFSMSHsm processes data sets that were uncataloged when they were backed up. DFSMSHsm calculates the number of days since the uncataloged backup version was created and compares the result to the days specified in the command. There is no default value for *days* for uncataloged backup versions. If the time since the uncataloged backup version was created is more than the value specified, DFSMSHsm deletes that version.

Deleting backup versions of specific data sets

Because non-SMS-managed data sets can be either cataloged or uncataloged and because you can have both cataloged and uncataloged backup versions with the same data set name, DFSMSHsm provides the ability to specify that you want to delete the backup versions of the uncataloged data set. Issue the following commands to delete backup versions of uncataloged data sets:

```
BDELETE (dsname ...) ALL
FROMVOLUME(volser)

BDELETE (dsname ...)
VERSIONS(backup version number ...) -
FROMVOLUME(volser)

HBDELETE (dsname ...) ALL
FROMVOLUME(volser)

HBDELETE (dsname ...) -
VERSIONS(backup version number ...) -
FROMVOLUME(volser)
```

DFSMSHsm deletes the uncataloged backup versions that were made from the data sets with the specified name on the specified volume.

The MCB record is not deleted when no existing backup versions exist if the data set is not SMS-managed and if the MCB record contains any ALTERDS information.

Recovering specific data sets

DFSMSHsm recovers specific data sets to non-SMS-managed volumes under the following conditions:

- When the FORCENONSMS parameter is specified on the RECOVER command
- When SMS is not active and the backup version or dump copy being recovered was made from a non-SMS-managed data set
- When SMS is active and ACS does not assign a storage class to the data set (indicating that the data set is not currently SMS-managed)
- When the FROMVOLUME parameter is specified on the RECOVER command
- When the catalog indicates that the data set is not SMS-managed

You can issue the following additional commands to recover a non-SMS-managed data set:

- RECOVER *dsname* FROMVOLUME(*volser*)

This command recovers an uncataloged data set to the volume from which it was backed up.

- RECOVER *dsname* FROMVOLUME(*volser*) REPLACE

This command recovers an uncataloged data set to the volume from which it was backed up, and any existing data set of the same name on the volume is replaced.

- RECOVER *dsname* TOVOLUME(*volser*) - UNIT(*unittype*)

This command recovers a data set to the volume specified.

- RECOVER *dsname* TOVOLUME(*volser*) - UNIT(*unittype*) FORCENONSMS

This command recovers what may have been an SMS-managed data set to the specified non-SMS-managed volume.

- HRECOVER *dsname* TOVOLUME(*volser*) - UNIT(*unittype*)

This is the unauthorized-user form of the command. It recovers a data set to the volume specified.

- RECOVER *dsname* NEWNAME(*newdsname*) - TOVOLUME(*volser*) UNIT(*unittype*)

This command recovers a data set to the volume specified and gives the data set a new name.

- RECOVER *dsname* NEWNAME(*newdsname*) - TOVOLUME(*volser*) UNIT(*unittype*) - FORCENONSMS

This command recovers what may have been an SMS-managed data set to the specified non-SMS-managed volume and gives the data set a new name.

- HRECOVER *dsname* NEWNAME(*newdsname*) - TOVOLUME(*volser*) UNIT(*unittype*)

This command is the unauthorized user form of the command. The data set is recovered to the volume specified and is given a new name.

- RECOVER *dsname* REPLACE

This command recovers a cataloged data set to the volume where the data set currently resides and replaces the existing data set with the recovered data set.

- RECOVER *dsname* REPLACE FORCENONSMS

This command recovers a cataloged data set that was backed up as an SMS-managed data set to the non-SMS-managed volume where the existing data set currently resides. The existing data set is replaced with the recovered data set.

- RECOVER *dsname* REPLACE TOVOLUME(*volser*) - UNIT(*unittype*)

This command recovers a data set to the specified volume and replaces any existing data set with the same name on the specified volume.

- RECOVER *dsname* REPLACE TOVOLUME(*volser*) - UNIT(*unittype*) FORCENONSMS

This command recovers a data set that was backed up as an SMS-managed data set to the specified non-SMS-managed volume. Any existing data set with the same name on the specified volume is replaced.

- HRECOVER *dsname* REPLACE TOVOLUME(*volser*) - UNIT(*unittype*)

This is the unauthorized-user form of the command. It recovers a data set to a specified volume and replaces any existing data set with the same name on the specified volume.

- RECOVER *dsname* FROMVOLUME(*volser*) - NEWNAME(*newdsname*)

This command recovers an uncataloged data set to the volume from which it was backed up and gives the recovered data set a new name.

- RECOVER *dsname* FROMVOLUME(*volser*) - REPLACE TOVOLUME(*volser*) UNIT(*unittype*)

This command recovers an uncataloged data set to the volume specified. The data set with the same name on the specified volume is replaced.

- RECOVER *dsname* NEWNAME(*newdsname*) - REPLACE TOVOLUME(*volser*) UNIT(*unittype*)

This command recovers a data set to the specified volume. The data set is given a new name, and any existing data set on the specified volume that has the same name as the new name is replaced.

- RECOVER *dsname* NEWNAME(*newdsname*) - REPLACE TOVOLUME(*volser*) - UNIT(*unittype*)
FORCENONSMS

This recovers a data set that was backed up as an SMS-managed data set to the specified non-SMS-managed volume. The data set is given a new name, and any existing data set on the specified volume that has the same name as the new name is replaced.

- HRECOVER *dsname* NEWNAME(*newdsname*) - REPLACE TOVOLUME(*volser*) UNIT(*unittype*)

This is the unauthorized-user form of the command. It recovers a data set to the specified volume. The data set is given a new name, and replaces any existing data set on the specified volume that has the same name as the new name.

- RECOVER *dsname* FROMVOLUME(*volser*) - NEWNAME(*newdsname*) TOVOLUME(*volser*) - UNIT(*unittype*)

This recovers an uncataloged data set to a specified volume and gives it a new name.

- RECOVER *dsname* FROMVOLUME(*volser*) - NEWNAME(*newdsname*) TOVOLUME(*volser*) - UNIT(*unittype*)
REPLACE

This recovers an uncataloged data set to a specified volume. The data set is given a new name, and any existing data set that has the same name as the new name on the specified volume is replaced.

The processing for recovering non-SMS-managed data sets is the same as for SMS-managed data sets with the following exceptions:

- When FROMVOLUME is specified, it implies that the data set is not SMS-managed.
- Selection of the target volume is somewhat different:
 - If TOVOLUME is specified, the target volume is the volume specified by TOVOLUME.
 - If TOVOLUME is not specified and FROMVOLUME is specified, the target volume is the volume specified by FROMVOLUME.
 - If neither TOVOLUME nor FROMVOLUME is specified, the target volume is the volume on which the data set is cataloged, unless DFSMSHsm backed up the data set from a migration volume. If DFSMSHsm backed up the data set from a migration volume, DFSMSHsm recovers the data set to the volume from which the data set migrated.
 - If DUMPVOLUME is specified, the target volume is the source volume from which the dump was made.
 - If the specified NEWNAME data set is not currently cataloged, if the device type and volume serial number of the volume from which the incremental backup version was made differ from the device type and volume serial number of the volume on which the original data set is currently cataloged, and if the volume on which the original data set is currently cataloged has a more recent physical dump copy, the target volume is the volume on which the original non-VSAM data set is currently cataloged.
 - If none of the preceding can be applied, the target volume is the volume from which the eligible backup version was made.

To request that DFSMSHsm recover backup versions of data sets that were uncataloged when DFSMSHsm backed them up, specify the FROMVOLUME parameter of the RECOVER command. If you do not specify FROMVOLUME, DFSMSHsm recovers a backup version of a cataloged data set with the same name even though the data set may no longer be cataloged.

When a generation data set is recovered, it is recovered as an ordinary non-GDS data set.

Note:

1. DFSMSHsm fails the recovery of a non-SMS generation data set that is not currently cataloged, and whose corresponding generation data group is no longer defined.
2. DFSMSHsm fails the recovery of a non-SMS generation data set that is not currently cataloged, and whose corresponding generation data group is not found through generic catalog locate.

To request that an SMS-managed data set be recovered to a non-SMS-managed volume, specify the FORCENONSMS and TOVOLUME parameters.

Recovery of VSAM data sets

The FROMVOLUME and TOVOLUME parameters of the RECOVER command, used when recovering non-VSAM data sets, have different results when DFSMSHsm recovers VSAM data sets:

- The FROMVOLUME parameter applies only to uncataloged data sets and, therefore, is not used for VSAM data sets.
- For VSAM data sets not cataloged, the TOVOLUME parameter can specify only a volume owned by the same catalog where the data set being recovered is cataloged or will be cataloged. When you do not specify the TOVOLUME parameter, DFSMSHsm recovers the data set to the volume specified in the current catalog entry. If no catalog entry exists, DFSMSHsm recovers the data set to the same volume from which DFSMSHsm backed up the data set.

Data set restore from a DFSMSHsm dump copy

The results of the commands, in order, are:

1. RECOVER *dsname* FROMDUMP(DUMPCCLASS(*class*)) - TOVOLUME(*volser*) UNIT(*unittype*)

This command recovers a data set from the most recent dump copy made in the specified dump class to the specified level 0 volume.

2. RECOVER *dsname* FROMDUMP(DUMPCCLASS(*class*)) - TOVOLUME(*volser*) UNIT(*unittype*)
FORCENONSMS

This command recovers a data set that was SMS-managed when it was dumped. The data set is recovered from the most recent dump copy made in the specified dump class to the specified non-SMS-managed level 0 volume.

3. RECOVER *dsname* FROMDUMP(DUMPVOLUME(*volser*)) - TOVOLUME(*volser*) UNIT(*unittype*)

This command recovers a data set from the specified dump volume to the specified level 0 volume.

4. RECOVER *dsname* FROMDUMP(DUMPVOLUME(*volser*)) - TOVOLUME(*volser*) UNIT(*unittype*)
FORCENONSMS

This command recovers a data set that was SMS-managed when it was dumped. The data set is recovered from the specified dump volume to the specified level 0 volume.

5. RECOVER *dsname* FROMDUMP(DUMPCCLASS(*class*)) - TOVOLUME(*volser*) UNIT(*unittype*) REPLACE

This command recovers a data set from the most recent dump copy made in the specified dump class to the specified level 0 volume. Any existing data set with the same name on the specified volume is replaced.

6. RECOVER *dsname* FROMDUMP(DUMPCCLASS(*class*)) - TOVOLUME(*volser*) UNIT(*unittype*) - REPLACE
FORCENONSMS

This command recovers a data set that was SMS-managed when it was dumped. The data set is recovered from the most recent dump copy made to the specified dump class in the specified level 0 volume. Any existing data set with the same name on the specified volume is replaced.

7. RECOVER *dsname* FROMDUMP(DUMPVOLUME(*volser*)) - TOVOLUME(*volser*) UNIT(*unittype*) REPLACE

This command recovers a data set from the specified dump volume to the specified level 0 volume. Any existing data set with the same name on the specified volume is replaced.

8. RECOVER *dsname* FROMDUMP(DUMPVOLUME(*volser*)) - TOVOLUME(*volser*) UNIT(*unittype*) -
REPLACE FORCENONSMS

This command recovers a data set that was SMS-managed when it was dumped. The data set is recovered from the specified dump volume to the specified level 0 volume. Any existing data set with the same name on the specified volume is replaced.

9. RECOVER *dsname* FROMDUMP(DUMPCCLASS(*class*)) - TOVOLUME(*volser*) UNIT(*unittype*) -
NEWNAME(*newname*)

This command recovers a data set from the most recent dump copy made in the specified dump class to the specified level 0 volume. The recovered data set is given a new name.

10. RECOVER *dsname* FROMDUMP(DUMPCCLASS(*class*)) - TOVOLUME(*volser*) UNIT(*unittype*) - NEWNAME(*newname*) FORCENONSMS

This command recovers a data set that may have been SMS-managed when it was dumped. The data set is recovered from the most recent dump copy made in the specified dump class to the specified level 0 volume. The recovered data set is given a new name.

11. RECOVER *dsname* FROMDUMP(DUMPVOLUME(*volser*)) - TOVOLUME(*volser*) UNIT(*unittype*) - NEWNAME(*newname*)

This command recovers a data set from the specified dump volume to the specified level 0 volume. The recovered data set is given a new name.

12. RECOVER *dsname* FROMDUMP(DUMPVOLUME(*volser*)) - TOVOLUME(*volser*) UNIT(*unittype*) - NEWNAME(*newname*) FORCENONSMS

This command recovers a data set that may have been SMS-managed when it was dumped. The data set is recovered from the specified dump volume to the specified non-SMS-managed level 0 volume. The data set is given a new name.

13. RECOVER *dsname* FROMDUMP(DUMPCCLASS(*class*)) - TOVOLUME(*volser*) UNIT(*unittype*) - REPLACE NEWNAME(*newname*)

This command recovers a data set from the most recent dump copy that was made in the specified dump class to the specified level 0 volume. The recovered data set is given a new name and replaces any existing data set with the same new name on the specified volume.

14. RECOVER *dsname* FROMDUMP(DUMPCCLASS(*class*)) - TOVOLUME(*volser*) UNIT(*unittype*) - REPLACE NEWNAME(*newname*) FORCENONSMS

This command recovers a data set that may have been SMS-managed when it was dumped. The data set is recovered from the most recent dump copy that was made in the specified dump class to the specified non-SMS-managed level 0 volume. The recovered data set is given a new name, and replaces any existing data set with the new name on the specified volume.

15. RECOVER *dsname* FROMDUMP(DUMPVOLUME(*volser*)) - TOVOLUME(*volser*) UNIT(*unittype*) - REPLACE NEWNAME(*newname*)

This command recovers a data set from the specified dump volume to the specified level 0 volume. The recovered data set is given a new name and replaces any existing data set with the new name on the specified volume.

16. RECOVER *dsname* FROMDUMP(DUMPVOLUME(*volser*)) - TOVOLUME(*volser*) UNIT(*unittype*) - REPLACE NEWNAME(*newname*) FORCENONSMS

This command recovers a data set that may have been SMS-managed when it was dumped. The data set is recovered from the specified dump volume to the specified non-SMS-managed level 0 volume. The recovered data set is given a new name and replaces any existing data set with the new name on the specified volume.

When restoring a non-SMS-managed data set from a dump volume, you can specify a TOVOLUME parameter and a UNIT parameter that cannot be specified for SMS-managed data sets. The TOVOLUME parameter directs that the data set be restored to the specified volume. The UNIT parameter identifies the unit type for restoring the data set to a volume not managed by DFSMSHsm.

If the dump volume specified has more than one valid dump copy stacked on it, you can specify the SOURCEVOLUME(*volser*) subparameter of the FROMDUMP parameter to tell DFSMSHsm which dump copy to use.

Data set recovery of retired data sets

You can restore a retired data set. If the retired data set has a backup version that is marked as a retired version and a physical data set restore is done for the data set without a new name, the retired-version

indication is removed from the backup control data set (BCDS). This allows the data set to be processed again by the incremental backup function.

Combining full-volume restore with volume recovery

When combining a full-volume restore with a volume-recovery, the following considerations apply to non-SMS-managed volumes:

DFSMSHsm verifies that the targeted data set has not been referred to before starting the APPLYINCREMENTAL process and the time that the data set is slated for recovery. If the data set has been referred to, the recovery fails with a return code of 67. Failing the recovery allows you to take action on any application that might have inadvertently used the old data set.

Restrictions:

1. DFSMSHsm does not honor the APPLYINCREMENTAL subparameter if it determines that a catalog that resides on the target volume owns the target volume. This restriction avoids conflicts in the way DFSMSHsm supports catalogs and data sets that are cataloged.
2. DFSMSHsm does not back up catalogs and therefore they cannot be recovered.

Volume recovery from incremental backup versions

In addition to the considerations discussed for volume recovery from backup versions for SMS-managed volumes, the following considerations apply for non-SMS-managed volumes.

If a catalog exists on the volume being recovered, you must recover the catalog before you use DFSMSHsm for the volume recovery. DFSMSHsm catalogs any data sets that were cataloged when DFSMSHsm backed them up, but that are not cataloged when DFSMSHsm recovers them. If a data set was uncataloged when DFSMSHsm backed it up, DFSMSHsm recovers the data set, but does not catalog it.

If a catalog existed on the volume the last time DFSMSHsm backed up the volume, DFSMSHsm recovers the base entry for each generation data group cataloged. Therefore, if you want DFSMSHsm to recover the base entry for each generation data group cataloged, the catalog must exist.

DFSMSHsm recovers the generation data groups that are on the volume being recovered. If the generation data group base was not on the same volume as the generation data sets, you must ensure that the base entry exists before the volume is recovered. You may have to recatalog valid generation data group data sets that are on other volumes.

DFSMSHsm tries only one time to recover generation data group base entries. The recovery is handled the same way as with VTOC copy data sets. If DFSMSHsm uses the next-latest VTOC copy data set to recover the volume because DFSMSHsm cannot use the latest VTOC copy data set, DFSMSHsm recovers the next-latest copy of the generation data group base entries.

DFSMSHsm attempts to recover the volume by using the *latest* VTOC copy data set and the latest copy of the generation data group base entries. DFSMSHsm attempts to recover the volume by using the *next latest* copy of the VTOC and generation data group base entries if one of the following occurs:

- An error occurs in allocating or opening the latest VTOC copy data set.
- The VTOC copy data set resides on a tape backup volume and the operator indicates before starting the actual recovery that the required tape volumes will not be available.

If similar errors occur again, the volume recovery fails.

When DFSMSHsm recovers a volume, it recovers the following:

- Any base entries for a cataloged generation data group residing on the volume being recovered.
- Any user catalogs that do not already exist on the volume being recovered. For information about recovering a catalog, see [“Backing up and recovering a catalog” on page 487](#).
- Unmovable data sets.
- All other data sets.

DFSMSHsm considers non-SMS uncataloged data sets to be unique by reason of the volume on which they reside. This is because multiple uncataloged data sets with the same name may exist on different volumes. Backup versions of uncataloged data sets are only recovered to the volume from which they were backed up.

DFSMSHsm considers a cataloged data set to be the same data set regardless of the volume on which it is currently cataloged. Therefore, DFSMSHsm recovers the most current backup version of a cataloged data set regardless of the volume on which it was cataloged when it was backed up.

Table 33 on page 317 shows the process of backup version data set selection for volume recovery.

Table 33. Backup Version Data Set Selection for Recovery

First Criterion	Second Criterion	Result
If only backup versions of cataloged data sets exist,	and if the data set is currently cataloged on the target volume,	then the cataloged backup copy is recovered.
	and if the data set is not currently cataloged,	then recovery of this data set fails.
	and if the data set is cataloged but not on the target volume,	then recovery is not attempted, and for APPLYINCREMENTAL, the data set is scratched from the volume.
If only backup versions of uncataloged data sets exist,	and if the data set is currently cataloged on the target volume,	then recovery fails.
	and if the data set is not currently cataloged,	then the uncataloged backup version, made from this volume, is recovered.
	and if the data set is cataloged but not on the target volume,	then the uncataloged backup version, made from this volume, is recovered.
If backup versions of cataloged and uncataloged data sets exist,	and if both backup versions are from the target volume,	then DFSMSHsm recovers the most recent backup copy. Recovery continues, depending on whether the data set was cataloged, as previously discussed.
	and if the backup version of a cataloged data set was made from a different volume, and the data set is currently cataloged on a volume other than the target volume,	then DFSMSHsm attempts to recover the uncataloged backup version.
	and if the backup version of a cataloged data set was made from a different volume, but the data set is currently cataloged on the target volume,	then DFSMSHsm attempts to recover the backup version of the cataloged data set.
	and if the backup version of a cataloged data set was made from a different volume, but the data set is not currently cataloged,	then DFSMSHsm attempts to recover the uncataloged backup version.

If a data set is a candidate for recovery, backup versions of the cataloged data set exist, and the data set is currently uncataloged, then DFSMSHsm does not recover the data set because it appears to DFSMSHsm that the data set was deleted after the backup version was created. For recovery of uncataloged data sets, a backup version of each data set is recovered to reflect the VTOC copy at the time of backup. It is up to you to delete any recovered uncataloged data sets that are unwanted.

If a data set is currently cataloged as MIGRAT, and a backup version of the cataloged data set was selected for recovery, then recovery is not performed because the data set migrated since backup.

If a data set was migrated from the target volume after the selected backup version of the uncataloged data set was created, then the recovery is not attempted because the uncataloged data set was deleted before the creation of the cataloged data set that was migrated.

If the volume you are recovering contains both a catalog and unmovable data sets, you could have a problem. After DFSMSHsm recovers the catalog, DFSMSHsm tries to recover the unmovable data sets. However, the allocation for the unmovable data sets can fail because the catalog could be allocated to the space where the unmovable data set must go. To solve this problem, perform the following steps:

1. After the volume recovery completes without recovering an unmovable data set, move the catalog to another volume.
2. Use the RECOVER command for the specific data sets that previously failed recovery.
3. Move the catalog back to the original volume.

After DFSMSHsm has recovered a volume, you can use the VOLUME parameter of the AUDIT command to verify the status of data sets on the volume.

Chapter 8. Aggregate backup and recovery support (ABARS)

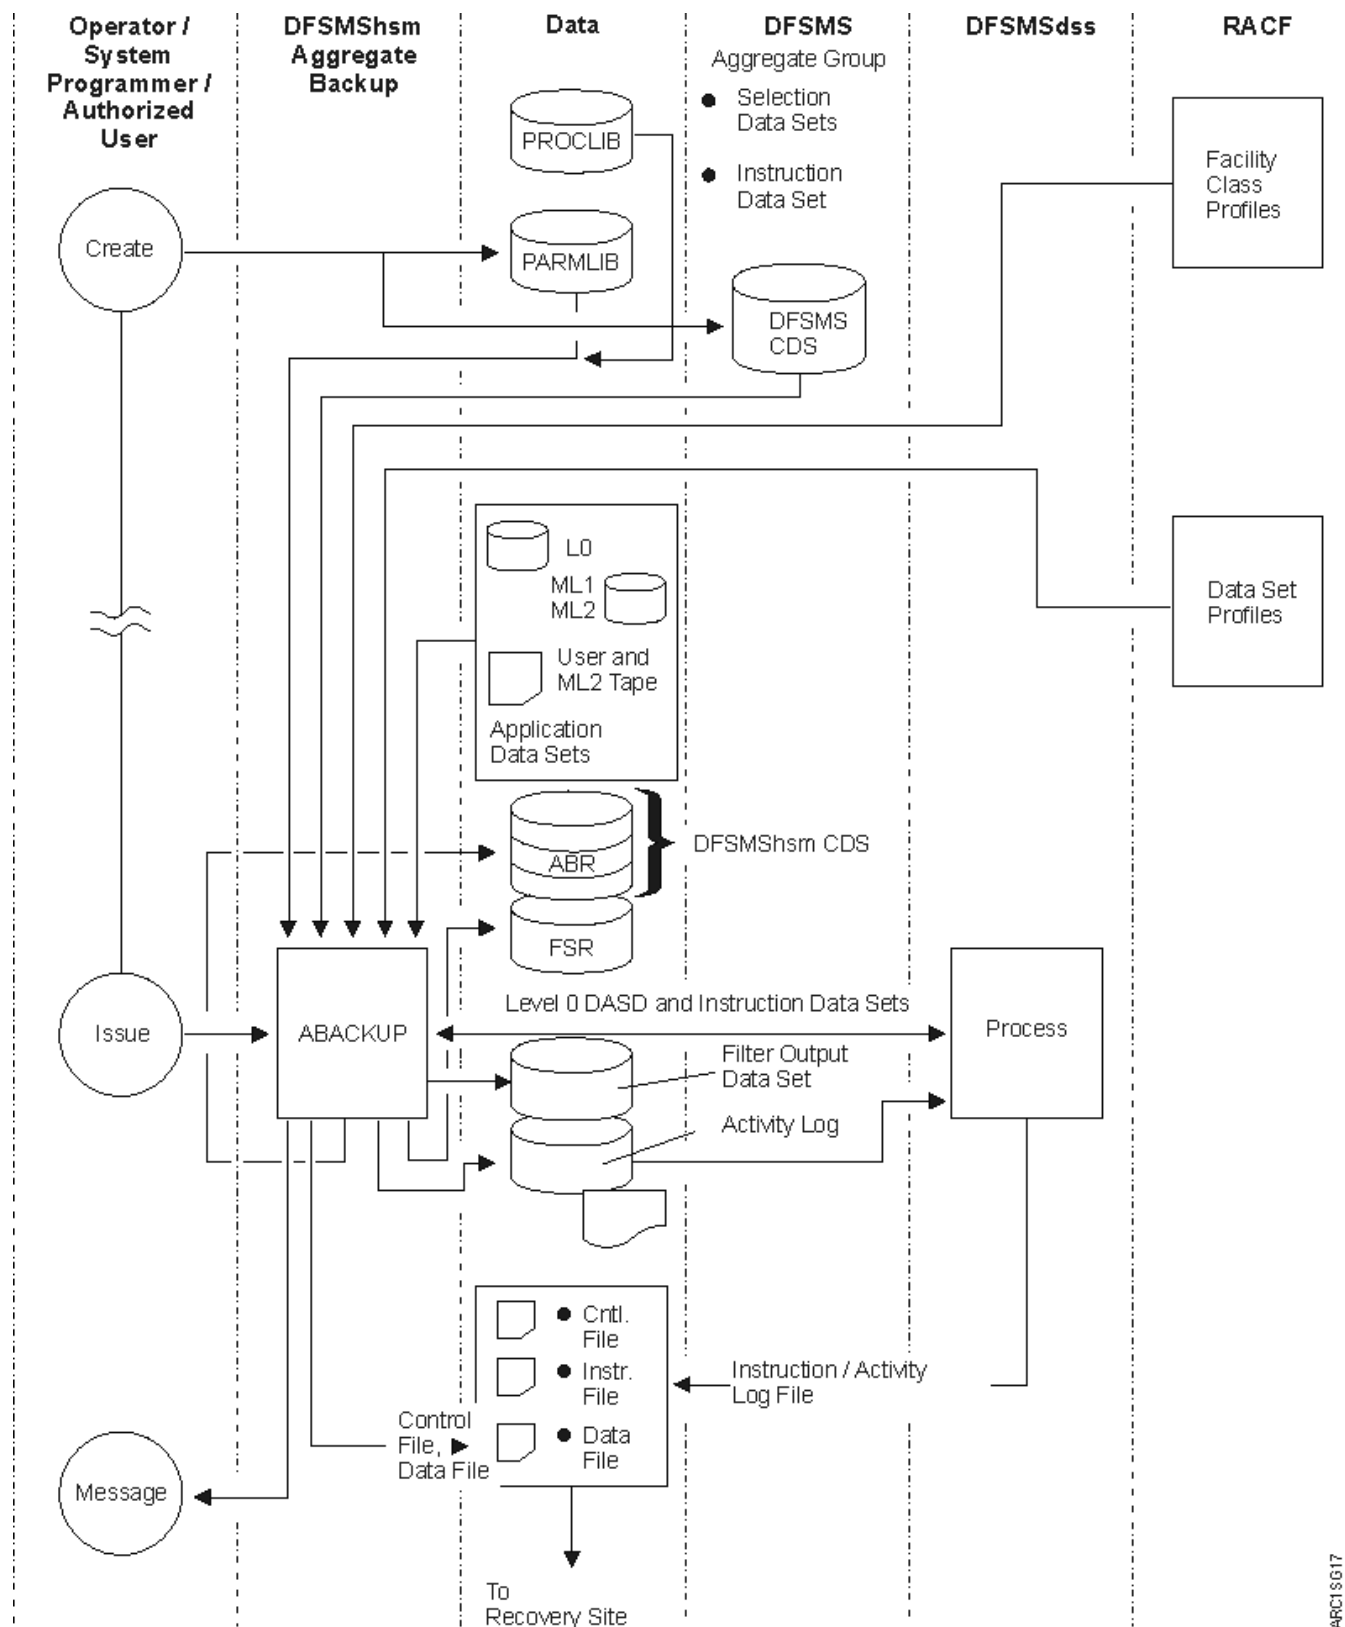

Aggregate backup is the command-driven function that backs up a user-defined group (called an aggregate group) of data sets for recovery at another computer site or at the same site. *Aggregate recovery* is the command-driven function that recovers the data sets that were previously backed up by aggregate backup.

Aggregate backup and recovery support can be used to back up and recover both SMS and non-SMS-managed data.

[Figure 34 on page 320](#) and [Figure 35 on page 321](#) show data movement during aggregate backup and recovery and how these functions interact with other products. The DFSMSHsm aggregate backup and recovery support function is also referred to as ABARS.

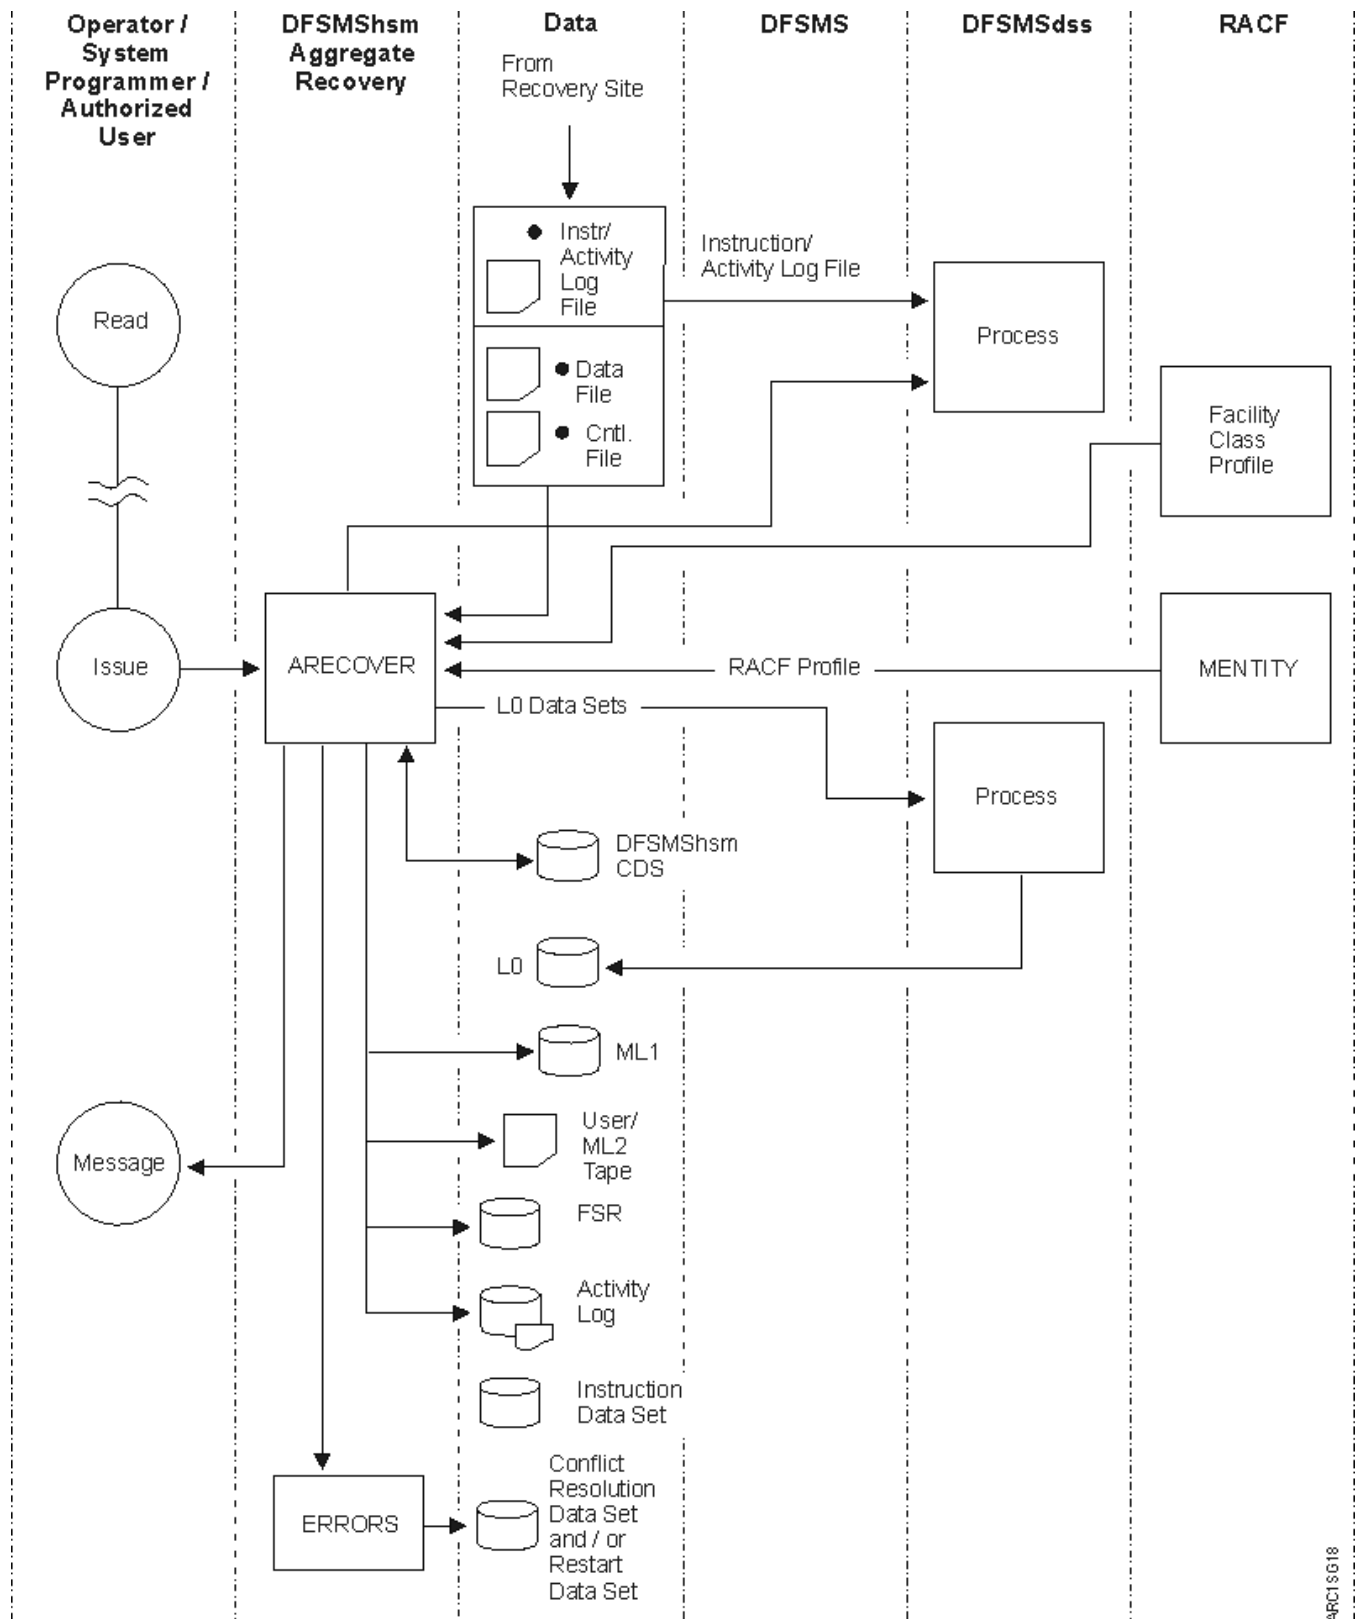

Note: Only a host designated with the HOSTMODE=MAIN attribute can execute aggregate backup or aggregate recovery.

Aggregate backup and recovery support (ABARS)

ARC1SG17

Figure 34. Aggregate Backup and Recovery Support (part 1 of 2)

APR15G18

Figure 35. Aggregate Backup and Recovery Support (part 2 of 2)

The aggregate group and management class used for aggregate backup are defined to DFSMS through Interactive Storage Management Facility (ISMF) panels.

DFSMSdss is used to move level 0 DASD data sets during aggregate backup and recovery processing.

DFSMSHsm can include ML1 and ML2 migration copies of data sets within the aggregate backup. Migration copies that are stored in the cloud (MLC) will not be included and will cause the backup to fail. ABACKUP does not support data sets migrated to the cloud. If the selection criteria results in any of these data sets being selected, then the ABACKUP command fails.

RACF is used to ensure that RACF-protected data sets that are backed up remain RACF-protected when recovered. When RACF facility class is active and the user has restricted command authority, RACF checking of data sets is performed during aggregate backup. See [“Checking authorization during aggregate backup”](#) on page 340 for more information.

Although the backup and recovery sites are referred to as two separate data processing centers, you can choose to perform both functions at the same data processing center. This might be useful if you want to divide your data processing center for work load management.

How aggregate backup works

In general, to use aggregate backup, you first specify the data sets to be backed up, and then use the ABACKUP command or ISMF panels to back up the data sets to tape files. These tape files can then be physically transported or transmitted, using a transmission program like the NetView file transfer program (FTP), to a recovery site where the data sets can be recovered.

The following topics describe how data sets are specified for backup, how the ABACKUP command is used, which tape files are created by aggregate backup, and how to use the Aggregate Backup Assist (ABA) program to produce a selection data set.

Specifying data sets to be backed up

Before you can run aggregate backup, you need to create one or more selection data sets and define an aggregate group and related management class to specify exactly which data sets are to be backed up. You may also decide to create an instruction data set to contain any information you want conveyed to the recovery site. One instruction data set name and up to five selection data set names can be defined within one aggregate group.

Aggregate group

The aggregate group lists the selection data set names, instruction data set name, and additional control information used by aggregate backup in determining which data sets are to be backed up. You create an aggregate group using Interactive Storage Management Facility (ISMF) panels.

The aggregate group optionally contains a management class name that is used to obtain a management class definition that specifies the new aggregate backup parameters.

If a management class is not specified in the aggregate group definition, then DFSMSHsm attempts to retrieve the contents of the default management class during aggregate backup processing. If a default management class has not been defined, then DFSMSHsm defaults are used. See [“Management class considerations”](#) on page 338 for information about these defaults.

Management class

The management class specifies such parameters as the maximum number of aggregate versions to be kept, the aggregate group retention parameters, the serialization option, and whether concurrent copy is requested.

Selection data set

The selection data set lists the names of the data sets to be processed during aggregate backup. You can identify the data set names in a single selection data set, or you can divide the names among as many as five selection data sets.

You can specify six types of data set lists in a selection data set: INCLUDE, EXCLUDE, ACCOMPANY, ALLOCATE, ACCOMPANYEXCLUDE, and ALLOCATEEXCLUDE. The type you specify determines which data sets are backed up and how they are recovered.

Your selection data set must have at least one INCLUDE, ALLOCATE, or ACCOMPANY data set.

An INCLUDE data set list is a list of data sets to be copied by aggregate backup to a tape data file where they can be transported to the recovery site and recovered by aggregate recovery. The list can contain fully qualified data set names or partially qualified names with placeholders. DFSMSHsm expands the list to fully qualified data set names.

An EXCLUDE data set list is a list of fully qualified or partially qualified data set names that are specifically excluded from being backed up. If the expansion of the partially qualified name results in one or more fully qualified names that should not be backed up, the EXCLUDE keyword prevents those data sets from being backed up.

An ACCOMPANY data set list is a list of tape data sets that physically accompany the control and data file from the backup site to the recovery site and that are cataloged as part of an aggregate recovery. These data sets are *not* written to the data file. You have to provide your own copy of the data set to the recovery site. For example, you may want to specify in the ACCOMPANY list any large tape data sets that would take a lot of time to copy to the data file.

An ACCOMPANYEXCLUDE data set list is a list of fully qualified or partially qualified data set names that are specifically excluded from being tracked in the control file during aggregate backup and eventually cataloged during aggregate recovery. If the expansion of the partially qualified name results in one or more fully qualified names that should not be processed, the ACCOMPANYEXCLUDE keyword prevents those data sets from being backed up.

An ALLOCATE data set list is a list of DASD data sets or GDG base names processed by aggregate backup and specified on the control file to be allocated and cataloged at the recovery site. ALLOCATE data sets are *not* copied to a data file. For example, you may want to specify an ALLOCATE data set for aggregate processing that requires the presence of an empty data set.

Note: An ALLOCATE data set list can also contain the names of ML2 migrated tape data sets.

An ALLOCATEEXCLUDE data set list is a list of fully qualified or partially qualified data set names that are to be specifically excluded from having allocation data collected during ABACKUP. If the expansion of the partially qualified name results in one or more fully qualified names that should not be allocated at the recovery site, the ALLOCATEEXCLUDE keyword prevents collecting allocation data for those data sets.

Skipped data sets

Regardless of how you specify data sets for backup, some data sets may be protected by the peer-to-peer remote copy (PPRC) function or by the extended remote copy (XRC) function. In either case, making backup copies is redundant and a waste of storage space. Use the ABACKUP SKIP(PPRC) command to direct ABACKUP to skip backing up any level 0 data sets that are totally contained on PPRC volumes. Use the ABACKUP SKIP(XRC) command to direct ABACKUP to skip backing up any level 0 data sets that are totally contained on XRC volumes. In addition, you can combine the parameters in the ABACKUP SKIP(PPRC XRC) command form.

Note: You can also use the SETSYS ABARSKIP(PPRC) command or the SETSYS ABARSKIP(XRC) command (or a combination of both subparameters) to specify which types of data sets that you want all ABACKUP processing to skip.

Instruction data set

The instruction data set is a data set you create that contains instructions or other information you want to send to the recovery site. The instruction data set is a free-form text file.

Backing up applications

Aggregate backup allows you to back up user-defined groups of data sets to be recovered later as an entity at another computer site. Figure 36 on page 324 shows the information flow of an aggregate backup.

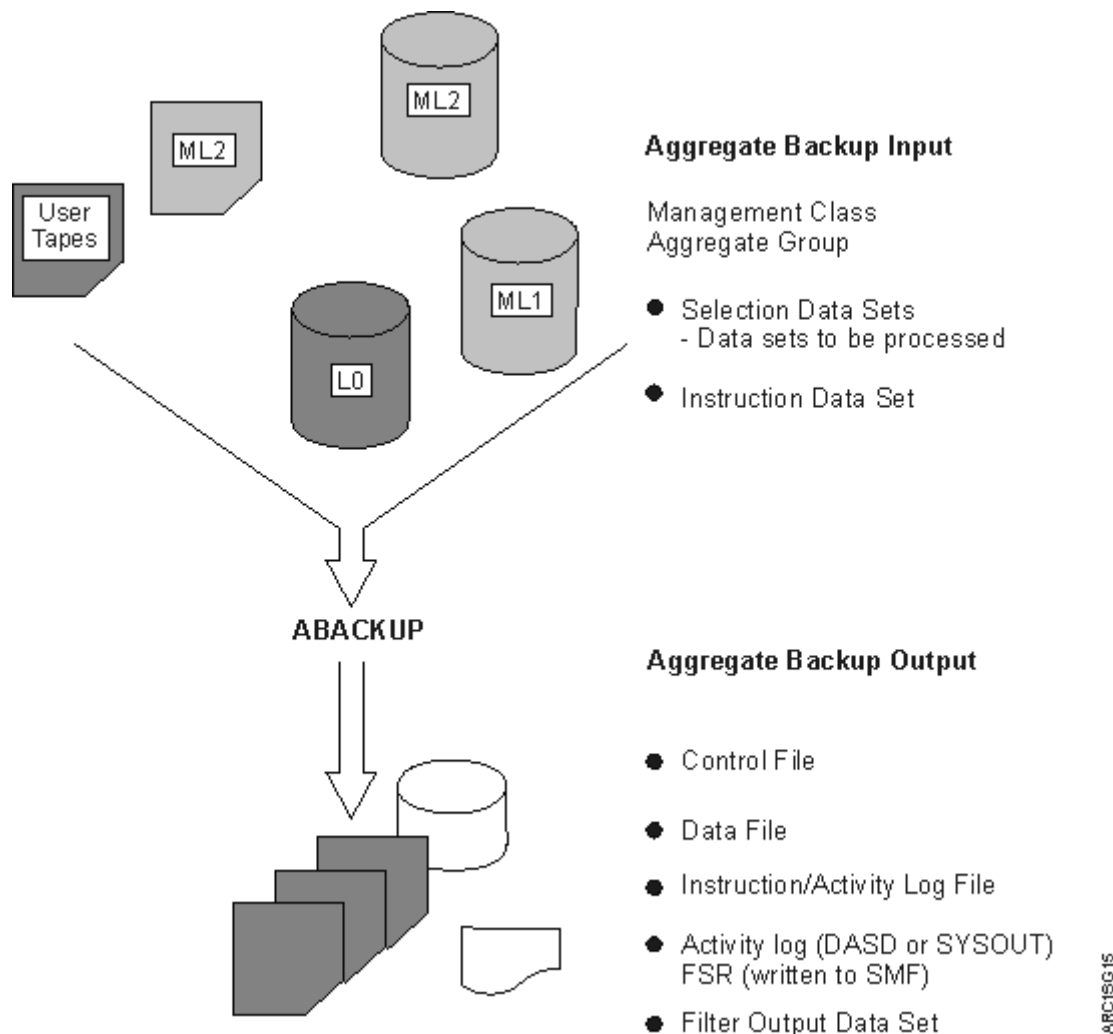

Figure 36. Aggregate Backup Information Flow

ABACKUP command

Two options are available with the ABACKUP command. You can choose to verify the contents of the aggregate backup without actually backing up any data sets, which is the same as performing a test run of aggregate backup. Then, when you are ready, you can perform the actual backup.

When you enter the ABACKUP command with the EXECUTE option, the following tape files are created for later use as input to aggregate recovery:

- Output data set tape files, which contain copies of the backed up data sets, as follows:
 - "D" data file, which contains copies of level 0 data sets that have been backed up.
 - "O" data file, which contains copies of migrated data sets or user tape data sets that have been backed up.

Note: The "D" file is created when you have level 0 disk data sets in the INCLUDE list. The "O" data file is created when you have user tape data sets or migrated data sets in the INCLUDE list. If you requested

stacking for the ABACKUP output files and you do not specify an INCLUDE statement, a dummy "D" and "O" file is created. If you did not request stacking for the ABACKUP output files and you do not specify an INCLUDE statement, no "D" or "O" files are written. For the format of these files, see [“Data files”](#) on page 351.

- A control file. This file contains control information needed by aggregate recovery to verify or to recover the application's data sets. The control file also specifies which ACCOMPANY and ALLOCATE data sets should be cataloged or allocated at the recovery site.
- An instruction/activity log file. This file contains the instruction data set, which is optional. The instruction data set contains the instructions or information that may be needed at the recovery site. A copy of the activity log is also written to this file if the activity log is directed to DASD by the SETSYS ABARSACTLOGTYPE command.

Note: This file is created only if an instruction data set name was specified in the aggregate group, or the ABACKUP activity log was allocated on DASD.

Also, aggregate backup creates the following:

- Filter output data set—Created if requested with the FILTEROUTPUTDATASET parameter of the ABACKUP command.
- Activity log—Contains messages issued during aggregate backup processing.
- Functional statistics record (FSR)—Containing additional aggregate backup processing information. This includes records of the amount of CPU time used for processing ABACKUP and ARECOVER requests that can optionally be written as an SMF record if the installation specifies SETSYS SMF(*smfid*).

Note: If the total number of volumes used for the data files, control file, instruction data set, and accompanying data set exceeds 5000, an extension FSR is created for the aggregate. Each extension FSR contains a maximum of 5000 volume serial numbers. In addition, each extension FSR has the constant "CONT" at offset X'7C'. There are as many extended FSRs as necessary to hold all volume serial numbers processed by a particular aggregate. The extension FSRs repeat all aggregate information except the volume serial number lists.

- An ABARS activity record (ABR) is created in the BCDS. This record contains information related to an aggregate backup and recovery performed on a particular aggregate group.

Rule: You must have a BCDS when performing an aggregate backup or aggregate recovery.

Example of data sets associated with an aggregate group

Table 34 on page 325 shows the data sets that exist in the database at the aggregate backup site. Throughout this topic, this example is used to show each task as you prepare for and perform aggregate backup of some of these data sets.

Table 34. Data Sets at the Example Aggregate Backup Site

Data Set Name	DASD	Tape	SMS	Migrated
PAY2.PY002.SOCSEC	X		X	
PAY2.PY002.STATUS.G0001V00	X			
PAY2.PY002.STATUS.G0002V00	X			
PAY1.PY001.CHECK	X			
PAY1.PY003.CHECK	X			
PAY2.PY001.BENEFIT	X			
PAY1.PY001.PGMLIB	X			
PAY1.PY002.IRA	X			ML1
PAY1.PY001.BONUS	X			ML1

Table 34. Data Sets at the Example Aggregate Backup Site (continued)

Data Set Name	DASD	Tape	SMS	Migrated
PAY1.PY002.LADDER	X			ML1
PAY1.PY001.NAMES		X		
PAY2.PY002.RETIRE		X		
PAY2.PY001.TAXES		X		

You want the following data sets to be copied to the data file:

- PAY2.PY002.SOCSEC
- PAY2.PY002.STATUS.G0002V00
- PAY1.PY001.CHECK
- PAY1.PY001.PGMLIB
- PAY1.PY002.IRA
- PAY1.PY001.BONUS
- PAY1.PY002.LADDER
- PAY1.PY001.NAMES

You want the data set PAY2.PY001.BENEFIT to be identified on the control file for allocation at the recovery site. You also want the data set PAY2.PY001.TAXES to be identified on the control file and to be cataloged at the recovery site.

Filtering for generation data sets

Extra care must be taken when using wildcard filtering for generation data sets. You must use either of the following names:

- The fully qualified data set name
Example: USER1.GDG.G0001V00
- The fully qualified name with relative generation
Example: USER1.GDG(-1)
- The partially qualified base name with the last qualifier (GggggVvv) not specified
Example: USER1.GDG.*

Partial qualification of the last qualifier (GggggVvv) is not supported unless a wildcard (%) or (*) is specified in the first character of the qualifier

Example: USER1.GDG.*V01 is valid but USER1.GDG.G* is not valid.

Another way to get all generations of a GDG using wildcards would be to specify USER1.GDG.%%%%%V%%.

Preparing for aggregate backup

You need to consider the following items as you prepare for aggregate backup:

- Minimizing data set contention on your system.

When ABACKUP is processing data sets on level 0 volumes and the status of a data set changes (for example, it is moved or deleted) after the list of data sets to process has been created but before backup processing has begun, ABACKUP processing fails. Then ABACKUP processing must be entirely rerun.

- Specifying data sets in one or more selection data sets so they can be processed by aggregate backup

- Writing instructions and useful information in an optional instruction data set
- Defining an aggregate group to identify the selection data sets, instruction data set, and other control information for aggregate backup
- Defining a management class
- Defining aggregate backup environmental options with the SETSYS command
- Using RACF facility class to authorize certain users or operators to issue the ABACKUP command

Table 35 on page 327 shows a checklist you might want to follow as you complete each of the steps needed to prepare for and perform aggregate backup.

Table 35. Aggregate Backup Checklist	
Step	Action
___ 1.	Negotiate with the recovery site to provide the support required to recover your data sets.
___ 2.	Review <i>z/OS Planning for Installation</i> .
___ 3.	Define the aggregate group to identify the selection data sets, the instruction data set, and any additional control information.
___ 4.	Define the management class.
___ 5.	<p>Create the selection data sets that list the data sets to be processed by aggregate backup. See <i>z/OS DFSMSHsm Implementation and Customization Guide</i>, Chapter 4, under the heading "Data Mover Support for Availability Management Functions" for a list of data set types that are supported for aggregate backup.</p> <ol style="list-style-type: none"> 1. Allocate the selection data sets. 2. Enter an INCLUDE list of the data sets to be backed up. This step is optional; however, if you omit an INCLUDE list, you must at least specify an ALLOCATE or ACCOMPANY list. 3. Enter an EXCLUDE list of the data sets that should not be backed up. This step is optional. 4. Enter an ACCOMPANY list of the tape data sets that should be taken with the aggregate backup data file and should be cataloged at the recovery site. This step is optional. 5. Enter an ACCOMPANYEXCLUDE list of data sets you want excluded from the ACCOMPANY list. This step is optional. 6. Enter an ALLOCATE list of data sets you want only allocated and cataloged at the recovery site. This step is optional. 7. Enter an ALLOCATEEXCLUDE list of data sets you do not want allocated and cataloged at the aggregate recovery site. This step is optional.
___ 6.	Create an instruction data set to contain any helpful information or instructions for the recovery site. This is optional.
___ 7.	Link-edit the aggregate backup installation exits. This step is optional.
___ 8.	Ensure that all level 0, ML1, and ML2 DASD volumes containing the data sets referred to for aggregate backup are online.
___ 9.	Ensure that the ABARS JCL procedure was installed in the systems JCL library (refer to the <i>z/OS DFSMSHsm Implementation and Customization Guide</i>).

Table 35. Aggregate Backup Checklist (continued)

Step	Action
___ 10.	Determine the SETSYS parameters to be used: <ul style="list-style-type: none"> • Specify maximum number of ABARS address spaces • Specify activity log type, message level, and deletion processing • Specify whether output tapes should be stacked or not • Specify whether you want the ABARS FSR record written as an SMF record • Specify how DFSMSdss backs up level 0 DASD during ABACKUP processing • Indicate ABARS procedure name • Indicate TAPESECURITY(RACF) if you have decided to use RACF TAPEVOL tape security. • Specify TAPESECURITY(EXPIRATION) if RACF DATASET security is to be used. • Activate desired installation exits • Specify ABARS buffer usage
___ 11.	Add the aggregate backup procedure name defined by SETSYS ABARSPROcname to the RACF started task table.
___ 12.	Use RACF FACILITY class to authorize certain users or operators to issue the ABACKUP command.
___ 13.	If you want to RACF protect output tape volumes, you can issue the SETSYS command with the TAPESECURITY(RACF) parameter and issue the RACF command RDEFINE TAPEVOL HSMABR; or you can instead use RACF DATASET class profiles to protect the tapes and create the DATASET profiles using ADDSD
___ 14.	Issue the ABACKUP command with the VERIFY parameter. <ul style="list-style-type: none"> • If aggregate backup verification completes successfully (RC=0), continue to step 16. • If aggregate backup verification fails, correct any errors and repeat this step until the aggregate backup verification completes with a return code of zero.
___ 15.	Issue the ABACKUP command with the EXECUTE parameter.
___ 16.	Review the activity log for messages ARC6060I and ARC6061I that list the aggregate backup control and data files volumes. The control file volume serial numbers are required as input for aggregate recovery.

SMS requirements during aggregate backup

You must have SMS active on your system to perform aggregate backup.

Prior planning is suggested if you want to back up SMS-managed data sets and have them recovered later in an environment compatible to that which existed at the backup site. It is recommended that the SMS classes retain the same attributes both at the backup and at the recovery sites. The ACS routines should also be compatible.

If you do not have identical SMS environments at both sites, SMS-managed data sets can still be successfully recovered, but not necessarily in the environment in which they existed at the backup site. The SMS-managed data sets are recovered in one of the ways described in [“Considering storage management subsystem requirements”](#) on page 378.

Note:

1. You might want to specify the required SMS class names and attributes in the instruction data set when you perform aggregate backup. See [“Creating an instruction data set”](#) on page 334.
2. All SMS class names that are encountered during aggregate backup processing—along with their associated attributes—are listed in the ABACKUP activity log. This information can be retrieved during ARECOVER PREPARE processing and used to define the SMS environment at your recovery site. You should also consider backing up the source control data sets (SCDSs) as a separate aggregate group so that you can recover them as an aggregate before recovering application data.

Creating selection data sets

A selection data set contains the names of the data sets to be processed during aggregate backup. You can identify the data set names in one selection data set, or you can split them up and list them in as many as five selection data sets.

For example, you may want to list a particular group of data sets in a separate selection data set that could then be used as part of more than one aggregate backup. Thus, a particular user's billing application could be listed in a separate selection data set to be backed up by itself. Then, if you decide you also want to back up the billing applications of all the users in your company, you can perform an aggregate backup using this same selection data set in addition to selection data sets for the other users.

A selection data set can be a partitioned data set (PDS) member, a sequential data set, or a partitioned data set extended (PDSE) member.

The Interactive Storage Management Facility (ISMF) panels allow you to allocate, browse, and edit the selection data sets.

If you create a selection data set outside of ISMF panels, you must allocate it as follows:

- Records must be in one of these two formats:
 - Fixed format, block size = 80, length = 80
 - Fixed block format, block size = any multiple of 80, length = 80
- Selection data sets must be cataloged.

Selection data set syntax

You must follow these general rules when creating a selection data set:

- Entries must be entered between columns 1 and 72 inclusive.
- A comment is a string of characters preceded by /* (forward slash and asterisk) and followed by */ (asterisk and backslash) symbols.
- A separator consists of a comma, one or more blanks, or a comment.
- INCLUDE, EXCLUDE, ACCOMPANY, ACCOMPANYEXCLUDE, ALLOCATE, and ALLOCATEEXCLUDE keywords are separated from one another by one or more separators.
- One or more blanks can optionally precede and follow each parenthesis in the pair.
- Continuation characters are not necessary but can be optionally specified by a hyphen (-) or plus (+) as the rightmost nonblank character, optionally preceded by one or more blanks. This follows the syntax conventions for TSO CLIST.
- INCLUDE, EXCLUDE, ACCOMPANY, ACCOMPANYEXCLUDE, ALLOCATE, and ALLOCATEEXCLUDE keywords can be specified in any sequence, but they can be specified only once within a selection data set.
- All keywords are optional. You must, however, specify at least one INCLUDE, ALLOCATE, or ACCOMPANY keyword.
- Data set names specified in the INCLUDE list cannot be specified in the ALLOCATE or ACCOMPANY lists.
- If the same fully qualified data set name is specified in both the INCLUDE list and the EXCLUDE list, the data set is not selected for processing, because EXCLUDE takes precedence over INCLUDE.

If the same fully qualified data set name is specified in both the ACCOMPANY list and the ACCOMPANYEXCLUDE list, the data set is not selected for processing, because ACCOMPANYEXCLUDE takes precedence over ACCOMPANY.

If the same fully qualified data set name is specified in both the ALLOCATE list and the ALLOCATEEXCLUDE list, the data set is not selected for processing, because ALLOCATEEXCLUDE takes precedence over ALLOCATE.

- Fully qualified names are supported.
- PDS member names are not supported.

- Fully or partially qualified data set aliases are not supported.
- Relative GDG names are supported when the GDG name is a fully qualified data set name without placeholders.

Partially qualified relative GDG names are supported in the INCLUDE statement, but not in the EXCLUDE, ALLOCATE, ALLOCATEEXCLUDE, ACCOMPANY, or ACCOMPANYEXCLUDE statements.

The following is an example of a partially qualified relative GDG name:
INCLUDE (USERHLQ.*.GDG.*(-1))

The statement above causes aggregate backup to back up all the minus-one generation data sets that are cataloged and match the specified filtering criteria. No other generations of the data set are backed up unless specifically requested by another data set filter or a fully qualified data set name.

Rule: You cannot specify positive generation (+*nnn*) numbers. Most positive generation numbers refer to data sets that are not yet created. In addition, the integer value within the parentheses must conform to MVS constraints and must be expressed in three digits or less.

- With the exception of relative GDG names (described above), partially qualified data set names are supported in the INCLUDE, EXCLUDE, ACCOMPANY, ACCOMPANYEXCLUDE, ALLOCATE, and ALLOCATEEXCLUDE lists. Use the following examples of partially qualified data set names as guidelines for the use of ** (double asterisk) and * (single asterisk):

PAY1.**

Specifies all data sets whose first or only qualifier is PAY1

USER2..LIST**

Specifies all data sets whose first and last qualifiers are USER2 and LIST, respectively, including USER2.LIST

PAY1.*

Specifies all data sets with two qualifiers, whose first qualifier is PAY1

PAY1.*.LOAD

Specifies all data sets with three qualifiers and whose first and last qualifiers are PAY1 and LOAD respectively

PAY1.UT*.LIST

Specifies all data sets with three qualifiers, whose first and last qualifiers are PAY1 and LIST, respectively, and whose second qualifier begins with UT

When used with other qualifiers, the double asterisk (**) indicates either the nonexistence of leading, trailing, or middle qualifiers, or the fact that they play no role in the selection process.

The single asterisk (*) is used in place of exactly one qualifier. It can also be used to indicate that only part of a qualifier has been specified.

The ignore character % (percent sign) is a placeholder character. Each % represents exactly one character in the data set name. Any character in that position in the name is ignored. Use the following examples as guidelines for the use of ignore character:

PAY1.PY001.I%%

This matches a data set name of PAY1.PY001.IRA.

PAY1.PY001.B%%%S

This matches a data set name of PAY1.PY001.BONUS.

ABARS supports both VSAM and non-VSAM data sets in the selection data set. ABARS allows VSAM base cluster names or VSAM component names in the selection lists. If VSAM component names are specified in the selection data set, ABACKUP processing determines the correct base cluster name that is associated with the component name and backs up the base cluster. If multiple VSAM component names are associated with the same base cluster name, the base cluster is backed up only once.

If a VSAM component name is encountered, ABACKUP processing backs up the associated base cluster and all components that are associated with that base cluster. When ABACKUP is invoking DFSMSdss, it passes DFSMSdss the base cluster name and requests SPHERE processing.

Note: If you are working with an ALLOCATE list, only the base cluster components will be processed.

When a VSAM data set is backed up from the INCLUDE list, all of its associations are backed up, including its components (base cluster, data, and index). However, when a VSAM data set is backed up from the ALLOCATE list, only the base cluster is backed up. This occurs because DFSMSdss dump processing moves actual data for a data set that is backed up from the INCLUDE list. No data (only allocation information that is necessary to allocate the data set at the recovery site) is moved for data sets backed up from the ALLOCATE list. In each instance, all information that is needed to restore the VSAM data set is backed up regardless in which list it appears. For a discussion of different data set types that ABARS supports in the INCLUDE and ALLOCATE lists, refer to [Data set type support for availability management functions in z/OS DFSMSHsm Implementation and Customization Guide](#).

Because of the way that ABARS handles VSAM components and because migrated VSAM data sets are cataloged as non-VSAM, the results of data set filtering can vary, depending on whether the data set is migrated and whether the VERIFY or EXECUTE keywords are specified in the ABACKUP command.

For example, if you have the following statements in your selection data set:

```
INCLUDE(hlq.TEST.CLUSTER.**)  
EXCLUDE(hlq.TEST.CLUSTER)
```

Then you could still back up the base cluster because the data and index components have not been excluded.

These statements work if the VSAM data set is not migrated. However, if the data set is migrated, the data component is located (ABARS does not know at the time it is VSAM) and the base cluster is backed up.

To ensure that all components of the above VSAM cluster are excluded, either exclude using a matching generic data set name; for example,

```
EXCLUDE(hlq.TEST.CLUSTER.**)
```

or exclude all fully qualified component names; for example,

```
EXCLUDE(hlq.TEST.CLUSTER.DATA,hlq.TEST.CLUSTER.INDEX)
```

- For more information about how to use the INCLUDE, EXCLUDE, ACCOMPANY, ACCOMPANYEXCLUDE, ALLOCATE, and ALLOCATEEXCLUDE keywords, see [“Selection data set keywords” on page 331](#).
- For more information about the TSO CLIST command, see [z/OS TSO/E Command Reference](#).

Processing user tape data sets in the include list

User tape data sets in the INCLUDE list are supported up to a block size of 256K-1, which is currently the maximum size supported for tape devices. The tape data set is restored to its original size upon recovery, as long as the allocated tape device supports the block size.

Selection data set keywords

The following six keywords can be used to identify data sets in a selection data set:

- INCLUDE
- EXCLUDE
- ACCOMPANY
- ACCOMPANYEXCLUDE
- ALLOCATE
- ALLOCATEEXCLUDE

You must specify at least one INCLUDE, ALLOCATE, or ACCOMPANY.

INCLUDE

Data sets listed by this keyword are written to the aggregate backup data file during ABACKUP processing. The INCLUDE keyword syntax is:

Keyword	Field
Include	(<i>dsn...</i> , <i>dsnmask...</i>)

- **Include** — Enter the whole word or an abbreviation of the word. The letter I is the minimum abbreviation allowed.
- *dsn...*, *dsnmask...* — Specifies the data set names or masks to be backed up. *dsnmask* represents a partially qualified data set name. Data sets to be backed up can be tape or DASD, migrated or nonmigrated, SMS-managed or non-SMS-managed. If a PDS is listed, all members are included in the aggregate backup. If you specify a fully qualified data set name, the data set must exist and must be cataloged, or aggregate backup fails.

Note: DFSMSHsm backs up, as is, any migrated data set in the INCLUDE list, without recalling it first.

EXCLUDE

Data sets listed by this optional keyword are *not* written to the aggregate backup data file. If you specify the same fully qualified data set name in both the INCLUDE and EXCLUDE lists, the data set is not selected, because EXCLUDE takes precedence over INCLUDE.

The EXCLUDE keyword syntax is:

Keyword	Field
Exclude	(<i>dsn...</i> , <i>dsnmask...</i>)

- **Exclude** — Enter the whole word or an abbreviation of the word. The letter E is the minimum abbreviation allowed.
- *dsn...*, *dsnmask...* — Specifies the data set names or masks to be excluded from the aggregate backup. *dsnmask* represents a partially qualified data set name.

Note: Aggregate backup combines the INCLUDE and EXCLUDE lists from all selection data sets for processing. The combination of lists must result in the selection of at least one data set, or aggregate backup fails.

ACCOMPANY

Tape data sets listed with this optional keyword physically accompany the control and data files from the aggregate backup site to the aggregate recovery site and are cataloged as part of an aggregate recovery. These data sets are *not* written to the data file. You must provide your own copy of the data set to be used at the aggregate recovery site.

Example: You can have a large tape data set that would take too much time to copy to the data file. If you can specify this data set in the ACCOMPANY list, and the data set is cataloged at the aggregate recovery site. Then you must transport the tape containing the data set to the aggregate recovery site.

The ACCOMPANY keyword syntax is:

Keyword	Field
ACCOMPANY	(<i>dsn...</i> , <i>dsnmask...</i>)

- **ACCOMPANY** — Enter the whole word, or the alias AC.

- *dsn..., dsnmask...* — Specifies the partially and fully qualified tape data set names or masks to accompany the data file from the aggregate backup site to the aggregate recovery site.

ACCOMPANYEXCLUDE

Data sets listed by this optional keyword are excluded from the list of ACCOMPANY data sets. Data sets in the ACCOMPANY list must not be in the INCLUDE or ALLOCATE lists, and must be cataloged tape data sets.

The ACCOMPANYEXCLUDE keyword syntax is:

Keyword	Field
ACCOMPANYEXCLUDE	<i>(dsn..., dsnmask...)</i>

- ACCOMPANYEXCLUDE — Enter the whole word or an abbreviation of the word. ACCEXCLUDE is the alias, and ACCOMPANYE is the minimum abbreviation.
- *(dsn..., dsnmask...)* — Specifies the data set names or masks to be excluded from the aggregate backup. *dsnmask* represents a partially qualified data set name.

ALLOCATE

DASD data sets listed with this optional keyword have their space allocated and are cataloged at the aggregate recovery site as part of an aggregate recovery. These data sets are *not* written to the data file.

The ALLOCATE keyword syntax is:

Keyword	Field
ALLOCATE	<i>(dsn..., dsnmask...)</i>

- **ALLOCATE** — Enter the whole word or the alias AL.
- *dsn..., dsnmask...* — Specifies the partially and fully qualified DASD data set names or masks to be allocated and cataloged at the aggregate recovery site as part of an aggregate recovery. Data sets in the ALLOCATE list must not be in the INCLUDE or ACCOMPANY lists, and must be cataloged DASD data sets. The DASD data sets must conform to one of the following data set organization types:
 - Physical sequential (PS)
 - Partitioned organization (PO)
 - Direct access (DA)
 - Virtual storage access method (VSAM)
 - Key sequenced data sets
 - Linear data sets
 - Relative record data sets
 - Entry sequenced data sets
 - User catalog
 - GDG base name

All other data set organizations are *not* supported.

To determine how to allocate space at ARECOVER time, DFSMSHsm recalls each migrated data set included in the ALLOCATE list.

Rule: During aggregate recovery, VSAM data sets from the ALLOCATE list must be recovered as SMS-managed data sets. Therefore, SMS must be active at the recovery site, and ACS filtering must direct these data sets to SMS-managed storage.

ALLOCATEEXCLUDE

Data sets listed by this optional keyword are excluded from the allocate list.

The ALLOCATEEXCLUDE keyword syntax is:

Keyword	Field
ALLOCATEEXCLUDE	<i>(dsn..., dsnmask...)</i>

- **ALLOCATEEXCLUDE** — Enter the whole word or an abbreviation of the word. ALLEXCLUDE is the alias, and ALLOCATE is the minimum abbreviation.
- *dsn..., dsnmask...* — Specifies the data set names or masks to be excluded from the aggregate backup. *dsnmask* represents a partially qualified data set name.

Examples of selection data sets

At the example site, two selection data sets are allocated: PAY1SDS1 and PAY1SDS2.

PAY1SDS1 contains the following lines:

```
INCLUDE (PAY1.**)
EXCLUDE (PAY1.PY%%3.**)
```

PAY1SDS1 causes aggregate backup to back up all data sets whose names begin with PAY1, excluding any data sets with the middle qualifier PY%%3. Use of the % character has been explained in a previous topic.

PAY1SDS2 contains the following lines:

```
INC (PAY2.PY002.SOCSEC -
      PAY2.PY002.STATUS.G0002V00 -
      PAY2.PY002.RETIRE)
ACC (PAY2.PY001.TAXES)
ALLOC (PAY2.PY001.BENEFIT)
```

PAY1SDS2 causes aggregate backup to back up all data sets listed. In addition, PAY2.PY001.TAXES is processed as an ACCOMPANY data set and PAY2.PY001.BENEFIT is processed as an ALLOCATE data set.

Creating an instruction data set

Creating the instruction data set is optional. The instruction data set contains instructions or any other information you think is necessary to assist the recovery site in recovering and running the application. It is an informal, free-form text file.

You may find it useful to include the following types of information in the instruction data set:

- SMS attributes
- Description of the application
- RACF environment
- Software requirements
- Hardware requirements
- Unique application execution instructions

If you decide to back up the instruction data set, you must create it before you issue the ABACKUP command. The instruction data set must be a sequential data set and it must be cataloged. ISMF panels allow you to allocate, browse, and edit the instruction data set.

The instruction data set can be recovered during the aggregate recovery prepare step, before actually recovering the aggregate data sets. This can be helpful, especially if people other than the backup site personnel will run the application at the recovery site.

You should include the instruction data set name in the aggregate group definition so that the instruction data set is identified to aggregate backup. During aggregate backup, the instruction data set is backed up to an instruction and activity log file.

Related reading

- For more information about creating the instruction data set, see [z/OS DFSMSdfp Storage Administration](#).
- For more information about the aggregate group, see [“Defining an aggregate group”](#) on page 336.

Example instruction data set

The instruction data set, PAYROLL.INSTRUCT, that was created at the example site is shown in [Figure 37](#) on page 335. PAYROLL.INSTRUCT is used for the example site aggregate group, PAY1.

```
THIS IS THE INSTRUCTION DATA SET FOR AGGREGATE GROUP PAY1.

PERFORMING AGGREGATE BACKUP ON PAY1 BACKS UP THE CRITICAL PAYROLL FILES AT
THE END OF A PAY PERIOD. RELEVANT FILES INCLUDE THE EMPLOYEE ROSTER
(PAY1.PY001.NAMES), AMOUNT OF EACH PAYCHECK (PAY1.PY001.CHECK), AMOUNT FROM
EACH CHECK PLACED IN IRA AND SOCIAL SECURITY DEDUCTION
(PAY1.PY002.IRA AND PAY2.PY002.SOCSEC), AND AMOUNT (IF ANY) OF CHECK
THAT WAS A BONUS IN ADDITION TO SALARY (PAY1.PY001.BONUS).

TO ENSURE PROPER EXECUTION, VERIFY THAT CORRECT RELEASE LEVELS ARE PRESENT FOR
DFSMSHsm, DFSMSdss, AND DFSMSdfp; AND THAT THE CORRECT SMS CLASSES ARE ACTIVE.

YOU WILL NEED THE FOLLOWING SMS CLASSES AND THEIR ASSOCIATED ATTRIBUTES
SET UP TO RECOVER THOSE FILES THAT WERE SMS-MANAGED AT ABACKUP, AND TO
ENSURE THAT THEY WILL BE SMS-MANAGED UPON RECOVERY.

DATA CLASS NAME: PHYSSEQ

```

Figure 37. Example of an Instruction Data Set

Defining an aggregate group

The aggregate group identifies the selection data sets, instruction data set, and additional control information required to perform aggregate backup. The aggregate group is an SMS construct you must define through a set of ISMF panels before you can perform aggregate backup. You must activate the newly defined SMS configuration before issuing the ABACKUP command.

Note: If you modify the aggregate group definition, the SMS configuration should be reactivated. This is not required if you are only changing the contents of the selection or instruction data sets.

You must specify the following information in the aggregate group:

Aggregate group name

The name can be up to 8 characters long.

Selection data sets

Insert the names of one-to-five selection data sets you created for this aggregate backup. See [“Creating selection data sets” on page 329](#).

Description

This is an optional description of the aggregate group.

Copies

Insert the number of copies of the ABARS output files to be created. The maximum number of copies is 15, and the default is one copy.

Output data set prefix

The prefix identifies the output data sets created by aggregate backup. These output data sets are created with the following naming conventions:

- *outputdatasetprefix.D.CnnVnnnn* and *outputdatasetprefix.O.CnnVnnnn* for the data file
- *outputdatasetprefix.C.CnnVnnnn* for the control file
- *outputdatasetprefix.I.CnnVnnnn* for the instruction/activity log file

Because they all share a common output data set prefix and version number, it is easier to identify all the output data sets from one aggregate backup.

Example: If you specify the *outputdatasetprefix* as 'PAY1', the data, control, and instruction/activity log files would have the names PAY1.D.C01V0001, PAY1.O.C01V0001, PAY1.C.C01V0001, and PAY1.I.C01V0001, respectively.

Note: *Cnn* is the copy number and *Vnnnn* is the version number generated during the ABACKUP operation.

Since you can make up to 15 copies in a single ABACKUP, the copy number identifies to which copy the file belongs. The version number is the same for all copies made in a single ABACKUP operation.

Example: If an aggregate group definition indicates that two copies are to be made, the first time that you perform an ABACKUP function on that aggregate group, the following files are created:

```
PAY1.D.C01V0001
PAY1.O.C01V0001
PAY1.C.C01V0001
PAY1.I.C01V0001

PAY1.D.C02V0001
PAY1.O.C02V0001
PAY1.C.C02V0001
PAY1.I.C02V0001
```

The next time that you perform an ABACKUP on that aggregate group, you create the following files:

```
PAY1.D.C01V0002
PAY1.O.C01V0002
PAY1.C.C01V0002
PAY1.I.C01V0002

PAY1.D.C02V0002
PAY1.O.C02V0002
```

```
PAY1.C.C02V0002
PAY1.I.C02V0002
```

Figure 39. Aggregate Group ISMF Panel 2

Notice that the same name was specified for the aggregate group and the output data set prefix. This makes it easier to remember later which control and data files belong to a specific aggregate group.

Management class considerations

The ABARS aggregate group definition can contain a management class name that is used to obtain a management class definition. Use the management class definition to determine the following aggregate backup parameters:

1. The maximum number of aggregate group backup versions to be kept (a specific number of versions up to 9999, or NOLIMIT).

Note: Specifying a limit allows the creation of a new version to roll off (delete) all existing versions that exceed the current limit.

NOLIMIT specifies that no roll-off occurs.

2. Aggregate group backup RETAIN parameters for ABACKUP versions:

```
RETAIN ONLY VERSION = DAYS | WEEKS | MONTHS | YEARS(nnnn) | NOLIMIT
RETAIN EXTRA VERSIONS = DAYS | WEEKS | MONTHS | YEARS(nnnn) | NOLIMIT
```

Note: These values do not affect the expiration date on the actual tape labels.

3. The serialization option:

```
COPY SERIALIZATION = C | F | blank
```

Specify C (continue) for “tolerate an enqueue failure”, and F (fail) for “do not tolerate an enqueue failure”. Blank means a null entry.

4. The ABACKUP COPY TECHNIQUE. You can specify:

PREFERRED (P)

A concurrent copy session is requested for each data set. The aggregate backup continues if a concurrent copy session is not obtained for a particular data set.

REQUIRED (R)

A concurrent copy session is requested for each data set. The entire aggregate backup fails if a concurrent copy session is not obtained for a particular data set.

STANDARD (S)

A concurrent copy session not be requested (default).

VIRTUAL PREFERRED (VP)

A virtual concurrent copy session is requested for each data set. The aggregate backup continues if a virtual concurrent copy session is not obtained for a particular data set.

VIRTUAL REQUIRED (VR)

A virtual concurrent copy session is requested for each data set. The entire aggregate backup fails if a virtual concurrent copy session is not obtained for a particular data set.

CACHE PREFERRED (CP)

A cache-based concurrent copy session is requested for each data set. The aggregate backup continues if a cache-based concurrent copy session is not obtained for a particular data set.

CACHE REQUIRED (CR)

A cache-based concurrent copy session is requested for each data set. The entire aggregate backup fails if a cache-based concurrent copy session is not obtained for a particular data set.

Note: Use these additional considerations when using cache-based concurrent copy to process large data sets or volumes, or when using multiple tasks to process a large number of data sets:

- Use concurrent copy only during periods of light update activity for the data sets or volumes involved.
- Spread multiple concurrent copy jobs across as many LPARs as possible.
- Ensure that jobs and address spaces that will use concurrent copy are assigned a WLM service class with a high execution velocity. Never assign a discretionary goal to concurrent copy work.
- Ensure that volumes that will be processed will not be reserved by another system during the concurrent copy.

In addition:

- DFSMShsm generates a default expiration date of 99365 for the ABARS output files. (Installation exit ARCEDEXT is called, if active, to allow you to specify expiration dates such as 99000 that have special meaning to tape management products).
- When rolling off an ABARS version, DFSMShsm expires tape data sets without regard to the tape expiration date.
- DFSMShsm saves the management class name in the ABR record so that EXPIREBV can obtain the latest retain values.

Note:

1. If the management class specified in the aggregate group definition does not exist, ABACKUP fails.
2. If a management class is not specified in the aggregate group definition, ABACKUP continues using the default management class. If a default management class is not defined, ABACKUP uses the following DFSMShsm defaults:
 - RETAIN ONLY VERSION = NOLIMIT
 - RETAIN EXTRA VERSIONS = DAYS(14)
 - NUMBER OF VERSIONS = 2
 - COPY SERIALIZATION = STATIC
 - ABACKUP COPY TECHNIQUE = STANDARD
3. The default management class name is never stored in the ABR record.

DFSMShsm coexistence considerations for aggregate groups and management classes

In DFSMShsm, the aggregate group definition has been modified from previous versions of DFSMShsm to add the NUMBER OF COPIES and MANAGEMENT CLASS NAME attributes. The DESTINATION attribute is no longer used in DFSMShsm. The TOLERATE ENQUEUE FAILURE attribute has been moved to the management class and is now called the COPY SERIALIZATION attribute.

Use ISMF to redefine the aggregate group definitions when converting to DFSMShsm and DFSMSdfp;. If the aggregate group is not redefined, the existing aggregate group definitions are still valid, but all new aggregate group attributes, as well as all new management class aggregate backup attributes, revert to defaults.

The COPIES attribute in the aggregate group will default to 1.

The defaults for the management class attributes are:

- RETAIN ONLY VERSION = NOLIMIT
- RETAIN EXTRA VERSIONS = DAYS(14)
- NUMBER OF VERSIONS = 2
- COPY SERIALIZATION = FAIL
- ABACKUP COPY TECHNIQUE = STANDARD

The NUMBER OF VERSIONS aggregate backup attribute in the management class is the only attribute that ABARS processing looks at when rolling off excess ABARS versions. It does not consider the RETAIN ONLY VERSIONS or RETAIN EXTRA VERSIONS attributes during this process (these attributes are only considered when the EXPIREBV ABARSVERSIONS command is issued).

The NUMBER OF VERSIONS management class attribute works like the LIMIT parameter used when defining a GDG base. Each time an ABACKUP is performed for a particular aggregate it determines if this will create an excess version; if so, the oldest version is rolled off without regard to the RETAIN ONLY VERSIONS or RETAIN EXTRA VERSIONS attributes.

The RETAIN ONLY VERSION management class attribute is used during EXPIREBV processing when expiring excess ABARS versions. This attribute indicates how long the latest ABARS version should be retained.

The RETAIN EXTRA VERSIONS management class attribute is also used during EXPIREBV processing when expiring excess ABARS versions. This attribute indicates how long any ABARS version other than the latest version should be retained.

EXPIREBV processing for excess ABARS versions does not consider the NUMBER OF VERSIONS attribute when expiring ABARS versions.

The UNIT attributes that apply to the RETAIN ONLY VERSION and RETAIN EXTRA VERSIONS attributes are calculated in the following way:

- WEEKS are multiplied by 7
- MONTHS are multiplied by 30
- YEARS are multiplied by 365

Protecting aggregate backup tape volumes

Before aggregate backup control file, data file, and instruction/activity log file tape volumes can be protected with RACF, you must first define an aggregate backup tape connected set by issuing the following command:

```
RDEFINE TAPEVOL HSMABR
```

RACF must be active and the SETSYS TAPESECURITY(RACF) or TAPESECURITY(RACFINCLUDE) options must be in effect for DFSMSHsm to use RACF to protect aggregate backup output tape volumes and add them to the HSMABR tape connected set. For more RACF information see [“RACF environment for DFSMSHsm”](#) on page 619.

Note: These tapes are not automatically added to RACF unless the above conditions are met at the recovery site. If these conditions are met, the tapes are added to RACF (at the recovery site) when the ARECOVER command is issued for this aggregate.

If TAPESECURITY(RACF) or TAPESECURITY(RACFINCLUDE) is specified and TAPESECURITY(EXPIRATION) TAPESECURITY(EXPIRATIONEXCLUDE) is *not* specified, then the expiration date is not written to the tape header label, and the ARCEEXT installation exit is not invoked.

Tape volumes added to the HSMABR RACF tape connected set are automatically removed by aggregate version rolloff processing during aggregate backup processing, during EXPIREBV processing, or if an aggregate backup failure occurs after the output tapes are opened. A tape volume may be deleted from the HSMABR tape connected set by entering the following RACF command:

```
RALTER TAPEVOL HSMABR DELVOL(volser)  
ADDSD 'outputdatasetprefix.**'
```

If you use RACF DATASET class profiles instead of TAPESECURITY(RACF) to protect the tapes and create the DATASET profiles, you could define ADDSD to specify that ABARS created aggregates are protected. You need a profile for each aggregate group you have defined that uses a different aggregate group prefix.

Checking authorization during aggregate backup

By using RACF FACILITY class profile support, you can permit all console operators or any users, including those who are not DFSMSHsm authorized, to issue the ABACKUP command.

If the RACF FACILITY class profile support is installed and activated, DFSMSHsm checks the RACF profile of the console operators or users for authorization to issue the ABACKUP command. The user ID of OPER must be defined to RACF before console operators can be given authority to issue the ABACKUP command. If the user ID OPER is given authority to the ABACKUP command, then all console operators

are authorized to issue the ABACKUP command. You can also define group names to RACF, using the RACF ADDUSER command.

If the RACF FACILITY class profile is not active, only DFSMSHsm-authorized users and console operators are authorized to issue the ABACKUP command.

You can define the DFSMSHsm ABACKUP command to RACF by defining the following profile names:

Command	Parameter	RACF Profile
ABACKUP		STGADMIN.ARC.ABACKUP
ABACKUP	agname	STGADMIN.ARC.ABACKUP.agname

Through the use of the RACF PERMIT command, you can authorize specific user IDs to issue these commands.

Related reading

- For more information about the RACF FACILITY class control of access to all commands, see [“Controlling command access with RACF FACILITY class” on page 625.](#)
- For more information about the RACF FACILITY class control of access to all commands, see [z/OS DFSMSHsm Implementation and Customization Guide.](#)

Authorizing comprehensive ABACKUP command authority

When users are added to the STGADMIN.ARC.ABACKUP profile, they receive comprehensive command authority. When users are also authorized to the STGADMIN.ARC.ABACKUP.agname profile, they receive RESTRICTED instead of COMPREHENSIVE command authority. When users have COMPREHENSIVE command authority, they may then issue the ABACKUP command for any aggregate group, and no RACF authorization checking is performed on the data sets being processed during aggregate backup.

When you define a RACF FACILITY class profile for the DFSMSHsm ABACKUP command, the Universal Access (UACC) keyword on the RDEFINE command defaults to NONE. This means that the ABACKUP command cannot be issued until a user is authorized to that profile using the RACF PERMIT command.

You can issue the following RACF command to define profiles that prevent or limit the authority of users to issue the ABACKUP command:

```
RDEFINE FACILITY STGADMIN.ARC.ABACKUP
```

The following command authorizes a user to issue the ABACKUP command for all aggregate groups:

```
PERMIT STGADMIN.ARC.ABACKUP CLASS(FACILITY) -  
ID(userID) ACCESS(READ)
```

Related reading

- For more information about the RACF FACILITY class control of access to all commands, see [“Controlling command access with RACF FACILITY class” on page 625.](#)
- For more information about the RACF FACILITY class control of access to all commands, see [z/OS DFSMSHsm Implementation and Customization Guide.](#)

Authorizing restricted ABACKUP command authority

When users are added to the STGADMIN.ARC.ABACKUP.agname profile, they receive RESTRICTED command authority. If users with this RESTRICTED authority issue the ABACKUP command, they must have a minimum of READ access to all RACF-protected data sets in the aggregate group. If they do not have READ or READ/WRITE access to a RACF-protected data set, the ABACKUP command fails for that

data set during verification processing. Each data set that fails authorization checking is listed in the aggregate backup activity log.

If a data set is not RACF protected, it does not fail during verification processing because no RACF authorization checking is performed on it.

You can issue the following RACF command to define profiles that prevent or limit the authority of users to issue the ABACKUP command with a specific aggregate group name:

```
RDEFINE FACILITY STGADMIN.ARC.ABACKUP.PAY1
```

The following RACF command authorizes all console operators to issue the ABACKUP command with a specified aggregate group name:

```
PERMIT STGADMIN.ARC.ABACKUP.PAY1 CLASS(FACILITY) -  
ID(OPER) ACCESS(READ)
```

Effect of activating the RACF OPERCMDS class on restricted ABACKUP command processing

Activation of the RACF OPERCMDS class can affect what user ID ABACKUP uses to check authorization to the data sets being backed up when a restricted FACILITY class profile is defined and the ABACKUP command is issued from an operator's console. Typically, all commands issued from an operator's console (including extended consoles) are considered to be authorized, and no RACF checking of data sets in the aggregate is performed. However, if the RACF OPERCMDS class is active, DFSMSHsm is able to extract the user ID that issued the command and uses that user ID when checking authorization to the data sets that are being backed up.

Using the aggregate backup installation exits

Programming Interface Information

Four installation exits are used by aggregate backup if they are accessible to the LOAD macro and if SETSYS EXITON(ARCM2EXT), SETSYS EXITON(ARCBEXT), SETSYS EXITON(ARCTVEXT), and SETSYS EXITON(ARCEEXT) commands have been issued. (You can use the QUERY SETSYS command to display the status of these exits.)

ARCM2EXT is called by aggregate backup when a data set on an ML2 volume is encountered, and it allows you to specify if the data set should be skipped or included in the aggregate backup.

ARCBEXT is called when:

- A data set encounters an input data set I/O
- A CDS I/O is encountered
- An SDSP allocation error occurs
- An uncataloged data set is encountered
- A data set fails serialization of the MAJOR NAME = ARCDNS, MINOR NAME = *datasetname* resource
- An error occurs during DFSMSdss dump processing

ARCBEXT allows you to specify if the data set should be skipped so that the aggregate backup can complete successfully, or if it should be included in the aggregate backup and cause aggregate backup to fail.

ARCEEXT is called to allow you to specify a tape volume expiration date other than 99365 for the aggregate backup output files.

ARCTVEXT is called to indicate to tape management systems, excluding DFSMSrmm, that ABARS is expiring a tape volume under any of the following conditions:

- When rolling off old ABARS versions during ABACKUP processing
- When expiring ABARS versions (EXPIREBV ABARSVERSIONS)
- When ABACKUP processing fails

End Programming Interface Information

For more information about installation exits, see [z/OS DFSMS Installation Exits](#).

Ensuring that the necessary volumes are online

Before performing aggregate backup, ensure that all level 0, ML1, and ML2 DASD volumes containing data sets to be processed by aggregate backup are online. If these volumes are not online during aggregate backup processing, a mount request is issued.

Defining SETSYS parameters for aggregate backup

The SETSYS command allows you to externally define various aggregate backup environmental options.

The system programmer should include SETSYS commands in the DFSMSHsm parmlib member (ARCCMDxx) to ensure that the settings are defined to DFSMSHsm at startup initialization. If you are an authorized DFSMSHsm user, you can issue the SETSYS command before an aggregate backup to modify the SETSYS parameters that control aggregate backup processing.

To specify how many ABACKUP commands can run concurrently, use the MAXABARSADDRESSSPACE parameter. MAXABARSADDRESSSPACE specifies the maximum number of concurrent ABARS secondary address spaces that DFSMSHsm supports, up to 64. When determining the value to specify for MAXABARSADDRESSSPACE, you should factor in such items as system load, resource contention, and aggregate backup and recovery activity. The overriding factor is the number of tape drives available. Aggregate backup uses at least one tape drive for each address space and uses two if backing up user tape data sets or data sets residing on ML2 tape (the default for MAXABARSADDRESSSPACE is 1).

Note: When an ABACKUP command completes, ABARS will determine if there is another ABARS request queued that has not been processed. If there is, DFSMSHsm will reuse the address space to process that command. The address space will remain active until there are no further ABARS commands queued, or the SETSYS MAXABARSADDRESSSPACE command has reduced the number of ABARS address spaces and this address space is no longer required.

Rule: If you issue two ABACKUP commands with the same aggregate group name, they cannot execute concurrently even if MAXABARSADDRESSSPACE is set to a value greater than 1.

The ABARSPROCNAME parameter specifies the procedure name that is used to start an ABARS secondary address space when no such address space is available for reuse.

The EXITON(*exitname*) parameter lets you specify which installation exits (ARCBEXT, ARCEEXT, ARCM2EXT, ARCTVEXT) are active during aggregate backup processing.

Each time you issue the ABACKUP command, an activity log is created. You can use the SETSYS ABARSACTLOGTYPE command to specify whether you want the ABACKUP activity log automatically written to SYSOUT or to DASD. You can use the SETSYS ABARSDELETEACTIVITY(Y | N) command to specify whether you want DFSMSHsm to automatically delete the ABARS activity log that corresponds to

the ABACKUP version being rolled off. The deletion occurs during ABARS roll-off processing or EXPIREBV ABARSVERSIONS processing, and removes the need to manually manage the ABARS activity logs.

You can use the SETSYS ABARSBUFFERS(*n*) command to specify the number of ABARS I/O buffers, up to a maximum of nine buffers. DFSMSHsm multiplies the number you specify by two to determine the total number of buffers to use for I/O processing (one-half for input, one-half for output). If the number of buffers is not specified by the SETSYS ABARSBUFFERS command, a default setting of one is used.

Use the ABARSKIP(PPRC XRC) parameter on the SETSYS command to specify that you want the backup to skip level 0 data sets that are protected by the peer-to-peer remote copy function or by the extended remote copy function.

The SETSYS ABARSTAPES(STACK) command allows you to place (stack) the ABACKUP output files from a single aggregate group on a minimum number of tape cartridges (as few as one). The stacking function applies only to tape cartridges. Attempts to redirect ABACKUP output files to DASD when the STACK option is in effect causes ABACKUP to fail.

You can select which DFSMSdss messages should be written to the ABACKUP activity log by using the SETSYS ABARSACTLOGMSG LVL(FULL | REDUCED) command. If you specify SETSYS ABARSACTLOGMSG LVL(FULL), all DFSMSdss messages are intercepted and written to the ABACKUP activity log. If you specify SETSYS ABARSACTLOGMSG LVL(REDUCED), only the DFSMSdss messages ending in a “W” (warning messages) or “E” (error messages) are written to the ABACKUP activity log; no informational messages are written.

ABARS records the CPU time for processing ABACKUP requests, along with any applicable account code information. This information is written to the ABR record and can be obtained using the LIST AGGREGATE command. It is also written to the FSR control block. The FSR can be written as an SMF record if the installation specifies SETSYS SMF(*smfid*). ABARS then writes the FSR as *smfid* + 1 in the SYS1.MANx or SYS1.MANY system data sets. Installations can use the information to calculate charge backs for ABARS requests.

The SETSYS ABARSOPTIMIZE(*n*) command allows installations to adjust performance when invoking DFSMSdss to back up level 0 DASD data sets that are specified in an ABARS INCLUDE data set list. You can specify that DFSMSdss read one, two, or five tracks at a time, or one cylinder at a time. You can override the SETSYS ABARSOPTIMIZE value on an individual ABACKUP command by issuing the ABACKUP command with the OPTIMIZE(*option*) parameter.

Note: If the SETSYS DEBUG option is in effect when the ABACKUP command begins processing, DFSMSHsm cannot move any data. The DEBUG option causes all ABACKUP commands to be processed as if the VERIFY option had been specified.

Related reading

- For more information about the SETSYS command, see [z/OS DFSMSHsm Implementation and Customization Guide](#).
- For more information about the SETSYS command, see Chapter 65, “SETSYS command: Establishing or changing the values of DFSMSHsm control parameters,” on page 1057.
- For more information about the ABARSPROCNAME parameter, see “ABARSPROCNAME: Specifying the base procedure name to start the ABARS secondary address space” on page 1096.

Example SETSYS commands for aggregate backup

The following SETSYS commands are entered for the example site before performing aggregate backup:

```
SETSYS MAXABARSADDRESSSPACE(2) ABARSPROCNAME(SAMPLE)
SETSYS ABARSACTLOGTYPE(DASD)
```

The maximum number of secondary address spaces is set to two, which means that only two ABARS commands can run at a time. The procedure name used to start the secondary address space is identified as SAMPLE, and the activity log will be allocated to DASD.

To review the SETSYS parameters in effect for aggregate backup and recovery enter:

```
QUERY ABARS
```

Determining the unit type for the control and data files

Before performing aggregate backup, you must determine the tape unit type to be allocated for the data, control, and instruction/activity log files. The unit type must be a supported tape device, as specified in the *z/OS DFSMSHsm Implementation and Customization Guide*. It is important that the unit type is compatible with the unit type that will be used at the aggregate recovery site.

You can specify the unit type in one of two ways:

1. Use the SETSYS ABARSUNITNAME(*unitname*) command. For *unitname*, substitute the name of a valid unit type.

If you use this method, you can issue ABACKUP and ARECOVER commands without using their UNIT parameters. When DFSMSHsm processes the ABARS control, data, and instruction/activity log files, it uses the unit type specified in the SETSYS ABARSUNITNAME command.

2. Specify the unit type later as part of the ABACKUP command. See [“ABACKUP command” on page 347](#).

Note: If you do not specify the unit type by using the SETSYS ABARSUNITNAME parameter or if you do not use the UNIT parameter with individual ABACKUP or ARECOVER commands, DFSMSHsm selects a default unit type of 3590-1.

Minimizing data set contention

The following are recommendations on how to minimize data set contention during aggregate backup. **If you do not follow these recommendations, aggregate backup may fail.**

- Do not perform ABACKUP processing during AUTOMIGRATION processing.
- Do not perform ABACKUP processing during AUTOBACKUP processing if you are processing VSAM data sets.
- Do not use aggregate backup while the application is in use.
- Use the concurrent copy feature of ABARS.

Performing ABACKUP processing concurrent with volume dumping or while backing up non-VSAM data sets is not a problem.

Data sets cannot be migrated or recalled during aggregate backup processing.

When ABACKUP processes data sets on level 0 volumes and the status of a data set changes (for example, it is moved or deleted) after catalog information about the list of data sets to process has been created (but before serialization), ABACKUP processing fails. The ABACKUP processing must be entirely rerun.

Data sets that DFSMSHsm dynamically allocates during aggregate backup processing

DFSMSHsm dynamically allocates the following data sets (SYSIN, FILTER, and authorization-checking) during aggregate backup processing. These data sets are used while aggregate backup is executing and are dynamically deallocated before completion of aggregate backup processing. These data sets are allocated with a unit type of SYSALLDA. (If they are non-SMS-managed, you must have at least one STORAGE- or PUBLIC-type device online to use the system.) You need to be aware of these data set names so that the high-level qualifiers used by ABARS can be defined to the system. You may want to modify your ACS filters to direct allocation of these data sets to specific volumes.

SYSIN data set

The SYSIN data set is used to pass DUMP parameters to DFSMSdss. The SYSIN data set name is: *authid.SYSIN.agname.Thhmmss.Dyyyyddd*

The variables in the data set name are explained:

authid

DFSMSHsm-authorized user ID.

agname

Aggregate group name that is processed.

hhmmss

Hours, minutes, and seconds.

yyyyddd

Four-digit year followed by the Julian day of the year.

FILTER data set

The FILTER data set is used to pass a list of data set names to DFSMSdss. The FILTER data set name is: *authid.FILTER.agname.Thhmmss.Dyyyyddd*

The variables in the data set name are explained:

authid

DFSMSHsm-authorized user ID.

agname

Aggregate group name that is processed.

hhmmss

Hours, minutes, and seconds.

yyyyddd

Four-digit year followed by the Julian day of the year.

Authorization-checking data set

The authorization-checking data set is used when checking RACF authorization for user tape data sets. The authorization-checking data set name is: *authid.Dyyddd.Thhmmss*

The variables in the data set name are explained:

authid

DFSMSHsm-authorized user ID.

yyddd

Year and Julian day.

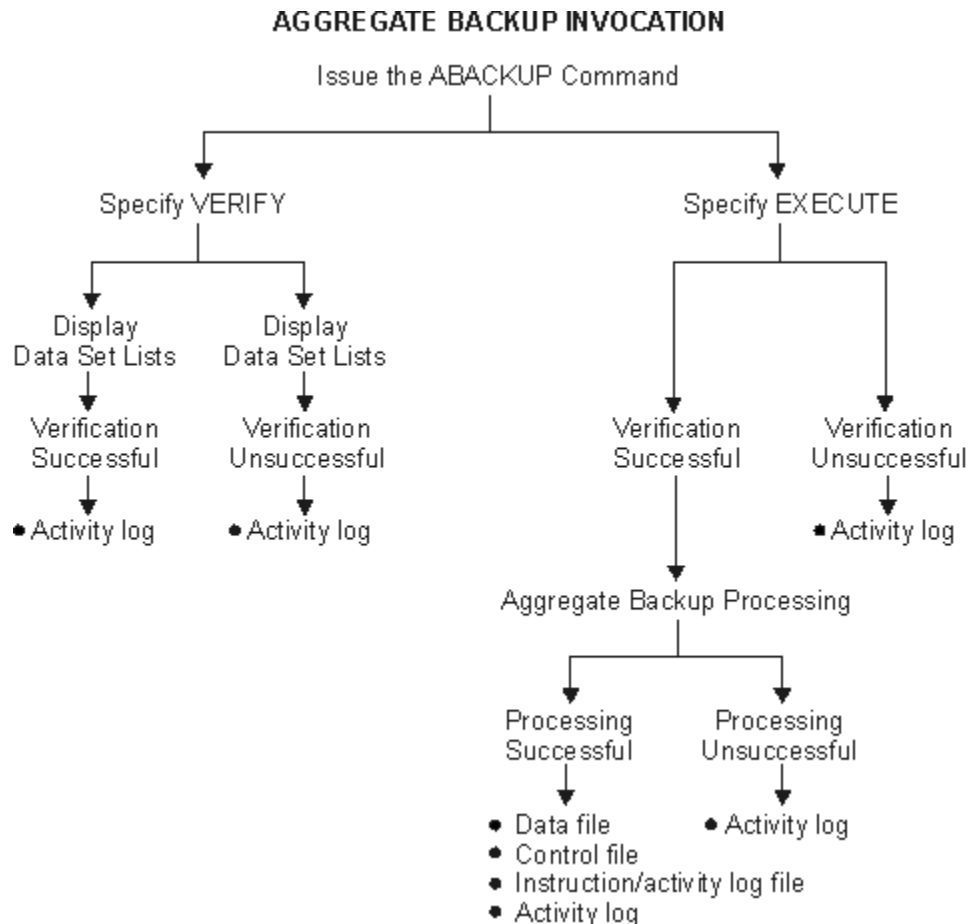

hhmmss

Hours, minutes, and seconds.

Performing aggregate backup

Figure 40 on page 347 shows what occurs when you invoke aggregate backup by issuing the ABACKUP command.

The following topics describe the aggregate backup invocation in more detail.

ARC15627

Figure 40. Aggregate Backup Invocation

ABACKUP command

To perform aggregate backup, enter the ABACKUP command. If you only want to verify the content of an aggregate backup without actually having the data sets backed up, specify the VERIFY parameter. This is like performing a test run of aggregate backup. After aggregate backup verification processing completes, the ABACKUP command stops. No data sets are backed up.

Note: If you have specified the FILTEROUTPUTDATASET parameter on the ABACKUP command, verification processing will place the results of the data set filtering into the data set specified. These results consist of a list of data sets selected for ABACKUP processing. This list can be useful when developing the data set filters in the selection data set.

When you are ready to have your data sets backed up, you can issue the ABACKUP command and specify the EXECUTE parameter. After successful data set verification processing, your data sets are backed up.

The following topics describe in more detail what occurs when you issue the ABACKUP command with the VERIFY or EXECUTE parameter.

The *aname* and EXECUTE | VERIFY parameters are required on the ABACKUP command.

For *aname*, specify the name of the aggregate group you defined earlier. See [“Defining an aggregate group”](#) on page 336.

The VERIFY parameter lists all input tape volumes that are required at the aggregate backup site if a subsequent ABACKUP EXECUTE command is submitted. It also performs verification processing of both migrated and nonmigrated data sets, detecting validation errors before data movement actually takes place.

For *unittype* in UNIT(*unittype*), specify the tape unit type to be allocated for the aggregate backup data, control, and instruction/activity log files.

After successful aggregate backup of an application, the optional MOVE parameter causes ABACKUP to delete all data sets in the application. The different data sets are affected in the following manner:

- DASD data sets are deleted
- Tape data sets are uncataloged
- ACCOMPANY data sets are uncataloged
- ALLOCATE data sets are deleted from DASD with the exception of user catalogs in the ALLOCATE list
- MIGRATED data sets are deleted

Note: If users with restricted RACF command authority issue the ABACKUP command with the MOVE parameter, they must have ALTER access authority for each data set belonging to the aggregate group, or aggregate backup verification fails with a related error message.

If a user has comprehensive RACF command authority and issues the ABACKUP command with the MOVE parameter, no RACF checking of individual data sets is required.

The optional FILTEROUTPUTDATASET(*dsname*) parameter allows DFSMSHsm to direct a fully-qualified list of data set names from the filtering criteria from the INCLUDE/EXCLUDE lists, as well as the names of ACCOMPANY, ACCOMPANYEXCLUDE, ALLOCATE, and ALLOCATEEXCLUDE data sets, to a separate output data set. If the user has restricted ABACKUP command authority, then that user must have a minimum of update authority to append to the existing RACF-protected filter output data set or allocation authority to create a new filter output data set. For *dsname*, substitute a data set name of up to 44 characters. FILTEROUTPUTDATASET can be abbreviated FODS.

When the FILTEROUTPUTDATASET parameter is specified along with the PROCESSONLY parameter, the filter output data set contains the data sets that pass the filtering criteria and also match the category designated in the PROCESSONLY parameter.

When you use the optional OPTIMIZE(*option*) parameter with an ABACKUP command it overrides the value specified by the SETSYS ABARSOPTIMIZE command. The OPTIMIZE parameter allows you to specify the performance level used by DFSMSdss during dump processing of level 0 DASD data sets. You can specify that DFSMSdss read one, two, or five tracks at time, or one cylinder at a time.

The optional PROCESSONLY parameter directs DFSMSHsm to process only the specified categories. You can specify one or more of the categories L0, ML1, ML2, and USERTAPE. The categories can be specified in any order. Specification of all categories will be accepted and is equivalent to not specifying the PROCESSONLY parameter.

Restriction: During ABACKUP, the PROCESSONLY parameter is processed only for data sets that exist (cataloged) during the creation of the control file. If the data set is deleted between the time that data set filtering is complete and the time that there is a successful search (locate) for it during the building of the control file, there is no way to determine where the data set (L0, ML1, ML2, or USERTAPE) resides, nullifying any meaning the PROCESSONLY option would have had.

PROCESSONLY can be abbreviated to PONLY. The following are recognized aliases for category names:

Category	Aliases
----------	---------

L0	
-----------	--

	LEVEL0, PRIMARY
--	-----------------

ML1	
------------	--

	MIGRATIONLEVEL1
--	-----------------

ML2	
------------	--

	MIGRATIONLEVEL2
--	-----------------

The optional, and mutually exclusive, STACK and NOSTACK parameters allow you to override the specified SETSYS ABARSTAPES value, or its default value of STACK. The STACK option causes ABACKUP to place the ABACKUP output files on a minimum number of tape cartridges. The STACK option only applies to

output being directed to tape. Using the STACK option and attempting to direct the ABACKUP output files to DASD causes ABACKUP to fail.

The SKIP option causes DFSMSHsm to skip data sets on volumes that are protected by PPRC or XRC. That is, these data sets are not backed up.

You might find it helpful to use the following DFSMSHsm commands to manage and query an ABACKUP command:

- HOLD ABACKUP prevents all currently queued aggregate backup requests from being processed.
- HOLD ABACKUP(*agname*) prevents currently queued requests for a specific aggregate group from being processed.
- HOLD ABACKUP EOD prevents currently queued requests from being processed, and additionally stops processing of any currently running ABACKUP requests.
- HOLD ABACKUP(*agname*) EOD stops processing of the aggregate group specified, and prevents further requests for this aggregate group from being selected for processing.
- RELEASE ABACKUP releases all queued aggregate backup requests that have been held by using the HOLD ABACKUP command or by DFSMSHsm.
- RELEASE ABACKUP(*agname*) releases all queued requests for the specified aggregate group.
- STOP causes an orderly shutdown of DFSMSHsm after any currently running ABACKUP commands complete processing.
- STOP DUMP causes DFSMSHsm to end processing immediately and to provide a dump. Any ABACKUP command in process is canceled immediately.
- QUERY or HQUERY can display information relevant to ABACKUP.
- CANCEL or HCANCEL can cancel any existing queued ABACKUP.

Related reading

For more information about the commands listed in this topic, see [Part 2, “DFSMSHsm Storage Administration Reference,”](#) on page 677.

Examples of ABACKUP commands

In the example system, the ABACKUP command is first issued with the VERIFY parameter:

```
ABACKUP PAY1 VERIFY
```

Aggregate backup verification is performed in the example system aggregate group, PAY1. Remember, no data sets are actually backed up.

To invoke aggregate backup processing, the ABACKUP command is issued with the EXECUTE parameter:

```
ABACKUP PAY1 EXECUTE
```

Aggregate backup processing is performed in the example system aggregate group PAY1. The data sets are backed up.

Issuing the ABACKUP command with the VERIFY parameter

When you want only to verify the content of your aggregate backup without actually backing up the data sets, issue the ABACKUP command with the VERIFY parameter. This optional test run allows aggregate backup to identify any errors, and it allows you to determine if the data sets that are backed up are what you intended. Remember, no data sets are backed up.

When you specify the VERIFY parameter, aggregate backup automatically performs verification processing. Before it directs all messages to the aggregate backup activity log, verification processing checks to see if the following conditions are met:

- The aggregate group identified in the ABACKUP command is defined.
- The management class identified in the aggregate group is defined.
- The selection data sets named in the aggregate group are allocated and cataloged and meet format restrictions.
- The instruction data set, if named in the aggregate group, is allocated and cataloged.
- Selection data set syntax is correct. See [“Selection data set syntax”](#) on page 329.
- All data sets in the ALLOCATE list are DASD data sets that conform to the supported data set organization types. See [“ALLOCATE”](#) on page 333.
- All data sets in the ACCOMPANY list are tape data sets.
- No data sets in any list, other than the ALLOCATE list, are catalogs.
- All fully qualified data sets are cataloged.
- The same data set name cannot appear in the INCLUDE, ACCOMPANY, or ALLOCATE lists.
- Installation exits, if requested, can be loaded.
- If RACF facility class is active and the user has restricted authority, the user’s authority to process data sets is verified.

When processing completes, determine if the ABACKUP command completed successfully with a return code of zero. You may want to review the activity log for message ARC6166I for a list of the data sets selected for INCLUDE, EXCLUDE, ACCOMPANY, ACCOMPANYEXCLUDE, ALLOCATE, and ALLOCATEEXCLUDE processing. If the list of data sets is acceptable, reissue the ABACKUP command with the EXECUTE parameter so that your data sets will be backed up as described in the following topic. If the list of data sets is unacceptable, modify the selection data set entries or installation exits and reissue the ABACKUP command with the VERIFY parameter until your list of data sets is acceptable.

To aid you in reviewing the results of data set filtering, you can use the FILTEROUTPUTDATASET parameter during verification processing.

If the ABACKUP command failed, as indicated by a nonzero return code, review the aggregate backup activity log for error messages. Correct any errors and reissue the ABACKUP command with the VERIFY parameter. Repeat this process until the ABACKUP command completes successfully with a return code of zero.

Issuing the ABACKUP command with the EXECUTE parameter

Issue the ABACKUP command with the EXECUTE parameter when you are ready to have your data sets actually backed up. Aggregate backup always performs verification processing, as described in the previous topic. The difference is that after verification processing completes successfully, aggregate backup proceeds to back up your data sets.

Aggregate backup directs all messages to the aggregate backup activity log. The aggregate backup starting and ending messages are also listed in the command activity log and displayed to the user who issued the command. When processing completes, determine if the ABACKUP command completed successfully with a return code of zero. Review the activity log for messages ARC6060I and ARC6061I for the volume serial numbers of the aggregate backup control and data files, ARC6071I for the volume serial number for the instruction/activity log file, and ARC6062I for the volume serial numbers for the tapes containing ACCOMPANY data sets. You will need these volumes later when you perform aggregate recovery.

If the ABACKUP command failed, as indicated by a nonzero return code, review the activity log for error messages. Correct any errors and reissue the ABACKUP command. The command always starts processing from the beginning. Repeat this process until the ABACKUP command completes successfully with a return code of zero. If the command fails, the data on the tape is invalid.

Since aggregate backup allows backing up of data sets that have been migrated to ML2 tapes, it is possible that the tape volumes containing the data sets to be backed up reside on an ML2 tape volume that is in use by another DFSMSHsm function. See [“Tape migration level 2 volume contention”](#) on page

136 for more information. If ABACKUP determines that it cannot allocate a tape volume because it is “in use”, it retries the allocation up to 90 times, at 20 second intervals. This takes approximately 30 minutes.

If the preceding retry scenario has been completed and the ML2 tape is still “in-use,” DFSMSHsm issues message number ARC6254A to the operator by way of a write to operator with reply (WTOR). The operator then has the option of canceling the aggregate backup or retrying the allocation retry logic.

Aggregate backup will copy multiple migrated data sets from a specific ML2 tape with a single mount, except when a data set spans to another tape.

Aggregate backup output

This topic describes the data, control, and instruction/activity log files, the activity log created by aggregate backup, and the FSR and ABR records containing ABACKUP CPU times and accounting codes.

Data files

The DFSMSdss data file is an output data set tape file that contains copies of the backed up data sets. They are the data sets you specified to be backed up in the selection data sets.

The format of the data file name is *outputdatasetprefix.D.CnnVnnnn*. This is the same *outputdatasetprefix* you previously specified in the aggregate group.

The name of the DFSMSdss data file in the example is PAY1.D.C01V0001. It contains copies of the following data sets, based on the selection data set entries previously made:

- PAY2.PY002.SOCSEC
- PAY2.PY002.STATUS.G0002V00
- PAY1.PY001.CHECK

The name of the internal I/O data file in the example is PAY1.O.C01V0001. It contains copies of the following data sets, based on the selection data set entries previously made:

- PAY1.PY002.IRA
- PAY1.PY001.BONUS
- PAY1.PY001.LADDER
- PAY1.PY001.NAMES

The format of the data file name is *outputdatasetprefix.O.CnnVnnnn*. This is the same *outputdatasetprefix* you previously specified in the aggregate group.

If you need to direct your ABACKUP internal I/O data file for a unique copy number to DASD, this can be done only if your DFSMSdss data file for the same copy number is directed to DASD.

The "D" data file is created if your INCLUDE statement specifies data sets that reside on Level 0 DASD volumes. The "O" data file is created if your INCLUDE statement specifies user tape data sets or data sets migrated to ML1 or ML2 DASD, or ML2 tape. If you specify the STACK option, a "D" and "O" data file is always created, even when you do not provide an INCLUDE statement. If you omit both the STACK option and the INCLUDE statement, neither data file is created.

If you choose to have any or all of your ABACKUP output files directed to DASD volumes, there are special precautions you must observe for successful recovery of the backed up data:

- The aggregate backup files must exist and be properly cataloged at the recovery site.
- You must use the XMIT and DATASETNAME parameters on your ARECOVER command.

Control file

The control file is the output data set tape file created by aggregate backup that is used later as input to an aggregate recovery. It contains control information necessary to recover the data sets, defined to the aggregate.

Note: The control file can reside on 1 to 15 volumes. If the 15-volume limit is exceeded, aggregate backup fails. If this occurs, either use tapes with a higher density to contain the control file or define multiple aggregate groups for the application so that each aggregate backup does not back up such a large amount of data. Reissue the ABACKUP command.

The format of the control file name is *outputdatasetprefix.C.CnnVnnnn*. This is the same *outputdatasetprefix* you previously specified in the aggregate group.

The name of the control file in the example is PAY1.C.C01V0001. The data set PAY2.PY001.BENEFIT is identified on the control file to be allocated at the aggregate recovery site. The data set PAY2.PY001.TAXES is identified on the control file to be cataloged at the aggregate recovery site.

Instruction and activity log file

If you have previously specified an instruction data set name in the aggregate group definition, or if the ABACKUP activity log is directed to DASD by using SETSYS ABARSACTLOGTYPE(DASD), then the optional instruction/activity log file is written to a different tape volume than the control and data files. See [“Creating an instruction data set” on page 334](#).

The format of the instruction/activity log data set name is *outputdatasetprefix.I.CnnVnnnn*. This is the same *outputdatasetprefix* you previously specified in the aggregate group. See [“Defining an aggregate group” on page 336](#).

The name of the instruction/activity log file in the example is PAY1.I.C01V0001. It contains a copy of the instruction data set, PAYROLL.INSTRUCT, that was previously created.

Note: This data set would not be created unless INSTRUCTION DATASET is specified or the ABACKUP activity log is directed to DASD.

Activity log

An activity log is created each time you issue the ABACKUP command. You might find the activity log useful because it contains messages written during aggregate backup processing. Review messages ARC6060I and ARC6061I for a list of the volume serial numbers for the control and data files, ARC6071I for the volume serial number for the instruction/activity log file, and ARC6062I for the volume serial numbers for the tapes containing the ACCOMPANY data sets. These volumes and their serial numbers are required later as input to aggregate recovery.

The format of the activity log name is: *mvtactn.Hmcthost.ABACKUP.agname.Ddyddd.Thhmmss*

The parts of the activity log name are explained:

mvtactn

Activity log high-level qualifier. The default value is HSMACT.

Hmcthost

DFSMSHsm host identification.

ABACKUP

Constant for aggregate backup.

agname

Name of the aggregate group being backed up.

Ddyddd

The date.

Thhmmss

The time.

The activity log is written to either SYSOUT or a DASD data set; you determine this by using the ABARSACTLOGTYPE parameter of the SETSYS command. If you specify DASD and the allocation attempt fails, an attempt is made to allocate the activity log to SYSOUT. If the activity log is directed to DASD, it is backed up to the instruction/activity log file. See [“Defining SETSYS parameters for aggregate backup” on page 343](#) for more information on setting the activity log output type.

You can use the SETSYS ABARSDELETEACTIVITY(Y | N) command to specify whether you want DFSMSshm to automatically delete the ABARS activity log that corresponds to the ABACKUP version being rolled off. The deletion occurs during ABARS roll-off processing or EXPIREBV ABARSVERSIONS processing, and removes the need to manually manage the ABARS activity logs. The default is N, which specifies no automatic deletion.

Figure 41 on page 353 is an example of the aggregate backup activity log.

Figure 41. Example of an Aggregate Backup Activity Log

ABACKUP CPU time and accounting codes

ABARS records the CPU time for processing ABACKUP and ARECOVER requests. This information is written to the FSR control block. The FSR can be written as an SMF record if the installation specifies SETSYS SMF(*smfid*). ABARS then writes the FSR as *smfid* + 1 in the SYS1.MANx or SYS1.MANy system data sets.

The ABACKUP CPU time and ARECOVER CPU time are also recorded in the ABR record.

The ISMF aggregate group definition panel allows you to specify an accounting code for an aggregate group. The accounting code gets written to the FSR control block (and associated SMF record where one exists) along with the ABACKUP CPU processing time for the aggregate. Installations can then use the information to assist in calculating charges to users for ABARS requests.

The accounting code is also written to the ABR record, and the ABACKUP control file. It is written to the ABACKUP control file so the code can be used at the recovery site without requiring an aggregate definition at the recovery site.

The accounting code is optional, and can be up to 32 characters in length. Valid characters are alphanumeric characters, blanks, commas, periods, parentheses, hyphens, slashes, ampersands, and apostrophes (single quotes).

DFSMSHsm coexistence considerations for new ABACKUP output data sets

In DFSMSHsm, the ABACKUP output files are physical sequential data sets, whereas in previous versions of DFSMSHsm these files were generation data sets. This change allows DFSMSHsm to fully manage the ABACKUP output files by using the management class aggregate backup attributes.

Once your installation has converted to DFSMSHsm and is processing aggregate backups, new GDSs are not created for existing ABACKUP output file GDGs. This means that GDG roll-off processing does not take place for the old ABACKUP output file GDSs, and these GDSs and their associated GDG base definitions need to be manually deleted once you have determined that they are no longer needed. You can do this by using an IDCAMS batch job with a DELETE statement for each remaining GDS and a DELETE GDG statement for each remaining GDG base.

Note: DFSMSHsm will not consider old GDSs and GDG bases during roll-off processing for old aggregate backup versions and EXPIREBV ABARSVERSIONS processing.

Expiring ABR records in the BCDS

You can use the EXPIREBV ABARSVERSIONS command to expire ABR records created during aggregate backup or recovery processing.

The ABARSVERSIONS keyword is mutually exclusive from any data set processing performed during EXPIREBV processing. ABARSVERSIONS is also mutually exclusive with the NONSMSVERSIONS parameter. The STARTKEY and ENDKEY parameters can be used with ABARSVERSIONS, as can OUTDATASET | SYSOUT. DISPLAY and EXECUTE are still required parameters and have the same processing affect. .

SETSYS BACKUP | NOBACKUP has no relevance with the ABARSVERSIONS parameter. However, a BCDS must exist or the EXPIREBV ABARSVERSIONS command fails.

When ABARSVERSIONS has been specified, the BCDS is searched and each ABR record is checked to see if the ABARS version has expired. For expired ABARS versions, the control file name is located in the catalog and a list of volume serial numbers that the control file resides on is requested. When necessary, the volumes are deleted from the RACF HSMABR tape volume list. The control file is uncataloged after the volume serial number list has been exhausted. When the file does not exist in the catalog, it is not an error condition, and the ABR record can still be deleted.

EXPIREBV must obtain the management class definition to determine which ABACKUP copies have expired. The management class definition contains the following:

- RETAIN EXTRA VERSIONS—This value is used to expire all versions except the latest version.
- RETAIN ONLY VERSION—This value is used to expire the last remaining version.

If, by using the ARCEDEXT installation exit, you have specified special tape management system expiration dates for the ABACKUP output files, the preceding two values should be set to NOLIMIT. This prevents DFSMSHsm from attempting to delete ABARS versions during ABACKUP and EXPIREBV processing by using management class criteria.

Note: The preceding two values have total control over deletion of ABARS versions, unless the EXPIREBV command is issued with the RETAINVERSIONS keyword.

If the management class specified in the most current version of the ABR record for a specific aggregate group does not exist, expiration of the aggregate group being processed is skipped. If an aggregate group name has been specified on the EXPIREBV command, the command fails for this case.

If it is active, installation exit ARCTVEXT is called for each volume being processed, indicating to the exit that the volume being expired is an ABARS tape volume.

This process is repeated for the data files and the instruction/activity log files.

After the control file, data files, and instruction/activity log file have been uncataloged and removed from the HSMABR tape connected set, the ABR record is deleted and processing continues with the next ABR record available in the BCDS.

Note: It is possible to code SMS ACS routines that will direct ABARS files to DASD. If this is done, and the files are migrated to DASD, an DFSMSHsm DELETE will be issued to remove them during expiration processing. If that delete fails, the file may remain cataloged with no ABR record pointing to it. If this happens, the data set should be manually deleted. See [“Directing ABARS files to DASD” on page 434](#) for more information.

When you use EXECUTE with the ABARSVERSIONS parameter, message ARC6377I is issued to show the status of each file in the ABR record. Message ARC6376I is also issued to show whether the ABR record was deleted.

When you use DISPLAY with the ABARSVERSIONS parameter, a report is generated that lists information about the ABR records that would have been omitted had EXECUTE been specified. The file status shows whether the file will be uncataloged when EXECUTE is run, or whether the file does not exist in the catalog (“Not in Catalog”). If “Catalog Error” is in the file status, an error has occurred when DFSMSHsm retrieved the catalog information, and the ABR record cannot be deleted.

A sample of the output obtained when the ABARSVERSIONS parameter is used with DISPLAY is shown in [Figure 42 on page 355](#).

ABACKUP considerations

If an instruction data set is specified in the aggregate group and DASD logging is specified, DFSMSdss is used to write the instruction data set and the activity log data set into one file on a tape (or tapes). To allow the control file to save the instruction and activity log volume serial number information, the instruction data set and activity log files must be written before the control file. Because of this restriction, the activity log written to tape does not contain volume serial number information for the control file, nor the completion code from ABACKUP processing.

In order to facilitate coexistence with previous releases of ABARS, where the control file is the first file sequence on the tape, the instruction and activity log files are written to a separate tape from the control file, if an instruction data set is specified in the aggregate group or DASD logging is specified.

The log is written to an output tape *only* if:

- The data file has been successfully written to tape.
- DASD logging has been specified at the aggregate backup site using the SETSYS ABARSACTLOGTYPE command, and the DASD activity log has been successfully processed.

If DASD logging is not specified during ABACKUP processing, the following processing takes place:

- A message is written to the log indicating that DASD has not been specified for the ABACKUP process.
- A blank activity log name is written to the ABR record and control file header.

The file containing the activity log data set and instruction data set has a naming convention of:
prefix.I.CnnVnnnn

The parts of the activity log data set and instruction data set name are explained:

prefix

Prefix specified on the Aggregate Group Define/Alter panel.

I

Constant to identify the file as containing the instruction data set and the activity log.

Cnn

The copy number specified for ABACKUP.

Vnnnn

Version number.

If the ABACKUP activity log is being written to SYSOUT and an instruction data set has not been specified in the aggregate group definition, DFSMSdss is not called to DUMP the data sets (there will *not* be a tape mount request for the instruction or activity files).

After the data files are written to tape, the ABACKUP activity log (DASD only) is closed and the instruction data set and activity log are DUMPed to tape using DFSMSdss. All messages are intercepted and stored in memory during DFSMSdss processing.

After the instruction and activity log files are written to tape, the DASD ABACKUP activity log is reopened to allow the stored messages—and any additional messages—to be written to it.

Note: These additional messages are not written to the activity log file that is seen at the ARECOVER site.

The internal I/O data file for a unique copy number can be directed to DASD only if the DFSMSdss data file for the same copy number was directed to DASD, or there is no data file for this invocation of ABACKUP.

If you choose to have any or all of your ABACKUP output files directed to DASD volumes, there are special precautions you must observe for successful recovery of the backed up data:

- The aggregate backup files must be properly cataloged and exist at the recovery site.
- You must use the XMIT and DATASETNAME parameters on your ARECOVER command.

ABARS user catalog and catalog alias ABACKUP support

When DFSMSShsm determines that there are user catalogs in the ALLOCATE list, it provides aggregate backup and recovery support for the catalogs and their associated ALIAS definitions.

When a user catalog is specified in the ALLOCATE list, the necessary data is obtained to define that catalog at the recovery location. The LISTCAT function also provides a list of the aliases defined to the specific catalog.

There is no limit to the number of user catalogs that the user may specify in the ALLOCATE list. If the user specifies any catalog type other than an user catalog, an error message is issued and ABACKUP verification fails.

If a catalog data set name is encountered in either the INCLUDE or ACCOMPANY lists, an error message is issued and ABACKUP verification fails.

The aggregate backup verification step lists the user catalogs specified in the ALLOCATE list and all of the aliases defined to those catalogs. This action is performed when the user specifies the ABACKUP command with the VERIFY parameter.

Note: All errors encountered when processing catalogs in the ALLOCATE list result in error messages.

Aggregate backup assist

Aggregate backup assist (ABA) is a stand-alone program that supports the DFSMSHsm ABARS function. It supports ABARS by producing a selection data set that can be used as input to the aggregate backup function.

How aggregate backup assist works

When supplied with a list of job names associated with an aggregate group (that is, a group of applications, an application, or a subset of an application) the ABA program scans system management facilities (SMF) records that have been collected over a period of time. ABA extracts the names of data sets that have been opened by the jobs on the supplied list. ABA then produces a list of those data set names in the form of a selection data set.

Note: The input SMF records must be collected for a sufficient period of time to capture the processing of all of the applications in the aggregate group.

To shorten ABA's run time, the IFASMFDP utility program may be used before ABA is run to extract the necessary types of SMF records from an installation's SMF data set. See ["Input requirements" on page 358](#).

What aggregate backup assist produces

ABA produces a selection data set consisting of one ABARS INCLUDE statement specifying all of the data set names found during analysis of the SMF records. The data set names are specified in three sections delimited by block comments: cataloged DASD data sets, cataloged tape data sets, and uncataloged data sets. The data set names in each section are sorted in alphabetical order.

Recommendation: Before you issue the ABACKUP command that uses the selection data set that has been created, you should edit the selection data set to delete the names of uncataloged data sets.

Special considerations for ABARS

ABA has been designed to assist you in identifying data sets related to an aggregate group. You need to ensure that all data sets necessary to rebuild the working environment are identified and collected during the aggregate backup process.

Note: Although the output selection data set is in a form that may be usable as input to the aggregate backup function, you need to examine closely and modify the selection data set, if necessary, before actually using it in an ABACKUP command. If you use the data set created by ABA as input to aggregate backup, the data set name must be the same as the selection data set in the aggregate group.

When verifying the contents of the ABA-generated selection data set, look for problems such as the data set:

- Not containing all necessary data set names associated with the aggregate group (data sets not allocated or not opened during the SMF interval)
- Containing data set names that are not part of the aggregate group
- Containing data set names that no longer exist (flagged as uncataloged)
- Containing tape data set names that can be moved to an ACCOMPANY list
- Containing DASD data set names that can be moved to an ALLOCATE list

The following hints assist you in determining which data sets to back up and how to collect them.

Uncataloged data sets: ABARS does not support uncataloged data sets. If you want to back up uncataloged data sets, you should manually catalog the data sets before issuing the ABACKUP command. Any uncataloged data sets you do not choose to catalog should be removed from the ABA-generated selection data set.

Nonaggregate group data sets: The generated selection data set may contain the names of data sets not in the aggregate group; for example, SYS1.LINKLIB. When these data sets are to be excluded, you must delete their names from the generated selection data set.

DASD data sets: The contents of some DASD data sets may not be required for execution of an application. Data set names that are used only for output should be moved to an ALLOCATE list.

Tape data sets: Tape data sets are candidates for the ACCOMPANY list in the selection data set. If you do not want the burden of copying the tapes, the tape data set names should be moved to the ACCOMPANY list.

Authorization and security requirements

For each data set eligible for the selection data set, ABA checks whether the data set is cataloged, and attempts to obtain certain catalog information. ABA should be installed in an APF-authorized library for the following reasons:

- If any of the catalogs contain password protection, ABA may cause the MVS catalog to prompt the system operator for the password. Having APF authorization allows ABA to bypass MVS catalog security checking.
- APF authorization enables ABA to query catalogs that are RACF protected and prevents ABENDs caused by RACF authorization failures.

Input requirements

The ABA program uses two sources of input: SMF data and a list of job names associated with an aggregate group.

SMF data

Before running ABA, you need to ensure that your system is set up to have SMF collect record types 14, 15, and 64. Furthermore, the recorded data must contain sufficient records to span the time frame wherein all desired jobs have been processed and recorded in the SMF data sets. An aggregate group may contain applications that run only monthly, quarterly, or annually, so that you need to plan in advance to collect sufficient SMF data.

The following SMF records are required for ABA:

Type 14

INPUT or RDBACK data set activity

Type 15

OUTPUT/UPDATE/INOUT/OUTIN data set activity

Type 64

VSAM component or cluster status

Aggregate job names

You need to identify all of the jobs that make up the applications in the aggregate group. If your installation has formal naming conventions for job names, then generic job names may be supplied. Substitute an asterisk (*) for a string, and substitute a percent sign (%) for a character. [Table 36 on page 358](#) shows acceptable forms of generic job names.

Table 36. Acceptable Generic Job Names

Specify	ABA collects data set names for:
*AB	Any job name that ends with the string AB.
A*	Any job name that starts with the letter A.
PAY	Any job name with the string PAY in it.

Table 36. Acceptable Generic Job Names (continued)

Specify	ABA collects data set names for:
NET*A	Any job name that begins with NET and ends with A.
NET%%A	Any job name that begins with NET and ends with A with two characters in between. % can be used in place of any character.

- The job names, generic or not, should be one to eight characters long.
- Each job name must be specified on a separate record in the input stream.
- A job name can occur anywhere in the record between columns 1 and 80, inclusive.
- The first non-blank string in each record is assumed to be the job name, and any other information in the record is ignored.

Storage requirements

The amount of storage required to run ABA depends on the number of input job names and generic job names specified, and the number of data set references found to be eligible for the selection data set. ABA has been designed to run in environments with the 24-bit residency mode (RMODE=24) and an addressing mode of ANY (AMODE=31). This enables ABA to take advantage of storage above the 16-megabyte line. To ensure that such storage is available to ABA, especially when you are processing large applications with many jobs and data sets, you may want to specify a large region size on the EXEC statement in the JCL which executes ABA.

DD statements used by ABA

Table 37 on page 359 shows the JCL DD statements used by ABA. If your installation specified DYNALOC=NO in the ICEMAC macro for DFSORT, the SORTWORK DD statements need to be specified in the JCL which executes ABA. DYNALOC=NO tells DFSORT not to dynamically allocate sort work data sets.

Table 37. DD Statements Used by ABA

DD name	Purpose
SMFIN	Defines the input SMF data set.
SORTIN	LRECL=80 and RECFM=FB defines an intermediate data set to be used as input to DFSORT. A temporary data set should be used.
SELECTDS	LRECL=80 and RECFM=F or FB defines the final output selection data set where the data set names are written. It can be either a sequential data set or a member of a partitioned data set. The record length must be 80 and the record format must be fixed or fixed block.
SYSPRINT	LRECL=133 and RECFM=FBA defines a sequential message data set.
SYSOUT	Defines a sequential message data set required by DFSORT.
SORTWK01	Specifies that SYSDA space of 2 cylinders and secondary extents of 3 cylinders each can be used for workspace by DFSORT.
SYSIN	Defines the input data set containing a list of job names in the aggregate group. This data can be in the job stream.
SYSDIAG	Defines an optional diagnostic data set. The DCB parameters are RECFM=FB and LRECL=74. The BLKSIZE must be supplied by the user. The data written to this file is binary and should not be directed to spool. Note: Output from the SYSDIAG data set may be required by IBM Customer Support to diagnose problems with this utility. Therefore, it is highly recommended that you always include this DD statement.

Aggregate stacking procedure

Current design of the aggregate backup function allows you to use the STACK parameter on the ABACKUP command to backup only one aggregate to a minimum of one tape. With the restriction of one aggregate backup per tape, performing aggregate backup to a high capacity tape might leave much of the tape empty. The aggregate stacking procedure describes how you can take existing aggregate backup output files, and utilize MVS utilities to stack multiple aggregates or multiple versions of the same aggregate onto a single tape, and then how to recover any of the stacked aggregates from the tape. This topic includes two sample JCL jobs, that you can use as templates to copy (stack) a second aggregate backup onto the same tape as the first version of the aggregate backup, and to restore an aggregate backup onto its original tape after a failure during the stacking procedure. You can modify this template to stack more than two aggregates onto a tape by duplicating the 4 steps and then modifying the data set name (ABACKUP output file) and the LABEL number. This procedure also describes how to:

- prevent roll-off of a backup version on the tape.
- prevent tape expiration.

- protect the stacked tape with RACF.
- handle end of volume (EOV) error during the stacking process.
- recover backup files after an error during the stacking process.

Warning: The steps documented in this procedure are intended to be used as an example of how to stack multiple aggregates or multiple versions of the same aggregate onto the same tape. This is a process that occurs outside of DFSMSHsm's knowledge and control. As DFSMSHsm will not be aware that a tape may contain multiple aggregates or multiple versions of the same aggregate, precautions need to be taken during roll-off and EXPIREBV ABARSVERSIONS processing to ensure that tapes are not returned to scratch that still contain valid aggregate backups on them. See [“Preventing aggregate roll off and tape expiration” on page 365](#) and [“Deleting specific versions of aggregates from a stacked tape” on page 365](#) for a description of these precautions.

Backing up data with ABARS aggregate backup function

To create an aggregate backup, use the STACK keyword on the ABACKUP command. If you specify the STACK keyword, ABARS places all of the output files from the aggregate backup onto one tape. You can then use the ABACKUP command to stack multiple aggregates or multiple versions of the same aggregate onto the same tape.

The example described in this topic shows how to create two versions of the aggregate named AGM1, and then stack them onto one tape. The serial numbers of the tapes used for this purpose are A00040 and A00041.

Step 1: create the first aggregate backup.

- Specify the STACK keyword on the ABACKUP command. The resulting ABACKUP Version 1 files reside on tape volser A00040.

Table 38. The sequence of files associated with ABACKUP Version 1 on the tape volser A00040.

ABACKUP Version 1	File Sequence on tape volser A00040
Data (D)	1
Other Data (O)	2
Instruction and Activity Log (I)	3
Control (C)	4

Step 2: create the second aggregate backup.

- Specify the STACK keyword on the ABACKUP command. The resulting ABACKUP Version 2 files reside on tape volser A00041.

Table 39. The sequence of files associated with ABACKUP Version 2 on the tape volser A00041.

ABACKUP Version 2	File Sequence on tape volser A00041
Data (D)	1
Other Data (O)	2
Instruction and Activity Log (I)	3
Control (C)	4

Note: The output files might span to multiple tape volumes, if the aggregate output files are larger than the tape capacity.

Related reading

For more information about the aggregate output files, see [“Aggregate backup output” on page 351](#).

Stacking multiple aggregates on one tape

To stack multiple aggregates onto one tape, copy the files associated with the second backup onto the tape containing the files from the first backup. You can use the sample JCL provided in this topic, to stack additional aggregate backup copies onto the tape by copying the 4 (JCL) steps, and then modifying the ABARS output file name, the volser, and the tape file sequence number.

Step 3: copy ABACKUP Version 2 files onto the tape containing ABACKUP Version 1 files.

Table 40. File sequence after ABACKUP 2 files are copied onto the tape containing ABACKUP 1 files. Tape's volser is A00040.

File Sequence on tape volser A00040	
ABACKUP Version 1:	
Data (D)	1
Other Data (O)	2
Instruction and Activity Log (I)	3
Control (C)	4
ABACKUP Version 2:	
Data (D)	5
Other Data (O)	6
Instruction and Activity Log (I)	7
Control (C)	8

The sample JCL provided in this example, COPYAGGR JCL, stacks the files resulting from the second aggregate backup (ABACKUP Version 2) from the tape volser A00041 onto the tape volser A00040 which contains the files resulting from the first aggregate backup (ABACKUP Version 1). COPYAGGR JCL uses the IEBGENER program to copy the files . IEBGENER is used to copy the aggregate backup files from ABACKUP Version 2 onto the tape containing the aggregate backup files associated with ABACKUP Version 1, uncataloging the original ABACKUP Version 2 files and cataloging the newly copied versions of ABACKUP Version 2. To use COPYAGGR JCL in your environment, modify the aggregate backup file names, volsers, and labeling information that designates the location of the backup files on the tape (presented here in bold text).

```

//COPYAGGR JOB ,CLASS=A,USER=userid,PASSWORD=pswd,
// MSGCLASS=A
//*****
//*
//* Job Name: COPYAGGR
//*
//* Function: STACK aggregate backup files onto a single tape.
//* *
//* Description of Process: This is a sample JCL batch job
//* that copies the aggregate backup output files from the
//* second ABACKUP of an aggregate named AGM1 onto the tape
//* where the files from the first ABACKUP of aggregate AGM1
//* reside, thus stacking both aggregate backups onto a single
//* tape.
//*
//* STEP 1, in this job, copies the D file, STEP 2 copies the
//* O file. STEP 3 copies the I file and STEP 4 copies the C
//* file. You will have to update the data set names (ABACKUP
//* files) and the tape volsters in each step in order to run this
//* job in your environment.
//*
//* To copy additional aggregate backups onto the stacked tape,
//* duplicate these 4 steps for each additional aggregate
//* backup and then update the ABACKUP output file (D, O, I or
//* C) names and the file sequence numbers.
//*
//* The job will copy the files from the original ABACKUP tape
//* onto the stacked tape, uncatalog the files from the original
//* tape and catalog the copied version onto the stacked tape.
//*
//* In order to recover any of the aggregates from the stacked
//* tape, use the ABARS ARECOVER command with the XMIT and
//* NOSTACK options specified.
//*
//* Example of ARECOVER command:
//*
//* ARECOVER DSN(control-file-name) XMIT NOSTACK EXECUTE
//*
//*****
//*
//*****
//* Copy the D file from the 2nd ABACKUP of aggregate AGM1 onto
//* the same tape containing the output files from the 1st
//* ABACKUP of aggregate AGM1. This D file is copied at file
//* sequence number 5. If the copy is successful uncatalog the
//* original version of the D file and catalog the new stacked
//* version.
//*****

```

Figure 44. Stacking Aggregates - Sample JCL (Part 2 of 2)

Aggregate recovery from the stacked tape

To recover aggregates from the stacked tape, specify the XMIT and the NOSTACK parameters on the ARECOVER command. The following example shows the syntax of the ARECOVER command needed to recover an aggregate that has gone through the stacking process. To use this sample command, replace

The example below shows the format of the EXPIREBV command that you can use to expire aggregate backup versions, where *aggregate_name* is the name of the aggregate group and *n* is the number of versions of that aggregate group that you want to keep.

```
EXPIREBV EXECUTE ABARSVERSIONS (AGNAME(aggregate_name) RETAINVERSIONS(n)
```

Note: If you specify SETSYS EXITON(ARCTVEXT), DFSMSHsm calls the installation exit ARCTVEXT for each volume that is being processed, indicating to the exit, that this is an ABARS tape volume. If you install DFSMSrmm, DFSMSHsm calls the EDGTVEXT installation exit instead.

The example below shows how you can use the EXPIREBV command to delete the oldest version of the aggregate, if four versions of the aggregate AGM1 are stacked on four separate tapes. After the command executes, the oldest version is deleted and the tape that it is on is returned to the tape installation exit (even if there are other valid aggregate backups on the tape). The three remaining versions that were backed up after the oldest version was backed up, are kept:

```
EXPIREBV EXECUTE ABARSVERSIONS (AGNAME(AGM1) RETAINVERSIONS(3)
```

As the tape installation exit (if active) will be called for any tape that contains the version being expired and deleted, you must either code your tape installation exit not to release ABARS tapes to scratch or do not run EXPIREBV ABARSVERSIONS unless you are expiring all the versions on a particular tape. If a tape is returned to scratch that still contains valid aggregates on it and the tape is reused by another job, future roll-off or EXPIREBV ABARSVERSIONS processing may again release the tape to scratch as ABARS still has record of the previously unexpired versions on the tape.

RACF protection of tapes used for stacking

You can use RACF protection for tapes with stacked aggregate backup files. In these examples *volser* is the serial number of the stacked tape's volume.

- If you are using a new tape to stack aggregates, use these commands to protect it with RACF:

```
SETSYS TAPESECURITY(RACF)  
RDEFINE TAPEVOL HSMABR  
RALTER TAPEVOL HSMABR ADDVOL(volser)
```

- If you are using a tape with existing ABACKUP version to stack additional aggregates, use the these commands to protect them with RACF:

```
SETSYS TAPESECURITY(RACF)  
RDEFINE TAPEVOL HSMABR
```

RACF protection of tapes after EXPIREBV processing of versions

When you enter the EXPIREBV ABARSVERSIONS command to expire specific aggregate backup versions from a stacked tape, the DFSMSHsm automatically removes the tape from the RACF tape volume set. If there are still valid aggregate backup files on the stacked tape, enter the RACF RALTER command to add the tape's *volser* back to DFSMSHsm's RACF tape volume set. In this example, *volser* is the serial number of the stacked tape.

```
RALTER TAPEVOL HSMABR ADDVOL(volser)
```

To remove a stacked tape from DFSMSHsm's RACF tape volume set, enter the RACF RALTER command:

```
RALTER TAPEVOL HSMABR DELVOL(volser)
```

End of volume during the stacking process

If you try to maximize the number of aggregate backup versions you can stack onto a single tape, you might reach the end of volume (EOV). If EOV occurs before all of the ABACKUP files associated with the specific version are copied, DFSMSHsm issues the error message IEC151I:

```
IEC151I A13-rc,mod,jjj,sss, ddname .-#. ,dev,ser,dsname
```

For example, if the sample COPYAGGR JCL, described in [“Stacking multiple aggregates on one tape”](#) on page 362 fails during the copy of the O file, in JCL STEP2, DDNAME SYSUT2, using output device address 0B31, writing to volser A00040, writing the data set AGM1.O.C01V00020, DFSMSHsm issues, this message:

```
IEC151I A13-18,IFG0195B,COPYAGGR,STEP2,SYSUT2,0B31,A00040,AGM1.O.C01V0002
```

If an EOV error occurs during an aggregate copy (stacking), you must follow the procedure described in the [“Cleanup after stacking errors”](#) on page 367 to recover that aggregate.

Cleanup after stacking errors

If a problem occurs during the stacking procedure, you must uncatalog the ABACKUP files associated with the bad aggregate version on the stacked tape, and recatalog the files on the original backup tape to avoid loss of data. The example described in [“End of volume during the stacking process”](#) on page 367 shows the EOV error that occurred during the writing of the O file. In the sample COPYAGGR JCL, described in [“Stacking multiple aggregates on one tape”](#) on page 362, the D file is copied first, followed by the O file, the I file, and the C file. After the EOV error, version 2 of the aggregate AGM1 has all of the D file, and part of the O file on the stacked tape volser (A00040). The I file and the C file are on the original tape volser (A00041). To recover the data associated with version 2 of the aggregate AGM1 or attempt to stack this version onto a new tape, you must:

1. Uncatalog the D file and the O file that reside on the stacked tape A00040.
2. Recatalog the D file and the O file onto their original tape A00041.

This example shows a sample JCL that you can use to recatalog an entire aggregate onto the original ABACKUP file. This JCL recatalogs all of the ABACKUP files associated with version 2 of aggregate AGM1 onto the original ABACKUP volser.

Figure 46. Sample JCL to recatalog an entire aggregate onto the original ABACKUP file

Copying ABARs aggregates to another device type

If you want to copy individual aggregates from one device type, for example from a 3490 to a 3590, use the following procedure.

Note that the current design of the aggregate backup function allows you to use the STACK parameter on the ABACKUP command to back up only one aggregate, to a minimum of one tape.

ABARs uses the prefix to define the aggregate. It identifies the output data sets created by aggregate backup. These output data sets are created with the following naming conventions:

- *outputdatasetprefix.D.CnnVnnnn* and *outputdatasetprefix.O.CnnVnnnn* for the data file
- *outputdatasetprefix.C.CnnVnnnn* for the control file

- *outputdatasetprefix.I.CnnVnnnn* for the instruction/activity log file

The sequence of files that are associated with ABACKUP:

1. Data (D)
2. Other Data (O)
3. Instruction and Activity Log (I)
4. Control (C)

When you copy individual aggregates from one device type to another, you should review your tape management retention rules to ensure that the newly copied aggregates are retained permanently. You may also need to expire the old tapes manually.

Aggregate backup can be performed in NOSTACK or STACK mode. The following sample JCL shows how to copy a C-, D-, I-, and O-file from an existing tape to a new scratch tape and a new device type, assuming that ABACKUP NOSTACK has been issued:

```
//*****
//* COPY THE D FILE FROM EXISTING TAPE TO A NEW SCRATCH TAPE
//* FILE SEQUENCE IS 1.
//* IF THE COPY IS SUCCESSFUL, THE D FILE NEW VERSION
//* WILL BE CATALOGED
//*****

//SYSIN DD DUMMY
//*

```

Figure 48. Sample JCL to copy files from an existing tape to a new scratch tape and new device type, after ABACKUP STACK

After the copy has completed, you can verify that the copies have been created and cataloged to the new device/volume by issuing LIST AGGREGATE(agname).

```
LIST AGGREGATE(agname)
```

If the new tape that was created does not show in LIST AGGREGATE(agname) output (this may also occur if you are at a disaster recovery site and the BCDS does not have the ABR record), you can instruct DFSMSHsm not to use the volser and unit information in the control file to drive the recovery by first performing an ARECOVER PREPARE with the XMIT parameter:

```
ARECOVER DSNAME(AGM1.C.C01V0001) XMIT PREPARE
```

ARECOVER will search the catalog for the control and data files and, if found, use the unit and volser from the catalog when allocating these data sets. Note that UNIT and VOLUMES are invalid if the XMIT parameter is used. If specified, you will receive an ARC6002E error message.

After ARECOVER PREPARE has successfully completed, you may perform aggregate recovery of data sets. Note that user tape data sets listed in the ACCOMPANY list will be recovered to the new device type.

This procedure does not release/scratch the source aggregate backup tape. The source aggregate backup tape must be manually released to the scratch tape pool through your tape management system. Please refer to the tape management system documentation to determine the steps that are required to release the tape to the scratch pool.

How aggregate recovery works

To perform aggregate recovery, you must have the control file, data files, and instruction/activity log file created by a previous aggregate backup. To use the simplified ARECOVER command, you must also have an ABARS activity (ABR) record at the recovery site. You can then use the ARECOVER command to recover the data sets from the tape files.

Figure 49 on page 372 shows the information flow of an aggregate recovery.

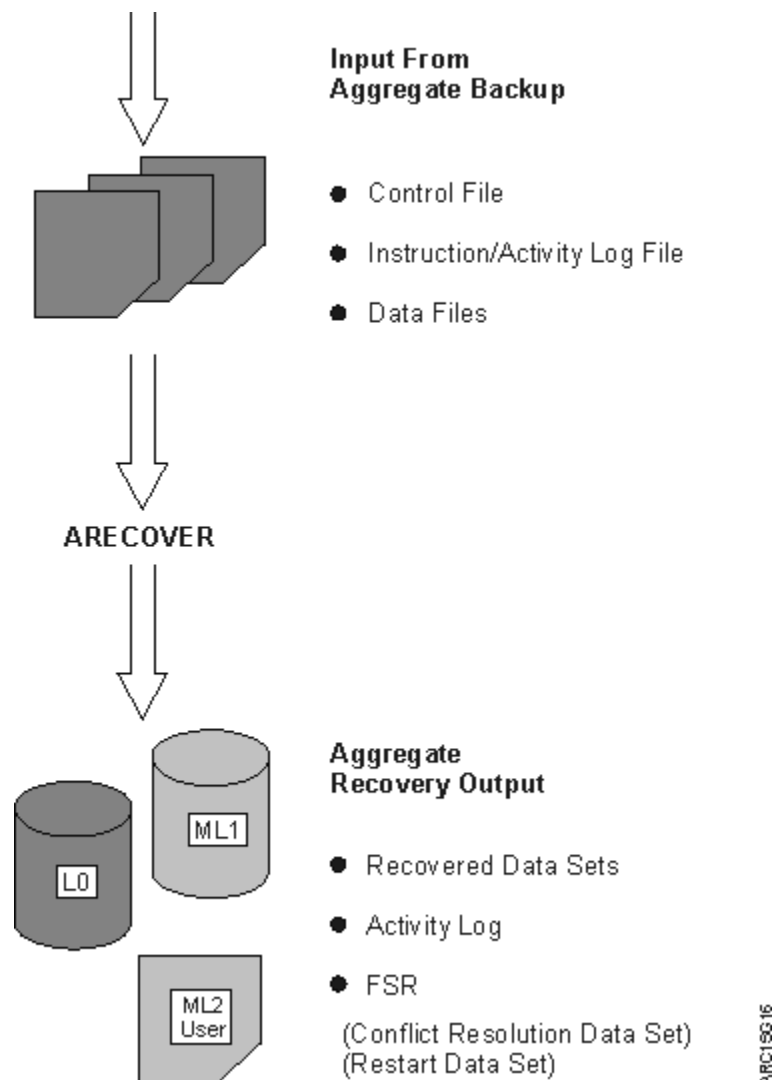

Figure 49. Aggregate Recovery Information Flow

You can choose to prepare the recovery site for the eventual recovery of the aggregate by issuing the ARECOVER command with the PREPARE parameter. You can also choose to verify the aggregate recovery

without actually recovering the data sets. Then, when you are ready, you can perform the actual recovery of your data sets.

The control file and data file were created as a result of aggregate backup and are used as input for aggregate recovery.

When you issue the ARECOVER command, DFSMSHsm creates:

- The recovered data sets, which are those data sets recovered from the aggregate backup tape data file. [Table 41 on page 373](#) shows the manner in which aggregate recovery recovers, allocates, and catalogs data sets.
- An activity log, which contains messages written during aggregate recovery processing.
- The FSR, which contains the statistics for aggregate recovery processing. This includes recording the CPU time for processing ARECOVER requests. The FSR can be written as an SMF record if the installation specifies SETSYS SMF(*smfid*).
- Updates to the ABR record, which shows the CPU time for processing ARECOVER requests. The ABR shows the accumulated CPU time of each restart until the recovery of the aggregate is successful.

Aggregate recovery can also create the following:

- A conflict resolution data set that is used as input to a subsequent ARECOVER command.

The *conflict resolution data set* contains names of data sets that the ARECOVER verification process determines to have like-named conflicts that were not resolved by the RECOVERNEWNAME parameters, the DATASETCONFLICT parameter, or the ARCCREXT installation exit. For each such data set encountered, an entry is placed into the conflict resolution data set, with a default action of BYPASS.

You can edit the conflict resolution data set before issuing the next ARECOVER command, and indicate which conflict resolution actions are to be taken by ARECOVER verification processing for each data set entry.

You then issue a subsequent ARECOVER command. The conflict resolution data set is read and used as input to the ARECOVER verification process.

- A restart data set is created when the recovery of data sets does not complete successfully. The restart data set contains the names of all the data sets recovered successfully. When an aggregate recovery is reissued, the restart data set ensures that data sets already processed are not recovered a second time. If you want to start aggregate recovery again from the beginning, delete the restart data set.
- Accounting code records that are written to the ABACKUP control file, FSR, and ABR. You can assign accounting codes to aggregates, which allows you to associate ABARS CPU time to specific aggregates. The codes are written to the ABACKUP control file so they can be propagated at the recovery site.

- See [“EAV considerations for recovery functions” on page 15](#).

Recovered aggregate data sets

A data set is recovered differently if it is an INCLUDE, ACCOMPANY, or ALLOCATE data set, as specified in a selection data set during aggregate backup. [Table 41 on page 373](#) summarizes how these different types of data sets are recovered.

Table 41. Aggregate Recovery Data Set Processing

Selection Data Set Keyword	Data Set Recovered	Data Set Allocated	Data Set Cataloged
INCLUDE	X	X	X
ALLOCATE		X	X

Table 41. Aggregate Recovery Data Set Processing (continued)

Selection Data Set Keyword	Data Set Recovered	Data Set Allocated	Data Set Cataloged
ACCOMPANY			X

Additionally, the type of device on which an INCLUDE data set is recovered is directly based on its disposition at the aggregate backup site.

Example aggregate recovery site

In “[BACKUPPREFIX: Specifying the prefix for the backup version name or the dump copy data set name](#)” on page 1107, an example aggregate backup site was used to show backup procedures. This same example is used to show how to recover applications at the example recovery site.

The following INCLUDE data sets are recovered to DASD:

- PAY2.PY002.SOCSEC
- PAY2.PY002.STATUS.G0002.V00
- PAY1.PY001.CHECK
- PAY1.PY002.IRA
- PAY1.PY001.BONUS
- PAY1.PY002.LADDER

The following INCLUDE data set are recovered to tape:

- PAY1.PY001.NAMES

The following ALLOCATE data set are allocated on a DASD:

- PAY2.PY001.BENEFIT

The following ACCOMPANY tape data set are cataloged:

- PAY2.PY001.TAXES

Preparing for aggregate recovery

You need to consider the following in order to prepare for aggregate recovery:

- Retrieving instructions or information from the instruction data set that may have been optionally created at the aggregate backup site.
- Issuing ARECOVER with the PREPARE parameter to:
 - Determine the amount of storage needed to recover aggregate groups.
 - Catalog ABACKUP outfiles.
 - Add volumes to RACF, if SETSYS TAPESECURITY(RACF) or SETSYS TAPESECURITY(RACFINCLUDE) is specified, RACF is active and the HSMABR tape volume set is defined.
- Issuing ARECOVER with the INSTRUCTION and ACTIVITY parameters
- Creating an ABR record
- Determining the aggregate recovery site constraints.
- Planning for aggregate recovery requirements for SMS.
- Defining the target volumes to be used for aggregate recovery of non-SMS data with the DEFINE ARPOOL command.

If you have multivolume, non-VSAM, non-SMS-managed data sets, ensure that you define an adequate number to level 0 volumes for this aggregate group, using the LOVOLS subparameter of the DEFINE ARPOOL command. If no ARPOOL is defined for this aggregate group, you must have an adequate

number of volumes ADDVOled as primary volumes, or you may have allocation failures during ARECOVER processing of this aggregate group.

- Defining aggregate recovery environmental options with the SETSYS command.
- Defining a model entity to define discrete data set profiles to RACF.
- Determining if the RACF facility class is active and at least one profile is defined, so that the user authority to use the ARECOVER command is verified.
- Determining if the RACF facility class is active and if there is a REPLACE action in either the conflict resolution data set, the DSCONFLICT parameter of the ARECOVER command, or the ARCCREXT exit. If so, define the following facility class profiles and add the user to at least one of them:

STGADMIN.ARC.ARECOVER

STGADMIN.ARC.ARECOVER.*agname*.REPLACE

STGADMIN.ARC.ARECOVER.*agname*.RENTGT

- Determining if the aggregate backup output has been sent by a transmit program such as the NetView FTP. If you are using NetView FTP, catalog the data file data sets (using the disposition parameter) and any accompanying data sets that have been transmitted. If you are using another file transfer program, ensure that the files are cataloged.
- If you choose to have any or all of your ABACKUP output files directed to DASD volumes, there are special precautions you must observe for successful recovery of the backed up data:
 - The aggregate backup files must be properly cataloged and exist at the recovery site.
 - You must use the XMIT and DATASETNAME parameters on your ARECOVER command.

Table 42 on page 375 shows a checklist you may want to follow as you complete each of the steps needed to prepare for and perform aggregate recovery.

Table 42. Aggregate Recovery Checklist	
Step	Action
___ 1.	Verify receipt of the aggregate backup tapes containing the control, data, and instruction/activity log files.
___ 2.	Issue the DEFINE ARPOOL command to specify the target volumes to be used by aggregate recovery for non-SMS-managed data.
___ 3.	Run ARECOVER with PREPARE, INSTRUCTION, and ACTIVITY parameters
___ 4.	Determine the aggregate recovery constraints. <ol style="list-style-type: none"> 1. Determine the DASD resources needed to perform the aggregate recovery. 2. Determine the tape unit name to be used for output data sets to be recovered. 3. Determine the tape unit name if recovering to ML2 tape.
___ 5.	Ensure that the ABARS JCL procedure has been installed in the systems JCL library (refer to the z/OS DFSMSshm Implementation and Customization Guide).

Table 42. Aggregate Recovery Checklist (continued)

Step	Action
___ 6.	<p>Determine the SETSYS parameters to be used:</p> <ul style="list-style-type: none"> • Specify the number of ABARS address spaces • Specify activity log type, message level, and deletion processing • Indicate ABARS procname • Indicate target unit name for recovering user tape data sets • Indicate target unit name if recovering to ML2 tape • Specify space utilization for non-SMS level 0 DASD • Specify ABARS buffer usage • Specify whether the ABACKUP output tapes were stacked • Specify whether you want the ABARS FSR record written as an SMF record (SETSYS SMF) • Indicate how SMS-managed GDSs backed up from level 0 DASD should be restored. • Indicate the desired ABARSVOLCOUNT environment
___ 7.	Add the aggregate recovery procedure name defined by SETSYS ABARSPROCNAME to the RACF started task table (ICHRIN03).
___ 8.	Define the model entity to define discrete data set profiles to RACF. This step is optional.
___ 9.	Link-edit the aggregate recovery installation exits. This step is optional.
___ 10.	If the aggregate backup output has been transmitted, ensure all aggregate backup output files and any ACCOMPANY data sets are cataloged. See “Preparing for aggregate recovery” on page 374.
___ 11.	Use RACF facility class to authorize certain users or operators to issue the ARECOVER command.
___ 12.	<p>Issue the ARECOVER command with the VERIFY parameter. This step is optional.</p> <ul style="list-style-type: none"> • If aggregate recovery verification completes successfully with a return code of zero, continue to step 13. • If aggregate recovery verification fails, use the conflict resolution data set to assist in resolving any conflicts, and repeat this step until the recovery verification completes successfully with a return code of zero.
___ 13.	<p>Issue the ARECOVER command with the EXECUTE parameter.</p> <ul style="list-style-type: none"> • Determine if aggregate recovery completed successfully with a return code of zero. If not, correct any errors and issue the ARECOVER command with the VERIFY parameter. If verification is successful, reissue the ARECOVER command with the EXECUTE parameter. • If aggregate recovery verification fails, use the conflict resolution data set to assist in resolving any conflicts, and repeat this step until the recovery verification completes successfully with a return code of zero. • Issuing the ARECOVER command with the VOLCOUNT(ANY) parameter can help overcome some SMS allocation failures.

Authorization checking during aggregate recovery

You can permit all console operators or any user, including those who are not DFSMSHsm authorized, to issue the ARECOVER command by using RACF FACILITY class profile support.

If the RACF FACILITY class profile support is installed and activated, DFSMSHsm checks the console operator or user RACF profiles for authorization to issue the ARECOVER command. The user ID of OPER must be defined to RACF before console operators can be given authority to issue the ARECOVER command. If the user ID OPER is given authority to the ARECOVER command, then all console operators are authorized to issue the ARECOVER command. You can also define group names to RACF, using the RACF ADDUSER command.

If the RACF FACILITY class profile is not active, only DFSMSHsm-authorized users and console operators are authorized to issue the ARECOVER command.

You can define the DFSMSHsm ARECOVER command to RACF by defining the following profile names:

Command	RACF Profile
ARECOVER	STGADMIN.ARC.ARECOVER
ARECOVER	STGADMIN.ARC.ARECOVER. <i>agname</i>
ARECOVER	STGADMIN.ARC.ARECOVER. <i>agname</i> .REPLACE

Specific user IDs can then be authorized to issue these commands through the use of the RACF PERMIT command.

You can restrict use of DSCONFLICT(REPLACE), REPLACE as conflict resolution data set action, or REPLACE specified by ARCCREXT, through the use of RACF facility class profile STGADMIN.ARC.ARECOVER.*agname*.REPLACE.

Related reading

For more information about the RACF FACILITY class and control of access to all commands, see “Controlling command access with RACF FACILITY class” on page 625 and [z/OS DFSMSHsm Implementation and Customization Guide](#).

Authorizing comprehensive ARECOVER command authority

When users are added to the STGADMIN.ARC.ARECOVER profile they receive comprehensive command authority. A user with comprehensive command authority for the ARECOVER command is authorized to issue any ARECOVER command.

You could use the following commands to prevent or limit the authority of users to issue the ARECOVER command:

```
RDEFINE FACILITY STGADMIN.ARC.ARECOVER
PERMIT STGADMIN.ARC.ARECOVER CLASS(FACILITY) -
  ID(user ID) ACCESS(READ)
```

The PERMIT command authorizes a user to issue the ARECOVER command for all aggregate groups.

Related reading

For more information about the RACF FACILITY class and control of access to all commands, see “Controlling command access with RACF FACILITY class” on page 625 and [z/OS DFSMSHsm Implementation and Customization Guide](#).

Authorizing restricted ARECOVER command authority

When users are added to the STGADMIN.ARC.ARECOVER.*agname* or STGADMIN.ARC.ARECOVER.*agname*.REPLACE profiles, the users have restricted command authority.

You can use the following commands to prevent or limit users authority to issue the ARECOVER command with a specific aggregate group name:

```
RDEFINE FACILITY STGADMIN.ARC.ARECOVER.PAY1
PERMIT STGADMIN.ARC.ABACKUP.PAY1 CLASS(FACILITY) -
  ID(OPER) ACCESS(READ)
```

The PERMIT command gives all console operators authority to issue the ARECOVER command with a specified aggregate group name.

Related reading

For more information about the RACF FACILITY class and control of access to all commands, see “Controlling command access with RACF FACILITY class” on page 625 and [z/OS DFSMSHsm Implementation and Customization Guide](#).

Considering storage management subsystem requirements

Prior planning is necessary if you want to recover storage management subsystem (SMS) managed data sets in an environment comparable to that which existed at the backup site. SMS must be active to recover VSAM data sets specified in the ALLOCATE list.

SMS class names and attributes are displayed in an ARC6119I message during the aggregate recovery verification. This may help you ensure that the SMS-managed data sets are recovered as you intend.

Note:

1. SMS status at the recovery site determines the status of the recovered data set. A data set that was SMS-managed at the backup site may not necessarily be recovered as SMS-managed and vice versa.
2. You may want to create an aggregate that includes the SMS control data sets from the aggregate backup site. This aggregate could then be restored before restoring the aggregates for application data. This would be the most efficient way to create an SMS environment at the recovery site that matches the SMS environment at the backup site.
3. When restoring an SMS-managed user catalog that was defined in the ALLOCATE statement, ABARS passes the volume serial number where the catalog resided at the backup site. If the target volume exists at the recovery site, the user catalog is allocated on that volume. If the original volume does not exist at the recovery site, the ACS routines at the recovery site direct the allocation. In the event that SMS determines the target volume to be invalid, ABARS requests SMS to relax the guaranteed space rules so that user catalogs can be directed to other volumes in a storage group associated with a guaranteed space storage class.

Rule: If the original volume does not exist at the recovery site, you must modify your ACS routines to remove that volume from any storage group definitions associated with a guaranteed space storage class. If you do not, the recovery will fail.

4. When restoring an SMS-managed NONVSAM data set which belonged, at the time it was backed up, to a storage class with the guaranteed space attribute, ABARS first attempts to allocate the data set to the same volumes that it was backed up from. If the original volumes are unavailable or no longer belong to a storage group that is associated with a guaranteed space storage class, the data set is allocated to different volumes existing in a storage group associated with a guaranteed space storage class.

Note: If the original volumes do not exist at the recovery site, modify the ACS routines to remove the volumes from any storage group definitions associated with a guaranteed space storage class. Otherwise the recovery fails.

Nonmigrated, SMS-managed data sets in an INCLUDE list are directed to the appropriate volumes during aggregate recovery by ACS routines. The following information is passed to ACS routines when restoring data sets backed up by DFSMSdss:

- Output volume serial numbers
- &ACSENVIR = RECOVER (environment in which ACS was invoked)
- Default data class name (if RACF installed)
- Default management class name (if RACF installed)
- Default storage class name (if RACF installed)
- Data set name
- Data set organization
- RACF owner or group (if RACF installed)
- Data set type

- Expiration date
- High-level qualifier of the data set name
- Low-level qualifier of the data set name
- Maximum size of the data set in kilobytes
- Number of qualifiers in the data set name
- Number of volumes specified by the user
- Data set record organization
- Retention period
- Size of data set in kilobytes
- Unit name

If the data sets are not directed by an ACS routine or if SMS is not active, the data sets are recovered to level 0 volumes defined with the DEFINE ARPOOL command. If no level 0 volumes are defined to an ARPOOL, aggregate recovery uses the primary volumes that have been ADDVOLD to DFSMSHsm.

The SETSYS ABARSVOLCOUNT(NONE |ANY) command affects the way in which SMS-managed data set allocations are performed by DFSMSdss for L0 data sets dumped from primary volumes.

Determining aggregate recovery site constraints

Before performing aggregate recovery, you need to determine the DASD and tape unit resources needed to recover the control file, data files, and user tape data sets. You need an equivalent number of tapes during ARECOVER as were used during ABACKUP, assuming the same technology. You can find this information using the LIST AGGREGATE command. For the most part, this information is determined at the backup site and may have been included in the instruction data set during aggregate backup. See [“Retrieving the instruction data set”](#) on page 379.

The DASD space requirements depend in part on the residency of the data sets at the backup site and to which device type they will be recovered.

DASD space requirements are displayed in the ARECOVER activity log, the ABACKUP activity log (if recovered), the ABR record created during the PREPARE step, and in the FSR.

Tip: During ABACKUP processing of an aggregate group, you can use the SETSYS ABARSKIP command to skip data sets on volumes that are protected by the peer-to-peer remote copy function or by the extended remote copy function. Ensure that those volumes are online before issuing an ARECOVER command against that aggregate group.

During aggregate backup, user tape data sets with a block size equal to or larger than 32K bytes can be included in the selection data set. User tape data sets with block sizes up to 256K-1 bytes can also be included in the selection data set. DFSMSHsm Version 2 Release 10 or a subsequent release is required to recover these data sets. In addition, your tape hardware must be capable of processing these large block sizes.

Related reading

For more information about the LIST AGGREGATE command, see [“AGGREGATE: Listing the aggregate backup and recovery activity information”](#) on page 925.

Retrieving the instruction data set

An instruction data set is optionally created for an aggregate backup. It may contain instructions or other information to help you perform that application's recovery. It is contained in the instruction data set, which is the second file on the control file tape.

The instruction data set may also include the following important information:

- Required SMS attributes

- Sample ACS routines
- Description of the application
- RACF environment
- Software requirements
- Hardware requirements
- Unique application execution instructions

To help you perform aggregate recovery, you should first retrieve the instruction data set. The instruction data set is contained in the instruction/activity log file, *outputdatasetprefix.I.CnnVnnnn*. The *outputdatasetprefix* was specified in the aggregate group during aggregate backup. You can retrieve the instruction data set by issuing the ARECOVER command with the INSTRUCTION parameter.

Example instruction data set

The instruction data set, PAYROLL.INSTRUCT, created at the example backup site and identified in the example aggregate group, PAY1, is shown in [Figure 50 on page 381](#).

```

THIS IS THE INSTRUCTION DATA SET FOR AGGREGATE GROUP PAY1.

PERFORMING AGGREGATE BACKUP ON PAY1 BACKS UP THE CRITICAL PAYROLL
FILES AT THE END OF A PAY PERIOD. RELEVANT FILES INCLUDE THE EMPLOYEE
ROSTER (PAY1.PY001.NAMES), AMOUNT OF EACH PAYCHECK (PAY1.PY001.CHECK),
AMOUNT FROM EACH CHECK PLACED IN IRA AND SOCIAL SECURITY DEDUCTION
(PAY1.PY002.IRA AND PAY2.PY002.SOCSEC), AND AMOUNT (IF ANY) OF CHECK
THAT WAS A BONUS IN ADDITION TO SALARY (PAY1.PY001.BONUS).
TO ENSURE PROPER EXECUTION, VERIFY THAT CORRECT RELEASE LEVELS ARE PRESENT
FOR DFSMSHsm, DFSMSdss, AND DFSMSdép; AND THAT THE CORRECT SMS CLASSES ARE ACTIVE.
YOU WILL NEED THE FOLLOWING SMS CLASSES AND THEIR ASSOCIATED ATTRIBUTES
SET UP TO RECOVER THOSE FILES THAT WERE SMS-MANAGED AT ABACKUP, AND TO
ENSURE THAT THEY WILL BE SMS-MANAGED UPON RECOVERY.

DATA CLASS NAME: PHYSSEQ
DESCRIPTION: PHYSICAL SEQUENTIAL DATA SETS

RECFM      : FB
LRECL      : 80

  AUTO BACKUP                        : YES

YOU SHOULD EXECUTE ARECOVER WITH THE VERIFY OPTION TO VERIFY THE AGGREGATE RECOVERY.

PAYROLL.INSTRUCT was copied to the instruction/activity log file,
PAY1.I.C01V0001, during aggregate backup.

```

Figure 50. Example of a Retrieved Instruction Data Set

Creating an ABR record in the BCDS

Before performing an ARECOVER execute or verify for a particular set of ABACKUP output tapes, issue an ARECOVER PREPARE command to create an ABR record for this recovery. This record contains an inventory of aggregate recovery activity for the aggregate version and allows you to use the simplified ARECOVER command syntax described in the [Chapter 29, “ARECOVER command: Recovering a specified aggregate group,”](#) on page 723 when you actually perform aggregate recovery.

The DATASETNAME(*dsname*) parameter determines the control file data set name. You can use DSNAME as an abbreviation for DATASETNAME.

VOLUMES and XMIT are mutually exclusive parameters. VOLUMES (UNIT is optional) specifies that the volume list be used to allocate the control file to be read. XMIT specifies that the required files must already be cataloged, and the system supplies the volume list.

PREPARE, VERIFY, and EXECUTE are mutually exclusive parameters. When PREPARE is specified with the ARECOVER DATASETNAME(*dsname*) command, the ABR record is created without verification processing or data movement. When VERIFY or EXECUTE are specified, an ABR record is created if it does not exist.

Related reading

For more information about the [Chapter 29, “ARECOVER command: Recovering a specified aggregate group,”](#) on page 723.

Defining ABARS tapes to RACF

The output tape volumes generated by aggregate backup processing can be defined to RACF during ARECOVER processing. This is done when the ABR record is created by the PREPARE, VERIFY, or EXECUTE functions and when the following conditions are met:

- RACF is active at the recovery site
- You have defined TAPEVOL resource class HSMABR at the recovery site
- You have specified SETSYS TAPESECURITY(RACF) or SETSYS TAPESECURITY(RACFINCLUDE)

Note: Tapes containing DFSMSHsm output files that are recovered by DFSMSHsm are also RACF-protected at the recovery site when the preceding conditions are met.

```
ADDSD 'outputdatasetprefix.**'
```

If you use RACF DATASET class profiles instead of TAPESECURITY(RACF) to protect the tapes and create the DATASET profiles, you could define ADDSD, which specifies that tapes created during the aggregate backup process are protected. You need a profile for each aggregate group you have defined that uses a different aggregate group prefix.

Issuing the DEFINE ARPOOL command

The DEFINE ARPOOL command allows you to determine the target DASD level 0 and ML1 volumes to be used for aggregate recovery. These are the volumes used as target volumes for migrated and DASD data sets that have not had their allocation directed to other volumes by SMS. Data sets can have their allocations directed by SMS only when it is installed and active at the recovery site.

To ensure that the settings are defined to DFSMSHsm at startup initialization, you should include the DEFINE command in the DFSMSHsm parmlib member (ARCCMDxx). If you are an authorized DFSMSHsm user, you can issue the DEFINE command before an aggregate recovery to modify existing pool configurations or add new pools.

To specify a pool of volumes to be used as target volumes for data sets recovered by aggregate recovery, use the ARPOOL(*agname*) parameter. The aggregate group name (*agname*) identifies a pool and relates that set of volumes to an aggregate group that was previously backed up with the ABACKUP command. These volumes are used as output volumes when the application is recovered. If an aggregate group name of * is specified, the volumes are assigned to a general pool of aggregate recovery volumes. A general pool is a group of volumes defined for recovering those aggregate groups for which no specific pool has been defined. If no aggregate group name is specified, the DEFINE command fails.

Note: Even though ABARS supports a general pool of volumes for all aggregates, you should define individual aggregate recovery pools for each aggregate. Define these pools so that the order of the volumes is varied, especially for those volumes defined with the ML1VOLS parameter. For example:

```
DEFINE ARPOOL(AGG1 ML1VOLS(VOL1,VOL2,VOL3) -  
  L0VOLS(VOLA,VOLB,VOLC))  
  
DEFINE ARPOOL(AGG2 ML1VOLS(VOL2,VOL3,VOL1) -  
  L0VOLS(VOLB,VOLC,VOLA))  
  
DEFINE ARPOOL(AGG3 ML1VOLS(VOL3,VOL1,VOL2) -  
  L0VOLS(VOLC,VOLA,VOLB))
```

The volumes defined with the ML1VOLS parameter are serially loaded in the order in which they are defined. If several aggregate recoveries are processing with ARPOOLS that have the same volume serial numbers in the same order, then volume and channel contention are increased. Varying volume order prevents different aggregate recoveries from attempting to use the same volumes. It is apparent that this is especially critical if multiple ARECOVER commands are processing simultaneously.

ALL specifies that all currently mounted ADDVOled level 0 and ML1 volumes are to be defined to the volume pools for aggregate recovery. It is equivalent to specifying the LOVOLS(*) and ML1VOLS(*) parameters.

ML1VOLS(*volser1,...volsern* | *) specifies a list of non-SMS-managed volumes to be used as target volumes to recover migrated data sets. If * is specified, all currently mounted ADDVOled ML1 volumes are used as the pool of ML1 volumes for aggregate recovery.

LOVOLS(*volser1,...volsern* | *) specifies a list of non-SMS-managed volumes to be used as target volumes to recover nonmigrated, non-SMS-managed data sets. If * is specified, all currently mounted ADDVOled primary volumes are used as the pool of level 0 volumes for aggregate recovery.

Note: If insufficient space is defined, the data set recovery fails. If the level 0 or ML1 volumes specified in the pool are not online and mounted, aggregate recovery fails.

If the DEFINE ARPOOL command is issued without the ALL, ML1VOLS, and LOVOLS parameters, the aggregate recovery pool specified by *agname* is deleted. If an aggregate group name of * is specified, the general pool of aggregate recovery volumes is deleted.

If a DEFINE ARPOOL command was not previously issued before an ARECOVER command, DFSMSHsm uses all currently mounted ADDVOled primary (59 maximum) and ML1 volumes as the ARPOOL.

The aggregate recovery pools that have been defined can be displayed by using the QUERY ARPOOL command. If LOVOLS have been specified, these volume serial numbers are passed to ACS by DFSMSdss. ACS routines may then use these volume serial numbers to determine the classes and placement of the data sets.

If ACS does not assign storage classes to the data sets, then DFSMSdss attempts to direct allocation to the volume serial number where the data set resided when backed up. If that particular volume serial number does not exist at the recovery site, recovery of the data set in question fails. In a non-SMS environment, all level 0 data sets are directed to LOVOLS volumes.

The ARPOOL volumes need not be added to DFSMSHsm using the ADDVOL command before issuing the DEFINE ARPOOL command; however, the following restrictions apply to the relationship between DFSMSHsm-owned and -managed volumes and volumes assigned to the aggregate recovery pool:

- A volume previously added to DFSMSHsm as anything other than a PRIMARY volume cannot be defined with the LOVOLS parameter of the DEFINE ARPOOL command.
- A volume previously added to DFSMSHsm as anything other than an ML1 volume cannot be defined with the ML1VOLS parameter of the DEFINE ARPOOL command.
- A volume previously defined to aggregate recovery with the ML1VOLS parameter of the DEFINE ARPOOL command can subsequently be added to DFSMSHsm only as an ML1 volume.
- A volume previously defined to aggregate recovery with the LOVOLS parameter of the DEFINE ARPOOL command can subsequently be added to DFSMSHsm only as a PRIMARY volume.
- A volume cannot be SMS managed.
- A volume defined as LOVOLS cannot also be defined as ML1VOLS. Conversely, a volume defined as ML1VOLS cannot also be defined as LOVOLS. This is true whether it conflicts with a previously defined pool or whether a conflict exists within the pool being defined.

You should use the ADDVOL command to add all aggregate recovery volumes to DFSMSHsm as soon as possible after an ARECOVER command has successfully completed processing. If you do not do this, failures can occur when an attempt is made to refer to those data sets.

Example DEFINE ARPOOL command for aggregate recovery

The following DEFINE ARPOOL command is entered at the example site before performing aggregate recovery:

```
DEFINE ARPOOL(PAY1 ML1VOLS(MIG102) L0VOLS(PRIM02))
```

This command specifies that the migration volume (MIG102) and the primary volume (PRIM02) are used for the aggregate recovery of data sets identified in the example aggregate group, PAY1.

To review the aggregate recovery pools that have been defined, enter

```
QUERY ARPOOL
```

Note: Define ARPOOLS to minimize volume contention when running more than one aggregate recovery at the same time. If two or more aggregate recoveries are attempted using the same level 0 volume, one or more of the aggregate recoveries can fail because of the inability of DFSMSdss to allocate the receiving volume.

Defining SETSYS parameters for aggregate recovery

The SETSYS command allows you to externally define various aggregate recovery environmental options.

To ensure that the settings are defined to DFSMSHsm at startup initialization, the system programmer should include the SETSYS command in the DFSMSHsm parmlib member (ARCCMDxx). If you are an authorized DFSMSHsm user, you can issue the SETSYS command before an aggregate recovery to modify the SETSYS parameters that control aggregate processing.

To specify how many ABARS commands can run concurrently, use the MAXABARSADDRESSSPACE parameter. MAXABARSADDRESSSPACE specifies the maximum number of concurrent ABARS secondary address spaces that DFSMSHsm supports (up to 64). When determining the value to specify for MAXABARSADDRESSSPACE, factor in such items as system load, resource contention, aggregate backup and recovery activity. The overriding factor is the number of tape drives available (the default for MAXABARSADDRESSSPACE is 1).

When an ARECOVER command completes, ABARS determines if there is another ABARS request queued that has not been processed. If there is, DFSMSHsm reuses the address space to process that command. The address space remains active until there are no further ABARS commands queued, or the SETSYS MAXABARSADDRESSSPACE command has reduced the number of ABARS address spaces and this address space is no longer required.

The tape unit type used for the control and data file must be compatible with the tape unit type used during aggregate backup. You will specify this unit type later as part of the UNIT parameter of the ARECOVER command or in the SETSYS ABARSUNITNAME parameter.

The ABARSPROCNAME parameter specifies the procedure name used to start an ABARS secondary address space when no such address space is available for reuse. The default is DFHSMABR.

The EXITON(*exitname*) parameter lets you specify which installation exits (ARCCREXT, ARCSKEXT, ARCTVEXT) are active during aggregate recovery processing.

The OPTIMUMDASDBLOCKING parameter allows efficient utilization of DASD when ABARS performs aggregate recovery at your recovery site. When ARECOVER recovers a data set to ML1 DASD and SETSYS OPTIMUMDASDBLOCKING has been specified, ARECOVER determines the maximum block size for the data set on the ML1 DASD. This information is used for the allocation block size of the migrated data set. The 2K records of the input migrated data set are reblocked to the optimum block size for the output data set.

If SETSYS NOOPTIMUMDASDBLOCKING is specified, DFSMSHsm does not define optimum block size for the output data set.

The ARECOVERUNITNAME parameter specifies a default tape unit name for user tape data sets being recovered to a tape unit during recovery processing. If the TARGETUNIT parameter of the ARECOVER command is specified, its value takes precedence over any value specified for the ARECOVERUNITNAME parameter. However, if neither parameter is specified, a default of 3590-1 is assumed. This parameter can be overridden if SMS is active and ACS routines assign a tape storage group to the data set.

The ABARSVOLCOUNT(NONE | ANY) command allows you to affect the method of invoking DFSMSdss for restoring L0 data sets that were dumped from primary volumes. If NONE is specified, the DFSMSdss VOLCOUNT parameter is not passed to DFSMSdss during the restore. If ANY is specified, the VOLCOUNT(ANY) parameter is passed to DFSMSdss during the restore. Specifying VOLCOUNT(ANY) to DFSMSdss results in the allocation of the target data set on as many volumes as required, up to a maximum of 59 volumes.

The ARECOVERPERCENTUTILIZED(*nnn*) parameter allows you to specify to what percent DFSMSHsm allows DFSMSdss to fill non-SMS DASD recovery volumes during any ARECOVER command processing. For *nnn*, substitute an integer number between 1 and 100. The default is 080 (80%).

Tip: When you issue any ARECOVER command, you can temporarily override the SETSYS ARECOVERPERCENTUTILIZED value by using the PERCENTUTILIZED parameter of the ARECOVER command.

Each time you issue the ARECOVER command, an activity log is created. You can use the SETSYS ABARSACTLOGTYPE parameter to specify whether you want the activity log automatically written to SYSOUT or to DASD. You can use the SETSYS ABARSDELETEACTIVITY(Y | N) command to specify whether you want DFSMSHsm to automatically delete the ABARS activity log that corresponds to the ABACKUP version being rolled off. The deletion occurs during ABARS roll-off processing or EXPIREBV ABARSVERSIONS processing, and removes the need to manually manage the ABARS activity logs.

The default, if you do not specify the SETSYS ABARSTAPES command, is the STACK option.

When SETSYS ABARSTAPES(STACK) is specified, ARECOVER attempts to process the ABACKUP output files as if they are stacked. If the files are not stacked, ARECOVER detects the error and attempts to process the files as if ARECOVER were issued with the NOSTACK option. When SETSYS ABARSTAPES(NOSTACK) is specified, ARECOVER attempts to process the ABACKUP output files as if they are not stacked. If the files are stacked, ARECOVER detects the error and attempts to process the files as if ARECOVER were issued with the NOSTACK option.

Specifying the XMIT parameter with the ARECOVER command when using stacked output tapes has the following effect on ARECOVER processing:

- ARECOVER relies on information in the catalog to determine the file sequence numbers during the allocation of ABACKUP files. If the ABACKUP files, with the exception of the control file, are not cataloged, ARECOVER obtains the file sequence numbers from the control file.
- XMIT processing for STACKED output remains basically the same as for data that is not stacked, meaning that deallocation and allocation occur for each ABACKUP file processed. This can result in several mount requests for the same tape volume.
- If the ABACKUP output is transmitted, it is possible for the data to be received on a device type and geometry different from that on which it was originally written. Because of this, you cannot assume that the files will still be stacked when received by the network transmission software.

ABARS records the CPU time for processing ARECOVER requests, along with any applicable account code information. This information is written to the ABR record and can be obtained using the LIST

AGGREGATE command. This information is written to the FSR control block. The FSR can be written as an SMF record if the installation specifies SETSYS SMF(*smfid*). ABARS then writes the FSR as *smfid* + 1 in the SYS1.MANx or SYS1.MANY system data sets. Installations can use the information to calculate charge backs for ABARS requests.

The new SETSYS ARECOVER TGTGDS(*option*) command provides greater flexibility for managing SMS-managed generation data sets that are being restored to level 0 DASD. You can specify the following options:

DEFERRED

Specifies that the target data set is to be assigned the DEFERRED status.

ACTIVE

Specifies that the target data set is to be assigned the ACTIVE status, for example, rolled into the GDG base.

ROLLEDOFF

Specifies that the target data set is to be assigned the ROLLEDOFF status.

SOURCE

Specifies that the target data set is to be assigned the same status it had when it was backed up.

The default option is SOURCE, which is consistent with prior releases of DFSMSHsm.

Installations are able to override the SETSYS ARECOVER TGTGDS(*option*) specification with a new ARECOVER command TGTGDS(*option*) keyword parameter. The options for ARECOVER TGTGDS are the same options as for SETSYS ARECOVER TGTGDS.

Note: If the SETSYS DEBUG parameter is specified before aggregate recovery processing, DFSMSHsm does not move any data. DEBUG causes all ARECOVER commands to be processed as if the VERIFY option is specified.

Related reading

- For more information about the ABARSPROCNAME parameter, see [“ABARSPROCNAME: Specifying the base procedure name to start the ABARS secondary address space”](#) on page 1096.
- For more information about the ABARSVOLCOUNT parameter, see [“ABARSVOLCOUNT: Specifying the method for determining volume count for SMS target data set allocations done by DFSMSdss”](#) on page 1097.

Example SETSYS commands for aggregate recovery

The following SETSYS commands are entered at the example site before performing aggregate recovery:

```
SETSYS MAXABARSADDRESSSPACE(2)
SETSYS ARECOVERUNITNAME(3490)
SETSYS ABARSPROCNAME(SAMPLE)
```

The maximum number of secondary address spaces is set to two, which means that two ABARS commands can run at a time. If the TARGETUNIT parameter is not specified when the ARECOVER command is issued, user tape data sets are recovered to 3490 tape units as specified by the ARECOVERUNITNAME(3490) parameter. The procedure name used to start the secondary address space is SAMPLE.

To review the SETSYS parameters in effect for aggregate processing, enter:

```
QUERY ABARS
```

or

```
QUERY SETSYS
```

Defining the model entity

If you specify the MENTITY parameter of the ARECOVER command, you must define a model entity. The model entity is used to define discrete data set profiles for RACF protection. The model entity is applicable only for level 0 DASD and migrated data sets that have been discretely RACF-protected at the backup site.

For more information on the MENTITY parameter, see [“ARECOVER command” on page 392](#).

Using the aggregate recovery installation exits

Programming Interface Information

If installation exits ARCSKEXT and ARCCREXT have been previously link-edited and if the SETSYS EXITON(ARCSKEXT) and SETSYS EXITON(ARCCREXT) commands have been issued (you can use the QUERY SETSYS command to display the status of these exits), ARCSKEXT and ARCCREXT are called during aggregate recovery verification. Installation exit ARCSKEXT is called for each data set to be recovered, allowing you to specify if that data set should be skipped or included in the aggregate recovery.

Installation exit ARCCREXT is called whenever a data set naming conflict is detected. This exit allows you to specify that the data set is to be:

- Skipped—The data sets are not recovered.
- Renamed—You give the source data sets on the data file new names. Data sets must not already exist with the new names you specify.

The rename process does not apply to migrated VSAM data sets. If you specify that a migrated VSAM data set should be renamed, it is skipped.

Note: DFSMSdss renaming of a VSAM sphere does not cause any alternate indexes to be renamed. If a data set naming conflict exists for alternate indexes, the alternate indices are not recovered.

- Replaced—The like-named data sets at the recovery site are replaced with the corresponding aggregate backup data sets. (This is the same result as if you had specified the DSCONFLICT(REPLACE) parameter on the ARECOVER command.)

Note: When using the DSCONFLICT(REPLACE) parameter, the data set is deleted before attempting the recovery of the data set from the aggregate backup output files. If the recovery fails, the data set remains deleted. Causes of recovery failure include:

- I/O errors on the input tape
- Failure to allocate the new data set
- Recovering at a site that does not support the type of data set being recovered
- Renamed target—The like-named target data sets at the recovery site are renamed using the new high-level qualifier specified. This is similar to the use of the DSCONFLICT RENAMETARGET(*level*) parameter.

If installation exit ARCTVEXT has been previously link-edited and if the SETSYS EXITON(ARCTVEXT) command has been issued (you can use the QUERY SETSYS command to display the status of this exit), ARCTVEXT is called during aggregate recovery. This exit is called when rolling off old ABARS versions to indicate to tape management systems, excluding DFSMSrmm, that ABARS is expiring a tape volume.

End Programming Interface Information

Processing generation data sets

The following topics discuss how backed-up generation data sets (GDSs) are restored during ARECOVER processing.

GDSs from level 0 DASD in the include list

Each generation data set (GDS) in the INCLUDE list that has been backed up from level 0 is recovered as a level 0 non-SMS-managed GDS with a status of ACTIVE if (1) ACS directs it to be recovered as not managed by SMS or if (2) SMS cannot manage the GDS because SMS is not active.

If the GDS is directed by ACS to be recovered as SMS-managed, it is recovered with the status specified by the SETSYS ARECOVER TGTGDS(*option*) command. The status can be specified as DEFERRED, ACTIVE, ROLLEDOFF, or SOURCE. SOURCE indicates that the SMS-managed data set being restored is to be assigned the same status it had when backed up. If the SETSYS ARECOVER TGTGDS command is not specified, the default is SOURCE.

If the ARECOVER command is issued with its optional TGTGDS(*option*) parameter, the value specified by the TGTGDS parameter overrides the value specified by the SETSYS ARECOVER TGTGDS command. The TGTGDS parameter, like the ARECOVER TGTGDS parameter, can be specified with the options of DEFERRED, ACTIVE, ROLLEDOFF, or SOURCE. [Table 43 on page 388](#) shows how level 0 GDSs are processed.

Table 43. Expected Results for Level 0 Data Sets in the INCLUDE List (Processed by DFDSS)

ABACKUP	ARECOVER			
	NON-SMS, NON-GDS	NON-SMS, ACTIVE GDS	SMS, Status as Specified or Default of SOURCE	SMS, NON-GDS
NON-SMS, NON-GDS	*			X
NON-SMS, ACTIVE GDS		*	X	
SMS, ACTIVE GDS		*	X	
SMS, ROLLED-OFF GDS		*	X	
SMS, DEFERRED GDS		*	X	
SMS, NON-GDS	*			X

* = Recovered as NON-SMS X = Recovered as SMS

Note: Non-SMS rolled-off GDSs are not processed.

Migrated GDSs in the include list

Non-SMS-managed GDSs in the INCLUDE list that were migrated data sets with a status of ACTIVE are always recovered as non-SMS-managed migrated GDSs, and retain a status of ACTIVE.

If SMS-managed migrated GDSs with ACTIVE status are directed by ACS to be recovered as non-SMS-managed or become non-SMS-managed because SMS is not active, they are recovered with a status of ACTIVE.

If an SMS-managed migrated GDS with a status of ACTIVE is directed by ACS to be recovered as SMS-managed, it is recovered with a status of ACTIVE.

SMS-managed migrated GDSs with a status of DEFERRED or ROLLED OFF that are directed by ACS to be recovered as SMS-managed maintain their original GDS status. If ACS directs these same data sets to be recovered as non-SMS-managed, or if they become non-SMS-managed because SMS is not active, they are recovered as uncataloged non-SMS GDSs, and DFSMSHsm issues message ARC6131I informing you of this status. You can issue the following Access Method Services command to catalog the generation data sets:

```
DEFINE NONVSAM(name(dsname) VOLUMES(MIGRAT) -
  DEVICETYPES(device) NORECATALOG)
```

The generation data sets are cataloged as non-SMS-managed GDSs with a status of ACTIVE. [Table 44 on page 389](#) shows how migrated GDSs are processed.

Table 44. Expected Results for Migrated Data Sets in the INCLUDE List

ABACKUP	ARECOVER						
	NON-SMS, NON-GDS	NON-SMS, ACTIVE GDS	NON-SMS, UNCATA- LOGED	SMS, ACTIVE GDS	SMS, ROLLED-OFF GDS	SMS, DEFERRED GDS	SMS, NON- GDS
NON-SMS, NON-GDS	*						
NON-SMS, ACTIVE GDS		*					
SMS, ACTIVE GDS		*		X			
SMS, ROLLED-OFF GDS			* (ARC6131I)		X		
SMS, DEFERRED GDS			* (ARC6131I)			X	
SMS, NON-GDS	*						X

* = Recovered as NON-SMS X = Recovered as SMS

Note: Non-SMS rolled-off GDSs are not processed.

When processing migrated data sets that are SMS-managed, ACS routines are invoked to determine if the data set should be recovered as SMS-managed or non-SMS-managed. If the ACS routines encounter a nonzero return code, they recover the migrated data sets that were SMS-managed at the backup site as non-SMS-managed data sets at the recovery site.

GDSs in the ALLOCATE list

Generation data sets in the ALLOCATE list are always recovered with a status of ACTIVE. You should not include SMS generation data sets with a status of ROLLED OFF or DEFERRED in the allocate list, because they will be recovered with a status of ACTIVE. This results in other GDSs with a status of ACTIVE being rolled off.

GDS processing order

The order in which the GDSs are processed determines which GDSs have an ACTIVE status after the recovery process has ended. The data sets in the INCLUDE list are processed first, and in the following order: the level 0 data sets are processed, followed by the migrated and user tape data sets. The data sets in the ALLOCATE list are processed next. The data sets in the ACCOMPANY list are processed last. If the limit is exceeded during the recovery process for a generation data group, then the oldest GDSs roll off.

Processing migrated data sets in the INCLUDE list

Migrated non-SMS-managed data sets in the INCLUDE list are always recovered as non-SMS-managed data sets. You can convert the data sets (with the exception of migrated GDSs) to SMS-managed data sets by recalling them with an ACS routine that does this conversion.

Processing VSAM data sets in the ALLOCATE list

During aggregate recovery, VSAM data sets from the ABACKUP ALLOCATE list must be recovered as SMS-managed data sets. Therefore, SMS must be active at the recovery site, and ACS filtering must direct these data sets to SMS-managed storage.

The following verification is performed during aggregate recovery. Error messages are issued for verification failures. If EXECUTE is specified on the ARECOVER command, only those data sets not receiving verification errors are recovered.

- If SMS is not active, an error message is issued that lists the VSAM data sets from the ALLOCATE list, indicating that these data sets will not be recovered.

- If SMS is active, ACS filtering is invoked to determine if the data set can be recovered as SMS-managed. If the data set will not be SMS-managed, or SMS errors occur, messages are issued, and the indicated data set is not recovered. The following ACS variables are passed to the ACS routines:
 - &ACSENVIR = ALLOC (data set recovery environment)
 - &DSN = VSAM cluster name. If the data set was renamed during ARECOVER processing, the new name is passed.
 - &DSTYPE = PERM (permanent data set)
 - &UNIT = Unit name of ABACKUP source data set
 - &DSORG = VS (VSAM data set organization)
 - &RECORG = ES, KS, RR, LS (VSAM type - ESDS, KSDS, RRDS, LINEAR)

If the ABACKUP source data set had associated SMS class names, these class names are passed as initial values to ACS routines. ACS may override these class names. If ACS does not override the SMS class name, and the name is not defined in the currently active configuration, an SMS ACS error occurs. The associated messages are written to the ARECOVER activity log, and verification fails.

 - &DATACLAS = source data class name
 - &MGMTCLAS = source management class name
 - &STORCLAS = source storage class name
- A data class should be defined and selected during aggregate recovery ACS filtering. This is particularly important when these data sets are allocated to a device with a different geometry than the source (that is, source=3380, target=3390). The source space allocation quantity is always recorded as an amount of cylinders or tracks, even if RECORDS was specified when the data set was defined. As a result, allocation to an unlike device may encounter over-allocation or under-allocation problems if the allocation quantity is not set by the data class.
- The storage group selected at the aggregate recovery site should contain enough volumes to support multiple volume allocation of those data sets that resided on multiple volumes at the aggregate backup site.
- Only base cluster information will be processed during ABACKUP for allocation and cataloging at the time of the ARECOVER. Users must define any alternate index (AIX) path associations at the ARECOVER site.

Note: If an AIX/PATH, as well as base cluster allocations, are needed at the time of the ARECOVER, place the entry in the INCLUDE list where the SPHERE processing is performed. When it is placed in the INCLUDE list, data for all components of the base cluster and the associations (AIX/PATH) are backed up and placed in the data file. This data file will be fully recovered during ARECOVER processing.

Catalog considerations during ARECOVER processing

There are at least three states that the catalog environment can be in at the recovery location:

1. The master and user catalogs exist at the recovery site with valid data set entries. You can issue the ARECOVER command with or without the DATASETCONFLICT(REPLACE) parameter. When you specify DATASETCONFLICT(REPLACE) parameter, be aware that you can unintentionally delete existing production data sets. If you do not specify DATASETCONFLICT(REPLACE), the data sets being recovered that have name conflicts are skipped during the recovery process.

Note: If a catalog entry exists for a VSAM RLS data set, existing attributes are maintained even if DSCONFLICT(REPLACE) was specified on the ARECOVER command. However, there is a PATCH that can be turned on to allow DFSMSHsm ABARS ARECOVER to use the backup version RLS attributes instead of the target's. See [Tuning DFSMSHsm](#) in *z/OS DFSMSHsm Implementation and Customization Guide*.

2. The Master and user catalogs exist at the recovery site but the data set entries are invalid. This means that either the volumes that are associated with a data set entry are not online or the volume does not contain a valid data set entry in the VTOC. This situation typically exists when catalogs have been

previously recovered as part of a full volume dump and restore of the operating system volumes containing these catalogs.

You can choose to issue the ARECOVER command with or without specifying the DATASETCONFLICT(REPLACE) parameter. If you do not specify DATASETCONFLICT(REPLACE), the data sets being recovered that have name conflicts are skipped during the recovery process. If you do specify DATASETCONFLICT(REPLACE), ARECOVER processing detects whether the catalog entry is valid or invalid. If the catalog entry is valid, a delete is issued for data sets in conflict before recovering the data set from the ABACKUP tapes. If the catalog entry is invalid, a DELETE NOSCRATCH is performed for data sets in conflict.

3. You can choose to DEFINE a new catalog and associated aliases before you issue the ARECOVER command. Doing so allows ARECOVER processing to catalog data set entries when data sets are being recovered, and avoids any data set naming conflicts.

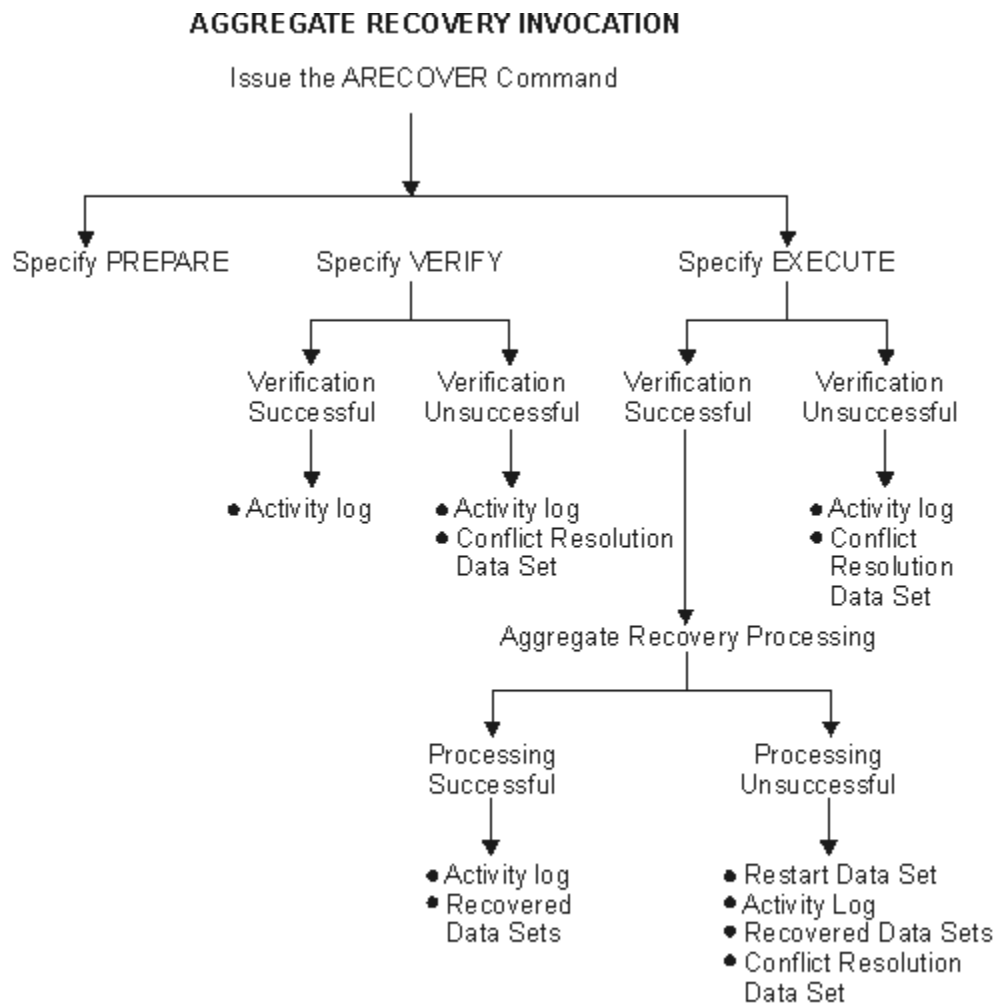

A situation can occur where migrated data sets in the catalog but the migration volume does not exist at the recovery site. ARECOVER processing deletes conflicting data sets when the DATASETCONFLICT(REPLACE) parameter is specified, and DFSMSHsm processing handles the situation where the migration volume is not online or the VTOC entry does not exist. If an ARC0184I message is issued when attempting to retrieve the MCV record for the migration volume, issue an ADDVOL command for the migration volume and reissue the ARECOVER command.

It is possible that the catalog has entries for migrated data sets, but the MCD record does not exist in the MCDS. ARECOVER processing detects this situation and issues a DELETE NOSCRATCH for the migrated data set if the DATASETCONFLICT(REPLACE) parameter was specified on the ARECOVER command. This allows the migrated data set to be deleted and aggregate recovery processing to successfully recover the migrated data set encountering this situation.

4. If you plan to recover the user catalogs specified in the ALLOCATE statement by using ARECOVER, and you have recovered the master catalog from the ABACKUP site that has alias entries for these user catalogs, it is best to first issue IDCAMS EXPORT DISCONNECT command before issuing the ARECOVER command to remove this connection.

Performing aggregate recovery

Figure 51 on page 392 shows what occurs when you invoke aggregate recovery by issuing the ARECOVER command.

ARC15G28

Figure 51. Aggregate Recovery Invocation

The following topics describe the aggregate recovery invocation in more detail.

ARECOVER command

Issue the ARECOVER command when you are ready to perform aggregate recovery.

You can specify the ARECOVER command with the PREPARE parameter to create the ABR record. You can specify the ARECOVER command with the VERIFY parameter to verify the accuracy of an aggregate recovery without actually having the data sets recovered. This is like performing a test run of aggregate recovery. After aggregate recovery verification processing completes, the ARECOVER command stops. No data sets are recovered. When you are ready to have aggregate recovery recover your data sets, you can issue the ARECOVER command and specify the EXECUTE parameter. After successful verification processing, your data sets are recovered.

Note: If SETSYS DEBUG is in effect, the VERIFY parameter is forced, regardless of other settings.

The following two topics describe in more detail what occurs when you issue the ARECOVER command with the EXECUTE parameter.

The DATASETNAME and VOLUMES | XMIT parameters are required if the ABR record was not previously created using the PREPARE parameter of the ARECOVER command. The AGGREGATE parameter is required if the DATASETNAME parameter is not used. Either the PREPARE, EXECUTE, or VERIFY parameters must be specified on the ARECOVER command.

For *dsname* in DATASETNAME(*dsname*), specify the data set name of the control file.

For *volser1,...volsern* in VOLUMES(*volser1,...volsern*), specify the serial numbers of the control files. The volume serial numbers must be specified in the same order as in message ARC6061I, issued during the aggregate backup.

When files are transferred by using a transmission program such as NetView FTP, issue the ARECOVER command using the XMIT parameter. This tells DFSMSHsm that the aggregate backup output has been transmitted. Do *not* use the VOLUMES and UNIT parameters on the ARECOVER command when XMIT is specified.

Note:

- Specify the XMIT parameter with the ARECOVER command only if all aggregate backup output files have been cataloged. For DFSMSHsm hosts that are running DFSMS Version 2 Release 10 or subsequent releases, only the control file needs to be cataloged before ARECOVER, as long as you are recovering the original ABACKUP files and as long as all of these files have been backed up to tape.
- If installations use a utility to convert their existing aggregate backup output files from one tape technology to another, ensure that the newly created tapes are cataloged at the recovery site with the newly created unit name and volume serial number, and use the XMIT parameter on the ARECOVER command. The XMIT parameter ensures that ARECOVER processing retrieves the allocation information for the ABARS files from the catalog rather than using the volser and unit stored on the control file tape.

If you choose to have any or all of your ABACKUP output files directed to DASD volumes, there are special precautions you must observe for successful recovery of the backed up data:

- The aggregate backup files must be properly cataloged and exist at the recovery site.
- You must use the XMIT and DATASETNAME parameters on your ARECOVER command.

For *agname* in AGGREGATE(*agname*), specify the aggregate group name. Do *not* use the AGGREGATE parameter if you use the DATASETNAME parameter.

The EXECUTE parameter allows the actual ARECOVER data movement to take place when the ARECOVER command is processed. Before you can use ARECOVER AGGREGATE, one of the following actions must occur:

- You must be performing aggregate recovery on the same system where ABACKUP has been issued, and where the ABR record still exists, or
- You must have previously issued the ARECOVER DATASETNAME(*dsname*) PREPARE command.

Specify the PREPARE parameter to build the ABARS CDS record (ABR record) at the recovery site if it does not already exist, without further verification and without data movement. The PREPARE parameter also catalogs ABACKUP output files and adds volumes to RACF, if required.

The optional ACTIVITY parameter specifies that the ABACKUP activity log is to be recovered.

The optional INSTRUCTION parameter specifies that the instruction data set is to be recovered.

When the ARECOVER command is issued with the VERIFY or PREPARE parameters, DFSMSHsm retrieves this information from the ABR record and issues messages during recovery processing indicating the amount of storage required to recover an aggregate group. The amount of storage required for level 0, ML1, and ML2 recovery is displayed separately, along with the combined total storage requirement. This information is maintained in the ABR record and is written to both the ARECOVER activity log and the FSR record.

Note:

1. If the aggregate recovery is being made from DFHSM V2.5.0 or V2.6.0 ABACKUP output tapes, no storage requirements are displayed.
2. When ARECOVER EXECUTE is issued, the storage requirements of data sets not recovered is written in the ARECOVER activity log. The amounts of level 0, ML1, and ML2 storage are kept separately, as well as the combined total storage requirement.

3. When ARECOVER VERIFY is issued, and DFSMSHsm determines that a RESTART data set exists, a message is written in the ARECOVER activity log indicating the storage requirements of data sets not successfully recovered in the previous pass. The amounts of level 0, ML1, and ML2 storage are kept separately, as well as the combined total storage requirement.

The optional, and mutually exclusive, STACK and NOSTACK parameters are only valid with the DATASETNAME parameter. They allow you to override the specified SETSYS ABARSTAPES value, or its default value of STACK. The option you select indicates to ARECOVER DATASETNAME processing whether the ABACKUP output you are going to recover is stacked. This information is needed before mounting the control file tape. When the control file tape is mounted, ARECOVER forward spaces to file sequence number 4 if the output is stacked, but does not if the output is not stacked.

The optional UNIT(*unittype*) parameter is only valid if the DATASETNAME and VOLUMES parameters are used. For *unittype*, specify the unit type to be allocated for the control file.

The DATE or VERSION optional parameters are valid only when the AGGREGATE parameter is used. For DATE(*yyyy/mm/dd*), specify the date of the aggregate group version to be recovered. *yyyy* is the 4-digit year, *mm* is the month (01–12), and *dd* is the day of the month (01–31). If more than one aggregate version has been created on the date you specify, the most current version is selected.

For *nnnn* in VERSION(*nnnn*), specify the specific version of the aggregate group to be recovered. If neither DATE nor VERSION is specified, the most current aggregate group version is recovered.

Use the optional DATASETCONFLICT parameter to specify how you want to handle data set name conflicts.

- The RENAMESOURCE(*level*) subparameter specifies that the ABACKUP data set be recovered with the new high-level qualifier specified by *level*.
- The RENAMETARGET(*level*) subparameter specifies that the data set at the recovery site be renamed with the high-level qualifier specified by *level*, and the ABACKUP data set be recovered with its original name.

RENAMETARGET(*level*) performs an ALTER NEWNAME for the existing data set name. Special care should be taken when you change the high-level qualifier so that the existing data set does not become uncataloged, which may occur when no catalog alias exists for the new high-level qualifier.

- The BYPASS subparameter specifies that the ABACKUP data set be skipped and not recovered.
- The REPLACE subparameter specifies that the data set at the recovery site be deleted and replaced by the ABACKUP data set.

Note:

1. When you use the DSCONFLICT(REPLACE) parameter, the data set is deleted before attempting the recovery of the data set from the aggregate backup output files. If the recovery fails, the data set remains deleted. Recovery failure results from the following causes:
 - I/O errors on the input tape
 - Failure to allocate the new data set
 - Recovering at a site that does not support the type of data set being recovered
2. The DATASETCONFLICT parameter may be specified in conjunction with the RECOVERNEWNAMEALL or RECOVERNEWNAMELEVEL parameters.
3. The DATASETCONFLICT parameter may be abbreviated DSCONFLICT, RENAMESOURCE may be abbreviated RENSRC, and RENAMETARGET may be abbreviated RENTGT.

If you want to specify a predefined model entity to be used for defining discrete profiles to RACF, use the optional MENTITY parameter. Only those data sets previously protected by discrete profiles and defined to RACF before aggregate backup are protected by using discrete profiles. If the model entity is specified in the ARECOVER command and is not predefined, aggregate recovery fails.

Attention: If MENTITY is not specified and data sets exist that have been discretely RACF-protected at the backup site, the data sets are recovered as RACF indicated, and a default discrete

profile is created. The profile owner is set to the high-level qualifier of the data set, and UACC is set to NONE.

If a RACF profile has been predefined for the data sets, they are recovered with this predefined profile.

Use the optional MIGRATEDDATA parameter to specify the migration level to be used when recovering migrated data sets:

- ML1 specifies that all migrated data sets are recovered to migration level 1 DASD (this is the default if you do not use MIGRATEDDATA).
- ML2 specifies that all migrated data sets are recovered to nonspecific tape volumes which are then ADDVOLed as ML2 volumes.

Note: You must specify the tape unit name to be used when recovering migrated data sets to nonspecific volumes by use of the ARECOVERML2UNIT parameter of the SETSYS command.

- SOURCELEVEL specifies that migrated data sets that have been ML1 at the ABACKUP site are recovered to ML1 DASD; migrated data sets that have been ML2 DASD or ML2 tape are recovered to nonspecific volumes which are then ADDVOLed as ML2 volumes.

Note: If the duplex tape option is specified for ML2 tapes, a TCN record is created to cause an automatic TAPECOPY during secondary space management. ARECOVER of ML2 data is not duplexed.

DFSMSHsm automatically creates MCL records for all data sets that are successfully recovered to ML1 DASD volumes unless directed otherwise. This causes these data sets to be backed up during automatic backup processing.

Note: MCL records are not created for data sets recovered to ML2 tape volumes.

The optional NOBACKUPMIGRATED parameter allows you to specify that recovered migrated data sets are *not* to be backed up during automatic backup. If you do not specify NOBACKUPMIGRATED, DFSMSHsm backs up recovered migrated data sets residing on ML1 DASD the next time automatic backup is run.

The optional ONLYDATASET parameter allows you to recover individual data sets from an aggregate backup version. You can specify a single fully qualified data set name using the NAME(*dsname*) subparameter of ONLYDATASET to recover a particular data set. To recover multiple data sets, you can supply the name of a data set that contains a list of data set names to be recovered on the LISTOFNAMES(*listdsname*) subparameter of ONLYDATASET. The LISTOFNAMES data set must be a sequential data set, fixed-block, record size of 80, and be cataloged. The LISTOFNAMES data set should contain one fully qualified data set name per record. The abbreviation for ONLYDATASET is ONLYDS and the abbreviation for LISTOFNAMES is LON.

The optional PERCENTUTILIZED(*nnn*) parameter allows you to change the percentage to which DFSMSHsm allows DFSMSdss to fill non-SMS DASD recovery volumes when recovering data sets to level 0 volumes. For *nnn*, substitute an integer number between 1 and 100. If SETSYS ARECOVERPERCENTUTILIZED has not been specified, the default value is 080 (80%). The value that you specify overrides any default value specified by the SETSYS ARECOVERPERCENTUTILIZED parameter.

The optional RECOVERNEWNAMEALL(*level*) parameter specifies that all data sets being recovered be renamed with the high-level qualifier specified by *level*.

The optional RECOVERNEWNAMELEVEL(*olevel1,nlevel1,...*) parameter specifies that all data sets that have a high-level qualifier *olevelx* are recovered with a new high-level qualifier *nlevelx*. The maximum number of *olevelx,nlevelx* qualifier pairs is 30.

The RECOVERNEWNAMEALL and RECOVERNEWNAMELEVEL parameters allow data sets to be renamed before verification checking for like-named conflicts. These parameters apply to data sets in the INCLUDE and ALLOCATE lists (except for user catalogs in the ALLOCATE list), but do not apply to ACCOMPANY data sets. In addition, migrated source VSAM data sets may not be renamed. If the rename criteria applies to a migrated source VSAM data set, a message is issued, and the data set is not renamed.

If the rename criteria applies to a nonmigrated source VSAM data set, the new component names are not generated by ARECOVER processing, but are generated by a) DFDSS if the data set is from the INCLUDE list, or b) SMS VSAM allocation if the data set is from the ALLOCATE list. As a result, conflict resolution checking does not check for new conflicts for individual components, since the new component names are unknown.

If RECOVERNEWNAMEALL is specified, a message is issued indicating that all data sets will be renamed with the specified level. If RECOVERNEWNAMELEVEL is specified, a message is issued listing the level pairs specified, and indicating that each data set matching the old level will be renamed to the corresponding new level. Each data set meeting the rename criteria is recovered with the new name during data movement. Like-named conflicts created by the new name are evaluated during the conflict resolution process.

If renaming a data set creates a data set name with more than 44 characters, the data set name is truncated to 44 characters, and if the last character is now a '.', it is also truncated. A message is issued indicating that truncation occurred and the resulting new name.

Programming Interface Information

Whether RECOVERNEWNAMEALL or RECOVERNEWNAMELEVEL is specified, if the ARECOVER installation exit ARCSKEXT (which allows any data set to be skipped) is active, it is called, before any conflict resolution, with the original data set name of each data set to be recovered. If a data set has been renamed by the RECOVERNEWNAMELEVEL or RECOVERNEWNAMEALL parameter, but was not selected to be skipped in ARCSKEXT by the original data set name, ARCSKEXT is called again with the new data set name. This allows a data set to be skipped based on either its original or new name.

End Programming Interface Information

The optional TARGETUNIT parameter is used to specify the unit type to be allocated to user tape data sets being recovered to a tape device. If TARGETUNIT is not specified, the unit type defaults to the current value of the SETSYS ARECOVERUNITNAME parameter.

ACS routines can override this parameter by assigning a tape storage group. If this is the case, the unit name specified by these parameters is ignored.

When you use the optional TGTGDS(*option*) parameter with the ARECOVER command, it overrides the value specified by the SETSYS ARECOVERTGTGDS command. The TGTGDS parameter allows you to specify DEFERRED, ACTIVE, ROLLEDOFF, or SOURCE for the SMS-managed generation data set that you are restoring to level 0 DASD. SOURCE causes the data set to be assigned the status it had at the time it was backed up.

You may find it helpful to use the following DFSMSHsm commands to manage and query an ARECOVER command:

- HOLD ARECOVER prevents all currently queued ARECOVER commands from being processed.
- RELEASE ARECOVER releases queued ARECOVER commands that have been held by using the HOLD command or by DFSMSHsm.
- STOP causes an orderly shutdown of DFSMSHsm after any currently running ABACKUP and ARECOVER commands complete processing.
- STOP DUMP causes an immediate shutdown of DFSMSHsm. Any ABACKUP and ARECOVER commands in process are ended and the secondary address space is released.
- QUERY or HQUERY displays information relevant to aggregate recovery.
- CANCEL or HCANCEL cancels any existing queued aggregate recovery.
- LIST displays information from existing ABR records.

Examples of ARECOVER Commands

For the example site, the ARECOVER command is first issued with the PREPARE parameter:

```
ARECOVER DATASETNAME(PAY1.C.C01V0001) VOLUMES(TAPE23) -
UNIT(3490) PREPARE
```

Using the example control file, PAY1.C.C01V0001, aggregate recovery prepare is performed. The control file volume, TAPE23, is mounted on a 3490 tape unit as specified by the UNIT(3490) parameter. This action prepares the recovery site for subsequent ARECOVER processing using the aggregate group name.

The ARECOVER command is then issued with the VERIFY parameter to verify the recovery environment:

```
ARECOVER AGGREGATE(PAY1) VERIFY
```

The ARECOVER command is then issued with the EXECUTE parameter to invoke aggregate recovery processing:

```
ARECOVER AGGREGATE(PAY1) EXECUTE
```

Aggregate recovery processing is performed using the example site control file, PAY1.C.C01V0001, with a 3490 tape unit used for the control file volume, TAPE23. User tape data sets are recovered to the 3490 tape unit device type because the SETSYS ARECOVERUNITNAME(3490) command was issued previously.

The following INCLUDE data sets are recovered to DASD:

- PAY2.PY002.SOCSEC
- PAY2.PY002.STATUS.G0002V00
- PAY1.PY001.CHECK
- PAY1.PY002.IRA
- PAY1.PY001.BONUS
- PAY1.PY002.LADDER

The following INCLUDE data set is recovered to tape:

- PAY1.PY001.NAMES

The following ALLOCATE data set is allocated on a DASD:

- PAY2.PY001.BENEFIT

The following ACCOMPANY tape data set is cataloged:

- PAY2.PY001.TAXES

If the following command had been issued:

```
ARECOVER AGGREGATE(PAY1) TARGETUNIT(3400-6) EXECUTE
```

Data set PAY1.PY001.NAMES would have been recovered to a 3420 tape device. The ARECOVER TARGETUNIT parameter takes precedence over the SETSYS ARECOVERUNITNAME parameter.

If data sets were transmitted by using a transmit program such as NetView FTP, issue the following command:

```
ARECOVER DATASETNAME(PAY1.C.C01V0001) XMIT -  
TARGETUNIT(3400-6) EXECUTE
```

When the aggregate backup output files are transmitted, you must catalog the control and data files before issuing the ARECOVER command with the XMIT parameter. Transmission programs such as NetView FTP provide the option to have transmitted data sets automatically cataloged at the recovery site.

Issuing the ARECOVER command with the PREPARE parameter

To create an ABR record without the overhead of verification processing or data movement associated with the VERIFY or EXECUTE parameter, issue the ARECOVER command with the PREPARE parameter.

If you specify the PREPARE parameter and an ABR record already exists for the specified aggregate group version, and all the associated ARECOVER input files are properly cataloged, a message is issued, and the PREPARE function ends. If an ABR record already exists but one or more associated files are not cataloged, a message is issued for each file that is not cataloged, the ABR record is deleted (with an accompanying message), and the PREPARE function continues.

Once an ABR record is created, the control file, data files, and instruction/activity log files associated with the aggregate group version are cataloged, if previously uncataloged. The volumes containing these files are added to the RACF HSMABR TAPEVOL set, if necessary. Messages are issued indicating the catalog and RACF action taken.

Storage requirement messages are also written to the ARECOVER activity log during the PREPARE function.

Issuing the ARECOVER command with the VERIFY parameter

When you want only to verify the accuracy of your aggregate recovery without actually recovering the data sets, issue the ARECOVER command with the VERIFY parameter. This optional test run allows aggregate recovery to determine if any errors or data set naming conflicts exist. In the event of unresolved data set naming conflicts, aggregate recovery fails and a conflict resolution data set is created to help you resolve the conflicts. Remember, no data sets are recovered.

When performing verification processing, aggregate recovery calls installation exits ARCSKEXT and ARCCREXT, if requested and successfully loaded. ARCSKEXT allows you to specify if a data set should be skipped so that it is not included in the aggregate recovery. ARCCREXT allows you to specify how a data set naming conflict should be resolved.

If the data set naming conflicts are not resolved, the verification fails and a conflict resolution data set is created.

When processing completes, make sure that the ARECOVER command completed successfully with a return code of zero.

Related reading

For more information about the ARCSKEXT and ARCCREXT installation exits, see [“Using the aggregate recovery installation exits” on page 387](#) and [z/OS DFSMS Installation Exits](#).

Issuing the ARECOVER command with the EXECUTE parameter

When you are ready to have your data sets actually recovered, issue the ARECOVER command with the EXECUTE parameter. Aggregate recovery automatically performs preparation processing, if required, and verification processing, as described in [“Issuing the ARECOVER command with the VERIFY parameter” on page 398](#). The difference is that after verification processing completes successfully or has encountered *only* data set name conflicts, then aggregate recovery proceeds to recover your data sets. Aggregate recovery directs all messages to the aggregate recovery activity log.

When processing completes, determine if the ARECOVER command completed successfully with a return code of zero.

If the ARECOVER command has failed, as indicated by a nonzero return code, review the activity log for error messages. Correct any errors, and reissue the ARECOVER command. Repeat this process until the ARECOVER command completes successfully with a return code of zero. The restart data set, created when the ARECOVER command fails, is used when you restart the aggregate recovery. The restart data set ensures that data sets already recovered before the failure will not cause a data set conflict when you reissue the ARECOVER command.

Related reading

For more information about the files created by an aggregate recovery, see [“Aggregate recovery output” on page 411](#).

Restart data set

A restart data set is created when the ARECOVER command specified with the EXECUTE parameter does not complete successfully. The restart data set contains the names of all data sets successfully recovered. When you reissue the ARECOVER command, the restart data set ensures that aggregate recovery does not attempt to recover these previously recovered data sets. In this way, the restart data set avoids the possibility of numerous data set naming conflicts when you reissue an ARECOVER command that previously did not complete successfully. The format of the restart data set name is: *authid.agname.RESTART.Dyyddd.Thhmmss*

The variables in the restart data set name are explained:

authid

DFSMSHsm-authorized user ID.

agname

Aggregate group being processed.

yddd

Date that the specific aggregate backup for this aggregate recovery was performed.

hhmmss

Time that the specific aggregate backup for this aggregate recovery was performed.

Tip: The error that caused the aggregate recovery to fail may have prevented the restart data set from being closed and cataloged. If this happens, you must manually close and catalog the restart data set so that it is available to aggregate recovery when it is restarted. Message ARC6111I in the activity log identifies the restart data set name.

Issuing the ARECOVER command with the ONLYDATASET parameter

You can use the ARECOVER command to recover individual data sets from an aggregate backup version. You can specify a single fully qualified data set name on the ARECOVER command to recover a particular data set. To recover multiple data sets, you can supply the name of a data set that contains a list of data set names to be recovered from a specific aggregate backup version. Examples of each are provided in this topic.

As an alternative to the ARECOVER command, you can perform these tasks through ISMF panels, as described in [“Using ISMF to recover individual data sets from an aggregate backup” on page 426](#).

Recovering an individual data set from an aggregate backup

To recover one data set from an aggregate backup version, enter the ARECOVER command with the ONLYDATASET parameter specified with the NAME subparameter:

```
ARECOVER ONLYDS(NAME(MY.OWN.DATASET))
```

In this example, *MY.OWN.DATASET* is the fully qualified name of the data set to be recovered from the aggregate version.

Recovering a group of data sets from an aggregate backup

To recover a group of data sets from an aggregate backup version, do the following:

1. Create a data set to use as the list of data sets to be recovered during ARECOVER processing. The data set must be a sequential data set, fixed-block, with a record size of 80, and be cataloged.
2. Edit the data set with the names of data sets to be recovered during ARECOVER processing. Specify one fully qualified data set name per record.
3. Enter the ARECOVER command with the ONLYDATASET parameter specified with the LISTOFNAMES subparameter:

```
ARECOVER ONLYDS(LON(MY.DATASET.LIST))
```

In this example, *MY.DATASET.LIST* is the fully qualified name of the data set that contains a list of data sets to be recovered from the backup copy of an aggregate group.

Recovering the ABARS instruction data set

You can use the INSTRUCTION parameter instead of a DFSMSdss batch job to recover the ABARS instruction data set.

ABACKUP considerations

If an instruction data set is specified in the aggregate group, DFSMSdss is used to write the instruction data set and the activity log data set (if DASD logging is specified), onto one file on a tape (or tapes). To save the volume serial numbers of this file in the control file, the instruction and activity log files are written before the control file. For coexistence with prior releases and for usability, the control file is the first file on the tape. Because of this necessity, the instruction and activity log files are written on a separate tape from the control file.

If an instruction data set is not specified in the aggregate group, the instruction data set name is left blank in the ABR record. A “DUMMY” instruction/activity log file is not created.

ARECOVER considerations

Specifying INSTRUCTION with the EXECUTE, VERIFY, or PREPARE parameters causes recovery of the instruction data set, if it exists. If the instruction data set does not exist when INSTRUCTION is specified, an informational message is issued and ARECOVER processing continues.

When the INSTRUCTION parameter is specified and DFSMSShsm ascertains that an instruction data set has been backed up, the following instruction and activity log file information is determined:

- If the DATASETNAME and VOLUMES parameters are used with the ARECOVER command, the control file is read to determine which volume serial numbers the instruction/activity log file resides on.
- If the DATASETNAME and XMIT parameters are used with the ARECOVER command, a check is made to ensure that the instruction/activity log file is cataloged.

Note: If installations use a utility to convert their existing aggregate backup output files from one tape technology to another, ensure that the newly created tapes are catalogued at the recovery site with the newly created unit name and volume serial number, and use the XMIT parameter on the ARECOVER

command. The XMIT parameter ensures that ARECOVER processing retrieves the allocation information for the ABARS files from the catalog rather than using the volser and unit stored on the control file tape.

- If the parameter AGGREGATE is used with the ARECOVER command, a check is made to ensure that the instruction/activity log file is cataloged.

If the instruction data set exists on an output tape, DFSMSdss is invoked to perform the RESTORE of the instruction data set onto a level 0 volume from the ARPOOL. If the instruction data set currently exists, it is replaced.

If the recovery of the instruction data set fails, or if the INSTRUCTION parameter is specified and there is no instruction data set on the output tape, a message is issued and processing continues.

Backing up and recovering the ABARS activity log

Since there is useful information in the ABACKUP activity log that can be used at the aggregate recovery site, ABARS includes the ABACKUP activity log data set with the instruction data set as a new file on a separate output tape.

The SETSYS ABARSACTLOGTYPE parameter

The SETSYS command ABARSACTLOGTYPE ([SYSOUT[(*class*)] | DASD]) is provided to select the ABARS activity log output data set type. If SETSYS ABARSACTLOGTYPE is not issued, it defaults to the type specified in the SETSYS ACTLOGTYPE command.

- SYSOUT(*class*) specifies that messages are written to a spool data set. For *class*, substitute an alphanumeric character for the class ABARS uses for output. If *class* is not specified, the default is the SETSYS ACTLOGTYPE SYSOUT class. If ACTLOGTYPE has been set to DASD, the ABARSACTLOGTYPE class defaults to the SETSYS SYSOUT class, which in turn defaults to "A".
- DASD specifies that an output data set is dynamically created and cataloged.
- SYSOUT is the initial default setting. If SETSYS ABARSACTLOGTYPE has not been issued, each time SETSYS ACTLOGTYPE is issued it makes the corresponding change to the setting of ABARSACTLOGTYPE.

Note: Once SETSYS ABARSACTLOGTYPE is issued, any subsequent SETSYS ACTLOGTYPE command does not affect the ABARSACTLOGTYPE.

The DFSMSHsm QUERY command, with the SETSYS or ABARS parameter specified, can determine and display the value specified in the ABARSACTLOGTYPE(*type*) parameter.

Conflict avoidance and conflict resolution processing options

The RECOVERNEWNAMELEVEL(*olevel*,*nlevel*) and RECOVERNEWNAMEALL(*level*) parameters provide options that allow you to avoid known data set name conflicts when you issue the ARECOVER command. Specifying these parameters, however, does not guarantee that a data set name conflict for a newly generated name will not occur. If the use of either of these parameters results in a data set name conflict, then conflict resolution processing that involves the newly generated name is invoked as shown in the following table.

**If you specify RECOVERNEWNAMELEVEL or RECOVERNEWNAMEALL and Then
you have also specified**

DATASETCONFLICT(RENAMETARGET(*level*))

The data set that exists at the recovery site is renamed by using the high-level qualifier specified in the RENAMETARGET(*level*) parameter, and the ABACKUP data set is recovered using the newly generated name as specified by the RECOVERNEWNAME parameter.

If you specify RECOVERNEWNAMELEVEL or RECOVERNEWNAMEALL and Then
you have also specified

DATASETCONFLICT(RENAMESOURCE(<i>level</i>))	<p>The data set is recovered with the data set name generated by using the high-level qualifier specified with the RENAMESOURCE(<i>level</i>) parameter.</p> <p>In this case, the high-level qualifier specified with the RENAMESOURCE parameter will override the high-level qualifier of the data set name that was originally backed up, along with the high-level qualifier generated by the RECOVERNEWNAMELEVEL or RECOVERNEWNAMEALL parameters.</p>
DATASETCONFLICT(REPLACE)	<p>The existing data set at the recovery site is deleted, and the data set is recovered with a data set name that uses the high-level qualifier specified with the RECOVERNEWNAMELEVEL or RECOVERNEWNAMEALL parameters.</p>

ARECOVER data set name conflict resolution

DATASETCONFLICT parameter

The optional DATASETCONFLICT parameter of the ARECOVER command allows more flexibility for conflict resolution options. This parameter applies to INCLUDE, ALLOCATE, and ACCOMPANY data sets, with some restrictions. Like-named conflicts are evaluated based on the new name for any data sets renamed by RECOVERNEWNAMEALL or RECOVERNEWNAMELEVEL.

The following subparameters of DATASETCONFLICT specify the action to be taken when a like-named conflict is found during ARECOVER verification.

- If you specify RENAMESOURCE(*level*), the ABACKUP data set is recovered with the new high-level qualifier specified by *level*.
- If you specify RENAMETARGET(*level*), the existing data set at the recovery site is renamed with the specified high-level qualifier, and the ABACKUP data set is recovered with its original name.
RENAMETARGET(*level*) performs an ALTER NEWNAME for the existing data set name. Special care should be taken when you change the high-level qualifier so that the existing data set does not become uncataloged, which may occur when no catalog alias exists for the new high-level qualifier.
- If you specify REPLACE, the existing data set at the ARECOVER site is deleted, and the ABACKUP data set is recovered.
- If you specify BYPASS, the ABACKUP data set is skipped and not recovered.
- BYPASS
- RENAMETARGET (if target data set restrictions are met)
- RENAMESOURCE (not supported for ACCOMPANY data sets)

If one or more verification errors occur (and are not resolved), the data sets receiving the verification errors are not recovered, but (when EXECUTE has been specified) processing continues. This causes a RESTART data set to be created. Data sets that did not receive verification errors are recovered.

Related reading

- For more information about using the DSCONFLICT parameter on ARECOVER to allow the EATTR information from the ABACKUP site to be restored, see [“EAV considerations for recovery functions” on page 15](#).
- For more information about the ALTER NEWNAME function, see [z/OS DFSMS Access Method Services Commands](#).

Conflict resolution data set

The use of the IDCAMS command data set is no longer valid. A conflict resolution data set is generated by ARECOVER to simplify the resolution of like-named conflicts discovered during ARECOVER verification.

Each time ARECOVER verification processing cannot resolve a like-named conflict for a data set, the data set name is written to the conflict resolution data set with a default action of BYPASS. A message is issued indicating the name of the conflict resolution data set that was created. The name is generated as follows:
id.agname.CONFLICT.Dyyddd.Thhmmss

The variables in the conflict resolution data set name are explained:

id

DFSMSHsm authorized user ID.

agname

Name of the aggregate group being recovered.

yyddd

Julian date the ABACKUP was performed.

hhmmss

Time the ABACKUP was performed.

The aggregate group name, ABACKUP date, and ABACKUP time are used to make this conflict resolution data set unique to the recovery of a specific ABACKUP version.

An example of a conflict resolution data set is shown in [Figure 52 on page 403](#). It is a physical sequential data set with fixed-length 80 byte records.

```

/* CONFLICT RESOLUTION DATA SET                               */
/* AGGREGATE GROUP=agname, VERSION=nnnn                        */
/* SPECIFY datasetname action ON EACH LINE                    */
/* VALID ACTIONS ARE BYPASS, REPLACE,                         */
/* RENAME SOURCE(level) or RENAMETARGET(level)                */
DATASETNAME1 BYPASS
DATASETNAME2 BYPASS
:
```

Figure 52. Conflict Resolution Data Set

To indicate different conflict resolution actions taken by ARECOVER verification processing for each data set entry in the conflict resolution data set, you may edit the conflict resolution data set before issuing the next ARECOVER command. As shown in [Figure 52 on page 403](#), the format of one line of the conflict resolution data set is a data set name followed by the action to be taken. The syntax of the action is the same as that of the ARECOVER command DATASETCONFLICT subparameters. Valid actions are RENAME SOURCE(*level*), RENAMETARGET(*level*), REPLACE, and BYPASS. Not all actions are valid for all data sets, based on restrictions discussed in topic [“Order of processing for conflict resolution” on page 406](#).

When a subsequent ARECOVER command is issued and the conflict resolution data set exists, it is read and used as input to the verification process. If the conflict resolution data set does not meet format restrictions, a message is issued and ARECOVER processing continues, but ends following verification processing, even if EXECUTE has been specified. The conflict resolution data set is ignored during the verification process when this error occurs.

The lines containing conflict resolution actions are parsed for valid syntax, and data set names or qualifiers are also parsed for validity. If invalid syntax is found, or a data set name entry in the conflict resolution data set does not match the name of a data set entry in the ARECOVER control file, or a data set name entry is a duplicate of another entry, a message is issued and ARECOVER processing continues, ignoring the erroneous entries during verification processing.

When a like-named conflict is found for a data set name that has an entry in the conflict resolution data set, the action specified in the conflict resolution data set is used to attempt to resolve the conflict.

When VERIFY is specified, the action is not actually performed, but restrictions are validated. If the action in the conflict resolution data set is invalid for the data set, a message is issued indicating this, and if the conflict is not resolved by other conflict resolution processing, the data set fails verification. The verification process continues with the next data set.

When you use the ARECOVER command with the VERIFY parameter, a conflict resolution data set may be created. This conflict resolution data set contains entries for data sets that had a name conflict during verification processing, and a default action of BYPASS is indicated for these data sets. If you determine that the conflicts can be handled by either the RECOVERNEWNAMEALL, RECOVERNEWNAMELEVEL, or DATASETCONFLICT parameters on a subsequent ARECOVER command, then you delete the conflict resolution data set before issuing the command. If this deletion is not done, ARECOVER processing uses the conflict resolution data set action of BYPASS, and the data sets are skipped.

When EXECUTE is specified, the conflict resolution action is validated. If valid, the action is performed during data movement. If the action in the conflict resolution data set is invalid for the data set, a message is issued indicating this. If the conflict is not resolved by other conflict resolution processing, the data set fails verification, and is not recovered. ARECOVER EXECUTE processing continues for the remaining data sets. If an error occurs while performing the action during EXECUTE processing, a message is issued, and the data set is bypassed and not recovered.

When EXECUTE is specified, if all conflicts are resolved, and if all data sets in the aggregate group have been recovered—not bypassed through use of the conflict resolution data set—the conflict resolution data set and the RESTART data set are deleted. Data sets which are bypassed by a conflict resolution data set action of BYPASS cause the RESTART data set and conflict resolution data set to be retained and a unique return code to be set. The bypass of these data sets may be intentional, but since the default action placed in the conflict resolution data set is BYPASS, and the default is also to use the conflict resolution data set if it exists, the data sets may be bypassed unintentionally. In this case, deletion of the conflict resolution data set and RESTART data set would make the recovery of the remaining data sets difficult. If your analysis at this point shows that all desired data sets have been recovered, you may then manually delete the RESTART data set and conflict resolution data set.

If the conflict cannot be resolved, an entry is added to the conflict resolution data set indicating a default action of BYPASS (if there is not an entry already, no duplicate entries are created and the action for a current entry is NEVER modified). The data set is not recovered and processing continues. An entry is *only* added to the conflict resolution data set if the conflict cannot be resolved by *any* of the preceding actions.

If the conflict has been found for a component of a VSAM data set being verified, the source VSAM cluster name is added to the conflict resolution data set (not the individual component names).

If the data set has been renamed before verification by a RECOVERNEWNAMEALL or RECOVERNEWNAMELEVEL subparameter, the original data set name is used for the entry in the conflict resolution data set.

Each data set successfully verified is recovered if the EXECUTE parameter is specified.

The following conflict resolution actions are supported.

- RENAMESOURCE(*level*)

Verification checks to see if a data set is already cataloged with the new name at the recovery site. If the source data set is a GDS, neither a GDS generation nor a related GDG base may exist for the new name (a unique message is issued indicating GDS/GDG base conflicts). Before recovery of a renamed GDS generation, a GDG base is defined with the proper new name by using the attributes of the source GDG base. If no like-named conflict is found for the new data set name, the data set is renamed when it is recovered with the new high-level qualifier.

If the new name would cause a like-named conflict, an appropriate message is issued and the data set is not recovered. If the original data set name is not already in the conflict resolution data set, an entry is created indicating the default action of BYPASS.

The RENAMESOURCE subparameter is not supported for ACCOMPANY data sets, or for migrated VSAM source data sets. In each case, a message is issued and the data set is not recovered. If the original data set name is not already in the conflict resolution data set, an entry is created indicating the default action of BYPASS.

- RENAMETARGET(*level*)

Verification checks the attributes of the existing data set cataloged at the recovery site. If the target data set is one of the following, a message is issued, the target data set is not renamed, and an entry in the conflict resolution data set for the original data set name is created, indicating the default action of BYPASS.

- tape data set
- catalog
- GDS
- GDG base

In addition, the target data set **MUST** be one of the following to be eligible for rename:

- non-VSAM DASD
- VSAM base cluster
- VSAM alternate index (AIX)
- Data component, index component, or path related to a VSAM cluster or AIX (but not related to a catalog)

If the target object in conflict is a component or path related to a VSAM cluster or AIX, the entire target cluster, including component associations, is renamed.

Verification checks to see if a data set is already cataloged at the recovery site with the new name. If so, an appropriate message is issued, the target data set is not renamed, and the data set is not recovered. If the original data set name is not already in the conflict resolution data set, an entry is created indicating the default action of BYPASS.

If the data set meets restrictions for renaming and EXECUTE is specified, the existing data set at the recovery site is renamed. A message is issued indicating the action taken. When the conflict occurs for a component of a target VSAM data set, the entire target cluster, including associated components, is renamed. The indicated new high-level qualifier is used to rename the target objects. The ABACKUP data set is recovered with the original name. When the target data set is migrated, the RENAMETARGET action causes it to be recalled. If the rename action fails, a message is issued, and the data set is not recovered. If the original data set name is not already in the conflict resolution data set, an entry is created indicating the default action of BYPASS.

RENAMETARGET(*level*) performs an ALTER NEWNAME for the existing data set name. Special care should be taken when you change the high-level qualifier so that the existing data set does not become uncataloged, which may occur when no catalog alias exists for the new high-level qualifier.

- BYPASS

The data set is not recovered during data movement. When a conflict occurs for a component of a source VSAM data set, the entire source VSAM cluster is bypassed and not recovered. A message is issued indicating the action taken.

- REPLACE

Verification checks to see if the existing data set at the recovery site meets restrictions for data sets that may be deleted. If restrictions are not met, a message is issued, and the data set is not recovered. If the data set name is not already in the conflict resolution data set, an entry is created indicating the default action of BYPASS.

Note: When using the DSCONFLICT(REPLACE) parameter, the data set is deleted before attempting the recovery of the data set from the aggregate backup output files. If the recovery fails, the data set remains deleted. Causes of recovery failure include:

- I/O errors on the input tape
- Failure to allocate the new data set
- Recovering at a site that does not support the type of data set that is being recovered

If a GDG base exists and DSCONFLICT(REPLACE) has not been specified, recovery of the associated GDSs fails and an entry is placed in the conflict resolution data set with a default action of BYPASS.

If restrictions are met and EXECUTE is specified, the data set at the recovery site is deleted. When a conflict occurs for a component of a source VSAM data set, the entire target VSAM cluster related to the object in conflict is deleted. A message is issued indicating the action taken. If the delete for the REPLACE subparameter fails, a message is issued and the data set is not recovered. If the original data set name is not already in the conflict resolution data set, an entry is created indicating the default action of BYPASS.

ARCCREXT installation exit

Programming Interface Information

If the like-named conflict has not yet been resolved, and the installation exit ARCCREXT is active, the exit is called to attempt to resolve the conflict. If a conflict is found for a component of a source VSAM cluster being verified, only the source VSAM cluster name is passed to the installation exit. The action specified for the VSAM cluster name is used to resolve the conflict for the entire related VSAM cluster.

The installation exit passes back a return code to indicate what action to take to resolve the conflict. If the installation exit returns an invalid action for the data set, a message is issued and the data set is not recovered. If the original data set name is not already in the conflict resolution data set, an entry is created indicating the default action of BYPASS.

Return codes indicate the following actions:

- 0 = no action
- 4 = bypass the data set
- 8 = replace the existing data set
- 12 = rename the source data set (the exit specifies the new name)
- 16 = rename the existing data set at the recovery site with the returned new high-level qualifier before recovery. The source data set is recovered with the original name. This action is comparable to the DATASETCONFLICT RENAMETARGET(level) parameter.

End Programming Interface Information

Migrated non-VSAM data sets can be renamed if only the high-level qualifier of the data set name is changed. Using this exit to rename more than just the data set's high-level qualifier causes an error (message ARC6325E) and the data set will not be processed during ARECOVER.

After conflict resolution processing for all data sets in the control file during verification and before actual data movement, a check is done to verify that no data sets to be recovered are renamed to the same name as another data set entry in the control file. When a data set name is renamed to the same name as an original source data set also being recovered, it is not renamed or recovered. When two or more data sets are renamed to the same name, only the first one is renamed and recovered. Error messages are issued for the other data sets that do not get recovered.

If all verification errors are resolved during ARECOVER EXECUTE processing, the conflict resolution data set is deleted.

DFSMSHsm allows a single ARECOVER to invoke DFSMSdss multiple times to RESTORE all required data sets. Two hundred fifty-five data sets are renamed per invocation of DFSMSdss, until all data sets have been recovered.

Order of processing for conflict resolution

A like-named conflict is identified when a catalog entry exists at the recovery site with the same name as the data set being recovered.

During like-named conflict checking, if the data set being recovered is a VSAM data set, each component of the source VSAM data set is used to locate a like-named conflict. The action taken to resolve the conflict is discussed below under each conflict resolution subparameter.

If a like-named conflict is detected, the conflict is resolved by the following order of conflict resolution actions:

1. If a conflict resolution data set exists and contains an entry for the data set in conflict, the requested action is validated.

If valid, a message is issued indicating an action to take to resolve the conflict during EXECUTE processing. If the action is invalid, a message is issued indicating this, and conflict resolution processing is continued for the data set.

If the conflict was found for a component of a VSAM data set, an entry must be found in the conflict resolution data set for the related source VSAM cluster name. If found, the action specified for the related source VSAM cluster name is used to resolve the conflict for the cluster and all the components.
2. If the conflict is not yet resolved, and the DATASETCONFLICT parameter is specified on the ARECOVER command, the requested action is validated.

If valid, a message is issued indicating an action to take to resolve the conflict during EXECUTE processing. If the action is invalid, a message is issued indicating this, and conflict resolution processing is continued for the data set.
3. If the conflict is not yet resolved and the installation exit ARCCREXT is active, the exit is called to resolve the conflict. The requested action is validated. If valid, a message is issued indicating an action to take to resolve the conflict during EXECUTE processing. If the action is invalid, a message is issued indicating this.

RACF facility class authorization checking

RACF facility class checking supports the DATASETCONFLICT subparameters of REPLACE and RENAMETARGET. When either of these actions is specified through the installation exit ARCCREXT, or through the conflict resolution data set, the user must have the same facility class authorization as when these subparameters are specified on the ARECOVER command.

When facility class authorization is denied for either REPLACE or RENAMETARGET specified as a subparameter of the DATASETCONFLICT parameter on the ARECOVER command, ARECOVER processing fails and a message is issued.

When facility class authorization is denied for REPLACE or RENAMETARGET specified as an action in the conflict resolution data set or in the installation exit ARCCREXT, ARECOVER verification processing fails for the individual data set, and a message is issued. Other data sets not receiving verification errors are processed as ARECOVER continues.

RACF data set authorization is checked before processing the REPLACE or RENAMETARGET action for individual data sets during ARECOVER verification processing, to obtain further security if restricted facility class authorization is indicated. Restricted facility class authorization is indicated when the user has READ or greater access to the following facility class profiles (where applicable):

- STGADMIN.ARC.ARECOVER.agname.REPLACE
- STGADMIN.ARC.ARECOVER.agname.RENTGT

When restricted facility class authorization is indicated, RACF ALTER access authority is required for individual data sets when conflict resolution indicates an action of REPLACE or RENAMETARGET for the existing data set at the ARECOVER site. If RACF access authority is denied, a message is issued and the data set fails verification processing, unless another conflict resolution action (BYPASS or RENAMESOURCE) is selected through the normal order of conflict resolution processing. Remaining data sets are verified and recovered if verification is successful.

The hierarchy of facility class command authorization is determined as follows:

1. Facility class must be active. If not active, the ARECOVER command fails if the user is not DFSMSshm-authorized.
2. If facility class is active but the appropriate profiles are not defined, processing continues as if facility class were inactive. The ARECOVER command fails if the user is not DFSMSshm-authorized.

3. ARECOVER processing checks for restricted authority. Restricted command authority is granted when the user is authorized to the following facility class profiles with an access authority of READ or greater.
 - STGADMIN.ARC.ARECOVER.agname
 - STGADMIN.ARC.ARECOVER.agname.REPLACE (for REPLACE)
 - STGADMIN.ARC.ARECOVER.agname.RENTGT (for RENAMETARGET)

When restricted command authority is indicated, RACF data set authorization checking is performed each time a conflict is detected during ARECOVER verification processing, and a conflict resolution action of REPLACE or RENAMETARGET is selected. The user must have ALTER access to the data set to allow the conflict resolution action to be taken.

4. If restricted authority is not granted, ARECOVER processing checks for comprehensive command authority. Comprehensive authority is granted when a user is authorized to the STGADMIN.ARC.ARECOVER Facility Class profile, with an access authority of READ or greater.

When comprehensive authority is granted, RACF data set authorization checking is not performed during ARECOVER processing.

Holding and releasing ABARS functions

The DFSMSHsm HOLD and RELEASE commands can be used to stop, hold, and release certain aggregate backup and aggregate recovery functions.

Related reading

- For more information about the HOLD command, see [Chapter 50, “HOLD command: Preventing DFSMSHsm functions from running,” on page 895.](#)
- For more information about the RELEASE command, see [Chapter 62, “RELEASE command: Releasing all or some DFSMSHsm functions for processing,” on page 1029.](#)

Holding ABARS functions

You can use the DFSMSHsm HOLD command to hold ABARS functions and to designate a specific aggregate group or control file data set name to be held. The commands HOLD ABACKUP or HOLD ARECOVER may be used to hold ABARS functions, and the commands HOLD ABACKUP(*agname*) or HOLD ARECOVER [DATASETNAME(*controlfiledsn*) | AGGREGATE(*agname*)] may be used to hold a specific aggregate group or control file within the ABARS functions.

If the HOLD EOD option is specified for ABACKUP or ARECOVER, the following processing takes place:

Note: If an aggregate group or control file data set name is specified, this processing takes place only when the specified name matches a currently running or pending ABACKUP or ARECOVER command.

- Currently executing ABACKUP or ARECOVER commands are stopped, at the end of processing a data set, and are not requeued for processing. Data sets and tapes are closed and deallocated, all memory is freed, and processing is immediately terminated.
- If the HOLD EOD option is specified for a currently running ABACKUP command, the ABACKUP output files are uncataloged and the tape volume serial numbers are removed from the HSMABR tape connected set if they are indicated to be RACF protected.
- Pending ABACKUP or ARECOVER commands that were submitted without using the WAIT option are held. They remain in the queue and are not executed until a RELEASE command is issued.
- Pending ABACKUP or ARECOVER commands submitted using the WAIT option are failed with an accompanying error message.

If the HOLD command is specified for the ABACKUP or ARECOVER function (without the EOD option), the following processing takes place:

Note: If an aggregate group or control file data set name is specified, this processing takes place only when the specified name matches a currently running or pending ABACKUP or ARECOVER command.

- Currently executing ABACKUP or ARECOVER commands run to completion. If an aggregate group or control file data set name has been specified, subsequent commands for that name are held.
- Pending ABACKUP or ARECOVER commands submitted without using the WAIT option are held. They remain in the queue and are not executed until a RELEASE command is issued.
- Pending ABACKUP or ARECOVER commands submitted using the WAIT option are failed with an accompanying error message.

When the HOLD command is specified for an ABACKUP or ARECOVER command using an aggregate group or control file data set name and the command is neither running nor pending, subsequent commands issued using that name are held.

Note: During ABACKUP processing, if the control file has already been written and a HOLD EOD is issued, ABACKUP completes normally. However, if ABACKUP has been issued with the MOVE option, ABACKUP will be held.

Releasing held ABARS functions

The RELEASE command, used with the ALL, ABACKUP, or ARECOVER parameters, releases a held ABARS function. The RELEASE command also can be used to specify the aggregate group name for ABACKUP and the aggregate group or control file name with the (ARECOVER AGGREGATE | ARECOVER DATASETNAME) parameter. The previously held ABARS function is released.

Querying held ABARS functions

You can use the QUERY ACTIVE command to perform the following tasks:

- List active ABACKUP or ARECOVER commands with their associated aggregate group or control file name
- Indicate if ABARS is active or inactive
- Indicate whether ABACKUP and ARECOVER is held, not held, or held EOD
- Indicate the specific ABACKUP(*agname*) and ARECOVER [AGGREGATE(*agname*) | DATASETNAME(*controlfiledsn*)] commands that are held

Displaying SMS class definitions during ABACKUP and ARECOVER

During DFSMSHsm ABACKUP processing, a list of SMS construct names—along with individual class definitions for the SMS data, management, and storage classes associated with the data sets in the aggregate group being processed—are written to the control file.

During subsequent ARECOVER processing, a message is issued to the ARECOVER activity log listing the attributes of each SMS data class, management class, and storage class definition present at the ABACKUP site. This allows the recovery site to make any necessary changes to either existing SMS constructs or the SMS environment.

If, however, it is determined that the ABACKUP activity log has been recovered by the ARECOVER command specified with the ACTIVITY parameter (see [“Backing up and recovering the ABARS activity log” on page 401](#)), the SMS construct definitions are not listed in the ARECOVER activity log.

Note:

1. Use the VERIFY or PREPARE option of the ARECOVER command before the EXECUTE option. By doing this, you can determine SMS class definitions, and any needed changes can be made to the SMS environment before actual data movement.
2. Use the ACTIVITY option for ARECOVER as an alternative method of retrieving the SMS construct information (see [“Backing up and recovering the ABARS activity log” on page 401](#)). By using this method, you can obtain SMS construct information from the ABACKUP activity log, if DASD logging has been specified.

ABARS user catalog and catalog alias ARECOVER support

If user catalogs have been specified in the allocate list during aggregate backup, the catalog data and alias definitions are stored in the control file and used by DFSMSHsm during aggregate recovery to define the catalog and its aliases at the recovery location.

The RECOVERNEWNAMEALL and RECOVERNEWNAMELEVEL parameters do not apply to user catalogs in the ALLOCATE list. This restriction prevents conflicts in defining an alias that is the same as the new high-level qualifier.

If the catalogs specified in the ALLOCATE list have conflicts with existing data set names, aggregate recovery verification processing must ensure that these conflicts are resolved with either the conflict resolution data set, the DATASETCONFLICT parameter of the ARECOVER command, or through the invocation of the conflict resolution installation exit ARCCREXT.

All conflict resolution actions are supported to resolve a like-named conflict for a catalog to be recovered, provided the restrictions for each action are met, as discussed in [“ARECOVER data set name conflict resolution” on page 402](#). (The most notable restriction is that RENAMETARGET and REPLACE are not allowed when the existing data set is a catalog.)

If all catalog name conflicts are not resolved, verification fails. An error message is issued for each unresolved catalog conflict. A default entry (BYPASS) is *not* added to the conflict resolution data set, since a catalog recovery should not be bypassed as the default. (The user may, however, manually add an entry in the conflict resolution data set to resolve the catalog name conflict.) The remaining verification is completed, and the ARECOVER processing ends. No further processing takes place, even if EXECUTE was specified.

The alias definitions associated with the user catalogs in the ALLOCATE list must be checked against the current catalog structure at the aggregate recovery site, to ensure the alias is not already defined to an existing catalog. If the alias is already defined, an error message is issued during aggregate recovery verification processing. This error message indicates to which catalog this alias is already defined. Aggregate recovery verification is not failed, but the particular alias definition is not issued.

If any user catalogs have been renamed during conflict resolution RENAMESOURCE processing, the new high-level qualifier must be checked against any aliases not yet defined to ensure that no like-named conflicts exist. If conflicts exist, a message is issued and the renamed user catalog is not recovered unless the conflict can be resolved through means other than RENAMESOURCE.

The DEFINE of the user catalogs in the ALLOCATE list and the DEFINE for the associated ALIASES are performed before the data sets for the particular aggregate are recovered. This allows the data sets in the aggregate being recovered to be cataloged in these catalogs if the data sets have an alias defined to one of these catalogs.

Note: ABARS does not allow multiple defines of aliases at the recovery location. If an alias is defined to a catalog being recovered and a catalog already in existence, the catalog in existence takes precedence.

The aggregate recovery verification step lists the user catalogs contained in the control file and all of the aliases defined to those catalogs. This action is performed when the user specifies the ARECOVER command with the VERIFY parameter.

Data sets that are dynamically allocated during aggregate recovery processing

In addition to the RESTART and conflict resolution data sets, DFSMSHsm dynamically allocates the following data sets during aggregate recovery processing. These data sets are used while aggregate recovery is executing and are dynamically deallocated before completion of aggregate recovery processing. These data sets are allocated with a unit type of SYSALLDA. (If they are non-SMS-managed, you must have at least one STORAGE- or PUBLIC-type device online to use the system, and if they are SMS-managed, your ACS routine must assign them to a storage group that contains storage-type volumes.) You need to be aware of these data set names so that the high-level qualifiers used by ABARS can be defined to the system. You may want to modify your ACS filters to direct allocation of these data sets to specific volumes.

SYSIN data set

The SYSIN data set is used to pass RESTORE parameters to DFSMSdss. The SYSIN data set name is: *authid.SYSIN.agname.Thhmmss*

The variables in the data set name are explained:

authid

DFSMSHsm-authorized user ID.

agname

Aggregate group name being processed.

hhmmss

Hours, minutes, and seconds.

FILTER data set

The FILTER data set is used to pass a list of data set names to DFSMSdss. The FILTER data set name is: *authid.FILTER.agname.Thhmmss*

The variables in the data set name are explained:

authid

DFSMSHsm-authorized user ID.

agname

Aggregate group name being processed.

hhmmss

Hours, minutes, and seconds.

Aggregate recovery output

The activity log, recovered data sets, FSR records, updated catalog entries, GDG base definitions, and updated DFSMSHsm CDS records are the output of aggregate recovery.

The conflict resolution data set and the restart data set are the output of the ARECOVER command when data set conflicts or errors occur. These have been described in previous topics. See [“Restart data set” on page 399](#).

Activity log

An activity log is created each time you issue the ARECOVER command. You may find the activity log useful because it contains messages output during aggregate recovery processing.

The format of the activity log data set name is:

mcvtactn.Hmcvthost.ARECOVER.agname.Dyyddd.Thhmmss

The parts in the data set name are explained:

mcvtactn

Field in the MCVT that contains the value stored for the activity log high-level qualifier. The default value is HSMACT.

Hmcvthost

DFSMSHsm host identification.

ARECOVER

Constant for aggregate recovery.

agname

Aggregate group being processed.

Dyyddd

The date.

Thhmmss

The time.

The activity log is written to either a SYSOUT or DASD data set as determined by the ABARSACTLOGTYPE parameter of the SETSYS command. If you specify DASD and the allocation attempt fails, an attempt is made to allocate the activity log to SYSOUT. See [“Defining SETSYS parameters for aggregate recovery” on page 384](#) for more information on setting the activity log output type.

Here is a partial example of the aggregate recovery activity log:

Recovered data sets at the example aggregate recovery site

At the example site, the following data sets have been recovered to the DASD volumes specified:

- Recovered to an SMS-managed volume:
PAY2.PY002.SOCSEC
- Recovered to the level 0 volume PRIM02:
PAY2.PY002.STATUS.G0002V00
PAY1.PY001.CHECK
- Recovered to the migration volume MIG102:
PAY1.PY002.IRA
PAY1.PY001.BONUS
PAY1.PY002.LADDER

The following data sets have been recovered to tape:

- PAY1.PY001.NAMES

Data set PAY2.PY001.BENEFIT has been allocated to the level 0 volume PRIM02. Data set PAY2.PY001.TAXES has been cataloged.

ARECOVER CPU time and accounting codes

ABARS records the CPU time for processing ABACKUP and ARECOVER requests. This information is written to the FSR control block. The FSR can be written as an SMF record if the installation specifies SETSYS SMF(*smfid*). ABARS then writes the FSR as *smfid* + 1 in the SYS1.MANx or SYS1.MANy system data sets.

The ABACKUP CPU time and ARECOVER CPU time are also recorded in the ABR record. There is a difference, however, between the ARECOVER CPU time recorded in the FSR control block and the ABR record. If an ARECOVER request fails and is reissued with a valid RESTART data set, the CPU time in the FSR only reflects the time to process the remaining data sets. The ABR record accumulates the CPU times of each restart until the recovery of the aggregate is successful.

The ISMF aggregate group definition panel allows you to specify an accounting code for an aggregate group. The accounting code gets written to the FSR control block (and associated SMF record where one exists) along with the ABACKUP and ARECOVER CPU processing time for the aggregate. Installations can then use the information to assist in calculating charges to users for ABARS requests.

The accounting code is also written to the ABR record, and the ABACKUP control file. It is written to the ABACKUP control file so the code can be used at the recovery site without requiring an aggregate definition at the recovery site.

The accounting code is optional, and can be up to 32 characters in length. Valid characters are alphanumeric characters, blanks, commas, periods, parentheses, hyphens, slashes, ampersands, and apostrophes (single quotes).

Using ISMF panels to perform aggregate backup

You can use ISMF panels to process aggregate backup instead of issuing the ABACKUP command. You can specify the DFSMSdfp; Aggregate Group Application Selection panel from TSO and use either the LIST or the ABACKUP option for aggregate group backup.

Use the ABACKUP option when you know the aggregate group name you want to back up.

Use the LIST option when you are unsure of the aggregate group name you want to back up or when you want to back up more than one aggregate group.

In the example system, ACTIVE is used for the CDS NAME and the aggregate group name PAY1 is backed up to a 3490 tape unit. Two methods of performing aggregate backup, using either the ISMF LIST or the ISMF ABACKUP option, are shown.

Using the ISMF LIST option to perform aggregate backup

To use the LIST option for aggregate backup, use TSO ISPF panels to access the DFSMSdfp; Aggregate Group Application Selection panel, shown in [Figure 53 on page 414](#).

```

                                AGGREGATE GROUP APPLICATION SELECTION
COMMAND ===> _

TO PERFORM AGGREGATE GROUP OPERATIONS,SPECIFY:

CDS NAME                ===> 'ACTIVE'                (1 to 44 character dataset name)

AGGREGATE GROUP NAME ===> *                (for Aggregate Group List, fully or

Figure 55. Aggregate Group Backup Panel

On the Aggregate Group Backup Panel, you do not need to enter the CDS NAME or the AGGREGATE GROUP NAME; they are carried over from the previous panel.

Note: You can change the aggregate group name and initiate backup for another aggregate group from this panel.

On the Aggregate Group Backup Panel:

1. Enter 3490 for **UNIT NAME**.
2. Enter a 1 for **PROCESSING OPTION**. to perform aggregate backup verification processing, If you specify VERIFY, no data movement will take place.

Enter a 2 for **PROCESSING OPTION** to EXECUTE aggregate group backup. Data movement will take place.
3. Enter a Y for **WAIT FOR COMPLETION** to specify that you want to wait for aggregate backup to complete. If you specify Y, you will not be able to perform any other functions from your terminal while aggregate backup is processing.

Enter an N for **WAIT FOR COMPLETION** to specify that you do not want to wait.
4. Enter an S for **STACK / NOSTACK** if you want to stack your ABARS output files on a minimum number of tape volumes.

Enter an N for **STACK / NOSTACK** if you do not want to stack your ABARS output files.

Enter a blank for **STACK / NOSTACK** to cause aggregate backup processing to default to the value specified by the SETSYS ABARSTAPES(STACK | NOSTACK) command. If SETSYS ABARSTAPES isn't specified, the default is STACK.
5. Enter one of the following values for OPTIMIZE, which ABACKUP processing passes to DFSMSDss when DFSMSDss is backing up the level 0 DASD data sets specified in the include list.

Value

Description

1

Causes DFSMSDss to read one track at a time.

2

Causes DFSMSdss to read two tracks at a time.

3

Causes DFSMSdss to read five tracks at a time.

4

Causes DFSMSdss to read one cylinder at a time.

blank

Causes this option to default to the setting specified in the SETSYS ABARSOPTIMIZE(n) command. If SETSYS ABARSOPTIMIZE is not specified, the default is 3 (DFSMSdss reads five tracks at a time).

6. Enter Y for **DELETE DATA SETS AFTER ABACKUP** if you want the data sets deleted following successful completion of ABACKUP processing.

Enter N for **DELETE DATA SETS AFTER ABACKUP** if you do not want the data sets deleted.

7. Enter a slash (/) to choose the **PROCESS ONLY** selection or selections you want to include in your processing. If you do not choose any PROCESS ONLY selections, then the PROCESS ONLY option is not in effect. When the PROCESS ONLY option is not in effect, it is the same as choosing all of the selections; LO, ML1, ML2, and USERTAPE data sets are all eligible for processing.

8. Press the Enter key to initiate processing.

Using the ISMF ABACKUP option to perform aggregate backup

To use the ABACKUP option for aggregate backup, use TSO ISPF panels to access the DFSMSdfp; Aggregate Group Application Selection panel, shown in [Figure 56 on page 416](#).

```

                                AGGREGATE GROUP APPLICATION SELECTION
COMMAND ===> _

TO PERFORM AGGREGATE GROUP OPERATIONS,SPECIFY:

CDS NAME                ===> 'ACTIVE'
                                (1 to 44 character dataset name)

AGGREGATE GROUP NAME ===> PAY1
                                (for Aggregate Group List, fully or

Figure 57. Aggregate Group Backup Panel

You do not need to enter the CDS NAME or the AGGREGATE GROUP NAME; they are carried over from the previous panel.

Note: You can change the aggregate group name and initiate backup for another aggregate group from this panel.

On the Aggregate Group Backup Panel:

1. Enter 3490 for **UNIT NAME**.
2. Enter a 1 for **PROCESSING OPTION**. to perform aggregate backup verification processing, If you specify VERIFY, no data movement will take place.

Enter a 2 for **PROCESSING OPTION** to EXECUTE aggregate group backup. Data movement will take place.
3. Enter a Y for **WAIT FOR COMPLETION** to specify that you want to wait for aggregate backup to complete. If you specify Y, you will not be able to perform any other functions from your terminal while aggregate backup is processing.

Enter an N for **WAIT FOR COMPLETION** to specify that you do not want to wait.
4. Enter an S for **STACK / NOSTACK** if you want to stack your ABARS output files on a minimum number of tape volumes.

Enter an N for **STACK / NOSTACK** if you do not want to stack your ABARS output files.

Enter a blank for **STACK / NOSTACK** to cause aggregate backup processing to default to the value specified by the SETSYS ABARSTAPES(STACK | NOSTACK) command. If SETSYS ABARSTAPES isn't specified, the default is STACK.
5. Enter one of the following values for OPTIMIZE, which ABACKUP processing passes to DFSMSdss when DFSMSdss is backing up the level 0 DASD data sets specified in the include list:

Value	Description
-------	-------------

- | | |
|---|--|
| 1 | Causes DFSMSdss to read one track at a time. |
|---|--|

2

Causes DFSMSdss to read two tracks at a time.

3

Causes DFSMSdss to read five tracks at a time.

4

Causes DFSMSdss to read one cylinder at a time.

blank

Causes this option to default to the setting specified in the SETSYS ABARSOPTIMIZE(n) command. If SETSYS ABARSOPTIMIZE is not specified, the default is 3 (DFSMSdss reads five tracks at a time).

6. Enter Y for **DELETE DATA SETS AFTER ABACKUP** if you want the data sets deleted following successful completion of ABACKUP processing.

Enter N for **DELETE DATA SETS AFTER ABACKUP** if you do not want the data sets deleted.

7. Enter a slash (/) to choose the **PROCESS ONLY** selection or selections you want to include in your processing. If you do not choose any PROCESS ONLY selections, then the PROCESS ONLY option is not in effect. When the PROCESS ONLY option is not in effect, it is the same as choosing all of the selections; LO, ML1, ML2, and USERTAPE data sets are all eligible for processing.

8. Press the Enter key to initiate processing.

Using ISMF panels to perform aggregate recovery

This topic demonstrates how, instead of issuing the ARECOVER command, you can use ISMF panels to process aggregate recovery. You can specify the DFSMSdfp; Aggregate Group Application Selection panel from TSO and use option 6 for aggregate group recovery.

For this example ISMF session, PAY1.C.C01V0001 is specified as the control file data set name, a 3490 unit type is specified, and volume 111111 is allocated for the recovery files.

To use the ARECOVER option for aggregate recovery, use TSO ISPF panels to access the DFSMSdfp; aggregate group application selection panel, shown in [Figure 58 on page 418](#).

```

                                AGGREGATE GROUP APPLICATION SELECTION
COMMAND ==> _

TO PERFORM AGGREGATE GROUP OPERATIONS, SPECIFY:

CDS NAME                ==> 'ACTIVE'                (1 to 44 character dataset name)

AGGREGATE GROUP NAME ==> PAY1                (for Aggregate Group List, fully or
                                           partially specified or &asterisk for all)

SELECT ONE OF THE FOLLOWING OPTIONS ==> 6

1 LIST      - Generate a list of Aggregate Groups
2 DISPLAY   - Display an Aggregate Group
3 DEFINE    - Define an Aggregate Group
4 ALTER     - Alter an Aggregate Group
5 ABACKUP   - Backup an Aggregate Group
6 ARECOVER  - Recover an Aggregate Group

IF OPTION 1 CHOSEN ABOVE,
RESPECIFY SORT CRITERIA                ==> N                (Y or N)

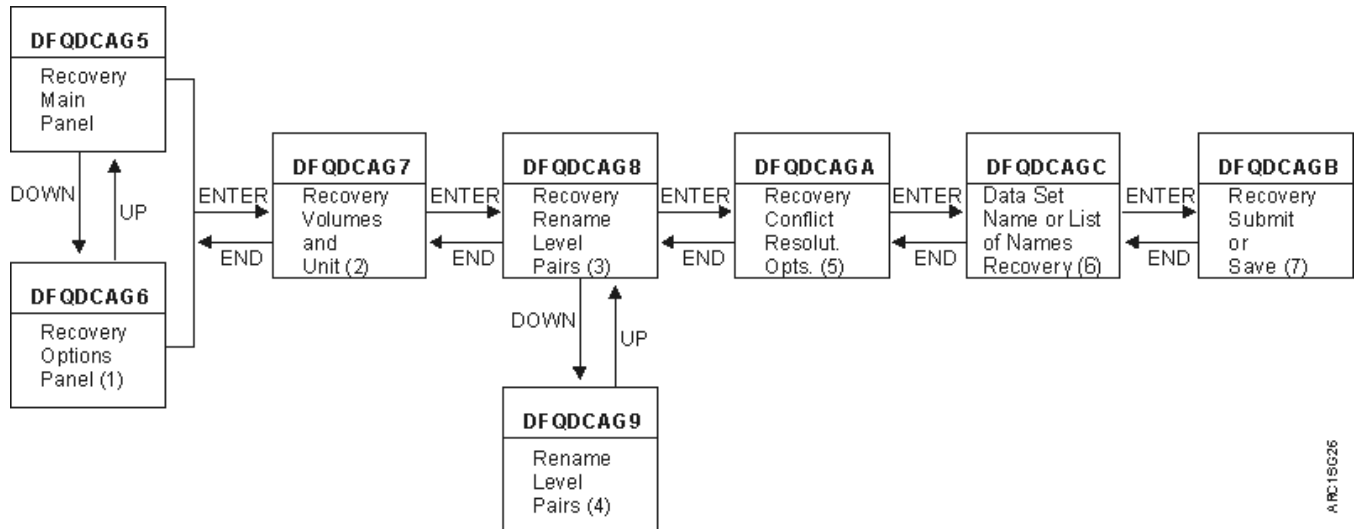

USE ENTER TO PERFORM SELECTION:
USE HELP COMMAND FOR HELP; USE END COMMAND TO EXIT.
```

Figure 58. Aggregate Group Application Selection Panel

On the Aggregate Group Application Selection Panel:

1. Enter 6 in the SELECT ONE OF THE FOLLOWING OPTIONS field to select the ARECOVER option.
2. Press the ENTER key to display the first aggregate group recovery panel.

Figure 59 on page 419, with associated notes, maps the progression through the aggregate group recovery panels, and tells how each panel is accessed.

Figure 60. Aggregate Recovery Panel DFQDCAG5

The following is a description of the fields of panel DFQDCAG5, and the entries that are made for the example system:

- The ABACKUP CONTROL DATASET field generates a DATASETNAME(*dsname*) parameter.
Enter 'PAY1.C.C01V0001' in this field
- The XMIT field indicates whether the ABACKUP files were independently transmitted to the ARECOVER site.
Enter N in this field.
- The STACK / NOSTACK field indicates whether the ABACKUP output files were stacked on a minimum number of tapes, or not.
Enter N in this field.
- The AGGREGATE GROUP NAME field generates an AGGREGATE(*agname*) parameter.
Leave this field blank.
- The DATE field generates a DATE(*yyyy/mm/dd*) parameter.
Leave this field blank.
- The VERSION field generates a VERSION(*nnnn*) parameter.
Leave this field blank.
- The PROCESSING OPTION field allows you to place either the PREPARE, VERIFY, or EXECUTE parameters in the ARECOVER command. A 1 generates the PREPARE parameter, a 2 generates the VERIFY parameter, and a 3 generates the EXECUTE parameter.
Enter a 3 in this field.
- The WAIT FOR COMPLETION field, if Y is entered, generates an HSEND WAIT ARECOVER command, and the terminal is locked until the ARECOVER command completes. If N is entered, this field generates an HSEND ARECOVER command, and the terminal remains unlocked.
Enter Y in this field.
- The TARGET GDG DATA SET STATUS field allows you to specify the status to which you want an SMS-managed generation data set returned. You can specify A for ACTIVE, D for DEFERRED, R for ROLLEDOFF, S for SOURCE, or leave the field blank. SOURCE indicates that you want the data set returned to the status it had when it was backed up. A blank will cause value specified by the SETSYS ARECOVERGTGDS to be used, or its default value of SOURCE.
Leave this field blank.

- The VOLUME COUNT field allows you to specify A for ANY, N for NONE, or a blank. If ANY is specified, the VOLCOUNT(ANY) parameter is passed to DFSMSdss during the restore, which results in the allocation of the target data set on as many volumes as required, up to a maximum of 59 volumes. If NONE is specified, the DFSMSdss VOLCOUNT parameter is not passed to DFSMSdss during the restore. If the field is left blank, the value specified by the SETSYS ABARSVOLCOUNT parameter, or its default value of NONE, is used.

Leave this field blank.

- The RECOVER INSTRUCTION DATA SET field, when Y is entered, generates the INSTRUCTION parameter. If AGGREGATE GROUP NAME is specified with the PREPARE option, either the RECOVER INSTRUCTION DATA SET field, the RECOVER ACTIVITY LOG field, or both must be used.

Enter N in this field.

- The RECOVER ACTIVITY LOG field, when Y is entered, generates the ACTIVITY parameter.

Enter Y in this field.

- The RECOVER INDIVIDUAL DATASET field specifies whether you want to recover an individual data set or a group of data sets from the backup copy of an aggregate group.

Enter N in this field.

Figure 61. Aggregate Recovery Panel DFQDCAG6

The following is a description of the fields of panel DFQDCAG6, and the entries that are made for the example system:

- The ABACKUP CONTROL DATASET field indicates the name of the ABACKUP CONTROL DATASET currently being processed.
- The MODEL ENTITY field allows the entry of a quoted, fully qualified data set name without a TSO *userid* prefix. This field generates, when filled in, a MENTITY(*dsname*) parameter.

Leave this field blank.

- The TARGET UNIT NAME field generates, when filled in, a TARGETUNIT(*unitname*) parameter.

Leave this field blank.

- The TARGET UTILIZATION PERCENTAGE field, if a percentage number is entered, generates a PERCENTUTILIZED(*nnn*) parameter.
Leave this field blank.
- The BACKUP MIGRATED DATA SETS field generates, if Y is entered, a BACKUPMIGRATED parameter. If N is entered, a NOBACKUPMIGRATED parameter is generated.
Enter Y in this field.
- The NEW MIGRATION LEVEL field indicates whether the MIGRATEDDATA parameter and associated subparameters are specified on the ARECOVER command. A 1 in this field generates a MIGRATEDDATA(ML1) parameter (the default), a 2 in this field generates a MIGRATEDDATA(ML2) parameter, and a 3 in this field generates a MIGRATEDDATA(SOURCELEVEL) parameter.
Enter 3 in this field.
- The RENAME ALL TO HIGH LEVEL QUALIFIER field accepts a valid, 1 to 8 character data set name qualifier that generates a RECOVERNEWNAMEALL(*level*) parameter, with the specified *level* as the subparameter. A value in this field is mutually exclusive with a Y in RENAME SELECTED DATA SETS.
Leave this field blank.
- The RENAME SELECTED DATA SETS field, if Y is entered, displays panel DFQDCAG8, shown in [Figure 63 on page 423](#). A Y in this field is mutually exclusive with a value in the RENAME ALL TO HIGH LEVEL QUALIFIER field.
Enter Y in this field.
- The SPECIFY CONFLICT RESOLUTION OPTION field, if Y is entered, displays panel DFQDCAGA, shown in [Figure 65 on page 424](#).
Enter Y in this field.

Panel DFQDCAG7

[Figure 62 on page 422](#) shows a representation of the ISMF DFQDCAG7 aggregate recovery volumes and unit panel.

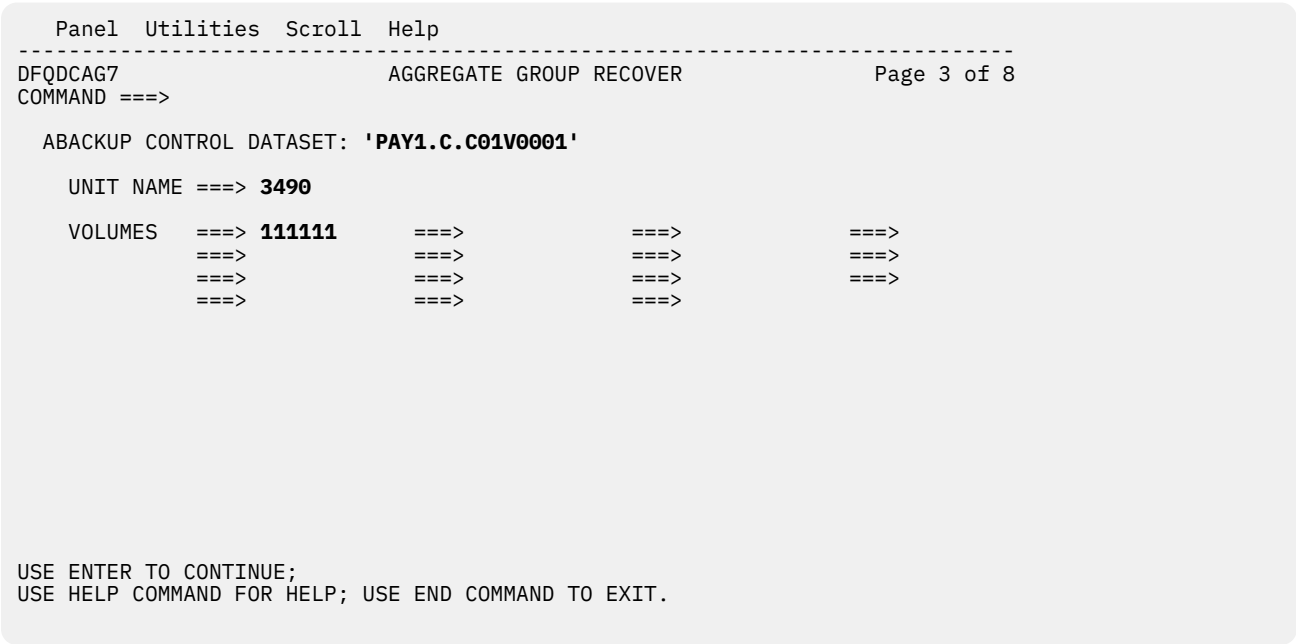

Figure 62. Aggregate Recovery Panel DFQDCAG7

The following is a description of the fields of panel DFQDCAG7, and the entries that are made for the example system:

- The ABACKUP CONTROL DATASET field indicates the name of the ABACKUP CONTROL DATASET currently being processed.
- The UNIT NAME field generates the UNIT(*unitname*) parameter, where *unitname* is the unit name that you enter in the field.

Enter 3490 in this field.

- The VOLUMES fields can accept up to 15 entries. These fields, when filled in, generate a VOLUMES(*volser1...*,*volsern*) parameter.

Enter 111111 in the first of these fields.

Figure 63. Aggregate Recovery Panel DFQDCAG8

The following is a description of the fields of panel DFQDCAG8, and the entries that are made for the example system:

- The ABACKUP CONTROL DATASET field indicates the name of the ABACKUP CONTROL DATASET currently being processed.
- The OLD LEVEL and NEW LEVEL fields can each contain a valid 1 to 8 character data set name. Values other than blanks in these fields generate the RECOVERNEWNAMELEVEL(*olevel1*,*nlevel1* [,*oleveln*,*nleveln...*]) parameter. At least one LEVEL pair must be specified. Each OLD LEVEL name specified must have a corresponding NEW LEVEL name. The OLD LEVEL name must differ from the corresponding NEW LEVEL name. Up to 15 pairs of names can be entered on this panel.

Enter the LEVEL names as shown in Figure 63 on page 423.

A second panel, DFQDCAG9, with fields for 15 more name pairs, can be displayed by using the DOWN command.

```

Figure 65. Aggregate Recovery Panel DFQDCAGA

The following is a description of the fields of panel DFQDCAGA, and the entries that are made for the example system:

- The **ABACKUP CONTROL DATASET** field indicates the name of the **ABACKUP CONTROL DATASET** currently being processed.

- The RENAME SOURCE NEW LEVEL field can contain a valid 1-to-8 character data set name that generates the RENAMESOURCE(*level*) subparameter of the DATASETCONFLICT parameter, indicating the specified level.

Leave this field blank.

- The RENAME TARGET NEW LEVEL can contain a valid 1-to-8 character data set name that generates the RENAMETARGET(*level*) subparameter of the DATASETCONFLICT parameter, indicating the specified level.

Leave this field blank.

- The REPLACE field, when Y is entered, generates the REPLACE subparameter of the DATASETCONFLICT parameter.

Enter N in this field.

- The BYPASS field, when Y is entered, generates the BYPASS subparameter of the DATASETCONFLICT parameter.

Enter Y in this field.

Note: The RENAME SOURCE NEW LEVEL, RENAME TARGET NEW LEVEL, REPLACE, and BYPASS fields are mutually exclusive: only one field can have an entry.

Panel DFQDCAGC

If you entered Y in the RECOVER INDIVIDUAL DATASET field of panel DFQDCAG5 (Figure 60 on page 420), your ISMF session includes panel DFQDCAGC. Figure 66 on page 425 shows a representation of the ISMF DFQDCAGC individual data set recovery panel.

SELECT OPTION    ===> 1                                (1-SUBMIT, 2-SAVE)

USE ENTER TO PERFORM SELECTION;
USE HELP COMMAND FOR HELP; USE END COMMAND TO EXIT.
```

Figure 67. Aggregate Recovery Panel DFQDCAGB

The following is a description of the fields of panel DFQDCAGB, and the entries that are made for the example system:

- The DFSMSHSM COMMAND AND PROCESSING OPTION field indicates the DFSMSHsm command and processing option currently being processed. In the case of the example, it appears as ARECOVER DATASETNAME(PAY1.C.C01V0001) EXECUTE.
- The SELECT OPTION field allows one of two choices: entering 1 saves the generated ARECOVER parameters and submits the ARECOVER command to DFSMSHsm, and entering 2 saves the generated ARECOVER parameters but does not submit the ARECOVER command.

Enter 1 in this field.

Using ISMF to recover individual data sets from an aggregate backup

To recover an individual data set from an aggregate backup version, you can use ISMF panels, as described in this chapter.

Perform the following steps to recover an individual data set from the backup copy of an aggregate group:

1. To access the ARECOVER option for aggregate recovery, use TSO ISPF panels to access the DFSMSdftp; aggregate group application selection panel, shown in [Figure 58 on page 418](#).
2. Select option 9, Aggregate Group, and press Enter. The Aggregate Group Application Selection panel is displayed.
3. Select option 6, ARECOVER, and press Enter to view the first Aggregate Group Recover panel DFQDCAG5."
4. Specify the values for the aggregate group. Specify Y for the field "Recover Individual Data Set". Press Enter to view the Aggregate Recovery Group Panel DFQDCAGC ([Figure 66 on page 425](#)).
5. On the Aggregate Recovery Group Panel DFQDCAGC, specify either a single data set name or the name of a data set that contains a list of data sets to be recovered from the backup copy of an aggregate group.

To create a list of data sets, use a fixed-block, sequential data set with a record size of 80 and logical record length (LRECL) of 80, and then catalog it. Edit the data set and specify one fully qualified data set name per record.

6. Enter the END command to submit the recover request.

Using the NetView file transfer program to transmit aggregate Backup files

You can use the NetView FTP to create file transfer requests for aggregate backup files and submit them to NetView FTP for processing. Requests can be created either by entering values in the input fields of the NetView FTP panels or by writing and running a batch job. After submitting one request, you can immediately submit another; you do not have to wait until NetView FTP has processed the first request.

Requests are submitted to a component of NetView FTP called the *queue handler*. The queue handler assigns a request number to your request and adds it to the request queue, where it waits to be processed. The request queue is located on DASD.

After your request has been added to the request queue, you can DELETE it from the queue or QUERY the queue for information about a request.

Before you can use NetView FTP to transmit your backup files, you will need to process the aggregate backup command. The ABACKUP command can create up to four data sets that should be transmitted to a remote location. The naming convention for these four data sets is as follows:

- outputdatasetprefix.D.CnnVnnnn

This data set contains data from the data file that originally resided on level 0 DASD before it was backed.

- outputdatasetprefix.O.CnnVnnnn

This data set contains data from the data file that was migrated or resided on user tape volumes before it was backed up.

- outputdatasetprefix.C.CnnVnnnn

This data set contains the control information from the control file.

- outputdatasetprefix.I.CnnVnnnn

This data set may contain valid instructions to the recovery site, or the ABACKUP activity log, if it was directed to DASD.

Note: Any ACCOMPANY data sets must also be transmitted.

Using NetView file transfer program panels

You can use NetView FTP panels to create, save, change, add, query, and delete your transfer requests. Which panels NetView FTP displays and the order in which it displays them, depend on the task you select and on the data you enter in the input fields of the panels. The following topics contain examples of NetView FTP panels and examples of how to use the panels to transfer copies of aggregate backup files to a receiving location.

Invoking NetView FTP panels

Invoke NetView FTP from your TSO selection menu. The Main Task Selection panel, which is shown in [Figure 68 on page 428](#), is displayed.

```
DVGSPEPE----- NetView FTP Main Task Selection -----
OPTION ==> 1

Select an option by number

1 Create          - Create a new file-transfer request
2 Control         - Query, delete, modify, hold, release submitted requests
3 List Saved      - List saved requests
4 Change Saved    - Change a saved request
5 Submit Saved    - Submit a saved request
6 Administer      - Administer the request queue

Specify the name of the request for option 4 or 5
Request Name ==>

Press the END PF key to return, HELP PF key for help
```

Figure 68. NetView FTP Main Task Selection Panel

Option 1 from the NetView FTP Main Task Selection panel is selected to show you how to create a file transfer request for the data file data set that contains the data backed up by using DFSMSdss.

Creating a request

Each request is made up of *parameters* that tell NetView FTP everything it needs to know to transfer this file.

In the example system, the aggregate backup file PAY1.D.C01V0001 is transferred to the *Remote Node ID* TKSMVS1. The file is stored on the labeled tape volume serial number ABRT01. You want the data set to be received at the remote location under the data set name PAY1.D.C01V0001 and stored on a 3490 tape volume, serial number ABRT01. You have decided that a data set transferred from tape will be given a *request class* of 3. To protect the request, you enter the *request password* ROSE. The password does not appear on the screen when typed. You do not want NetView FTP to process the request before 6:00 p.m. today. You want NetView FTP to notify the sending user ID, X999999 at node XYZMVS4, and the receiving user ID, Z000000 at node TKSMVS1, that the data set has been transferred.

This is how you use the NetView Main Transfer Parameters panel, which is shown in [Figure 69 on page 428](#), to tell NetView FTP how to conduct this file transfer.

```
DVGIT20E----- Main Transfer Parameters -----
COMMAND ==>

Specify whether you want to transfer a file to or from a remote node
Transfer Mode      ==> TO      (TO, FROM)

Specify either a remote node ID or a remote LU name
Remote Node ID     ==> TKSMVS1
Remote LU name     ==>

Specify a request class, priority, and password
Request Class      ==> 3      (0 to 9; A to Z)
Request Priority    ==> 0      (0 to 9)
Request Password    ==>      optional

Specify a running mode for each server
Sending Server     ==> CONT    (CONT, SINGLE)
Receiving Server   ==> CONT    (CONT, SINGLE)

Press the ENTER key to continue, END PF key to return, HELP PF key for help
```

Figure 69. Main Transfer Parameters Panel

After the Main Transfer Parameters panel is filled in, press the Enter key. The NetView FTP Main Data Set Parameters panel shown in [Figure 70 on page 429](#) is displayed.

```
DVGIT1SE----- Main Data Set Parameters -----
COMMAND ==>

Sending Data Set (Local):

Data Set Name ==> 'PAY1.D.C01V0001'
DD Name       ==>
Member Name   ==> (blank=list, *=all)
Data Set Type ==> LAB (blank,VSAM,P0,PS,LAB,UNLAB,USER)
Volume       ==>

Recipient of Report from Receiving Program ==> Z000000 at TKSMVS1

Local LU Name ==> LU name of local server to be used

Installation Exit Routine Input
==> tape check

Press the ENTER key to continue, END PF key to return, HELP PF key for help
```

Figure 71. Additional Transfer Parameters Panel

After you complete your entries on the Additional Transfer Parameters panel and press Enter, NetView FTP displays the Additional Sending Data Set Parameters panel, where you specify the device type, volume serial number, user ID (user ID is required), and security parameters as shown in [Figure 72 on page 430](#).

You do not need to fill in these fields when transferring any of the data sets, because they are cataloged during aggregate backup processing.

```
DVGID2RE Additional Parameters for the Sending Data Set (PO,PS,LAB,UNLAB) -----
COMMAND ==>

DCB Parameters:
  Record Format      ==>                               (F,FB,V,VB,U,VS,VBS)
  Logical Record Length ==>
  Physical Block Size ==>

Security parameters:
  User ID ==> X999999
  Password ==>
  Group ID ==>

Specify values for the following if data set not cataloged:
  Device Type      ==> 3490
  Volume Serial Numbers ==> ABRT01 ==> ==>
  ==> ==> ==>

Press the ENTER key to continue, END PF key to return, HELP PF key for help
```

Figure 72. Additional Parameters for the Sending Data Set Panel

Press Enter after you fill in the additional parameters for the Sending Data Set panel. NetView FTP displays the additional parameters for the Receiving Data Set panel, where you specify the disposition, device type, volume serial number, user ID (user ID is required), and security parameters for the receiving data set, as shown in [Figure 73 on page 430](#).

Note: If CAT is not entered in the disposition field, the data set must be manually cataloged at the receiving location.

```
DVGID2RE Additional Parameters for the Receiving Data Set (PS,LAB,UNLAB) -----
COMMAND ==>

Disposition      ==> CAT      (NEW,OLD,CAT)

Security Parameters:
  User ID      ==> Z000000
  Password     ==>
  Group ID     ==>

Specify values for the following if data set is not cataloged
  Device Type      ==> 3490
  Volume Serial Numbers ==> ABRT01 ==> ==>
  ==> ==> ==>

Press the ENTER key to continue, END PF key to return, HELP PF key for help
```

Figure 73. Example 2: Additional Parameters for the Receiving Data Set Panel

After you fill in the additional parameters for the Receiving Data Set panel and press Enter, NetView FTP has all the input it needs to conduct the file transfer.

Using a batch job to transmit aggregate backup files

You can transmit your data files, without using NetView FTP panels, by creating a batch job as shown in [Figure 74 on page 431](#):

```
//STEP0012 EXEC PGM=DVGIFBI                                INVOKE NBT
//*
//DVGLOG      DD SYSOUT=A
//SYSABEND    DD DUMMY
//SYSIN       DD *
FUNCTION=ADD
XMODE=TO
REMNODE=TKSMVS1
SNOTIFY=(X999999.XYZMVS4)
RNOTIFY=(Z000000.TKSMVS1)
SSECURP=(X999999.ROSE)
RSECURP=(Z000000.CLIFF)
WAIT=YES
SFTYPE=LAB
SFILEID='PAY1.D.C01V0001'
RFTYPE=LAB
RFILEID='PAY1.D.C01V0001'
RTDISP=CAT
/*
```

Figure 74. Sample Batch Job Used to Transmit Aggregate Backup Files

Attention: Because you cannot specify a file sequence number with the volume serial number when you are using NetView FTP or transmitting a batch job, you must catalog the data set if you need to transmit a second file of the data file.

Related reading

For more information about how to use the NetView FTP panels, see *NetView File Transfer Program for MVS: User's Guide*.

Issuing the ARECOVER command when using NetView FTP

When you use NetView FTP to transmit aggregate backup files, the following steps must be taken before you issue the ARECOVER command:

1. Ensure that all control file and data file data sets and any accompany data sets are cataloged before issuing the ARECOVER command.
2. Use the XMIT parameter on the ARECOVER command to indicate you are recovering data sets that have been transferred using NetView FTP.
3. *Do not* specify the UNIT and VOLUME parameters when XMIT is specified on the ARECOVER command, as shown in this example:

```
ARECOVER PAY1.C.C01V0001 REPLACE XMIT
```

4. Do not use the AGGREGATE parameter with the XMIT parameter.

ABARS considerations for sequential data striping

DFSMSHsm does aggregate back up and aggregate recover processing for single-stripe and multiple-stripe sequential extended format data sets. To process these data sets, the data mover must be DFSMSdss, and the data sets must be SMS-managed.

Aggregate backup processing

DFSMSHsm ABACKUP processing invokes DFSMSdss to perform a logical data set dump when it encounters a sequential extended format data set—both single-stripe and multiple-stripe—in the INCLUDE list.

If a sequential extended format data set resides on a non-SMS-managed volume, the logical data set dump fails.

Aggregate recovery processing

DFSMSHsm invokes dynamic allocation (SVC 99) to allocate the data sets in the ALLOCATE list:

- During ARECOVER processing, dynamic allocation allocates the data set as sequential extended format or not sequential extended format (regardless of the number of stripes at the backup site) according to what was specified at the recovery site for the DATA SET NAME TYPE attribute in the data class.
- Dynamic allocation also allocates the data set as single-stripe or multiple-stripe sequential extended format (regardless of the number of stripes at the backup site) according to what was specified at the recovery site for the SUSTAINED DATA RATE attribute in the storage class. If GUARANTEED SPACE = YES is specified, the number of volsers or VOLCNTs specified is the number of stripes; the value for SUSTAINED DATA RATE is ignored.
- Dynamic allocation allocates the data set as a data set that is not sequential extended format if the attribute DATA SET NAME TYPE in the data class is defined as (EXTENDED,C), and one of the following conditions is met:
 - SMS is not active at the recovery site.
 - None of the SMS-managed volumes is defined.
 - None of the SMS-managed volumes is connected to an ESCON 3990 model 3.
 - None of required volumes are available.
- Dynamic allocation does *not* allocate a data set if the attribute DATA SET NAME TYPE in the data class is specified as (EXTENDED,R), and one of the following conditions is met:
 - SMS is not active at the recovery site.
 - None of the SMS-managed volumes is defined.
 - None of the SMS-managed volumes is connected to an ESCON 3990 model 3.
 - Insufficient volumes are available to meet the allocation.
 - Insufficient space is available on the selected volumes.

DFSMSdss performs a logical data set restore for a sequential extended format data set as follows:

- A sequential extended format data set that was multiple-stripe when it was backed up can be restored as a multiple-stripe or single-stripe sequential extended format data set, depending on the storage class SUSTAINED DATA RATE value, and the availability of the required volumes.
- Conversely, a sequential extended format data set that was single-stripe when it was backed up can be restored as a multiple-stripe or single-stripe sequential extended format data set, depending on the storage class SUSTAINED DATA RATE value and the availability of the required volumes.
- A data set that was sequential extended format when backed up is recovered as a non sequential extended format but still SMS-managed data set if no SMS volumes supporting sequential extended format data sets are available.
- A data set that was not sequential extended format when it was backed up is always recovered as a data set that is not sequential extended format. DFSMSHsm will not convert a data set that is not sequential extended format to a sequential extended format data set through ARECOVER processing.

If the data class attribute DATA SET NAME TYPE is modified to indicate that the data set should be allocated as a data set that is not sequential extended format, the restore does not occur.

Aggregate roll-off processing

When a new version of an aggregate group is created, ABARS processing ensures that the number of versions kept does not exceed the amount specified by the NUMBER OF VERSIONS attribute in the management class. If NUMBER OF VERSIONS is exceeded, ABARS rolls off (deletes) the oldest version of that aggregate.

Roll-off processing can occur each time a new ABR record is written to the BCDS. Since ARECOVER creates an ABR record if one does not exist, roll-off processing can occur there as well as during ABACKUP.

Roll-off processing does not occur when the VERIFY parameter is used, because no ABR record is created.

When an aggregate group is removed during roll-off processing, its control file name is located in the catalog and a list of volume serial numbers that the control file resides on is requested. When necessary, the volumes are deleted from the RACF HSMABR tape volume list. The control file is uncataloged after the volume serial number list has been exhausted. When the file does not exist in the catalog, it is not an error condition, and the ABR record can still be deleted.

If it is active, installation exit ARCTVEXT is called for each volume being processed, indicating to the exit that the volume being expired is an ABARS tape volume.

This process is repeated for the data files and the instruction and activity log files.

After the control file, data files, and instruction and activity log file have been uncataloged and removed from the HSMABR tape volume set, the ABR record is deleted and processing continues with the next ABR record for the group being processed.

Note: It is possible to code SMS ACS routines that direct ABARS files to DASD. If this is done, and the files get migrated to DASD, an HSM DELETE is issued to remove them during roll-off processing. If that delete fails, the file may remain cataloged with no ABR record pointing to it. If this happens, the data set must be manually deleted. See “Directing ABARS files to DASD” on page 434 for more information.

You can use the SETSYS ABARSDELETEACTIVITY(Y | N) command to specify whether you want DFSMSshm to automatically delete the ABARS activity log that corresponds to the ABACKUP version being rolled off. The deletion occurs during ABARS roll-off processing or EXPIREBV ABARSVERSIONS processing, and removes the need to manually manage the ABARS activity logs. The default is N, which specifies no automatic deletion.

Defining GDGs at the recovery site

An alternative way to have GDGs defined at the recovery site is to specify a GDG base name in the ALLOCATE statement and have ABARS predefine the GDG base name during ARECOVER processing. This can be done even if the installation has not specified an associated GDS name in the selection data set. During ARECOVER processing, all GDG base names are defined before restoring any GDSs specified in the aggregate. GDG base names specified in the ALLOCATE statement have the following restrictions:

- They are only defined if they do not already exist at the recovery site.
- The DSCONFLICT parameter of the ARECOVER command does **not** apply to these GDG base names.
- The ARCCREXT installation exit does **not** get control when active for conflicts that arise with GDG base names in the ALLOCATE statement.
- RECOVERNEWNAMELEVEL and RECOVERNEWNAMEALL **do** apply to these GDG base names.

Ensuring backup copies of ARECOVERed SMS-managed data sets exist at the recovery site

When ABARS is used to move data sets to a recovery site, DFSMSdss moves the catalog information for all data sets residing on primary volumes from the disaster site to the recovery site. If backup copies of these data sets are not also moved to the recovery site, the LBACKUP dates in the catalog are not correct when the data sets are ARECOVERed. If these data sets are not updated, then no backup is created for SMS-managed data sets because the LBACKUP dates in the catalog show that valid backup copies exist at the recovery site when, in fact, they do not. This creates a potential data integrity problem if the original data sets are ever lost or damaged.

Two methods can be used to ensure that backup copies of these data sets are made:

- Issue a BACKVOL TOTAL for ARECOVERed volumes. This creates backup copies unless the management class specifies that no backups should be made.
- Use CLIST to allow the ARECOVER activity log to process the data sets, opening them for output so that the change bit is set.

Directing ABARS files to DASD

It is possible to code SMS ACS routines that direct ABARS files to DASD. If this is done, and the files get migrated to DASD, an HSM DELETE is issued to remove them during roll-off processing. If that delete fails, the file may remain cataloged with no ABR record pointing to it. If this happens, the data set must be manually deleted.

Because ABARS is designed to write to tape, space parameters are not passed. When directing ABARS files to DASD, the space parameters must be obtained using the SPACE parameter of the ALLOCxx PARMLIB member. You can verify these parameters by issuing:

```
D ALLOC,OPTIONS
```

Note that changing these parameters may affect any other allocations using the defaults.

By defining DATACLAS and using the PRIMARY, SECONDARY, and AVGREC fields, you can specify how many records will be contained in primary and secondary storage. Your specification can be done in kilobytes (K), megabytes (M), or bytes (U).

In addition, you need to define and assign a management class for ABARS files that will be allocated to DASD using the NOLIMIT operand for the following fields:

- EXPIRE NON-USAGE
- EXPIRE DATE/DAYS
- RET LIMIT

This will ensure that the aggregate backups are not prematurely expired or deleted. The retention period is controlled by the management class specified in the aggregate definition. You may wish to omit the backup attribute, depending on your requirement. If not omitted, DFSMSHsm will take incremental backups of the ABARS files that are allocated to DASD. Note that there may be two separate management classes, one that applies only to the ABACKUP output files, and one that defines how to manage the aggregate group as a whole.

When creating an ABARS aggregate to be directed to DASD, use the NOSTACK parameter. Otherwise, it will fail and you will receive message ARC6055I and a return code of 94. You can either specify NOSTACK on the ABACKUP command, or you can use the SETSYS command to specify NOSTACK for all aggregate backups, as follows:

```
SETSYS ABARSTAPES(NOSTACK)
```

Chapter 9. Making disaster backup copies of DFSMSHsm-owned tape volumes

The ABACKUP and ARECOVER functions described in [Chapter 8, “Aggregate backup and recovery support \(ABARS\),” on page 319](#) provide comprehensive recovery of your data in case of a disaster.

However, you also need protection against damage or loss of your backup and ML2 tape volumes. DFSMSHsm allows you to make copies of your backup and ML2, single-file-format tape volumes for storage at a site different from the computer site or for use at the computer site to recover lost or damaged tape volumes.

In addition to considering tape-capacity usage, you should consider the tape-related implications of disaster backup described below, in deciding whether you want to handle partially full tapes by SETSYS PARTIALTAPE(MARKFULL) or SETSYS PARTIALTAPE(REUSE).

For more information about the SETSYS command, see [Chapter 65, “SETSYS command: Establishing or changing the values of DFSMSHsm control parameters,” on page 1057](#).

Planning disaster recovery

The premise for disaster recovery is that you will have copies of all your vital data sets stored at a location separate from your computer site and that a computer system of approximately the same capabilities will be available to be used to resume operations. Consider what this implies:

- You must have a copy of all your system control data sets stored at the off-site location. System control data sets change every time maintenance is applied, which for some installations is weekly or biweekly, so having automated scheduled backups are recommended. You can also dump the data sets by command whenever necessary.
- You must have copies of all your vital user data sets. You can use SMS to ensure that all of the vital user data sets are stored on the appropriate DASD volumes. You can provide these copies by using the DFSMSHsm ABACKUP function.
- You must have copies of your ML1 volumes in order to recall any vital data sets that have migrated to ML1. You can use the DFSMSHsm ABACKUP or automatic dump functions to provide these copies of DASD ML1 volumes.
- You must have copies of your ML2 volumes in order to recall any vital data sets that have migrated to ML2. If you use DASD for ML2, you can provide these copies by using the DFSMSHsm ABACKUP or command dump functions. If you use cartridge-type, single-file-format tape for ML2, you can use the duplex tape option when creating the ML2 tapes, or you can use other DFSMSHsm disaster backup facilities as discussed in this topic. ABACKUP can be used for ML2 tape data sets as well.
- You should have copies of your backup volumes in order to reconstruct your user volumes. If you make copies of your backup volumes, you can make fewer automatic dump copies of entire user volumes. You reconstruct the user volumes from the combination of the latest dump copy and the incremental backup versions of data sets made after the dump copy was made. If you use DASD for backup, you can provide these copies by using the DFSMSHsm ABACKUP or command dump functions. If you use cartridge-type, single-file-format tape for backup, you can use the duplex tape option when creating backups, or you can use other DFSMSHsm disaster backup facilities as discussed in this topic.

Note: ABACKUP cannot be used for incremental versions stored on backup DASD. Only full volume dumps can provide offsite copies of data on backup DASD.

- You must have VTOC copy data sets for some cases. The VTOC copy data sets are required when you are restoring data from dump copies combined with incremental backup versions. By dumping ML1 volumes you have VTOC copy data sets available at the recovery site.

- You need a set of instructions for reconstructing the system and resuming operations.

Disaster backup facilities

To provide disaster backup, two things are necessary: (1) a way to make copies of DFSMSHsm-owned tape volumes and to identify the copied volumes to DFSMSHsm; and (2) a way to cause DFSMSHsm to use the copied volumes instead of the original volumes. To fulfill these needs, DFSMSHsm provides the duplex tape option or the TAPECOPY command, and the TAPEREREPL command.

Making copies of DFSMSHsm-owned tape volumes

There are two methods of making copies of DFSMSHsm-owned tape volumes. One method is by using the duplex tape option. The other method is by using the TAPECOPY command.

Duplex tape option

The duplex tape option provides an alternative to TAPECOPY processing for backup and migration cartridge-type tapes. Two tapes are created concurrently with one designated the original, the other the alternate. The intent is that the original tape be kept onsite, while the alternate can either be created in a remote tape library, or taken offsite.

The alternate tape must have the same tape geometry as the original. For example, if the original tape is a 3590-1 tape, the alternate must be also.

The duplex tape option also requires one additional tape drive per writing task. Adequate numbers of drives must be available for the tasking level used by the functions using duplexing during the time periods those functions run. This includes recycle.

With the SETSYS DUPLEX command you can specify that the duplex tape option be used for backup tapes only, migration tapes only, or both backup and migration tapes. If you use duplex creation for both migration and backup and you have been auto scheduling tape copying, you probably want to remove the auto scheduling. If you are duplexing either migration or backup tapes but not both, you can auto schedule tape copies based on the type indicated in the ARC0421I message.

In an SMS environment, the ACS routines can direct the alternate tape to the same or to a different tape library. Different tape libraries can exist at the same location, or a remote location. ESCON technology defines how distant the remote location can be. In a non-SMS environment, the output restrictor is used for both the original and the alternate. ACS filtering can be set up to cause the desired tape allocations to occur.

Tapes created by the duplex tape option are compatible with tapes created by TAPECOPY.

DFSMSHsm initial tape selection selects tapes for the duplex option using the following selection process:

- A partial tape and its alternate are selected.
- If no partial tapes with alternates are found, an empty ADDVOLed volume with a scratch volume as an alternate are selected.
- If there are no empty ADDVOLed volumes, two scratch volumes are selected.

When problems occur that allow an original tape to be created, but prevent the alternate from being created by the duplex tape option, DFSMSHsm automatically schedules internal TAPECOPY processing to ensure that valid alternate tapes exist. If the original tape is demounted before being filled it is marked as duplexed but unavailable for output until the alternate is successfully created. At either the EOV for the original volume or the end of the task, DFSMSHsm schedules TAPECOPY processing to create an alternate tape. If that is unsuccessful, automatic scheduling of internal TAPECOPY processing occurs during secondary space management for migration volumes, and during automatic backup processing on the primary host for backup volumes.

As part of the automatic internal scheduling of TAPECOPY processing, a tape copy needed (TCN) record is written in the OCDS. When the automatic internal TAPECOPY completes successfully, the TCN record

for the source volume (which is the original volume of the duplexed pair) is deleted, and the original tape volume is made available for reuse.

In a SETSYS PARTIALTAPE(REUSE) environment, both the duplexed original and its alternate can be reused (extended). If you have a non-duplexed original with an alternate created by TAPECOPY, only the original can be reused. The alternate is discarded.

The SETSYS DUPLEX command also allows you to specify that alternate and original migration tapes are to be marked full if an error occurs when writing to the alternate tape volume. To do so, enter the SETSYS DUPLEX(MIGRATION(Y ERRALT(MARKFULL))) command with the ERRORALTERNATE(MARKFULL) parameter specified:

```
SETSYS DUPLEX(MIGRATION(Y ERRALT(MARKFULL)))
```

The default for ERRORALTERNATE is CONTINUE. Here, if the alternate tape volume encounters an I/O error, the alternate is demounted and returned to scratch, but DFSMSHsm continues writing to the original. When the writing is completed, DFSMSHsm schedules a TAPECOPY request to create a new alternate tape.

A new flag has been added to the ARCTVEXT installation exit parameter list. When an alternate tape is being replaced and returned to scratch, and if the ARCTVEXT installation exit is active, the flag indicates if the action is the result of a user-issued TAPECOPY command. This information is provided so users are aware that an alternate tape is being returned to scratch, and that the original tape is not.

You can use the LIST and HLIST commands to show duplex tape status and alternate tape volume serial numbers.

Duplex tape does not support SETSYS TAPEUTILIZATION NOLIMIT set for the output unit being duplexed. This is because the alternate tape must match the original tape exactly, and with SETSYS TAPEUTILIZATION set to NOLIMIT this is impossible to guarantee, since either tape could be longer than the other. When TAPEUTILIZATION is set to NOLIMIT, the duplex tape option causes the tapes to reach a logical EOVS when they are 97% full.

The duplex tape option does not support creating duplex copies of ML2 tapes during ARECOVER processing. Instead, one copy of the ML2 tape is recovered by ARECOVER processing, and a TCN record is written in the OCDS. The TCN record causes a TAPECOPY to be scheduled during the next occurrence of secondary space management processing. The TAPECOPY is not scheduled immediately because a TAPECOPY running during the recovery process might not be wanted.

The duplex tape option handles errors in the following way:

- When an attempt is made to allocate and mount a partially full duplexed tape, but the associated alternate volume cannot be found, both the original and alternate are rejected and marked as unavailable for the duration of DFSMSHsm processing.
- When an attempt is made to allocate and mount an empty original tape and a new alternate scratch tape, but the scratch tape cannot be allocated or mounted, the duplex tape option continues to write the original volume. When the original volume (ADDVOLed or scratch) is demounted, DFSMSHsm marks the volume as duplexed and unavailable for output, and schedules an internal TAPECOPY for that volume. DFSMSHsm makes the original volume available after internal TAPECOPY processing successfully creates an alternate tape volume.
- If the duplexed original encounters an I/O error, both the original and alternate tapes are marked full, demounted, and two different tapes are selected. The user data set related to the I/O error is restarted from the beginning on the different tapes.
- If the alternate tape volume encounters an error, duplex tape processing depends on whether you specified the ERRORALTERNATE(MARKFULL) option on the SETSYS DUPLEX(MIGRATION) command. If so, both the original and alternate tapes are marked full if the alternate tape volume encounters an error. This option applies to migration tapes, for both initial migrations and subsequent RECYCLE processing. The option is not available for backup tapes. The ERRORALTERNATE(MARKFULL) option is recommended for installations that use higher capacity tapes and perform tape duplexing for disaster recovery purposes.

If you choose not to use this option, the default error handling is in effect. If the alternate tape volume encounters an error, the alternate is demounted and returned to scratch, but the original continues to be written. The original is marked as duplexed and unavailable for output, and an internal TAPECOPY is scheduled to automatically create an alternate tape. DFSMSHsm makes the original volume available after internal TAPECOPY processing successfully creates an alternate tape volume.

- When the original tape reaches its percent-full capacity, DFSMSHsm must flush all the data to both tapes before performing a FEOV. If natural EOV is reached on either tape, DFSMSHsm marks the tapes as *FULL* and restarts processing of the current data set from its beginning on two new tapes.

TAPECOPY command

The TAPECOPY command allows you to make copies of single-file-format, DFSMSHsm-owned tapes. The copies are known as alternate tapes and are identified in the offline control data set (OCDS) as alternates to the tapes that are copied.

DFSMSHsm provides commands to copy categories of DFSMSHsm-owned tape volumes:

```
TAPECOPY BACKUP
```

```
TAPECOPY MIGRATIONLEVEL2
```

```
TAPECOPY ALL
```

These commands cause DFSMSHsm to make alternate copies of full, single-file-format tapes that do not already have an alternate copy. The TAPECOPY MIGRATIONLEVEL2 and TAPECOPY ALL commands also cause DFSMSHsm to make alternate copies of partially full ML2 tapes if the environment is PARTIALTAPE(MIGRATION(MARKFULL)).

You can make copies of all volumes categorized as either ML2, backup (or both), or of individual tape volumes. You can issue one TAPECOPY command per DFSMSHsm host as long as the requests do not overlap. For example, you can issue a TAPECOPY ML2 command on one host and a TAPECOPY BACKUP command on another.

For individual tape volumes, you can make copies of either partial or full volumes, and of volumes with or without an alternate copy already existing.

The TAPECOPY command provides for copying only cartridge-type, single-file-format tapes. If you have data on multi-file format tapes (such as reel tapes), you can transfer the data onto new cartridge tapes by using the recycle function. These cartridge tapes can then be copied, and use of the reel tapes can be discontinued.

The output or alternate tape volumes used by the tape copy process begin as scratch tape volumes. These scratch tape volumes cannot be volumes that have been added to DFSMSHsm with the ADDVOL command. Using scratch tape volumes not added to DFSMSHsm eliminates backup, dump, or ML2 tape volumes from being used as alternate tape volumes.

DFSMSHsm copies the security information (RACF and expiration date) of the original volume, or you can specify a different expiration date when an alternate volume is created. Because password protection is not copied to an alternate volume, you should use RACF or an expiration-date protection for the alternate volume. If the alternate volume is in the RACF DFSMSHsm tape volume set, the RACF protection is removed from the alternate volume when it is returned to scratch status. If the tape resource class (TAPEVOL) is inactive during a recycle request for a RACF-protected original volume with an alternate, the RACF protection for the alternate will be deleted based on the TTOC information available for the original volume.

Information about the alternate tape volumes is stored in the tape table of contents (TTOC) records of the OCDS. While, over time, a given tape volume might be copied to several alternate volumes, only the most current alternate tape volume reference is stored in the TTOC record.

Attention: Be aware that some tape management products do not protect DFSMSHsm data tapes from being mounted for output in response to a nonspecific mount PRIVAT request, and therefore they can allow DFSMSHsm to write over some of its own tapes. This exposes alternate tapes because DFSMSHsm does not maintain a way to quickly identify an alternate tape as a DFSMSHsm

tape, so there is no check to prevent an alternate from being overwritten. DFSMSrmm does not have this exposure.

Assigning expiration dates to tapes provides only partial protection from inadvertent rewriting over valid data. The general solution is to use policies defined with a function like "vital record specifications" in a tape management product like DFSMSrmm. DFSMSHsm uses tape-volume exit ARCTVEXT to communicate to tape management products, except DFSMSrmm, when a tape can safely be returned to scratch status.

Related reading

For more information about using DFSMSHsm with DFSMSrmm, see [Chapter 16, "Using DFSMSHsm with DFSMSrmm,"](#) on page 591.

Copying individual volumes

You may want to make copies of individual volumes under the following conditions:

- Message ARC0421I, written to the console when a tape volume is marked full, allows making an alternate copy of that volume automatically, if you are not using the duplex tape option to create alternate tapes.
- You have replaced an original volume with an alternate volume. You would then immediately want to make a new alternate volume for protection against loss of what is now the only usable volume.
- An alternate volume is lost so that you must make a new alternate volume, even though it appears (in a TTOC record) that an alternate volume already exists.

When DFSMSHsm makes an alternate volume, it records the alternate volume in the OCDS, thus associating the alternate volume with the original volume. For copying individual volumes, if an alternate volume already exists:

- DFSMSHsm replaces the old alternate volume with the new alternate volume.
- DFSMSHsm issues message ARC0436I.
- No record is kept of the old alternate volume.
- For duplex tapes only, the tape volume exit ARCTVEXT is invoked, if active, to release the previous alternate tape volume through the tape management system. A flag in the ARCTVEXT parameter list indicates that the tape being released is an alternate tape being replaced by a user TAPECOPY, and that the original tape is not being released.
- If SETSYS PARTIALTAPE(MARKFULL) is specified, the original volume is marked full.

The command to make alternate volumes for individual volumes is:

```
TAPECOPY ORIGINALVOLUMES(ovol1,ovol2,...,ovoln)
TAPECOPY ORIGINALVOLUMES(ovol1,ovol2,...,ovoln) -
    ALTERNATEVOLUMES(avol1,avol2,...,avoln)
```

This command copies the volumes specified, creating an alternate tape volume for each. If you use the first form of the command, a default volume serial number of PRIVAT is used for the alternate tape volumes. PRIVAT indicates to DFSMSHsm that a scratch volume be mounted for each alternate tape volume. However, if you use the second form of the command, DFSMSHsm uses the volumes you specify with the ALTERNATEVOLUMES parameter to become the alternate volumes. If you use the ALTERNATEVOLUMES parameter, you must specify exactly the same number of volumes with the ALTERNATEVOLUMES parameter as you specified with the ORIGINALVOLUMES parameter. There is a one-to-one correspondence between the original volumes and alternate volumes that you specify. That is, *ovol1* is copied to *avol1*, *ovol2* is copied to *avol2*, and so forth.

An alternative exists for copying your existing DFSMSHsm-owned volumes. You can issue a LIST command to obtain a list of your ML2 and backup volumes. You can then issue a LIST TTOC command to determine which of the volumes have alternate copies already. Send the LIST TTOC command output to a data set.

Edit the data set to remove those volumes for which you do not want to make an alternate copy, convert the data set to the format required for the input data set, and issue the following command:

```
TAPECOPY INDATASET(volcopy.list.dsname)
```

DFSMSHsm makes an alternate copy of each of the volumes contained in the list of volumes provided by the data set.

- For more information about using the LIST command, see [Chapter 14, “Obtaining information from DFSMSHsm,”](#) on page 559.
- For more information about the TAPECOPY command, see [Chapter 68, “TAPECOPY command: Making copies of selected cartridge-type tape volumes,”](#) on page 1227.

Converting tape volumes marked partially full to marked full

The DFSMSHsm default behavior is to mark a tape volume full only when the tape volume reaches the maximum block count specified by the SETSYS command TAPEUTILIZATION parameter. This is known as a "reuse environment." In a reuse environment, issuing a generic TAPECOPY command processes only the tape volumes that are marked full and that do not already have an alternate tape copy. In addition, partially full tape volumes without an alternate tape volume are not selected for tape volume duplexing. Therefore, it is advantageous to convert tape volumes marked partially full in the DFSMSHsm inventory to marked full.

There are two methods for converting tape volumes marked partially full to marked full:

- Use the DELVOL BACKUP(MARKFULL) or DELVOL MIGRATION(MARKFULL) command to mark each partially full tape volume full. This method is immediate and applies to tape volumes used for both volume and data set migration and backup.
- Use the SETSYS command PARTIALTAPE(MARKFULL), PARTIALTAPE(MIGRATION(MARKFULL)), or PARTIALTAPE(BACKUP(MARKFULL)) parameters to operate DFSMSHsm in what is known as a "mark-full environment." In a mark-full environment, DFSMSHsm will mark partially full tape volumes without an associated duplex copy as full when processing a generic TAPECOPY command or at the end of volume migration, backup, or both (depending on the SETSYS setting). However, tape volumes will not be marked full during data set migration or backup. This method is gradual as a partially full tape volume must be selected for volume migration or backup before being marked full.

Replacing an original with an alternate tape volume

If an original ML2 or backup volume is lost or damaged, the volume can be replaced with its alternate volume:

1. To determine if an alternate tape volume exists for the original volume, use the LIST TTOC(*volser*) command.
2. Issue the TAPERPL ORIGINALVOLUMES(*ovol*) command to replace the original volume with the alternate. After the command completes, the alternate tape volume reference in the TTOC record replaces the original volume reference.

3. Issue the TAPECOPY ORIGINALVOLUMES(*newovol*) command to make a new copy of the volume (using the volume serial number of the old alternate volume) to provide a new alternate volume.

When the TAPERREPL command successfully replaces a tape volume, DFSMSHsm issues the ARC0427I message and (with two exceptions) invokes the tape-volume exit ARCTVEXT to indicate to a tape management product that the original volume can be returned to scratch. The two exceptions are when you are using TAPERREPL with the DISASTERALTERNATEVOLUME optional subparameter, or when your tape management product is DFSMSrmm.

For duplex tapes, after the original volume is replaced, it is marked full and is no longer a duplex tape.

Creating duplex tapes off site

With the duplex tape option, you can write the alternate volumes directly to a remote tape library. ESCON technology defines how distant the remote location can be.

When you process the RECYCLE command, DFSMSHsm invalidates the alternate tapes at the same time that it invalidates the tapes from which they were copied. Invalidated alternate tapes are returned to the scratch pool at their respective sites.

Sending alternate tapes off site

To use alternate tapes for disaster backup by sending them to a safe site, you must determine what tapes to send away and determine when to bring the tapes back and reuse them. Use the following procedure to send alternate tapes offsite:

1. Issue the TAPECOPY command for your non-duplexed tapes (backup, migration, or all, as you desire).
2. Issue LIST TTOC to determine which volumes have alternate copies.
3. Send the alternate tapes off site.
4. When you process the RECYCLE command, DFSMSHsm invalidates the alternate tapes at the same time that it invalidates the tapes from which they were copied. Both the original and the alternate tape are passed to the ARCTVEXT installation-wide exit.
5. Request the return from the offsite location of the alternate tapes that have been invalidated, and return the tapes to the scratch pool.

Managing alternate volumes

DFSMSHsm provides full support for producing and managing one alternate tape for each volume in the categories of ML2 and backup tapes. As shown above, this includes using the duplex tape option, or using a generic TAPECOPY command to copy full tapes not already having a copy, and optionally interfacing to the DFSMSHsm installation exit ARCTVEXT to return emptied tapes to scratch status.

Examples

Although it is possible for you to make multiple alternate tapes, that comes with the price of doing additional management of them, as detailed in the following two examples:

1. If you issue the TAPECOPY command to create an alternate tape for an original volume not marked full, then the original will likely be extended later.

When entries are being added to a base TTOC or when a tape is marked full for reasons other than a DELVOL MARKFULL command, any existing alternate volume is no longer valid. If, in either case, the tape already has an alternate volume, then message ARC0441I is issued to the console and appropriate activity log, and the existing alternate is removed. DFSMSHsm does not take exit ARCTVEXT, unless it was a duplexed alternate, since it is not known whether the alternate tape should be returned to scratch status. If it was a duplexed alternate, DFSMSHsm takes the ARCTVEXT installation exit, doesn't get rid of the alternate, and doesn't issue the ARC0441I message.

2. If you issue a specific TAPERREPL command specifying the alternate volume to replace the original tape, and the specified alternate is different from the alternate volume DFSMSHsm knows about, then

message ARC0439I is issued to the submitter and the command activity log. The alternate previously known to DFSMSHsm is not retained. It is also not passed to the ARCTVEXT exit (although the original is) because DFSMSHsm does not know whether you want it to be returned to scratch status.

For duplex tapes, after the original volume is replaced, it is marked full and is no longer a duplex tape.

The first example above is an instance where DFSMSHsm directs a specific message to the console so that if automatic operations are desired, they can be implemented based on intercepting a console message.

If an ML2 or backup tape is deleted using the DELVOL command, DELVOL processing issues message ARC0420I for the alternate volume recorded by DFSMSHsm.

Disaster alternate volumes

DFSMSHsm provides a way—once you have created alternate tapes or have duplexed alternate tapes—to use those alternates in place of the original tapes for doing recalls or recovers.

If an actual disaster happens at your home site or if you are running a disaster recovery test, you should proceed as follows to establish operations at your recovery site:

1. Bring up the system by restoring the system packs, libraries, and DFSMSHsm CDSs.
2. If your strategy includes dump tapes, set the DEFINE command at the recovery site to limit DFSMSHsm recovery to those dump classes that are present there. It is likely that the CDS indicates the dump classes at the recovery site are those available at the home site.
3. Start DFSMSHsm, and restore the required data sets from DASD.
4. If you have created alternate copies of DFSMSHsm-owned tape volumes and the alternate volumes are present at the recovery site, run the TAPEREPL command to convert all of DFSMSHsm's information about the original volume serial number to the alternate volume serial number. Since this process is very time-consuming, a significantly reduced form of the TAPEREPL command can be run during the earliest stages of bringing up a recovery site. This command consists of TAPEREPL, followed by required parameters, followed by DISASTERALTERNATEVOLUMES, abbreviated to DAVOLUMES. For example:

```
TAPEREPL ALL DAVOLUMES
```

When the DAVOLUMES parameter is used, only base OCDS TTOC records of ML2 and backup tapes that have alternate volumes are updated as having *disaster alternate volumes*.

The designation of "disaster alternate volumes" can help distinguish between alternate volumes initially present at the recovery site, and alternate volumes created later at the recovery site.

Note: When the DAVOLUMES option is used, DFSMSHsm does *not* invoke the tape-volume exit ARCTVEXT, since the original tape is not being totally replaced. For example, if this is done for a disaster recovery test, the resulting control data sets may be discarded after the test, and the original tapes again used at the home site.

DFSMSHsm invokes ARCTVEXT when the complete replacement is done, using TAPEREPL without the DAVOLUMES option.

5. Before running customer jobs, issue the SETSYS command with the DISASTERMODE parameter. For example:

```
SETSYS DISASTERMODE
```

One approach would be to put the SETSYS DISASTERMODE command in a startup ARCCMDxx PARMLIB member that is used exclusively for starting DFSMSHsm in disaster mode.

While DFSMSHsm is running in disaster mode, recalls and recovers from tape volumes that are marked as having disaster alternate volumes will substitute the volume serial number of the disaster alternate volume from the TTOC record for the original volume serial number that appears in the data set records.

6. If you use TAPEDELETION(HSMTAPE) or PARTIALTAPE(REUSE) options then the inventory will likely contain empty and partially filled backup and migration tapes that were destroyed at the home site. These tapes will be selected for output at the recovery site. To prevent DFSMSHsm from requesting tapes that are not available, identify these tapes using the LIST TTOC SELECT(NOTFULL) command, then mark the tapes full with the MARKFULL option of the DELVOL command:

```
DELVOL volser BACKUP(MARKFULL)
DELVOL volser MIGRATION(MARKFULL)
```

7. As jobs run at the recovery site and new data sets are created, backup versions and migration copies are created. As tapes are filled, they may be copied. These “new” alternate copies are not considered “disaster alternate volumes” and will not be substituted for the original volumes during recall or recover.
8. If you have finished running a disaster recovery test or you are finished using the alternates, reset the Disaster Alternate Volume flag in the TTOCs by issuing the following command:

```
TAPEREPL ONLYDISASTERALTERNATES(RESET)
```

If you were performing a disaster recovery test, you may want to make scratch tapes out of any DFSMSHsm output tapes created at the recovery site. You may leave the alternate volumes for future disaster recovery.

9. If you are recovering from a true disaster, you now need to plan for the return to your home site. You need to convert the disaster alternate volumes to original volumes. You can issue:

```
TAPEREPL ONLYDISASTERALTERNATES
```

to replace all, and only, those original volumes identified as having disaster alternate volumes. The command HOLD TAPEREPL may be used if the TAPEREPL command needs to be stopped.

10. You can also replace specific original volumes with their disaster alternates. First, issue

```
LIST TTOC SELECT(DISASTERALTERNATEVOLUMES)
```

to identify those tape volumes with disaster alternate volumes, and then issue the TAPEREPL command without the DAVOLUMES parameter. For example, the command:

```
TAPEREPL OVOLS(TKS001,TKS002,TKS003)
```

where TKS001, TKS002, and TKS003 are volume serial numbers that were among those returned from the LIST TTOC command—will replace these specific original volumes with their disaster alternates.

These newly converted original tapes need to be copied now for future disaster recovery.

Note: The AUDIT MEDIACONTROLS processing will fail the audit of a tape volume that is marked as having a disaster alternate volume.

Considerations when using disaster alternate volumes

When doing a generic RECYCLE or TAPECOPY, a tape volume marked as having a disaster alternate volume that is otherwise selected is skipped. A specific volume RECYCLE or TAPECOPY for such a

Making disaster backup copies of DFSMSHsm-owned tape volumes

volume fails; message ARC0424I is issued for a TAPECOPY failure and message ARC0445I is issued for a RECYCLE failure.

Chapter 10. Other availability management considerations

The following additional topics are related to each of the aspects of availability management: backup, dump, recover, and restore.

Additional considerations for backup

Additional topics related to backup are:

- Possible tape volume contention in single and multiple DFSMSHsm-host environments
- Recover tape takeaway contention
- Implications of redefining the backup cycle
- Inline backup of data sets in the middle of a job
- Preventing backup processing
- GUARANTEED SPACE attribute and VSAM data sets

Backup volume contention resolution

DFSMSHsm resolves volume contention among the different tasks that can request the same tape volume. The data set backup by command function may hold a tape for an extended period of time. Consequently, DFSMSHsm allows a backup tape to be taken away from a backup or recycle task to satisfy a recover request. Table 45 on page 445 summarizes the contention possibilities and scope of what DFSMSHsm does to resolve volume contention for both single and multiple DFSMSHsm-host environments.

Table 45. Volume Contention in Single and Multiple DFSMSHsm Host Environments

Function That Has Volume	Function That Needs Volume	Result
Backup	Backup	Backup selects a new target volume.
Recover	Backup	Backup selects a new target volume.
Recycle (source)	Backup	Backup selects a new target volume.
Recycle (target)	Backup	Backup selects a new target volume.
Tapecopy (source)	Backup	Backup selects a new target volume
Backup (data set)	Recover	Recover initiates a tape takeaway and waits for the tape to become available or to reach the maximum delay time. Data set backup completes any data set that is currently being processed, releases the tape, and selects a different target tape.
Backup (volume)	Recover	Recover fails.
Recover	Recover	In a single DFSMSHsm-host environment, there is no contention. In a multiple DFSMSHsm-host environment, the Recover fails.
Recycle (source)	Recover	Recover initiates a tape takeaway and waits for the tape to become available or to reach the maximum delay time. When recycle processing is complete for the data set that is being processed, the allocated volume is released and a new volume is selected for recycle processing.
Recycle (target)	Recover	Recover initiates a tape takeaway and waits for the tape to become available or to reach the maximum delay time. When recycle processing is complete for the data set that is being processed, the allocated volume is released and a new volume is selected for recycle processing.

Table 45. Volume Contention in Single and Multiple DFSMSHsm Host Environments (continued)

Function That Has Volume	Function That Needs Volume	Result
Tapecopy (source)	Recover	Recover initiates a tape takeaway and waits for the tape to become available or to reach the maximum delay time. If tapecopy does not complete before the maximum time, tapecopy fails. Either way, recover takes the tape.
Backup	Recycle source	Recycle of this volume fails. Recycle of other eligible volumes continues.
Recover	Recycle source	Recycle of this volume fails. Recycle of other eligible volumes continues.
Recycle (source)	Recycle source	In a single DFSMSHsm-host environment, there is no contention. In a multiple DFSMSHsm-host environment, Recycle skips the volume because another host is recycling it.
Recycle (target)	Recycle source	In a single DFSMSHsm-host environment, Recycle selects a new target volume. In a multiple DFSMSHsm-host environment, Recycle skips the volume, because another host is recycling it.
Tapecopy (source)	Recycle source	In a single DFSMSHsm-host environment, Recycle skips the volumes, and recycle of other volumes continues. In a multiple DFSMSHsm-host environment, Recycle skips the volumes, and recycle of other volumes continues.
Backup	Recycle target	Recycle selects a new target volume.
Recover	Recycle target	Recycle selects a new target volume.
Recycle (source)	Recycle target	Recycle selects a new target volume.
Recycle (target)	Recycle target	In a single DFSMSHsm-host environment, there is no contention. In a multiple DFSMSHsm-host environment, Recycle selects a new target volume.
Tapecopy (source)	Recycle target	Recycle selects a new target volume.
Backup	Tapecopy source	Tapecopy of this volume fails. Tapecopy of other eligible volumes continues.
Recover	Tapecopy source	Tapecopy of this volume fails. Tapecopy of other eligible volumes continues.
Recycle (source)	Tapecopy source	Tapecopy of this volume fails. Tapecopy of other eligible volumes continues.
Recycle (target)	Tapecopy source	Tapecopy of this volume fails. Tapecopy of other eligible volumes continues.
Tapecopy (source)	Tapecopy source	No contention.

Implications of redefining the backup cycle

If you redefine the backup cycle, you might leave daily backup volumes unused.

Example: Assume the following conditions:

- You have specified the DEFINE BACKUP(YNNYNNY) command. Automatic backup occurs on days 1, 4, and 7.
- You have assigned volume A to day 1, volume B to day 4, and volume C to day 7.
- You later specify DEFINE BACKUP(YNYN). Automatic backup occurs on days 1 and 3.

These are the results:

- Volume A remains assigned to day 1.
- Volume B is still assigned to day 4, but automatic backup no longer runs on day 4. Therefore, DFSMSHsm does not use volume B unless someone issues a BACKVOL command on day 4 in the backup cycle.

- DFSMSHsm does not use volume C any more because it was assigned to day 7 and the new cycle has only four days.

To remove volume C (and volume B, if you want) from its day in the backup cycle and to make it an unassigned backup volume, use the DELVOL command. However, do not specify the PURGE parameter, because any backup version on the tape backup volume would be lost to DFSMSHsm and the volume information for the tape or DASD volume would be deleted. The UNASSIGN parameter of the DELVOL command does not destroy any of the backup versions already contained on the volume or prevent DFSMSHsm from accessing these backup versions during recovery, but it allows the volume to be used again if necessary.

In redefining the backup cycle, you can also use the CYCLESTARTDATE subparameter to redefine the starting date for the cycle.

Inline backup

Inline backup allows you to request a back up of a data set or UNIX file in a batch environment. Inline backup is a way of overcoming the problems of executing the terminal monitor program (TMP) in the background in order to issue HBACKDS commands.

When using inline backup, you can use the JCL data set reference capabilities. This allows you to specify a relative generation number for a GDG. Also, in executing a batch job with TMP, if a data set is created (DISP=NEW), an exclusive enqueue is done on the data set name, and the enqueue is not released until the last job step referring to that data set has ended. If a job step after the TMP job step backward-references a newly created data set, the HBACKDS command fails.

Inline backup allows you to back up data sets or UNIX files in the middle of a job. You add a new step to a job by specifying the inline backup module as the program to execute. You specify the data sets or UNIX files being backed up on specially named DD statements. Inline backup extracts the data set or UNIX file names associated with these DDnames and then performs the back up.

You can use the ARCINBAK program to make a quick backup that can be used in a later step (of the same job). This quick backup enables a restart in the middle of a job stream. Because it is mandatory that the target backup volume is available to perform a recovery even if a continuous backup load exists, DFSMSHsm has a backup tape takeaway capability from data set or UNIX file backup.

The results of each attempted data set or UNIX file backup can be written to a specially named output data set. SNAP dumps of storage relating to inline backup can be written to a specially named output data set for certain error conditions.

The following data sets are not supported:

- Uncataloged data sets
- Backup-while-open data sets
- Non-SMS-managed VSAM data sets that are open for processing by another task at the time of inline backup processing

Related reading

- For more information about how to start the ARCINBAK program, see [“Invoking inline backup” on page 447](#).
- For more information about how to start the ARCINBAK program, see [z/OS DFSMSHsm Managing Your Own Data](#).

Invoking inline backup

To use inline backup:

1. Include a step at the correct place in the job to execute a program called ARCINBAK.

2. Specify the name of the data set or UNIX file to be processed by including a valid DD statement with a DDNAME of BACKxxxx (where xxxx is 1 to 4 characters). Do this for each data set or UNIX file you want backed up.

Note:

1. Only cataloged data sets are supported for inline backup. If volume and unit information is specified on the DD statement, an uncataloged data set is assumed, and the data set is not processed.
2. ARCINBAK does not support data sets allocated with any of the following three dynamic allocation options: XTIO, UCB NOCAPTURE, and DSAB above the line, except when the calling program supplies an open DCB.
3. A UNIX path must be specified with the PATH= parameter. Since the JCL PATH statement only supports absolute pathnames up to 255 characters in length, this is the maximum length filename that ARCINBAK can process.

Any form of the data set name is acceptable to ARCINBAK. Specification of a relative generation number for a GDG or a reference to a DDname in a previous step is acceptable. A DD statement with a DDNAME of ARCPRT can be optionally included in the ARCINBAK program job step. This DD statement defines a SYSOUT data set to contain messages about data sets for which a backup was attempted.

The possible messages are as follows:

```
BACKUP FOR (DSNAME) SUCCESSFUL
DDNAME (DDNAME) NOT BACKED UP, UNABLE TO GET ASSOCIATED JFCB
BACKUP FOR (DSNAME) FAILED, DATA SET NOT CATALOGED
BACKUP FOR (DSNAME) FAILED, RC = (RETURN CODE), REAS = (REASON CODE)
```

At the completion of the ARCINBAK program job step, one of the following return codes is displayed:

- 0 — All backups are successful.
- 4 — No DDnames prefixed with BACK are found or the JFCB associated with a DDname cannot be found.
- 8 — Backup of an uncataloged data set has been attempted. Uncataloged data sets are not supported by inline backup.
- 12 — Backup of a data set failed. One of the following reason codes is also displayed:

RC100 : DFSMSHsm is not active; request rejected.

RC1–RC99 : For message return codes and reason codes, see message ARC13XXI, where XX is the return code.

A DD statement with a DDNAME of ARCSNAP can be included in the ARCINBAK program job step. This DD statement defines a SYSOUT data set for the output from a SNAP macro. The following conditions cause a SNAP dump of storage relating to inline backup:

- MWE storage can be dumped when an error occurs in issuing the service call.
- A complete image of the task storage can be dumped when no DDnames or data sets are processed.

A job stream example of data sets that can and cannot be backed up by ARCINBAK in a batch environment is shown in [Figure 75 on page 449](#).

BACKUP FOR USERID.N01.PSFB	SUCCESSFUL
BACKUP FOR USERID.N02.UNCAT	FAILED, DATA SET NOT CATALOGED
BACKUP FOR USERID.N01.KSDS	SUCCESSFUL
BACKUP FOR USERID.N02.KSDS	SUCCESSFUL
BACKUP FOR USERXX.N02.PSFB	FAILED, RC = 039, REAS = 008

Figure 76. Example of Messages Resulting from Inline Backup Job Stream

Preventing backup processing when using the HOLD BACKUP command

You can use the HOLD BACKUP command to prevent all backup processing, prevent only automatic backup processing, or prevent fast replication backup processing. If you do not want any backup processing at all (for volume, data sets, and auto backups), issue the HOLD BACKUP command by itself. You can specify the AUTO subparameter to prevent only automatic backups from running. You can specify the DSCOMMAND subparameter to prevent only data set backups from running.

Note:

1. The DSCOMMAND option applies to the BACKDS, HBACKDS, ARCHBACK, and ARCINBAK data set backup requests and to backups that are performed as INUSE RETRY from automatic backup.
2. The HOLD ALL command prevents all DFSMSShm functions (except logging) from running.
3. If you are using SETSYS BACKUP parameters or a data set backup installation exit (ARCBDEXT) to direct DFSMSShm to retry backup requests that fail because data sets are in use (see [“Specifying how DFSMSShm should respond to a data set in use”](#) on page 191), and if DFSMSShm has scheduled any such retries during automatic backup, those backup retries will not be affected by the HOLD BACKUP(AUTO) command. You will need to use HOLD BACKUP(DSCOMMAND).

The following command prevents processing of all data set backups (BACKDS, HBACKDS, ARCHBACK, and ARCINBAK), and it prevents the processing of all backups that would be the result of INUSE RETRY from automatic backup. All WAIT requests fail, and control returns to the requester.

```
HOLD BACKUP(DSCOMMAND)
```

The following command prevents processing of data set backups that are directed to ML1 DASD. All WAIT requests that target DASD fail, and control returns to the requester.

```
HOLD BACKUP(DSCOMMAND(DASD))
```

The following command prevents processing of data set backups that are directed to tape. All WAIT requests that target tape and all WAIT requests for large data sets that do not specify a target fail. Control returns to the requester.

```
HOLD BACKUP(DSCOMMAND(TAPE))
```

The following command prevents processing of automatic backups, data set backups that are directed to tape, and all WAIT requests for large data sets that do not specify a target. However, data set backups to ML1 DASD are not affected.

```
HOLD BACKUP(AUTO DSCOMMAND(TAPE))
```

The following command prevents processing of automatic backups and data set backups that are directed to ML1 DASD. Data set backups to tape are not affected.

```
HOLD BACKUP(AUTO DSCOMMAND(DASD))
```

During automatic or volume backup, you can specify whether the holding action occurs immediately at the end of processing each data set or at the end of processing each volume currently being backed up. If you hold backup at end of volume, it can take some time for all of the volumes that are being processed by the different backup tasks to complete and the hold to take full effect. If you hold backup at the end of data sets, DFSMSShm resumes data set backup with the next queued entry when the hold is released. However, for automatic backup, the volume interrupted by the HOLD at end of data set remains eligible for processing if automatic backup is restarted.

The holding action begins when an MWE is selected for processing, not when the HOLD command is entered. If you enter a wait-type backup request and the backup function is held, DFSMSShm fails the wait-type backup request because the hold backup function gives no indication when the backup function will be available.

When a non-wait-type backup request is issued and the appropriate backup function is held, the request remains on the queue and is processed when the appropriate backup request function is released. The held backup processing function can be released with the RELEASE BACKUP command.

Related reading

For more information about other ways to prevent DFSMSShm from processing, see [“Preventing the processing of data sets during space management”](#) on page 149.

GUARANTEED SPACE attribute

The storage class attribute of GUARANTEED SPACE allows the volumes on which an SMS data set is to reside to be chosen explicitly when the data set is created. If GUARANTEED SPACE is used and if any of the volumes specified are not part of one of the storage groups to which the storage class maps, the data set creation fails. The use of GUARANTEED SPACE requires some special considerations if DFSMSHsm is to manage data sets assigned to such a storage class.

DFSMSHsm is used as the data mover on partitioned data sets, catalogs, and other data sets that are not supported by DFSMSdss. When DFSMSHsm is the data mover, the Access Method Services functions of EXPORT and IMPORT back up and recover VSAM data sets. The IMPORT function redefines a VSAM data set by using a copy of the catalog information saved in the EXPORT copy of the data set. This defines the request explicitly specifies the volumes from which the data set was exported. The explicit specification of the volume affects the way data sets are imported with the GUARANTEED SPACE attribute. Likewise, for non-VSAM data sets, VTOC Data Set Services uses the volume serial number passed by DFSMSHsm if the storage class is GUARANTEED SPACE.

Results of recovering GUARANTEED SPACE data sets

With DFSMSHsm as the data mover, data sets recovered with the GUARANTEED SPACE attribute are normally placed on the volume from which they were backed up. Consider the effects on a backed up, multiple-volume VSAM data set. A subsequent recover preserves the volume-to-component relationship that originally existed as long as the data set remains SMS-managed. For a data set in a GUARANTEED SPACE storage class, the relationship includes returning the data set to the same volumes from which it was backed up. Thus, if a data set has been originally defined with the data component on one volume and the index component on another, a backup and recover sequence preserves the relationship between the components and the volumes. Similarly, if a key range data set has three key ranges on three separate volumes, the relationship is preserved.

Problems that can occur

In an environment in which the storage groups and storage classes do not change, the preceding results are adequate to allow DFSMSHsm to manage the data sets. However, you can expect problems in an environment that is subject to storage group reconfiguration or subject to changes in the mapping of data sets to storage classes. These problems can discourage the use of DFSMSHsm space management for these data sets and might require special contingency procedures for availability management. The problems that occur relate to:

- Changes in the storage group
- Changes in the storage-class-to-data-set mapping
- Conversions of data sets to the GUARANTEED SPACE storage class

Changes in the storage group

Consider the consequence of making a specific volume request in a storage group configuration that has changed. Assume that a data set with the GUARANTEED SPACE storage class has been backed up. Sometime later, one or more of the volumes on which the data set has resided are removed from the storage groups that contain GUARANTEED SPACE data sets. A subsequent recover of the data set fails because at least one of the requested volumes is no longer part of a storage group for a GUARANTEED SPACE request. The result is the same for both single-volume data sets and multiple-volume VSAM data sets if the specific volume required is unavailable in the necessary storage group. Use of EAV volumes in mixed environments where the volume cannot be brought online to all systems can also result in problems recalling/recovering data sets that belong to a Storage Class having the Guaranteed Space attribute.

If a storage group is changed to remove volumes that data sets migrated from, you must do one of the following:

- Change the ACS storage class routine so that a storage class with GUARANTEED SPACE is not assigned to the data set.

- Change the volume configuration again so the storage group contains the volumes from which the data set was backed up.
- Change the set of storage groups to which the GUARANTEED SPACE storage class maps to include one that already has the necessary volumes defined. This step applies only if the volumes are already SMS-managed.
- Use the RECOVER command with the FORCENONSMS and the VOLUME parameters. This RECOVER command causes the data set to be recovered to a non-SMS-managed volume as a non-SMS-managed data set. You can then move, copy, or convert the data set as necessary.

Note: If the data set was multiple-volume when it was backed up, it is recovered to a single volume.

Changes in the storage-class-to-data-set mapping

Consider the consequence of making a specific volume request in a storage class mapping that has changed. Assume that a data set is defined and one of the following conditions occur:

- The ACS routines do not assign the data set to any storage class.
- The ACS routines assigns the data set to a storage class that does not have the GUARANTEED SPACE attribute.

Later, assume one of the following changes occur:

- The ACS routine is changed so that it assigns the data set to a storage class with the GUARANTEED SPACE attribute.
- The original storage class is changed to include the GUARANTEED SPACE attribute.

Now, when you recover this data set, the recovery might fail because the requested volumes are not in the storage groups that receive GUARANTEED SPACE requests.

If an SMS-managed data set's original storage class is changed to specify the GUARANTEED SPACE attribute before the data set is recovered, you must do one of the following:

- Change the ACS storage class routine so that a storage class without GUARANTEED SPACE is assigned to the data set.
- Change the storage class of the data set to a storage class without GUARANTEED SPACE, without recalling the data set, by using the IDCAMS ALTER command.
- Change the volume configuration in the appropriate storage groups to contain the volumes from which the data set was backed up. The volumes might need to be converted to SMS management first. It can be difficult to determine all of the volumes involved. DFSMSHsm does not save all of the original volume serial numbers, only that of the volume on which the base data component resided.
- Change the set of storage groups to which the GUARANTEED SPACE storage class maps to include one that already has the necessary volumes defined. This step applies only if the volumes are already SMS-managed.
- Use the RECOVER command with the FORCENONSMS and the VOLUME parameters. This RECOVER command causes the data set to be recovered to a non-SMS-managed volume as a non-SMS-managed data set. You can then move, copy, or convert the data set as necessary.

Note: If the data set was multiple-volume when it was backed up, it is recovered to a single volume.

Conversions of data sets to GUARANTEED SPACE

If the data set was non-SMS-managed when it was backed up and is assigned a storage class with GUARANTEED SPACE during recover, it is assigned to a volume in a storage group that contains GUARANTEED SPACE data sets.

If the data set was SMS-managed when it was migrated but did not have GUARANTEED SPACE, the volumes from which it was backed up might not be in a storage group that receives GUARANTEED SPACE requests. To avoid errors, you must do one of the following before the recover:

- Change the target storage class with GUARANTEED SPACE to map to a storage group that contains the original volumes.

- Add the original volumes to a storage group mapped to by the target storage class with GUARANTEED SPACE.

Data set or UNIX file backup with concurrent copy

The data set or UNIX file backup function allows the use of either concurrent copy (or UNIX file Snapshot) or a standard backup method for copying both SMS-managed and non-SMS-managed data sets or UNIX files. Use the concurrent copy (CC) keyword to specify that you want concurrent copy (or UNIX file Snapshot for UNIX files), rather than standard backup methods, to back up your data sets by command.

Note: For SMS data sets, you do not have to use the CC keyword. Use the CC keyword only if you want to override SMS concurrent copy specifications.

To control the use of concurrent copy (CC) for a data set (or the use of UNIX file Snapshot processing for a UNIX file), several options are available for the data set backup function. If the options are omitted, DFSMSHsm backs up the data set or UNIX file using the management class attributes for SMS-managed data. The issuer of the backup will not receive notice until physical completion. For non-SMS managed data sets or UNIX files, DFSMSHsm uses the standard backup method if the concurrent copy option is omitted.

The following keywords can be specified in the CC parameter of HBACKDS and BACKDS commands, ARCHBACK macro or the ARCINBAK program and control the concurrent copy usage:

REQUIRED

DFSMSHsm uses concurrent copy to backup the data set. If virtual concurrent copy is unavailable DFSMSHsm uses cachebased concurrent copy . If both types of concurrent copy are unavailable, the backup fails. When processing a UNIX file, UNIX File SnapShot processing will be used. If UNIX File SnapShot processing is unable to be used, the backup fails.

PREFERRED

DFSMSHsm uses concurrent copy to backup the data set. If virtual concurrent copy is unavailable, DFSMSHsm uses cache-based concurrent copy. If both types of concurrent copy are unavailable, the data set backup continues as if the CC keyword were not specified. When processing a UNIX file, UNIX File SnapShot processing will be used. If UNIX File SnapShot processing is unable to be used, the backup continues as if the CC keyword were not specified.

STANDARD

DFSMSHsm backs up the data set without using concurrent copy (the default). Control returns to the requester at the physical end of the copy. When processing a UNIX file, file is processed without using UNIX File SnapShot. Control returns to the requester at the physical end of the copy.

VIRTUALREQUIRED

DFSMSHsm uses virtual concurrent copy to backup the data set. If virtual concurrent copy is unavailable, the backup fails. When processing a UNIX file, UNIX File SnapShot processing will be used. If UNIX File SnapShot processing is unable to be used, the backup fails.

VIRTUALPREFERRED

DFSMSHsm uses virtual concurrent copy to backup the data set. If virtual concurrent copy is unavailable, the data set backup continues as if the CC keyword was not specified. When processing a UNIX file, UNIX File SnapShot processing will be used. If UNIX File SnapShot processing is unable to be used, the backup fails.

CACHEREQUIRED

DFSMSHsm uses cache-based concurrent copy to backup the data set. If cache-based concurrent copy is unavailable, the backup fails. When processing a UNIX file, UNIX File SnapShot processing will be used. If UNIX File SnapShot processing is unable to be used, the backup fails.

CACHEPREFERRED

DFSMSHsm uses cache-based concurrent copy to backup the data set. If cache-based concurrent copy is unavailable, the data set backup continues as if the CC keyword was not specified. When processing a UNIX file, UNIX File SnapShot processing will be used. If UNIX File SnapShot processing is unable to be used, the backup continues as if the CC keyword were not specified.

PHYSICALEND

Users receive data set backup results when the backup operation is complete (the default). For a WAIT-type request, the job receives control only after the physical end of the copy.

LOGICALEND

DFSMSHsm releases serialization for the data set or UNIX file and returns control to the data set backup WAIT requester after concurrent copy initialization successfully completes. If concurrent copy initialization fails and PREFERRED was specified, notification is delayed until the end of the backup operation. If concurrent copy initialization fails and REQUIRED was specified, the request fails. Because users are not notified at the physical end of the backup operation, use caution if you use this option.

Note: Use these additional considerations when using cache-based concurrent copy to process large data sets or volumes, or when using multiple tasks to process a large number of data sets or UNIX files:

- Use concurrent copy or UNIX file Snapshot only during periods of light update activity for the data sets UNIX files, or volumes involved.
- Spread multiple concurrent copy jobs across as many LPARs as possible.
- Ensure that jobs and address spaces that will use concurrent copy are assigned a WLM service class with a high execution velocity. Never assign a discretionary goal to concurrent copy work.
- Ensure that volumes that will be processed will not be reserved by another system during the concurrent copy.

Authorizing concurrent copy with RACF

By default, all users can use the CC options. However, if RACF indicates a lack of authority, DFSMSHsm fails the data set backup request if the specified concurrent copy request was specified with the REQUIRED,VIRTUALREQUIRED or CACHEREQUIRED subparameters. If the CC option was used without the REQUIRED,VIRTUALREQUIRED or CACHEREQUIRED subparameters and RACF indicates a lack of authority, DFSMSHsm continues to back up the data set as if the CC keyword were not specified on the backup command.

Data set backup using NEWNAME

The NEWNAME parameter of the (H)BACKDS command allows you to create a data set backup copy and store it under a different, specified data set name. This functionality allows you to keep a permanent copy of data (for example, a year-end copy of a critical data set) as long as a unique new name is specified for the permanent version. The command can be used for many other purposes, such as to create special backup copies to be used for disaster recovery, or to populate a test environment with backup versions of data sets copied to that system under a different name.

You can also use the (H)BACKDS dsname NEWNAME(newdsname) command to convert backup copies created with a competitive product to be DFSMSHsm-managed backup copies by following the steps below:

- Restore all backup versions from the competitive product with temporary names
- (H)BACKDS the oldest temporary version of the data set using the original name in the NEWNAME parameter (No allocation of the original data set required.)
- (H)BACKDS the next oldest temporary version of the data set with original name in the NEWNAME parameter. Repeat until the most recent version has been backed up
- Delete the temporary data set copies

To preserve the original creation date and time of the backup copy, specify the DATE and TIME parameters on the (H)BACKDS NEWNAME command. If DATE is not specified, the current date will be assigned to the backup copy. If DATE is specified, DFSMSHsm will use the date to chronologically position the backup copy in relation to other existing backup versions. If DATE is specified without TIME, the current time will be assigned to the backup version. If the TIME keyword is not specified, and a backup copy with the data specified on the command and the current time already exists, the command will fail.

The BACKDS NEWNAME command will fail when:

- The 'dsname' data set is migrated, uncataloged, or is a catalog
- The 'dsname' and 'newname' data sets do not have the same dataset organization
- The 'dsname' and 'newname' data sets do not have the same SMS-managed or non-SMS-managed status
- More than one 'dsname' or more than one 'newname' is specified
- The 'newname' data set is pre-allocated on tape

UNIX file backup using NEWNAME

The NEWNAME parameter of the (H)BACKDS command allows you to create a UNIX file backup copy and store it in the DFSMSHsm inventory under a directory name that is a subset of the existing directory path. This functionality can be used to populate a test environment with backup versions of UNIX files copied to that system under a temporary directory.

You can also use the (H)BACKDS '/pathname/' NEWNAME('/subpath/') command to convert backup copies created with a competitive product to be DFSMSHsm-managed backup copies by following these steps:

- Restore directory tree backup versions from the competitive product into a temporary directory.
- (H)BACKDS the oldest temporary version of the directory structure, specifying RECURSE. Specify the absolute directory path of the original in the NEWNAME parameter.
- (H)BACKDS the next oldest temporary version of the directory structure, specifying RECURSE. Specify the absolute directory path of the original in the NEWNAME parameter. Repeat until the most recent version has been backed up.
- Delete the temporary UNIX file copies.

To preserve the original creation date and time of the backup copy, specify the DATE and TIME parameters on the (H)BACKDS NEWNAME command. If DATE is not specified, the current date will be assigned to the backup copy. If DATE is specified, DFSMSHsm will use the date to chronologically position the backup copy in relation to other existing backup versions. If DATE is specified without TIME, the current time will be assigned to the backup version. If the TIME keyword is not specified, and a backup copy with the data specified on the command and the current time already exists, the command will fail.

Tip: It is best if the NEWNAME directory exists at the time of the backup. DFSMSHsm will store the name of the containing zFS data set in the backup record for future SMS-management checks. (This attribute is used for the number of versions to keep for roll-off processing, ALTERDS checking, and whether the Recover processing should end due to a No-Crossmounts condition on a recursive file request. If the NEWNAME directory doesn't exist, DFSMSHsm cannot store the containing zFS name, and some functions, such as ALTERDS may be unable to be performed.

Additional considerations for dump

Several additional topics are related to dump:

- Dumping DFSMSHsm-owned volumes
- Dumping control data sets
- Dumping the journal data set
- Preventing dump processing
- Invoking full-volume dump compression
- Bypassing enqueue processing between full-volume dump and DFSMSdfp functions

Dumping DFSMSHsm-owned volumes

DFSMSHsm-owned DASD backup and migration level 2 volumes are not automatically dumped. You must issue a DFSMSHsm BACKVOL command for each migration level 2 volume you want to dump. The activity

against the volumes should be at an absolute minimum while they are being dumped. The volumes do not have any internal DFSMSHsm serialization performed for them to prevent migration copies or backup versions from being created on them while they are being dumped, so it is imperative to dump these volumes when no migration or backups are being done at the same time. Also, no VTOC copy data sets are created for DFSMSHsm-owned volumes regardless of the VTOCCOPIES subparameter of the target dump classes.

Dumping control data sets

If you dump the volumes that contain the control data sets, *you will destroy your control data sets if you do a restore of the volume*. If you restore the control data sets, you must immediately recover the control data sets. If you dump the volume containing the BCDS, no concurrent dump activity should be processing on another host. A lockout can occur.

Related reading

For more information about how to recover control data sets, see [“Reasons for recovering the control data sets” on page 507](#).

Dumping the journal data set

If you dump the volume containing the journal data set, if your environment consists of multiple hosts with a global resource serialization product, and if the journal resource QNAME=ARCGPA and RNAME=ARCRJRN and the resource QNAME=SYSVTOC and RNAME=volser-containing-journal, both resources must be treated as either local resources or as global resources.

If the resource QNAME=SYSVTOC and if RNAME=volser-containing-journal is named in the systems exclusion resource name list, the resource QNAME=ARCGPA and RNAME=ARCRJRN must also be named in the systems exclusion resource name list. In this case, global resource serialization treats both as local resources. The reserve conversion resource name list is not searched, and the system is allowed to issue a hardware reserve for these resources.

If the journal data set shares a volume with a data set that has a higher access priority requirement than the journal data set and if the resource QNAME=ARCGPA and RNAME=ARCRJRN is named on the reserve conversion resource name list, then the resource QNAME=SYSVTOC and RNAME=volser-containing-journal must also be named on the reserve conversion resource name list. In this case, global resource serialization treats both as global resources to be processed around the ring and suppresses any hardware reserves for these resources.

Preventing dump processing

You can use the DFSMSHsm HOLD command to prevent all dump processing or to prevent only automatic dump processing.

The following command prevents both command and automatic dump processing:

```
HOLD DUMP
```

The following command prevents automatic dump processing without preventing command dump processing:

```
HOLD DUMP(AUTO)
```

The following command prevents fast replication target volumes from being dumped by command:

```
HOLD DUMP(FRBACKUP)
```

You can specify whether you want the holding action to occur immediately at the end of processing each data set currently being dumped or to occur at the end of each volume being dumped. If you hold dump

at end of volume, it can take a long time for all of the volumes that are being processed by the different dump tasks to be completed and the hold to take full effect. If you hold dump at the end of data sets, DFSMSHsm resumes command dump with the next queued entry when the hold is released. However, for automatic dump, the volume that was being processed when the HOLD at end of data set occurred remains eligible for processing if automatic dump is restarted.

The holding action begins when an MWE is selected for processing, not when the HOLD command is entered. If you use an HSEND CMD command to enter a wait-type dump request and the dump function is held, DFSMSHsm fails the wait-type dump request because the hold dump function gives no indication of when the dump function is available.

When a non-wait-type dump request is issued and the dump function is held, the request remains on the queue and is processed when the dump function is released. The held dump function is released with the RELEASE DUMP command.

Related reading

For more information about other ways to prevent DFSMSHsm from processing a dump function, see [“Preventing the processing of data sets during space management” on page 149](#).

Dumping all allocated space

Programming Interface Information

DFSMSHsm’s full-volume dump invocation of DFSMSdss specifies the ALLEXCP and ALLDATA(*) parameters. If the field in the DSCB that shows the last-used track and the block on that track contain zeros, the ALLEXCP option dumps all allocated space. When ALLDATA(*) is specified, all allocated space of SAM and PAM data sets, and data sets with a null DSORG field and whose last-used track and block on that track is greater than zero, are dumped. Use the following PATCH commands to suppress these parameters:

To suppress ALLEXCP:

```
PATCH.MCVT.+3C3 BITS(1.....)
```

To suppress ALLDATA(*):

```
PATCH.MCVT.+3C3 BITS(01.....)
```

To suppress both ALLEXCP and ALLDATA(*):

```
PATCH.MCVT.+3C3 BITS(11.....)
```

End Programming Interface Information

Invoking full-volume dump compression

You can compress all volume dumps by specifying the compress parameter at the DFSMSHsm full-volume dump invocation of DFSMSdss. Use the following PATCH command to specify the compress parameter:

Programming Interface Information

```
PATCH .MCVT.+3C3 BITS(001.....)
```

End Programming Interface Information

Note: This is ignored if HWCOMPRESS(YES) is active.

Bypassing enqueue processing between full-volume dump and DFP functions

To avoid contention problems between DFSMSHsm full-volume dump and DFP scratch, rename, and allocate services, major resource name ADRLOCK and minor resource name NONSPEC are allocated EXCLUSIVE when the volume is not known.

Since this process can have an impact on dump performance, you can bypass it by using the following patch:

Programming Interface Information
PATCH .MCVT.+38F X'10' VERIFY(.MCVT.+38F X'00')
End Programming Interface Information

Volume recovery and restore considerations

The following topics discuss items to consider when doing volume recovery and restore:

- Restoring data sets or volumes directly with DFSMSdss
- Requesting a list of dump volumes for a dump copy
- Determining the dump copy data set name
- Invoking DFSMSdss's RESTORE function
- Preventing recovery and restore processing
- Use of the date-last-referenced field for recovery

Restoring data sets or volumes directly with DFSMSdss

It is possible to invoke DFSMSdss directly to restore a data set or volume from a DFSMSHsm-owned dump copy. This requires you to perform the following steps:

1. Request from DFSMSHsm a list of the tape volumes that comprise the dump copy.
2. Determine the data set name that is used for the dump copy.
3. Invoke the DFSMSdss RESTORE function directly.

Requesting a list of dump volumes for a dump copy

Use the DFSMSHsm LIST command to request the set of dump volumes that compose the required dump copy. You must know the volume serial number of the volume you need to restore or the volume serial number of the volume on which the data set you want to restore resided when it was dumped.

Determining the dump copy data set name

DFSMSHsm generates a unique data set name for each dump copy that it has created through DFSMSdss. This data set name must be known in order to allocate the dump volumes. If you need to perform a restore using DFSMSdss directly without DFSMSHsm, you need the DFSMSHsm-generated data set name. This name can be obtained by issuing the following command:

```
LIST DUMPVOLUME(volser) DUMPCONTENTS
```

Related reading

For more information about the format of these data set names and how to determine the name of a specific dump copy, see [“Names of dump copy data sets” on page 197](#).

Invoking the DFSMSdss RESTORE function

You can invoke DFSMSdss in one of two ways: either write the necessary JCL to submit a batch job, or if you have ISMF, use the menu-driven panels of ISMF to build a job stream that will perform a DFSMSdss RESTORE.

If you received an invalid track format error (ADR367E) during a DFSMSdss full-volume restore, you can restore this volume by issuing the following DFSMSdss restore command in your JCL or ISMF job stream:

```
RESTORE FULL INDDNAME(tapename) OUTDDNAME(dasdname)
PURGE COPYVOLID
```

This restore restriction exists because DFSMSHsm uses the CANCELERROR keyword in its full-volume dump restore. Volumes that receive invalid track format errors (ADR367E) can only be restored outside of DFSMSHsm by using the DFSMSdss restore command, as previously explained.

Attention: DFSMSdss cannot directly restore dump tapes that are password protected by DFSMSHsm. Such tapes require special consideration during restore processing. Because DFSMSdss uses EXCP for reading, OPEN requires that the data be protected from destruction. Therefore dump tapes with password protection must be write-protected (ring removed or cartridge knob set) before they are mounted for restore processing.

Related reading

For more information about using DFSMSdss JCL code or the ISMF panels for DFSMSdss, see [z/OS DFSMSdss Storage Administration](#).

Preventing recovery and restore processing when using the HOLD RECOVER command

You can use the HOLD RECOVER command to prevent all recovery, to restore processing, or to prevent recovery alone from tape.

The following command prevents recovery processing from tape without preventing recovery processing from DASD:

```
HOLD RECOVER(TAPEDATASET)
```

Note: Holding tape recovery has the effect of holding all restores, because all dump copies managed by DFSMSHsm are on tape. Holding tape recovery does not hold the data set recovery from a mounted backup tape already in use.

The following command prevents both tape and DASD recovery processing:

```
HOLD RECOVER
```

The holding action begins when an MWE is selected for processing, not when the HOLD command is entered. If you enter a wait-type recovery or restore request and the recovery function is held, DFSMSHsm fails the wait-type recovery request because the hold recovery function gives no indication of when the recovery function will be available.

When a non-wait-type recovery or restore request is issued and the appropriate recovery or restore function is held, the request remains on the queue and is processed when the appropriate recovery function is released. The held recovery or restore function can be released with the RELEASE command.

Using the date-last-referenced field for recovery

When a data set is recovered or restored by an unauthorized user (HRECOVER), the date-last-referenced field in the data set VTOC entry of the data set is updated with the current date. When a data set is recovered or restored by an authorized user, the date-last-referenced field in the data set VTOC entry is

updated with the date-last-referenced field from the data set's VTOC entry that was saved at the time of backup or dump. When a data set is recovered or restored with the NEWNAME parameter of the RECOVER command, the date-last-referenced field in the data set VTOC entry is updated with the current date regardless of the authorization of the user.

Deferred generation data sets

Deferred generation data sets are generation data sets for which a failure has occurred before the data set is correctly associated with the generation data group. These data sets are temporary in the sense that at some time they may become associated with the GDS. DFSMSHsm treats deferred generation data sets as permanent non-GDS data sets.

Security considerations for availability management

DFSMSHsm does not check data set security during automatic backup and dump. DFSMSHsm also bypasses security checking when it processes operator commands entered at the system console or commands issued by a DFSMSHsm-authorized user.

DFSMSHsm checks security for data sets when a user who is not DFSMSHsm-authorized issues an HBACKDS, HBDELETE, HALTERDS, or HRECOVER command. Security checking is not done when DFSMSHsm-authorized users issue the user commands. If users are not authorized to manipulate data, DFSMSHsm does not permit them to back up data sets, delete backup versions, change the conditions for backup versions, or recover data sets. [Table 46 on page 460](#) shows the RACF authority required to perform each availability management function.

Table 46. Resource Access Authority Required for DFSMSHsm Functions

DFSMSHsm Function	RACF Resource Access Authority Required
Back up a data set	Update
Recover a backup version without specifying the NEWNAME parameter	Alter If profile recovery is required, authority is needed to create a discrete RACF profile for the recovered data set.
Recover a backup version and specify the NEWNAME parameter	Read authority to the data set being recovered. Alter authority to the newly named data set if one exists. If profile recovery is required, authority is needed to create a discrete RACF profile for the recovered data set.
Changing backup parameters	Alter
Deleting backup versions	Alter

Authorization checking during recovery

During recovery, DFSMSHsm makes a first authorization check against the original profile. If it cannot find either a generic profile or a discrete profile for a cataloged data set that was RACF-indicated at the time of backup or recovery, DFSMSHsm determines whether a backup profile exists. If a backup profile exists, DFSMSHsm makes a second authorization check with the backup profile name. If the second authorization check fails, the recovery fails.

When DFSMSHsm is the data mover, a new RACF access control environment element (ACEE) is created that describes the user's RACF status. This ACEE exists for the duration of the cataloging operation and is effective only for the recovery task. After the cataloging operation has completed, DFSMSHsm removes the ACEE.

For a non-VSAM data set, DFSMSdfp catalog management is invoked to catalog the data set. DFSMSdfp does its own security checking of the requester against the catalog using this ACEE. If security checking

against the catalog fails for lack of correct authority, DFSMSHsm sets a return code to reflect the failure of the catalog operation. RACF issues messages describing the reasons for denying access to the catalog.

For a VSAM data set, a new RACF ACEE is created when the target data set of the Access Method Services IMPORT has not been cataloged at the start of the recovery operation. This ACEE is effective for the duration of DFSMSHsm's invocation of Access Method Services to perform the IMPORT operation. DFSMSdftp catalog management will use this ACEE to verify the requester's authority to catalog the data set. If the catalog operation fails, the IMPORT fails and generates an appropriate return code. RACF issues messages describing the reasons for denying access to the catalog.

When DFSMSdss is the data mover, the authorization process is the same, except that DFSMSdss does the cataloging.

Recovering or restoring RACF-indicated data sets

When you use the RECOVER or HRECOVER command to recover or restore a RACF-indicated, cataloged, non-VSAM data set and the target volume is different from the source volume, DFSMSHsm changes the volume serial number and device type information in the RACF discrete data set profile to indicate the volume where DFSMSHsm has recovered the data set.

If the attempt to change a profile fails because the profile cannot be found, DFSMSHsm attempts to recover a backed up profile for the recovered data set.

When a RACF naming conversion table converts a data set name to a different profile name, DFSMSHsm will not be able to recover the discrete profile. The RACF administrator will need to enable access.

Recovering RACF discrete profiles

If a recovered data set was cataloged and RACF-indicated when it was backed up or when it was recovered or restored, DFSMSHsm tries to recover the RACF discrete profile for the data set even if you specified the NOPROFILEBACKUP parameter of the SETSYS command or if the profile already exists.

DFSMSHsm creates a RACF discrete profile during recovery by performing the following actions:

1. Modeling the new profile after the original profile, and if that isn't possible,
2. Modeling the new profile after the backup profile and if that isn't possible,
3. Creating a minimal discrete profile.

DFSMSHsm tries to recover the RACF discrete profile by using the profile of the original data set as a model for creating a profile. If the original data set's profile no longer exists, DFSMSHsm tries to create a profile by using a backup profile for the model.

If a backup profile does not exist, DFSMSHsm tries to create a minimal discrete profile. A minimal discrete profile is one for which DFSMSHsm supplies no access list and no model profile. The access authority with which users can address the data set is taken from the defaults defined for the user (or group if the high-level qualifier is a group name). If a DFSMSHsm-authorized user recovers the data sets, defaults are taken from the user ID associated with the DFSMSHsm-started procedure.

DFSMSHsm creates a minimal discrete profile only if neither the original profile nor a backup profile exists for the recovered data set. If the profile creation fails because a profile already exists for the recovered data set, DFSMSHsm considers the profile recovery to be successful, and normal processing continues. When this occurs, RACF may issue message ICH408I at the security console to indicate that the resource is already defined.

Note: DFSMSHsm recovers a discrete profile if one existed at the time of backup or recovery. If you change from RACF discrete profile protection to generic profile protection, DFSMSHsm still recovers the discrete profiles when it recovers the backup versions of data sets that were once protected with discrete profiles. So, discrete profiles can reappear even if you now use generic profile protection.

Related reading

For more information about the installation of generic profile options, see [z/OS DFSMSHsm Implementation and Customization Guide](#).

Authorization checking during profile recovery

When a DFSMSHsm-authorized user issues a RECOVER or HRECOVER command, no security checking is performed. If the recover request originates with a non-DFSMSHsm-authorized user, the recover is done with the user's ACEE, which is a control block for RACF. DFSMSHsm informs RACF that security checking is to be done, and the recover request fails if RACF determines that the user is not authorized to create a discrete profile for the data set.

Characteristics of the recovered profile

When a DFSMSHsm-authorized user issues a RECOVER or HRECOVER command, DFSMSHsm recovers profiles using DFSMSHsm's ACEE. Consequently, the recovered profile shows the group name from the user ID associated with the DFSMSHsm-started procedure. If a minimal profile is created when a DFSMSHsm-authorized user issues a recover request, additional information from this user ID is placed in the recovered profile. This information includes levels of auditing, access authority required by other users (universal access), and profile ownership.

If a non-DFSMSHsm-authorized user issues the recover request, the user's ACEE is used to create a new profile. The recovered profile reflects the group name of the requester. If a minimal profile is created, the profile also reflects the requester's user ID in the owner field and the requester's defaults for audit level and universal access authority.

Note: For steps “2” on page 461 and “3” on page 461, if the DFSMSHsm-started procedure is not associated with a RACF user ID, the user and group names of the recovered profile appear as an asterisk (*) if the data set is recovered by a DFSMSHsm-authorized user.

Effects of profile modeling on profile recovery

Profile modeling is a RACF function that merges information from a *model profile* into a new profile when it is created. Profile modeling is available at both the user ID and group level. If the user ID associated with the DFSMSHsm-started procedure has a model profile, information from the model is put into all backup profiles. Model profiles can provide information for universal access, auditing level, profile owner, level field, installation-defined data, and an access list. If a profile is subsequently recovered, the additional information from the profile model can be carried along and inserted into the recovered profile.

When a non-DFSMSHsm-authorized user issues a recover request that results in profile recovery, the user's ACEE is used to create the profile. Consequently, if profile modeling is active for the user or the user's group, information from the appropriate profile is merged into the newly created, recovered profile.

Related reading

For more information about profile modeling, see [z/OS Security Server RACF Security Administrator's Guide](#).

Accessing a data set when the profile cannot be recovered

Even if DFSMSHsm cannot recover a discrete profile, you can access the recovered data set. [Table 47 on page 463](#) shows how to access data sets using the DFSMSHsm RECOVER command when recovering data sets that are RACF-protected with discrete profiles and DFSMSHsm is unable to recover a discrete profile. These data sets were generally backed up by DFHSM before Version 2 Release 2.0.

Table 47. Recovering RACF-Protected Data Sets Backed Up under DFHSM before Version 2 Release 2.0

Type of Data Set	Parameter	Result	How to Access the Data Set
Cataloged Non-VSAM	RECOVER NEWNAME	If the RACF indicator was on when the backup version was created for the current data set, the RACF indicator is on in the recovered data set.	If a RACF profile does not already exist, create a generic profile or use the RACF ADDSD command with the NOSET parameter to create a RACF discrete profile for the data set with the new name.
Cataloged VSAM	RECOVER NEWNAME	DFSMSHsm scratches the newly named data set. The recovered data set replaces the newly named data set, including the catalog record.	If the original data set was protected with a discrete profile and the newly named data set was not, use the ADDSD NOSET command to create a new discrete profile. Or, you can create a generic profile for the newly named data set.
Uncataloged	RECOVER TOVOLUME (Volume different from the one the data set was backed up from)	If the RACF indicator was on when the backup version was created or the newly named data set is RACF indicated, the RACF indicator is on in the recovered data set.	If a RACF profile does not already exist, use the RACF ADDSD command with the NOSET parameter to create a RACF profile for the data set.
Cataloged Non-VSAM or VSAM	RECOVER (NEWNAME is not specified)	If the RACF indicator was on when the backup version was created for the current data set, the RACF indicator is on in the recovered data set.	If a RACF profile does not already exist, create a generic profile or use the RACF ADDSD command with the NOSET parameter to create a RACF discrete profile for the data set.

Maintaining password protection for recovered data sets

Password protection in MVS is implemented differently for non-VSAM and VSAM data sets. Password protection is not applicable to SMS-managed data sets. The passwords for all non-VSAM data sets are stored in one system password data set. The password for each VSAM data set is stored in a catalog record for the specific VSAM data set. Therefore, VSAM passwords are maintained during DFSMSHsm processing as a part of regular catalog record creation and updating.

If you are recovering an existing VSAM data set, the password is the current password. If you are recovering a VSAM data set that has been deleted, the password is the password that existed when DFSMSHsm backed up the data set.

If you specify the NEWNAME parameter of a RECOVER command for a password-protected, non-VSAM data set, DFSMSHsm marks in the DSCB of the recovered data set the same password protection as the original data set had. Enter a password for the recovered data set in the system password data set. Then, use the password to access the recovered, non-VSAM data set.

For VSAM data sets, whether you specify the NEWNAME parameter, DFSMSHsm marks in the catalog that the recovered data set is protected and enters the old password in the catalog record of the recovered data set. Use the old password when you want to access the recovered VSAM data set.

If DFSMSHsm migrated a password-protected VSAM data set whose backup versions are to be deleted, you must specify the password or DFSMSHsm fails the request. When deleting backup versions of VSAM data sets that no longer exist or that were migrated by DFSMSHsm Version 1 Release 3, DFSMSHsm does not check the password.

Be aware of the following password issues when you attempt to change password protection while data sets are backed up:

- You can change the password of a backed up non-VSAM data set by using the IEHPROGM utility. However, to change the password of a backed up VSAM data set you must use the Access Method Services facility. For a backed up VSAM data set, the password required to recover a backup version is the one that existed when the backup version was created if the data set is not currently cataloged.
- If you try to add password protection to a non-existing non-VSAM data set that has backup versions, the password is added to the system password data set. However, the backup versions do not

have protection, and when DFSMSHsm recovers the data set, the DSCB does not indicate password protection. If an existing non-VSAM data set is password protected at the time it is recovered or restored, even if it was not protected when the data set was backed up or dumped, the data set is password indicated after the recovery or restore.

- If you try to add password protection to a backed up VSAM data set, you must use the Access Method Services facility. If you recover the backup versions, DFSMSHsm does not protect the recovered data set if the data set was not protected when DFSMSHsm backed it up.

Note: If a catalog has update protection, you are prompted for the password when DFSMSHsm tries—during an unauthorized DFSMSHsm function from an unauthorized DFSMSHsm user—to create a catalog entry in the protected catalog.

DFSMSHsm retrieval of management classes

If you are changing the definitions of management classes, you must know when the new definitions will take effect. When DFSMSHsm begins automatic availability management or availability management from a volume command, it retrieves a list of all currently defined management classes before it begins processing unless volume-type processing is operating or has just completed. Volume-type processing consists of the following functions:

- Automatic backup
- BACKVOL command

If volume-type processing is in progress or has just been completed when a new volume-type processing is to begin, DFSMSHsm uses the list of management classes that exists from the prior processing. If you are changing the management classes, DFSMSHsm must complete its volume-type processing before you can expect the changes in the management classes to become effective.

Availability management considerations for extended SAM and extended and compressed VSAM data sets

When DFSMSHsm does backup and recovery processing for extended format SAM and VSAM compressed data sets, be aware of the following results:

- When DFSMSHsm backs up an extended format VSAM compressed data set, it recovers that data set only as an extended format compressed data set.
- When DFSMSHsm backs up an extended format SAM compressed data set, it recovers that data set as either an extended format compressed or nonextended format SAM data set.
- When DFSMSHsm backs up a compressed SAM or VSAM data set, it suspends software compression for that data set.
- When a compressed SAM or VSAM data set is backed up, DFSMSHsm records in the BCDS that it is a compressed data set. It also records both the compressed size of the data set and the size the data set would be if it were not compressed. This information is passed to DCOLLECT.

Availability management considerations for sequential data striping

DFSMSHsm does backup and recovery processing for single-stripe and multiple-stripe sequential data sets. To process these data sets, the data mover must be DFSMSdss, and the data sets must be SMS managed.

Backup processing

Incremental backup processing backs up a single-stripe or multiple-stripe data set when the data set's name is specified in the BACKDS command, and other required conditions are satisfied.

During volume incremental backup processing, DFSMSHsm backs up a sequential extended format data set when the first stripe (volume) is being processed. Backup is skipped when subsequent stripes (volumes) are being processed.

If a sequential extended format data set is larger than the available free space on one DASD backup volume, then the backup fails. Note that it is not advisable to use extended address volumes (EAVs) as backup volumes because the cylinder managed space will not be utilized.

The space used on all volumes is reported (message ARC0734I) for the sequential extended format data set backed up.

During full physical volume dump processing, DFSMSHsm dumps only the stripe on the volume being dumped. You are responsible for performing full physical volume dumps for each volume containing a stripe of a sequential extended format data set. It is recommended that you use incremental backup versions for multiple-stripe sequential extended format data sets.

Incremental backup processing does not occur under the following conditions:

- A sequential extended format data set is not backed up if it is on a non-SMS-managed volume.
- A multiple-stripe sequential extended format data set is not backed up if a SETSYS USERDATASETSERIALIZATION is not presented to DFSMSHsm.
- A multiple-stripe sequential extended format data set is not backed up if it is protected by a RACF discrete profile.

Recover and restore processing

DFSMSHsm recovers or restores a sequential extended format data set (indicated in the MCC record) using DFSMSdss as the data mover.

During full volume restore with APPLYINCREMENTAL, DFSMSHsm does not apply the incremental backup version that is more recent than the full physical dump copy to a currently cataloged multiple-stripe sequential extended format data set. The stripe restored from the dump copy is scratched from the volume if the data set is no longer cataloged on the volume being processed.

During data set recovery of a multiple-stripe sequential extended format data set, without FROMDUMP(DUMPVOLUME(*volser*)) being specified, DFSMSHsm always recovers an incremental backup version made by DFSMSdss, even if a physical full-volume dump copy is more recent than the incremental backup version. A message is issued to indicate that an incremental backup version has been recovered instead of a more recent dump copy.

During a recovery attempt of a multiple-stripe sequential extended format data set, when FROMDUMP(DUMPVOLUME(*volser*)) has not been specified, recovery fails if the data set has only been backed up by physical full-volume dump.

DFSMSdss restores a sequential extended format data set as follows:

- A sequential extended format data set that was multiple-stripe when it was backed up or dumped can be recovered or restored as a multiple-stripe or single-stripe sequential extended format data set, regardless of the existence of the target data set before the RECOVER command is issued.

The number of stripes depends on the storage class SUSTAINED DATA RATE value and the availability of the required volumes.

- A sequential extended format data set that was single-stripe when it was backed up or dumped can be recovered or restored as a multiple-stripe or single-stripe sequential extended format data set, regardless of the existence of the target data set before the RECOVER command is issued.

Again, the number of stripes depends on the storage class SUSTAINED DATA RATE value and the availability of the required volumes.

A sequential extended format data set that was either single-stripe or multiple-stripe when it was backed up or dumped is recovered or restored as a sequential extended format data set or non sequential extended format data set, regardless of the existence of the target data set before the RECOVER command is issued.

A data set that was not sequential extended format when it was backed up is always recovered or restored as a data set that is not sequential extended format. DFSMSHsm does not convert a data set that is not sequential extended format to a sequential extended format data set through recovery or restore processing, even if the data set is preallocated as sequential extended format before the RECOVER command is issued.

If ACS filter routines are modified to direct a data set that was sequential extended format when it was backed up to a non-SMS-managed volume, the recovery or restore fails.

If FORCENONSMS is specified on the RECOVER command to force a sequential extended format data set to be recovered or restored to a non-SMS-managed volume, the data set will be recovered as a non sequential extended format data set. The maximum size of the non-SMS SAM data set is 1 volume.

If FROMVOLUME is specified on the RECOVER command to recover a sequential extended format data set, the recovery or restore fails.

If reblocking is required for a sequential extended format data set, DFSMSHsm passes the requirement to DFSMSdss, which performs the reblocking.

To restore a single-stripe sequential extended format data set from a physical full volume dump tape, you can issue the RECOVER *dsname* FROMDUMP(DUMPVOLUME(*volser*)) command for the stripe dumped to the specified dump tape.

To restore an existing multiple-stripe sequential extended format data set from physical full volume dump tapes, you must issue the RECOVER *dsname* FROMDUMP(DUMPVOLUME(*volser*)) command for each stripe of the data set. If the sequential extended format data set no longer exists, you must catalog the data set after the restores, since DFSMSdss and DFSMSHsm do not catalog a multiple-stripe sequential extended format data set during physical data set restore processing.

DFSMSHsm fails the recovery of a sequential extended format data set if the desired backup version indicates that the data set was sequential extended format when it was backed up, and the data mover was DFSMSHsm.

Note: DFSMSHsm recovery or restore processing does not honor the “stripedness” specified in the data class DSNTYPE in the ACS filter routine. Changing the DSNTYPE definition or allocating the target data set before issuing the recover command has no effect on converting to or from striped data during DFSMSHsm recovery or restore processing.

DFSMSHsm does not recover a multiple-stripe sequential extended format data set during incremental full volume recovery.

If the target data set is preallocated and the REPLACE keyword is specified, DFSMSHsm data set recovery, restore, incremental volume recovery, and full volume restore with APPLYINCREMENTAL processing delete the non-VSAM target data set, both SMS-managed and non-SMS-managed, before recovering or restoring the backup or dump copy.

DFSMSHsm command data set recovery always lets DFSMSdfp select the target SMS-managed volume for a non-VSAM data set, even if the target data set is cataloged before the RECOVER command is issued. The volume the data set is cataloged on is still passed to DFSMSdfp, but the final target volume is selected by DFSMSdfp.

Common dump queue

The common dump queue (CDQ) is a queue of DFSMSHsm dump requests from BACKVOL VOLUMES commands, BACKVOL STORAGE GROUP DUMP commands, FRBACKUP COPYPOOL DUMP commands, and auto dump requests. The CDQ is shared by multiple DFSMSHsm hosts. It is implemented through the use of the cross-system coupling facility (XCF), to balance the dump workload across the resources available in each DFHSMhsm host in an HSMplex. A DFSMSHsm host is defined to XCF as a member of a group to be used for dump processing. Distributing dump work to all of the members in the group increases the number of available tasks to perform the work, improving the throughput of the dump function, as the dump workload is not concentrated on a single host's address space.

To maximize the use of available tasks in the CDQ group, you can use a MINSTACK (minimum stack) option, in conjunction with the STACK option, on the DEFINE DUMPCLASS and BACKVOL commands. MINSTACK indicates that fully using the available dump tasks in the CDQ group takes priority over optimizing stacking; in other words, maximizing the use of available dump tasks may result in less stacking of volumes on the tape. However, more stacking is possible as volumes from different copy pools are allowed to be stacked onto the same tape, up to the maximum value specified by STACK, if they have the same dump class. This applies to the dump function running in a non-CDQ environment, as well. For example:

- With STACK(100), if there are 100 volumes and 10 available dump tasks, all 100 volumes are dumped using a single task to the same tape.
- If the MINSTACK(10) option is defined, 10 volumes are stacked on a single tape from each of the 10 dump tasks.
- With more volumes, stacking continues on a single tape up to the maximum of 100 volumes defined with STACK(100).

Figure 77 on page 467 shows a CDQ that is shared by three DFSMSHsm hosts that are connected to an XCF defined group, where submitted dump requests are distributed and processed among the dump resources available in the CDQ group, with results returned back to the host where the request originated.

Figure 77. Common Dump Queue

As illustrated in Figure 78 on page 468, the CDQ group allows for flexible configurations. This provides the capability to:

- Define multiple queues in the same HSMplex
- Allow group members to both receive and process requests, only process requests, or only receive requests.

Figure 78. CDQ -- Flexible Configurations

In CDQ environments:

- A CDQ cannot span an HSMplex
- System affinity is not supported
- Priority of requests is supported
- A host can be connected to only one CDQ.

Results are returned to the submitting host, but progress and status messages are recorded on the host processing the request. By using the message simplification support along with CDQ processing, each CDQ group member writes all DFSMSHsm and DFSMSdss messages related to the processing of a particular copy pool to a single shared message data set. This simplifies diagnostics, as all messages are collected from each host into a single data set. The data set is managed by the master scheduler (MS) host for the CDQ. Refer to the description of the FASTREPLICATION(MESSAGE DATASET(YES)) option in Chapter 65, “SETSYS command: Establishing or changing the values of DFSMSHsm control parameters,” on page 1057.

Types of hosts used in a common dump queue

The master scheduler (MS) is the DFSMSHsm host that manages all of the dump requests in the CDQ. All dump requests are sent to it, and it assigns work to all of the other hosts in the group that are eligible to process requests from the CDQ. Each group needs a master scheduler to manage CDQ processing for the group; otherwise, dump requests are processed locally.

The other principal types of DFSMSHsm hosts are the submitting host and the processing host.

Submitting host

Host that receives requests from commands and, using XCF messaging, sends it to the master scheduler host. Performs command complete processing and posts the user that the command has completed.

Master scheduler (MS)

- Accepts requests from submitting host members and locally submitted requests and maintains them as a single common queue of all requests for the CDQ function. The master scheduler can be the submitting host – in this case the command is not sent.
- Assigns or distributes the requests among the available tasks across all of the eligible hosts (processing hosts) connected to the CDQ while balancing the requests among all the hosts.

- Manages "work completed" messages received from a processing host to support functions like stacking.
- Sends "command complete" messages back to the submitting host.

Processing host

- Receives assigned work requests from the master scheduler and places them on its local queue for processing.
- Sends "work complete" messages back to the master scheduler with specific protocols to support functions like stacking.
- The processing host could be the submitting host and/or the master scheduler host.

Figure 79 on page 469 shows a CDQ group where:

- HSM1 is the submitting and processing host
- HSM2 is the master scheduler and processing host. It receives all requests, managing them on a single queue, and distributes the requests among the eligible hosts connected to the common queue, through XCF messaging.
- HSM3 is a processing host.

Figure 79. CDQ Host Types

Connecting to a common dump queue

The SETSYS COMMONQUEUE(DUMP(CONNECT(*basename*))) command defines the CDQ group name to XCF, and connects a DFSMSHsm host to it. *basename* is a four-character suffix to be added to the DFSMSHsm-designated group name prefix, ARCD. For example, a SETSYS CQUEUE(DUMP(CONNECT(QUE1))) command defines a DFSMSHsm host as a member of the XCF group named ARCDQUE1.

The first DFSMSHsm host from which the SETSYS command with the CONNECT option is issued defines the XCF group and connects itself to this group. After that, DFSMSHsm hosts connect to the XCF group defined by the first host.

Master scheduler

The first member to join the CDQ group that is a master scheduler candidate becomes the master scheduler host for the CDQ group.

The master scheduler candidate (MSC) setting can be defined:

- In conjunction with the CONNECT option of the SETSYS command:

```
SETSYS COMMONQUEUE(DUMP(CONNECT(basename) MSC(YES|NO))
```

MSC defaults to YES.

- Separately, to set the MSC state before the CONNECT option or to change it afterward:

```
SETSYS COMMONQUEUE(DUMP(MSC(Y)))
```

For example, an MSC(N) option on the SETSYS command issued for each host prior to the CONNECT option being used ensures that no host becomes a master scheduler candidate. In this case the CDQ group status is DISABLED and no CDQ processing occurs. All work is processed locally. After all SETSYS commands with the CONNECT option have been issued, the MSC state for one or more hosts could be changed with the MSC(Y) option, to allow that host to take on the master scheduler responsibilities. A DFSMSHsm host with a MSC(Y) state is eligible to take over when the current master scheduler host fails or disconnects from the group.

It is recommended that all of your DFSMSHsm hosts be defined to be master scheduler candidates. This ensures that one host will take on the master scheduler responsibilities when a CDQ group is defined, and ensures that another host will take on the master scheduler responsibilities once the current one is removed from the group due to a disconnection or system errors. However, if a system might not have enough capacity to perform this work, you may want to define it to not be a master scheduler candidate.

Query commands

To display the current SETSYS setting, use the QUERY SETSYS command and look for message ARC1500I. To display the master scheduler status, use the QUERY ACTIVE command and look for message ARC1560I.

The DISPLAY XCF,GROUP command shows the group name (ARCDQUE1 in the example) and the member name as HOST#*hsmid*, where *hsmid* is the HSM ID of this host.

For more information

For more information, refer to Chapter 65, “SETSYS command: Establishing or changing the values of DFSMSHsm control parameters,” on page 1057.

Placing requests on the common dump queue

A host that is participating in CDQ processing places its dump requests onto the CDQ for processing. The following considerations apply:

- To verify that a host is connected to the CDQ, issue the QUERY ACTIVE command, then look for CONNECTION STATUS of CONNECTED in message ARC1560I.
- HOLD DUMP (any type) issued on the host that issued the dump request places the request on the CDQ if the master scheduler is also not held, (WAIT type requests are failed if the master scheduler is held). Both WAIT and NOWAIT type requests are placed as the master scheduler is available to assign and process requests in the CDQ. Tasks for this host will subsequently not be assigned by the master scheduler for processing.
- HOLD DUMP (any type) issued on the master scheduler host prevents it from assigning and processing requests. Note that NOWAIT request types are placed on the CDQ even though dump was held on the master scheduler. To keep the master scheduler's responsibilities intact, that is, if you do not want tasks on the master scheduler host to be used by the CDQ, issue a SETSYS MAXDUMPTASKS(0) command instead of HOLD DUMP. Alternatively, you can transition the master scheduler responsibilities to another host with SETSYS CQUEUE(D(MSC(N))) prior to issuing the HOLD.
- HOLD DUMP (any type) issued on all the hosts in the CDQ places the master scheduler in the DISABLED state. Use the messages issued in response to the QUERY ACTIVE to verify this state. Note that the MASTER SCHEDULER STATUS is DISABLED(HELD). When DISABLED:
 - New WAIT request types are failed locally
 - New NOWAIT request types are queued locally
 - Queued WAIT request types in the CDQ master scheduler host are failed
- SETSYS MAXDUMPTASKS(0) issued on the host that issued the dump request places the request on the CDQ, but tasks will subsequently not be assigned by the master scheduler for processing.

- Any request that is not submitted to the master scheduler host (for example, due to errors) is placed on the local queue of the host that issued the request.
- Requests submitted on the master scheduler host are placed on its local queue.
- Requests that are sent to the master scheduler host from other members are placed on the local master scheduler queue and then selected to run locally on the master scheduler, or assigned to be processed on another member in the CDQ group.
- The default priority of WAIT dump requests over NOWAIT dump requests does not change with the CDQ. However, the ALTERPRI command does support change requests currently queued to the CDQ.

Selecting requests from the common dump queue

The master scheduler is the DFSMSHsm host that manages all of the dump requests in the CDQ. All dump requests are sent to it, and it assigns work to all of the other hosts eligible to process requests from the CDQ. The following considerations apply to selecting requests to be processed by the CDQ:

- The master scheduler selects hosts to process requests based on the current utilization of available tape resources in each host relative to each other. The first host with the lowest utilization is selected to process the request.
- A host's resources are not available if the HOLD DUMP or EMERGENCY command has been issued, or if the SETSYS MAXDUMPTASKS(0) has been issued. Each command indicates to the master scheduler with XCF messaging that this host has no resources available.
- Selected hosts that are not the master scheduler are assigned the work with XCF messaging. The assigned processing host selects the task to use.
- When the master scheduler selects its own dump task to process a CDQ request, the task is attached and assigned the work.

Processing requests off of the common dump queue

The master scheduler selects a host member of the CDQ to process a request placed on the CDQ. This host could be the master scheduler itself, another member in the CDQ, or even the member that placed the request on the CDQ that the request originated from. This selected member is the processing host and is responsible for selecting an available task to use for the copy-to-tape processing that it will perform. The following considerations apply to a processing host in the CDQ:

- The processing host selects an available task to process the request.
- Status and progress messages, along with diagnostic trace data that is generated, are recorded on the processing host. A single dump request may generate many different volume dumps, with each one processed by individual CDQ group members. Messages and diagnostic data are placed on the host processing the request, making it difficult to put together the message flow of an individual dump command from all the processing hosts.
- By using the message simplification support along with CDQ processing, each CDQ group member writes all DFSMSHsm and DFSMSdss messages related to the processing of a particular copy pool to a single shared message data set that is managed by the master scheduler host. This simplifies the understanding of the message flow for the original fast replication copy pool command, as all messages are collected from each host into this single data set. XCF messages are used to perform this function. Refer to the SETSYS FASTREPLICATION(MESSAGE DATASET(YES)) option in [Chapter 65, “SETSYS command: Establishing or changing the values of DFSMSHsm control parameters,” on page 1057](#).
- As volumes complete processing, the selected processing host working in conjunction with the master scheduler host manages the process of stacking the minimum (specified with MINSTACK) up to the maximum (specified with STACK) number of volumes to be placed on a single tape. This is accomplished with XCF messaging.
- The processing host could be the submitting host and/or the master scheduler host, or a host that is neither the submitting host nor the master scheduler host.

Disconnecting from the common dump queue

The SETSYS COMMONQUEUE(DUMP(DISCONNECT)) command requests that a member of the CDQ group that this host is currently connected to is to leave the group. The following considerations apply to this disconnect process:

- All CDQ requests being processed on this host, and requests that originated from this host and are selected to be processed in the CDQ, are waited upon for completion before the host is disconnected from the CDQ. This host will no longer be selected to process new dump work from the CDQ.
- A HOLD DUMP issued prior to the disconnect command prevents queued requests from being selected to be processed. After the disconnect has completed, a RELEASE DUMP allows the queued requests to be processed locally.
- When the disconnect is for the host that is currently the master scheduler, all CDQ active and queued work to is waited upon for completion before the host is disconnected. Once the host is disconnected, another member in the CDQ group that has been previously defined as a master scheduler candidate automatically takes over the master scheduler responsibilities. A HOLD DUMP prior to a disconnection prevents queued requests from being selected for processing. A subsequent RELEASE DUMP after the disconnecting allows these requests to be processed locally.
- To verify the disconnection, use the QUERY ACTIVE command and look for message ARC1560I.
- Dump resources available on this host after the disconnection has completed are not known or available to the remaining CDQ members. All dump requests received are placed on this host's local queue and processed locally.
- For shutdown procedures, a DISCONNECT should first be issued on each host being removed from the HSMplex to allow CDQ requests to complete first.
- The DISCONNECT FORCE option should be reserved for emergency situations. With FORCE specified, requests that originated from this host and are selected to be processed in the CDQ are not waited upon for completion before disconnecting. Messages are issued to indicate that a request has been failed but still may complete in the CDQ.

For more information, refer to [Chapter 65, “SETSYS command: Establishing or changing the values of DFSMSHsm control parameters,” on page 1057.](#)

Using QUERY, CANCEL and ALTERPRI in the common dump queue

The QUERY, CANCEL and ALTERPRI commands support the CDQ. The following considerations apply to QUERY processing:

- QUERY SETSYS displays the current SETSYS settings for the CDQ on the host that issued the query command. Message ARC1500I displays the SETSYS settings on this host.
- QUERY ACTIVE displays the current state of the CDQ and active requests running it.
 - The state and active requests that are reported are those that originated from the host issuing the query command
 - Active requests reported could be active in any member in the CDQ. XCF messaging is used to retrieve active requests by sending the query command to the master scheduler. These requests could be running in any member of the CDQ group and must match the filter criteria of the query. In this case, the active requests must have originated from the host issuing the query command. The generated messages on the master scheduler are returned to the query host using XCF and in turn the query host reports them. The query host then goes on to report its own active requests.
 - When the query host is also the master scheduler, no XCF messaging is used to obtain the active requests, as the CDQ queues are located on the master scheduler host.
 - For auto functions running in the CDQ, only requests running on the host that issued the QUERY ACTIVE command are displayed.
- QUERY REQUEST or USER display requests that originated from the host issuing the query command that match the REQUEST or USER filter criteria.

- Active requests reported could be active in any member in the CDQ and queued in the master scheduler. XCF messaging is used to retrieve these requests by sending the query command to the master scheduler. These active requests could be running in any member of the CDQ group or queued in the master scheduler and must match the filter criteria of the query. In this case, the requests must have originated from the host issuing the query command and match the REQUEST or USER criteria on the query command. The generated messages on the master scheduler are returned to the query host using XCF messaging and in turn the query host reports them. The query host then goes on to report its own requests.
- When the query host is also the master scheduler, no XCF messaging is used to obtain the queued and active requests, as the CDQ queues are located on the master scheduler host.
- QUERY WAITING displays the number of requests that are queued in the CDQ that originated from the host issuing the query command.
 - Queued requests in the CDQ are queued in the master scheduler. XCF messaging is used to retrieve these queued request numbers by sending the query command to the master scheduler. These queued requests in the master scheduler must match the filter criteria of the query. In this case, the requests must have originated from the host issuing the query command. The generated messages on the master scheduler are returned to the query host using XCF messaging, and the query host reports them. The query host then determines its own queued request numbers, combines them with what was returned from the CDQ, and reports the totals.
 - When the query host is also the master scheduler, no XCF messaging is used to obtain the queued request numbers, as the CDQ queues are located on the master scheduler host.
- QUERY COMMONQUEUE(DUMP) displays all queued and active requests being managed by the CDQ. Use this query to get a snapshot of all CDQ activity from any host connected to the CDQ.
 - Queued and active requests in the CDQ are managed by the master scheduler for the CDQ group. XCF messaging is used to retrieve these requests by sending the query command to the master scheduler. These queued and active requests in the master scheduler have no matching criteria to satisfy. All requests are reported. The generated messages on the master scheduler are returned to the query host using XCF messaging, and the query host reports them.
 - When the query host is also the master scheduler, no XCF messaging is used to obtain the queued and active requests as the CDQ queues are located on the master scheduler host. The filter criteria is all queued requests running in the CDQ regardless of where the dump request command originated.
 - Messages ARC1562I and ARC1563I are reported for the active and queued requests in the CDQ.
- The CANCEL REQUEST or USERID commands cancel queued requests in the CDQ for requests originating in the host that issued the CANCEL command and matching the REQUEST or USERID filter criteria.
 - Queued requests in the CDQ are managed by the master scheduler for the CDQ group. XCF messaging is used to cancel these requests by sending the cancel command to the master scheduler. These queued requests in the master scheduler must have originated from the host issuing the CANCEL command and match the filter criteria of the REQUEST and USERID parameters. When matching, the requests are canceled. The generated messages on the master scheduler are returned to the cancel host using XCF messaging and the cancel host reports them.
 - When the cancel host is also the master scheduler, no XCF messaging is used to cancel the queued requests, as the CDQ queues are located on the master scheduler host.
 - To cancel an active request in the CDQ, issue CANCEL TCBADDRESS on the host that this request is active in.
- The ALTERPRI REQUEST or USERID commands change the priority of queued requests in the CDQ for requests originating in the host that issued the ALTERPRI command and matching the REQUEST or USERID filter criteria.
 - Queued requests in the CDQ are managed by the master scheduler for the CDQ group. XCF messaging is used to alter the priorities of these requests by sending the ALTERPRI command to the master scheduler. These queued requests in the master scheduler must have originated from the host issuing the ALTERPRI command and match the filter criteria of the REQUEST and USERID

parameters. When matching, the requests priority is altered. The generated messages on the master scheduler are returned to the ALTERPRI host using XCF messaging, and the ALTERPRI host reports them.

- When the ALTERPRI host is also the master scheduler, no XCF messaging is used to alter the priority of the queued requests, as the CDQ queues are located on the master scheduler host.

Processing of failures in the common dump queue

The CDQ group support uses XCF facilities to detect when members lose their connection to the CDQ. This could be due to one or more of the following reasons:

- A host requested a disconnection with the SETSYS CQUEUE(DUMP(DISCONNECT))
- An XCF-related failure caused the member to be removed from the group
- A z/OS image failed

In all of these cases the host is considered to be no longer defined to the group.

When the host that is now not defined was the master scheduler, all remaining hosts in the CDQ group are notified that the master scheduler is now not defined. From the hosts in the CDQ group that are master scheduler candidates, a host takes the master scheduler responsibilities. For each of these hosts, any work that was placed on the CDQ prior to this event is placed on the CDQ, managed by the new master scheduler host. This may result in some volumes being processed again.

When the host that is now not defined is not the master scheduler, the master scheduler host is notified that this host is no longer defined to the group. The CDQ in this case searches for requests previously selected to run on this now not defined host, and fails them with an ARC1327I or ARC1829I message, with a return code of 105. This indicates that a host in the common queue group became not defined, with the return code indicating that the work was selected by the master scheduler to run in this host of the CDQ, but the master scheduler cannot determine if the work completed.

Common recover queue

The common recover queue (CVQ) is a queue of DFSMSHsm volume restore requests from FRRECOV COPYPOOL, FRRECOV TOVOLUME, and RECOVER TOVOLUME with FROMDUMP commands that is shared by multiple DFSMSHsm hosts. See Table 48 on page 474, for details on which command variations are supported. The common recover queue is implemented through the cross-system coupling facility (XCF) to balance the volume restore workload across the resources in each DFSMSHsm host in an HSMplex. Individual DFSMSHsm hosts are defined to XCF as a member of a group to be used for volume restore processing. By distributing volume restore work to all the members in the group, the number of available tasks to perform the work is increased which also improves throughput of the volume restore function as the workload is no longer concentrated on a single host's address space.

Table 48. CVQ Scope. The CVQ Scope table uses three columns where the first row is the header for each column.

Command/Function	Qualifications	Supported in CVQ
FRRECOV COPYPOOL	None. From dump determined by HSM for latest version	YES
	FROMDUMP specified	YES
	FROMDASD specified or latest version from DASD determined by HSM	N/A
FRRECOV TOVOLUME (Individual volume restore)	FROMCOPYPOOL From dump determined by HSM for latest version	YES
	FROMCOPYPOOL FROMDUMP specified	YES

Table 48. CVQ Scope. The CVQ Scope table uses three columns where the first row is the header for each column. (continued)

Command/Function	Qualifications	Supported in CVQ
	FROMCOPYPOOL FROMDUMP APPLYINCREMENTAL specified	YES
	FROMCOPYPOOL FROMDASD specified or latest version from DASD determined by HSM	N/A
FRRECOV DSNAME	None	NO
RECOVER DSNAME	FROMDUMP	NO
RECOVER DSNAME	From dump not specified	NO
RECOVER *	TOVOLUME FROMDUMP	YES
	TOVOLUME FROMDUMP APPLYINCREMENTAL	YES

The CVQ scope table shows that the FRRECOV, and RECOVER commands volume restores, as well as the optional APPLYINCREMENTAL, are eligible to be processed in the CVQ. The DSNAME function command is not eligible.

Figure 80. Common Recover Queue

Figure 80 on page 475, shows that the CVQ consists of one or more DFSMSHsm hosts that are connected to an XCF defined group, where submitted volume restore requests will be distributed and processed among the volume restore resources available in the CVQ group, with results returned back to the host where the request originated.

Figure 81 on page 476, shows the CVQ group allows for flexible configurations. This provides the capability to:

- Define multiple queues in the same HSMplex

- Allow group members to both receive and process requests, only process requests, or only receive requests.

Figure 81. CVQ -- Flexible Configurations

In CVQ environments:

- A CVQ can not span an HSMplex
- The priority of requests is supported in a CVQ
- A host can be connected to only one CVQ
- The progress and status messages are recorded on the host processing the request
- A CVQ can coexist with a CDQ environment with the same host or subset of hosts
- The CVQ flexible configurations allow group members to receive and process requests, only process requests, or only receive requests

Results are returned to the submitting host, but progress and status messages are recorded on the host processing the request. By using the message simplification support along with CVQ processing, each CVQ group member will write all DFSMSshm and DFSMSdss messages related to the processing of a particular copy pool (FRRECOV COPYPOOL FROMDUMP) or individual volume restore from a copy pool (FRRECOV TOVOLUME FROMDUMP) to a single shared message data set. This simplifies diagnostics as all messages are collected from each host into a single data set. The data set is managed by the Master Scheduler (MS) host for the CVQ. See the SETSYS FASTREPLICATION(MESSAGE DATASET(YES)) option in Chapter 65, “SETSYS command: Establishing or changing the values of DFSMSshm control parameters,” on page 1057.

Types of hosts used in a common recover queue

The master scheduler (MS) is the DFSMSshm host that manages all of the volume restore requests in the Common Recover Queue (CVQ). All volume restore requests are sent to the master scheduler, and it assigns work to all of the other hosts eligible in the group to process requests from the CVQ. Each group needs a master scheduler to manage CVQ processing for the group; otherwise, volume restore requests are processed locally.

The other principal types of DFSMSshm hosts are the submitting host and the processing host.

Submitting host

Host that receives requests from commands and, using XCF messaging, sends it to the master scheduler host. Performs command complete processing and posts the user that the command has completed.

Master scheduler (MS)

- Accepts requests from submitting host members and locally submitted requests, and maintains them as a single common queue of all requests for the CVQ function. The MS can be the submitting host. In this case, the command is not sent
- Assigns the requests to the available tasks across all of the eligible hosts (processing hosts) that are connected to the CVQ, while balancing the requests among all the hosts.
- Manages "work completed" messages received from a processing host to support functions like stacking.
- Sends "command complete" messages back to the submitting host.

Processing host

- Receives assigned work requests from the master scheduler and places them on its local queue for processing.
- Sends "work complete" messages back to the master scheduler with specific protocols to support functions like stacking.
- The processing host could be the submitting host and/or the master scheduler host.

Figure 82 on page 478, shows a CVQ group where:

- HSM1 is the submitting and processing host
- HSM2 is the master scheduler and processing host. It receives all requests, manages them on a single queue, and distributes the requests among the eligible hosts connected to the common queue, through XCF messaging.
- HSM3 is a processing host.

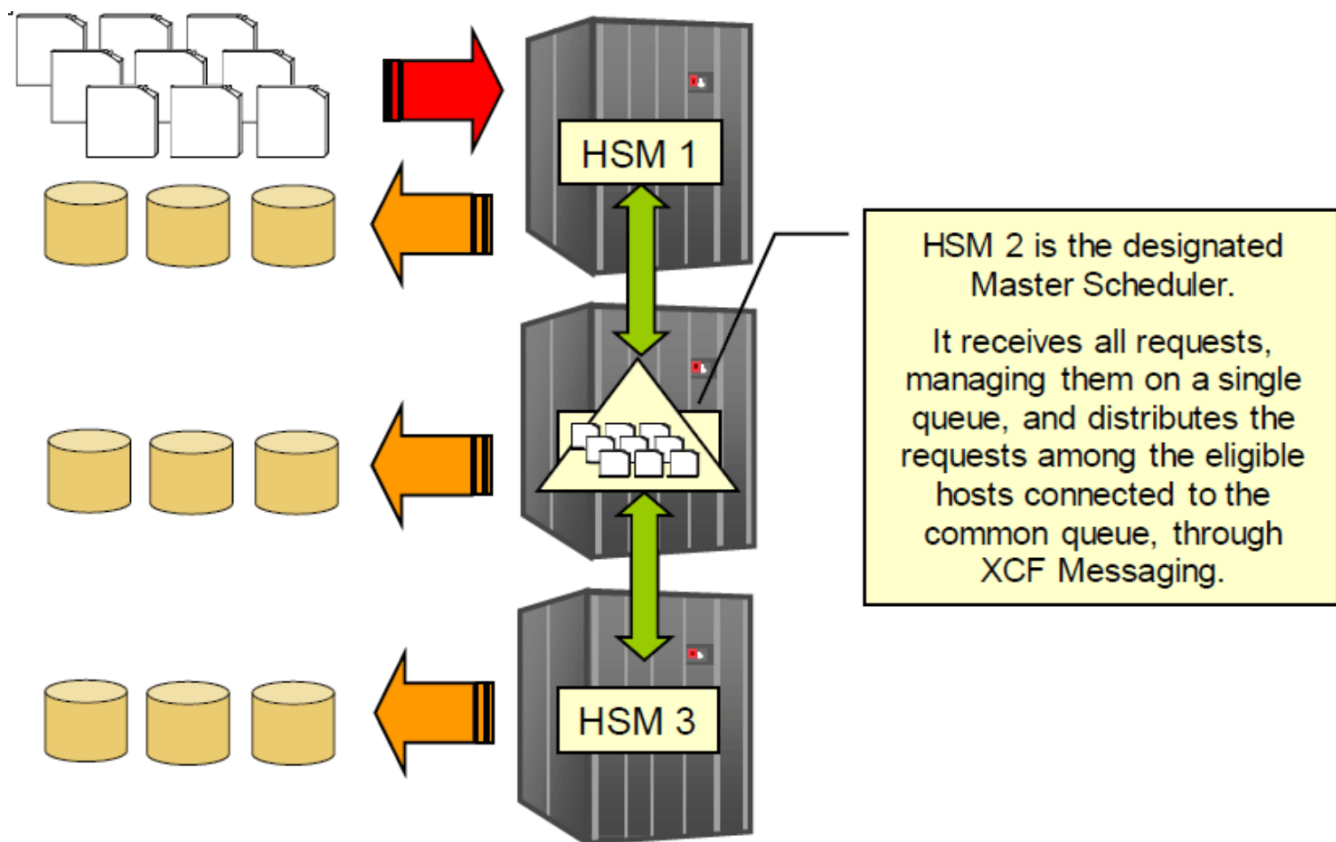

Figure 82. CVQ Host Types

Connecting to a common recover queue

The SETSYS COMMONQUEUE(RECOVER(CONNECT(*basename*))) is used to define the CVQ group name to XCF and to connect this DFSMSHsm host to it. The *basename* is a four-character suffix to the HSM designated group name prefix. It has the following format: ARCV*basename*.

The first DFSMSHsm host to issue the SETSYS command with CONNECT option will define the XCF group, and connect itself to this group, while subsequent DFSMSHsm hosts will connect to the XCF group defined by the first host.

For example, a DFSMSHsm host is defined as a member of the XCF group named, ARCVQUE1, as follows:

```
SETSYS CQUEUE(RECOVER(CONNECT(QUE1))
```

The current SETSYS setting and the MS status can be displayed with QUERY SETSYS (message ARC1500I) and QUERY ACTIVE (message ARC1560I) respectively.

Master scheduler

The first member to join the CVQ group that is a master scheduler candidate becomes the master scheduler host for the CVQ group.

The master scheduler candidate (MSC) setting can be defined:

- In conjunction with the CONNECT option of the SETSYS command:

```
SETSYS COMMONQUEUE(RECOVER(CONNECT(basename) MSC(YES|NO))
```

MSC defaults to YES.

- Separately, to set the MSC state before the CONNECT option, or to change it afterward:

```
SETSYS COMMONQUEUE(RECOVER(MSC(Y))
```

For example, an MSC(N) option on the SETSYS command issued for each host prior to the CONNECT option ensures that no host becomes a master scheduler candidate. In this case, the CVQ group status is DISABLED, and no CVQ processing occurs. All work is processed locally. After all SETSYS commands with the CONNECT option have been issued, the MSC state for one or more hosts could be changed through the MSC(Y) option, to allow that host to take on the master scheduler responsibilities. A DFSMSHsm host with a MSC(Y) state is eligible to take over when the current master scheduler host fails, or disconnects from the group.

It is recommended that all of your DFSMSHsm hosts be defined to be master scheduler candidates. This ensures that one host will take on the master scheduler responsibilities when a CVQ group is defined, and ensures that another host will take on the master scheduler responsibilities once the current one is removed from the group due to a disconnection or system errors. However, if a system might not have enough capacity to perform this work, you may want to define it to not be a master scheduler candidate.

Query commands

To display the current SETSYS setting, use the QUERY SETSYS command and look for message ARC1500I. To display the master scheduler status, use the QUERY ACTIVE command and look for message ARC1560I.

Using the DISPLAY XCF,GROUP command, the output for this command will identify the group as ARCVQUE1 and identify the member name as HOST#*hsmid* for this host.

For more information

For more information, refer to Chapter 65, “SETSYS command: Establishing or changing the values of DFSMSHsm control parameters,” on page 1057.

Placing requests on the common recover queue

The common recover queue (CVQ) is a queue of DFSMSHsm volume restore requests. These volume restore requests include all requests from RECOVER *, FRRECOV COPYPOOL, FRRECOV TOVOLUME when FROMDUMP is specified, or when DFSMSHsm determines that the most current version is from a dump (volume restores). APPLYINCREMENTAL can be applied. However, data set recovers are not eligible for the CVQ. A host that participates in CVQ processing places its volume restore requests onto the CVQ for processing. The following items apply to placement status:

- To verify that a host is connected to the CVQ, issue the QUERY ACTIVE command. Look for CONNECTION STATUS of CONNECTED in message ARC1560I for the Common Recover Queue.
- HOLD RECOVER or HOLD FRRECOV(TAPE) issued on a host prevents tasks for this host from being selected by the master scheduler as a processing host.
- HOLD RECOVER or HOLD FRRECOV(TAPE) issued on the host that issued the volume restore request places that request on the CVQ, when the master scheduler is not disabled. Note that the MASTER SCHEDULER STATUS is QUERY ACTIVE, *not* DISABLED(HELD).

Both WAIT and NOWAIT type requests are placed as the master scheduler is available to assign and process requests in the CVQ. Tasks for this host subsequently are not assigned by the master scheduler for processing.

- HOLD RECOVER and FRRECOV(TAPE) issued on the master scheduler host prevents it from assigning and processing requests. Note that NOWAIT request types are placed on the CVQ (even though the function was held on the master scheduler), while WAIT type requests are failed. A HOLD of a specific type (RECOVER or FRRECOV) affects only the assignment of that type by the master scheduler. To keep the master scheduler responsibilities intact, that is, to prevent tasks on the MS host from being used by the CVQ, issue an SETSYS MAXDUMPRECOVERTASKS(0). Alternatively, you can transition the MS responsibilities to another host with SETSYS CQUEUE(RECOVER(MSC(N))), prior to issuing the HOLD.

- HOLD RECOVER and FRRECOV(TAPE), issued on all the hosts in the CVQ places the master scheduler in the DISABLED state. Use the messages issued in response to the QUERY ACTIVE to verify this state. Note that the MASTER SCHEDULER STATUS is DISABLED(HELD). When DISABLED:
 - New WAIT request types are failed locally
 - New NOWAIT request types are queued locally
 - Queued WAIT request types in the CVQ master scheduler host are failed
- SETSYS MAXDUMPRECOVERTASKS(0) issued on the host that issued the volume restore request places the request on the CVQ. Tasks for this host subsequently are not assigned by the MS for processing.
- Any request that is not submitted to the master scheduler host (for example, due to errors) is placed on the local queue of the host that issued the request.
- Requests submitted on the master scheduler host are placed on its local queue
- Requests that are sent to the MS host from other members are placed on the local MS queue, then selected to run locally on the MS, or assigned to be processed on another member in the CVQ group.
- The default priority of WAIT volume restore requests over NOWAIT volume restore requests does not change with the CVQ. However, the ALTERPRI command supports change requests that are currently queued to the CVQ.

Selecting requests from the common dump queue

The master scheduler is the DFSMSHsm host that manages all of the volume restore requests in the CVQ. All volume restore requests are sent to it, and it assigns work to all of the other hosts eligible to process requests from the CVQ. The following items apply to selecting requests to be processed by the CVQ:

- The master scheduler selects hosts to process requests based on the current utilization of available tape resources in each host relative to each other. The first host with the lowest utilization will be selected to process the request.
- A host's resources are not available if the HOLD RECOVER, FRRECOV or SETSYS EMERGENCY commands has been issued or if the SETSYS MAXDUMPRECOVERTASKS(0) has been issued. In each case the system will indicate back to the MS with XCF messaging that this host has no resources available.
- Selected hosts that are not the Master Scheduler are assigned the work with XCF messaging. The assigned processing host selects the task to use.
- When the master scheduler selects its own volume restore task to process a CVQ request, the task is attached and assigned the work.

Processing requests off of the common recover queue

The master scheduler selects a host member of the CVQ to process a request placed on the CVQ. This host could be the master scheduler itself, another member in the CVQ and even the member that placed the request on the CVQ that the request originated from. This selected member is the processing host and is responsible for selecting an available task to use for the copy to tape processing that it will perform. The following items apply to a processing host in the CVQ:

- The assigned processing host selects an available task to process the request.
- Status and progress messages along with diagnostic trace data that is generated are recorded on the processing host. A single copy pool recover request may generate many different volume restores with each one processed by individual CVQ group members. Messages and diagnostic data are placed on the host processing the request, making it difficult to put together the message flow of an individual volume restore from all the processing hosts.
- By using the message simplification support along with CVQ processing, each CVQ group member will write all DFSMSHsm and DFSMSdss messages related to the processing of a particular copy pool to a single shared message data set that is managed by the MS host. This simplifies the understanding of the message flow for the original fast replication copy pool command as all messages are collected from each host into this single data set. XCF messages are used to perform this function. Refer to the SETSYS

FASTREPLICATION(MESSAGE DATASET(YES)) option in Chapter 65, “SETSYS command: Establishing or changing the values of DFSMSHsm control parameters,” on page 1057.

- As volumes complete processing, the selected processing host, in conjunction with the MS host, determines if another volume restore is needed by the currently mounted tape. If this is the case, that task is assigned to process the additional volume restore. This is accomplished with XCF messaging.
- The processing host can be both the submitting host and MS host, either the submitting host or the MS host. And it can be neither the submitting host nor the MS host.
- When the SETSYS COMMONQUEUE(RECOVER(CONNECT(*basename*))) is specified, the preference by the system will be to utilize the available recover tasks as defined by MAXDUMPRECOVERTASKS on all the recover group members in the HSMplex. However, the number of concurrent tasks is limited by the stacking of the volumes on the dump tapes. For example, if 100 volumes are being recovered, and all volumes are on a single tape, then only a single recover task will be used.

Using QUERY, CANCEL and ALTERPRI in the common recover queue

The QUERY, CANCEL and ALTERPRI commands support the Common Recover Queue (CVQ).

The following items apply to QUERY processing:

- QUERY SETSYS displays the current SETSYS settings for the CVQ on the host that issued the QUERY command. Message ARC1500I displays the SETSYS settings on this host.
- QUERY ACTIVE displays the current state of the CVQ and active requests running it.
 - The state and active requests reported on are those that originated from the host issuing the QUERY command
 - Active requests reported could be active in any member in the CVQ. XCF messaging is used to retrieve active requests by sending the QUERY command to the Master Scheduler. These requests could be running in any member of the CVQ group and must match the filter criteria of the query. In this case, the active requests must have originated from the host issuing the QUERY command. The generated messages on the MS are returned to the query host using XCF and in turn the query host issues them. The query host then goes on to report its own active requests.
 - When the query host is also the MS, no XCF messaging is used to obtain the active requests as the CVQ queues are located on the MS host.
- QUERY REQUEST or USER display requests that originated from the host issuing the QUERY command that match the REQUEST or USER filter criteria.
 - Active requests reported could be active in any member in the CVQ and queued in the MS. XCF messaging is used to retrieve these requests by sending the QUERY command to the Master Scheduler. These active requests could be running in any member of the CVQ group or queued in the MS and must match the filter criteria of the query. In this case, the requests must have originated from the host issuing the QUERY command and match the REQUEST or USER criteria on the QUERY command. The generated messages on the MS are returned to the query host using XCF messaging and in turn the query host reports them. The query host then goes on to report its own requests.
 - When the query host is also the MS, no XCF messaging is used to obtain the queued and active requests as the CVQ queues are located on the MS host.
- QUERY WAITING displays the number of requests that are queued in the CVQ that originated from the host issuing the QUERY command.
 - Queued requests in the CVQ will be queued in the MS. XCF messaging is used to retrieve these queued request numbers by sending the QUERY command to the Master Scheduler. These queued requests in the MS must match the filter criteria of the query. In this case, the requests must have originated from the host issuing the QUERY command. The generated messages on the MS are returned to the query host using XCF messaging and in turn the query host reports them. The query host then goes on to determine its own queued request numbers, combines them with what was returned from the CVQ, then reports the totals.
 - When the query host is also the MS, no XCF messaging is used to obtain the queued request numbers as the CVQ queues are located on the MS host.

- **QUERY COMMONQUEUE(RECOVER)** displays all queued and active requests being managed by the CVQ. Use this query to get a snapshot of all CVQ activity from any host connected to the CVQ.
 - Queued and active requests in the CVQ are managed by the MS for the CVQ group. XCF messaging is used to retrieve these requests by sending the **QUERY** command to the Master Scheduler. These queued and active requests in the MS have no matching criteria to satisfy. All requests will be reported. The generated messages on the MS are returned to the query host using XCF messaging and in turn the query host reports them.
 - When the query host is also the MS, no XCF messaging is used to obtain the queued and active requests as the CVQ queues are located on the MS host. The filter criteria is all queued requests running in the CVQ regardless of where the volume restore request command originated.
 - Messages **ARC1562I** and **ARC1563I** are reported for the active and queued requests in the CVQ.
- The **CANCEL REQUEST** or **USERID** command cancels queued requests in the CVQ for requests originated in the host that issued the **CANCEL** command that also matches the **REQUEST** or **USERID** filter criteria.
 - Queued requests in the CVQ are managed by the MS for the CVQ group. XCF messaging is used to cancel these requests by sending the cancel command to the Master Scheduler. These queued requests in the MS must have originated from the host issuing the **CANCEL** command and match the filter criteria of the **REQUEST** and **USERID** parameters. When matching, the requests are cancelled. The generated messages on the MS are returned to the cancel host using XCF messaging and in turn the cancel host reports them.
 - The **QUERY COMMONQUEUE(RECOVER)** command can be used to determine the requests running in the CVQ which will also identify the **HOST** id of where each request originated from.
 - When the cancel host is also the MS, no XCF messaging is used to cancel the queued requests as the CVQ queues are located on the MS host.
 - To cancel an active request in the CVQ, issue the **CANCEL TCBADDRESS** on the host that this request is active in.
- The **ALTERPRI REQUEST** or **USERID** command changes the priority of queued requests in the CVQ for requests originated in the host that issued the **ALTERPRI** command that also matches the **REQUEST** or **USERID** filter criteria.
 - Queued requests in the CVQ are managed by the MS for the CVQ group. XCF messaging is used to alter the priorities of these requests by sending the **ALTERPRI** command to the Master Scheduler. These queued requests in the MS must have originated from the host issuing the **ALTERPRI** command and match the filter criteria of the **REQUEST** and **USERID** parameters. When matching, the requests priority is altered. The generated messages on the MS are returned to the **ALTERPRI** host using XCF messaging and in turn the **ALTERPRI** host reports them.
 - The **QUERY COMMONQUEUE(RECOVER)** command can be used to determine the requests running in the CVQ which will also identify the **HOST** id of where each request originated from.
 - When the **ALTERPRI** host is also the MS, no XCF messaging is used to alter the priority of the queued requests as the CVQ queues are located on the MS host.

Disconnecting from the common recover queue

SETSYS COMMONQUEUE(RECOVER(DISCONNECT)) is used to request that a member of the CVQ group that this host is currently connected too is to leave the group. See the syntax of this command for specifics on other options and defaults. The following items apply to this disconnect process:

- All CVQ requests being processed on this host and requests that originated from this host and selected to be processed in the CVQ are waited upon for completion before disconnecting the host from the CVQ. This host will no longer be selected to process new volume restore work from the CVQ.
- A **HOLD RECOVER** or **FRRECOV** issued prior to the disconnect command will prevent queued requests from being selected to be processed. After the disconnect has completed, a **RELEASE RECOVER** or **FRRECOV** will allow the queued requests to be processed locally.

- A disconnection of the host that is currently the Master Scheduler will wait for all CVQ active and queued work to complete prior to disconnecting. Once disconnected another member in the CVQ group that has been previously defined as a Master Scheduler candidate will automatically take over the responsibilities for it. A HOLD RECOVER or FRRECOV prior to a disconnection will prevent queued requests from being selected for processing. A subsequent RELEASE RECOVER or FRRECOV after the disconnecting will allow these requests to be processed locally.
- The QUERY ACTIVE command response in message ARC1560I will verify the disconnection.
- Volume restore resources available on this host after the disconnection has completed are not known or available to the remaining CVQ members. All volume restore requests received will be placed on this host's local queue and processed locally.
- For shutdown procedures, a DISCONNECT should first be issued on each host being removed from the HSMplex to allow CVQ requests to complete first.
- The DISCONNECT FORCE option should be reserved for emergency situations. With FORCE specified, requests that originated from this host and selected to be processed in the CVQ are not waited upon for completion before disconnecting. Messages will be issued to indicate that a request has been failed but still may complete in the CVQ.

For more information, refer to [Chapter 65, “SETSYS command: Establishing or changing the values of DFSMSHsm control parameters,” on page 1057.](#)

Processing of failures in the common recover queue

The CVQ group support uses XCF facilities to detect when members lose the connection to the CVQ. The connection might be lost for one or more of the following reasons:

- An host requested a disconnection with the SETSYS COMMONQUEUE(RECOVER(DISCONNECT))
- An XCF related failure causes it to be removed from the group
- A z/OS® image fails

When the host that is now not defined was the master scheduler, then master scheduler responsibilities are managed by a master scheduler candidate from the CVQ group. All hosts would have been notified that the MS was the one that went not defined. For each of these hosts, any work that was placed on the CVQ prior to this event is placed on the CVQ, and managed by the new master scheduler host. This may result in some volumes being processed again.

When the host that is now not defined is not the master scheduler, the master scheduler host is notified that this host is no longer defined to the group. The CVQ in this case searches for requests previously selected to run on this now not defined host, and fails them with ARC1127I or ARC1829I, and with return code 105. This indicates that a host in the common queue group is not defined, and that the work was selected by the master scheduler to run in this host of the CVQ, but the host cannot determine if the work completed.

Chapter 11. Availability management procedures

This topic details specific backup, recovery, and full-volume dump procedures associated with DFSMSHsm availability management.

Backup and recovery procedures

This topic tells you how to perform the following functions:

- Interrupt and restart backup processing
- Define a new automatic backup start window
- Back up and recover a catalog

Interrupting and restarting backup processing

To stop the first phase of automatic backup, which is the backup of the control data sets, you must use the STOP command.

You can use the following methods to interrupt automatic backup processing during its last three phases. The last three phases of automatic backup processing consist of the following functions:

- Movement of backup versions
- Backup of migrated data sets
- Backup of DFSMSHsm-managed volumes having the automatic backup attribute

There are four methods you can use to interrupt automatic backup processing during its last three phases:

- **Holding backup processing**—You can hold backup processing by specifying the BACKUP, BACKUP(AUTO), or ALL parameter of the HOLD command. If you hold backup processing with the ENDOFDATASET parameter while DFSMSHsm is moving backup versions or backing up migrated data sets, processing ends after DFSMSHsm has finished processing the current backup version. If you hold backup processing with the ENDOFVOLUME parameter while DFSMSHsm is moving backup versions or backing up migrated data sets, processing ends after the current phase of automatic backup has completed. If you hold backup processing with the ENDOFVOLUME parameter while DFSMSHsm is backing up managed volumes, DFSMSHsm continues processing the current volumes and does not process any new volumes. Otherwise, DFSMSHsm finishes processing the current data set. DFSMSHsm does not start any new volume backup tasks.
- **Disabling backup processing**—You can disable backup processing by specifying the NOBACKUP parameter of the SETSYS command. If you disable backup processing while DFSMSHsm is moving backup versions or backing up migrated data sets, processing ends after DFSMSHsm has finished processing the current backup version. If you disable backup processing while DFSMSHsm is backing up DFSMSHsm-managed volumes, DFSMSHsm finishes processing the current data set and does not start any new volume backup tasks.
- **Placing DFSMSHsm in emergency mode**—You can place DFSMSHsm in emergency mode by specifying the EMERGENCY parameter of the SETSYS command. If you place DFSMSHsm in emergency mode while DFSMSHsm is moving backup versions or backing up migrated data sets, processing ends after DFSMSHsm has finished processing the current data set.

If you are in a multiple DFSMSHsm-host environment and have enabled the secondary host promotion function, another DFSMSHsm host takes over the unique functions of the primary DFSMSHsm host that you have put in emergency mode. Those functions include automatic movement of backup versions from ML1 to tape, and automatic backup of migrated data sets. If promotion occurs during an automatic backup window (as defined on the primary host), and it is not past the latest start time, the promoted host takes over where the primary host left off. If the promoted host was an automatic backup host before being promoted, it performs backups of DFSMSHsm-owned volumes after performing the

automatic movement of backup versions from ML1 to tape, and automatic backup of migrated data sets. If the promoted host was *not* an automatic backup host before being promoted, it does not back up DFSMSHsm-owned volumes.

If you place DFSMSHsm in emergency mode while DFSMSHsm is backing up DFSMSHsm-managed volumes, DFSMSHsm finishes processing the current data set before ending the volume backup tasks that are in progress and does not start any new volume backup tasks.

- **Stopping DFSMSHsm**—You can stop DFSMSHsm by entering the MVS or DFSMSHsm STOP command. If you shut down DFSMSHsm while DFSMSHsm is moving backup versions or backing up migrated data sets, processing ends after DFSMSHsm has finished processing the current data set. If you shut down DFSMSHsm while DFSMSHsm is backing up DFSMSHsm-managed volumes, DFSMSHsm finishes processing the current data set before ending the volume backup tasks that are in progress and does not start any new volume backup tasks. If you issue the DFSMSHsm STOP command while DFSMSHsm is backing up the control data sets or the journal data set, DFSMSHsm finishes processing the current data set and does not start backing up any other control data sets or the journal data set.

If you are in a multiple DFSMSHsm-host environment, have enabled secondary host promotion, and you have issued a STOP PROMOTE command, another DFSMSHsm host takes over the unique functions of the primary DFSMSHsm host that you have stopped. Those functions include automatic movement of backup versions from ML1 to tape, and automatic backup of migrated data sets. If promotion occurs during an automatic backup window (as defined on the primary host), and it is not past the latest start time, the promoted host takes over where the primary host left off. If the promoted host was an automatic backup host before being promoted, it performs backups of DFSMSHsm-owned volumes after performing the automatic movement of backup versions from ML1 to tape, and automatic backup of migrated data sets. If the promoted host was *not* an automatic backup host before being promoted, it does not back up DFSMSHsm-owned volumes.

You can restart automatic backup processing by entering the corresponding commands if certain conditions are met:

- RELEASE BACKUP or RELEASE ALL
- SETSYS BACKUP
- SETSYS NOEMERGENCY
- START DFSMSHSM (MVS command)

If secondary host promotion did not continue backup processing where the primary DFSMSHsm host left off, automatic backup restarts at the point of interruption if the date of the defined start time for the current automatic backup window is the same as the date that automatic backup last started from the beginning (same cycle date). When automatic backup restarts, it uses the same set of daily backup volumes it was using when it first started. Those daily backup volumes are the ones assigned to the day in the backup cycle that was in effect when automatic backup started.

After you restart automatic backup processing, DFSMSHsm continues with the next DFSMSHsm-managed volume under automatic backup control. However, there are a few considerations:

- If you issued a DFSMSHsm STOP command and then a START DFSMSHsm command, DFSMSHsm can start automatic backup at the point of interruption only:
 - If you add the primary volumes under automatic backup control in the same order in each startup of DFSMSHsm
 - If you do not change the volumes associated with the storage groups
- If you interrupted a BACKVOL PRIMARY command, DFSMSHsm can resume backup at the start of the next volume only if you issued HOLD BACKUP or SETSYS NOBACKUP. You must issue RELEASE BACKUP, RELEASE ALL, or SETSYS BACKUP during the same startup of DFSMSHsm if you want the BACKVOL PRIMARY command to resume processing.
- DFSMSHsm does not restart a BACKVOL command issued for one volume.

For more information about using the secondary host promotion function, see [z/OS DFSMSHsm Implementation and Customization Guide](#).

Defining a new automatic backup start window

As you increase the number of volumes that DFSMSHsm backs up, you might want to change the automatic backup start window. In a test environment, you might want daily automatic backup to run more than once on a single day. This topic describes how to define a new start window.

Defining a new start window when automatic backup is running

You can change the automatic backup start window at any time, even when automatic backup is currently running on the affected DFSMSHsm host.

If automatic backup is running but completes before the newly defined start time is reached, automatic backup processing starts again at the newly defined start time.

If automatic backup is running and processing continues beyond the newly defined start time, automatic backup processing does not start again until the next time the newly defined start time occurs.

If you specify a quiesce time for the new automatic backup start window while automatic backup is running and the current time is outside of the newly specified window, automatic backup processing stops.

If automatic backup is released or DFSMSHsm is restarted during the automatic backup start window, automatic backup starts, unless prevented by one of the commands discussed in [“Interrupting and restarting backup processing”](#) on page 485, or by denying permission to the SETSYS REQUEST command.

Defining a new start window when automatic backup is not running

If you define a planned start time that is later than the time that automatic backup last ended, automatic backup starts at the new planned start time if it has not already processed all the requested volumes on this day. Otherwise, automatic backup starts at the new planned start time on the next day.

If you define a planned start time that is earlier than the time that automatic backup last ended, automatic backup starts only if it has not run to completion on this day.

Backing up and recovering a catalog

There are no special requirements to back up a catalog. Either the catalog is backed up during volume backup of the volume it is on, or it can be backed up by the BACKDS command. Although the catalog is open when the backup occurs, DFSMSHsm enqueues on the catalog to prevent it from being updated while DFSMSHsm makes the backup version.

Because this enqueue prevents access to the catalog by any other user, for the duration of the backup, it is imperative that the elapsed time of the backup be kept as short as possible.

Defining the user catalog with as large a data control interval size as possible dramatically reduces the elapsed time to back up a user catalog. Therefore, the user catalogs should be defined with a data control interval size of one half track.

Use the following procedure to recover a backup version of a catalog:

1. Purge all jobs that allocate the volume.
2. Issue the F CATALOG,OPEN(*volser*) command to determine which catalogs on the target volume are allocated.
3. Issue, for each catalog that is open:

```
F CATALOG,UNALLOCATE(catalogname.)
```

to cause the catalog address space to close the catalog and deallocate it.

4. Issue the RECOVER command to DFSMSHsm.

If DFSMSdss is installed, aliases of the catalog are backed up and recovered. When DFSMSHsm attempts to recover a catalog, the following rules apply:

- If the catalog does not exist, it is defined, along with its aliases, from the backup version.
- If the catalog is empty, any aliases for that catalog in the system catalog are not deleted. Aliases that were backed up are defined for the recovered catalog if they do not already exist in the system catalog.
- If the catalog is not empty, it is deleted and redefined from the backup version. Any aliases for that catalog in the system catalog are not deleted. Aliases that were saved with the backup version are not added to the system catalog.

The recovery of a catalog has the following restrictions:

- A catalog cannot be recovered with a new name.
- Aliases in the catalog are not backed up or recovered unless DFSMSdss is installed on the system.
- If you need to recover the master catalog, you must recover it on a different z/OS image.
- You must be a DFSMSHsm-authorized user.
- Recovery of a non-SMS managed catalog fails with message ARC1001I, return code 58, reason code 30, when the catalog is recovered to a volume that is not the same as the volume it was backed up from. (Recovery to another volume would cause DFSMSHsm to lose RACF discrete-profile security protection).
- If the catalog contains entries for VSAM data sets that are protected by RACF discrete profiles, IBM recommends that you recover the catalog to the same volume it was on when it was backed up. If the catalog is recovered to a different volume, all VSAM data sets that were protected by a discrete profile are now either unprotected or protected by a generic profile that might not provide the level of access and security desired.

The RACF profile of a VSAM data set reflects the catalog volume. DFSMSHsm does not update these profiles when it recovers a catalog. To restore the level of protection that a discretely-protected VSAM data set had before the catalog was recovered to a different volume, you have to update the data set's discrete profile to indicate the new volume. The task of deciding whether to update a discretely-protected VSAM data set's discrete profile, and making the update, can be left to the owner of the data, if an installation so desires.

When recovering non-SMS-managed catalogs, you can use the TOVOLUME parameter to specify the volume from which the catalog was backed up.

When recovering SMS-managed catalogs, you can assign a storage class with the GUARANTEED SPACE attribute as a means of requesting that the catalog is recovered to its original volume.

- The HRECOVER command will fail if an ALIAS is substituted for the data set name of a catalog, even if the user is DFSMSHsm-authorized.

Backing up and recovering RLS user catalogs

If you use DFSMSHsm to back up and recover RLS user catalogs, ensure that the DFSMSHsm authorized user identification (UID) has been granted READ access to the IGG.CATLOCK FACILITY class profile and ALTER access to the user catalogs. DFSMSHsm invokes DFSMSdss to back up and recover RLS ICF user catalogs. During recover of an RLS user catalog, DFSMSHsm specifies the BCSRECOVER(LOCK) parameter, and DFSMSdss will perform LOCK and UNLOCK on behalf of DFSMSHsm when the user catalog is preallocated. The RECOVER command will fail if DFSMSHsm UID has insufficient authority, or if the IGG.CATLOCK FACILITY class profile has not been defined.

Related reading

For more information on using RLS catalogs and IGG.CATLOCK FACILITY class profile, see [z/OS DFSMS Managing Catalogs](#). For more information on the DFSMSdss BCSRECOVER(LOCK|SUSPEND) parameter, see [z/OS DFSMSdss Storage Administration](#).

Restoring a catalog from a dump copy

You cannot use DFSMSHsm to restore a catalog from a dump copy. DFSMSHsm issues a LOCATE for the catalog name before invoking DFSMSdss, which causes the catalog to be opened. DFSMSdss does not restore a catalog that is open. You can, however, use DFSMSdss directly to restore a catalog from a DFSMSHsm-owned dump copy.

Use the following procedure to restore a catalog:

1. Use the procedure in topic [“Restoring data sets or volumes directly with DFSMSdss” on page 458](#) to find the appropriate dump copy and to invoke DFSMSdss.
2. Ensure that all dump tape volumes are available at the time of the restore.
3. Follow the procedure, with one exception, described in [“Backing up and recovering a catalog” on page 487](#) for recovering a backup version of a catalog. The exception is in the last step. Instead of starting DFSMSHsm and recovering the catalog, use the DFSMSdss RESTORE command to restore the catalog.

Note: You cannot restore a catalog that was dumped with compression, as described in [“Invoking full-volume dump compression” on page 457](#).

Full-volume dump procedures

This topic explains:

- Interrupting and restarting dump procedures
- Defining a new automatic dump start window

Interrupting and restarting automatic dump processing

You can use the following methods to interrupt automatic dump processing during the three phases of automatic dump. These three phases are:

- Automatic deletion of expired dump copies
- Automatic dump of DFSMSHsm-managed or owned volumes
- Deletion of excess volume table of contents (VTOC) copy data sets

There are four methods you can use to interrupt automatic dump processing:

- **Hold dump processing** — You can hold dump processing by specifying the DUMP, DUMP(AUTO), or ALL parameter of the HOLD command. If you hold dump processing with the ENDOFDATASET parameter while DFSMSHsm is automatically deleting expired dump copies or excess dump VTOC copy data sets, processing ends after DFSMSHsm has finished processing the current dump generation. If you hold dump processing with the ENDOFVOLUME parameter while DFSMSHsm is automatically deleting expired dump copies or excess VTOC copies, processing ends after the current phase of automatic dump has completed. If you hold dump processing with the ENDOFVOLUME parameter, DFSMSHsm continues processing the current volumes and does not process any new volumes. Otherwise, DFSMSHsm dump processing ends the next time DFSMSdss reads or writes a record. DFSMSHsm does not start any new volume dump tasks.
- **Disable dump processing** — You can disable dump processing by specifying the NOBACKUP parameter of the SETSYS command. If you disable dump processing while DFSMSHsm is automatically deleting expired dump copies or excess dump VTOC copy data sets, processing ends after DFSMSHsm has finished processing the current dump generation. If you disable dump processing while DFSMSHsm is dumping DFSMSHsm-managed volumes, DFSMSHsm dump processing ends the next time DFSMSdss reads or writes a record. DFSMSHsm does not start any new volume dump tasks.
- **Place DFSMSHsm in emergency mode** — You can place DFSMSHsm in emergency mode by specifying the EMERGENCY parameter of the SETSYS command. If you place DFSMSHsm in emergency mode while DFSMSHsm is automatically deleting expired dump copies or excess dump VTOC copy data sets, processing ends after DFSMSHsm has finished processing the current dump generation.

If you are in a multiple DFSMSHsm-host environment, and have enabled the secondary host promotion function, another DFSMSHsm host takes over the unique functions of the primary DFSMSHsm host that you have put in emergency mode. Those functions include automatic deletion of expired dump copies and excess dump VTOC copy data sets. If promotion occurs during an automatic dump window (as defined on the primary host), and it is not past the latest start time, the promoted host restarts automatic dump processing.

If you place DFSMSHsm in emergency mode while DFSMSHsm is dumping DFSMSHsm-managed volumes, DFSMSHsm dump processing ends the next time DFSMSdss reads or writes a record. DFSMSHsm does not start any new volume dump tasks.

- **Stop DFSMSHsm processing** — You can stop DFSMSHsm by entering the MVS or DFSMSHsm STOP command. If you shut down DFSMSHsm while DFSMSHsm is deleting expired dump copies or excess dump VTOC copy data sets, processing ends after DFSMSHsm has finished processing the current dump generation. If you shut down DFSMSHsm while DFSMSHsm is dumping DFSMSHsm-managed volumes, DFSMSHsm dump processing ends the next time DFSMSdss reads or writes a record. DFSMSHsm does not start any new volume dump tasks.

If you are in a multiple DFSMSHsm-host environment, have enabled secondary host promotion, and you have issued a STOP PROMOTE command, another DFSMSHsm host takes over the unique functions of the primary DFSMSHsm host that you have stopped. Those functions include automatic movement of backup versions from ML1 to tape, and automatic backup of migrated data sets. If promotion occurs during an automatic backup window (as defined on the primary host), and it is not past the latest start time, the promoted host takes over where the primary host left off. If the promoted host was an automatic backup host before being promoted, it performs backups of DFSMSHsm-owned volumes after performing the automatic movement of backup versions from ML1 to tape, and automatic backup of migrated data sets. If the promoted host was *not* an automatic backup host before being promoted, it does not back up DFSMSHsm-owned volumes.

You can restart automatic dump processing by entering the corresponding commands:

- RELEASE DUMP or RELEASE ALL
- SETSYS BACKUP
- SETSYS NOEMERGENCY
- START DFSMSHSM (MVS command)

After you restart automatic dump processing, DFSMSHsm continues with the next DFSMSHsm-managed volume under automatic dump control. Automatic dump restarts at the point of interruption if less than 24 hours have passed since automatic dump was last started from the beginning and if the time is still within the dump start window.

Related reading

For more information about using the secondary host promotion function, see [*z/OS DFSMSHsm Implementation and Customization Guide*](#).

Defining a new automatic dump start window

As you increase the number of volumes that DFSMSHsm dumps, you might want to change the automatic dump start window. In a test environment, you might want automatic dump to run more than once on a single day.

This topic describes:

- Defining a new start window when automatic dump is running
- Defining a new start window when automatic dump is not running

Defining a new start window when automatic dump is running

You can change the automatic dump start window at any time, even when automatic dump is currently running on the particular DFSMSHsm host. Automatic dump runs when the new planned start time occurs if the currently running automatic dump completes before the planned start time of your newly defined start window. If the currently running automatic dump runs past the new planned start time, automatic dump will not start automatically until the next time the planned start time occurs. However, if automatic dump is released or DFSMSHsm is restarted during the newly defined automatic dump start window, automatic dump starts unless it is prevented by one of the commands discussed in [“Interrupting and restarting automatic dump processing” on page 489](#) or by denying permission to the SETSYS REQUEST command.

Defining a new start window when automatic dump is not running

If you define a planned start time that is later than the time that automatic dump last ended, automatic dump starts at the planned start time.

If you define a planned start time that is earlier than the time that automatic dump last ended, automatic dump starts only if it has not run to completion on this day.

Chapter 12. Maintaining DFSMSHsm control data sets

DFSMSHsm maintains three control data sets:

- backup control data set (BCDS)
- migration control data set (MCDS)
- offline control data set (OCDS)

These control data sets and the DFSMSHsm journal are what make it possible for you to rely on DFSMSHsm's record keeping to perform all of its activities. Therefore, you need backup copies of them to allow you to recover data should the active control data sets become lost or damaged.

DFSMSHsm provides for automatic backup of the control data sets and the journal each time that automatic backup is performed for the system. In addition, you can back up the control data sets by command.

The primary host is the only host that normally performs an automatic CDS backup. If the primary host fails, a secondary host can take over the functions of the failed primary host.

To enable you to recover a lost or damaged control data set, DFSMSHsm maintains a journal of each transaction that occurs to the control data sets. Should a control data set be damaged or lost, you can recover a backup version of the control data set and apply the transactions recorded in the journal to bring the control data set back to current status.

In addition to showing how to manage the control data sets automatically, the method of issuing commands necessary to determine the condition of the data sets and to repair them if necessary is discussed.

Related reading

Tasks for maintaining the control data sets

The tasks for controlling automatic backup of the control data sets require adding DFSMSHsm commands to the ARCCMDxx member. The tasks for retrieving the backup control data sets require the invocation of CDS recovery utilities. The following tasks maintain the control data sets:

- Code SETSYS CDSVERSIONBACKUP to tell DFSMSHsm how to back up the data sets automatically.
- Manually back up the control data sets using the BACKVOL CDS command, when automatic backup is not used.
- Recover the control data sets by using the enhanced CDS recovery utilities.
- Issue a DFSMSHsm command to determine if the control data sets match the contents of the computing system catalogs and the VTOCs of the DASD volumes.
- Issue commands to repair errors in the control data sets.

Specifying how DFSMSHsm backs up the control data sets

You can use the CDSVERSIONBACKUP parameter of the SETSYS command to control backup of the control data sets. Within the CDSVERSIONBACKUP parameter, subparameters specify the number of backup versions to keep for the control data sets, the device type on which to store the backup versions, whether to run CDS backup in a parallel or nonparallel mode, the names of the backup data sets, and the data mover.

Note: If you are converting from a SETSYS NOCDVERSIONBACKUP environment, you no longer need the MIGCATBU, BAKCATBU, and OFFCATBU DD statements in your DFSMSHsm startup procedure.

Allocating backup data sets

Whether you choose DFSMSdss or IDCAMS as the data mover when copying the control data sets, the backup data sets are allocated in the following manner:

- If backing up to DASD, you must preallocate the backup data sets.
- If backing up to tape, the data sets are dynamically allocated by DFSMSHsm.

The backup data set names are given a low-level qualifier of either Dxxxxxxx (if DFSMSdss is used for copying) or Vxxxxxxx (if IDCAMS is used for copying), where xxxxxxx is the version number. Backup data set names for multiclusder CDS data sets are given a low-level qualifier of DSy.Dxxxxxxx, where y is the volume number and xxxxxxx is the version number. When CDS version backup fails, the data set name of the failed backup is given a low-level qualifier of Xxxxxxxx, where xxxxxxx is the version number. This data set naming convention supports the use of automated CDS-recovery procedures that determine the latest good control data set backup versions from catalog information.

Choosing the data mover to be used

The SETSYS CDSVERSIONBACKUP subparameter DATAMOVER allows you to indicate which of the following datamovers that DFSMSHsm can use to back up the control data sets. (The DFSMSHsm journal is always backed up by sequential I/O.)

- DATAMOVER(DSS) — tells DFSMSHsm to use DFSMSdss logical dump to back up the control data sets
- DATAMOVER(HSM) — tells DFSMSHsm to use IDCAMS EXPORT to back up the control data sets

When you use DFSMSdss—rather than IDCAMS—to copy the data, concurrent copy can be used, and the control data sets will be validated as they are backed up. Concurrent copy allows the CDS backup to complete as soon as the journal has been backed up, so that DFSMSHsm can begin processing requests before the CDS backups are completed.

Rule: If you access the control data sets in RLS mode, you must use DFSMSdss as the data mover.

If you use IDCAMS, you need to examine the number of records copied each day (check the record count in message IDC0005I from IDCAMS EXPORT), because a broken VSAM index for a CDS will likely result in significant data loss in the backup copy. This loss can go unnoticed for a considerable period of time.

Recommendation: DFSMSHsm development strongly recommends that you specify DATAMOVER(DSS), which provides advantages of validation during backup as well as (with the concurrent copy function) reduced serialization of the control data sets. DATAMOVER(HSM) is retained as an option for purposes of coexistence with previous releases.

DFSMSdss as data mover

You can use DFSMSdss and the concurrent copy function to back up the control data sets. Concurrent copy lets you make a *point in time* copy of a control data set even while it is being updated. DFSMSdss also validates the CDS while the CDS is being backed up. This function is similar to AMS EXAMINE.

The use of the concurrent copy function will reduce the duration of complex-wide serialization of the DFSMSHsm CDS resources when performing CDS version backup and, when SETSYS JOURNAL(RECOVERY) is specified, non-intrusive journal backup is used to further reduce the duration (see [“Using non-intrusive journal backup”](#) on page 496). This time reduction increases the availability of DFSMSHsm functions and non-intrusive journal backup allows DFSMSHsm activity to continue during the journal backup. To achieve the highest level of DFSMSHsm availability, you should place the control data sets on SMS-managed devices that support the concurrent copy function, and you should use DFSMSdss to back up the control data sets. If DFSMSdss backs up to tape, each CDS (or each cluster if multi-cluster control data sets are used) is copied to an individual tape drive (in parallel). Use of concurrent copy is required in order to use non-intrusive journal backup.

If a control data set is on an SMS-managed device that supports the concurrent copy function, and the management class attribute BACKUP COPY TECHNIQUE is specified as a value other than STANDARD, DFSMSdss establishes a concurrent copy session. (See [“Concurrent copy management class support”](#) on page 495 for information about the BACKUP COPY TECHNIQUE management-class attribute.) Otherwise, DFSMSHsm directs DFSMSdss to dump the data set without the benefit of concurrent copy. All control data sets, if they are SMS-managed, should be specified with the same SMS backup copy technique.

After all resources have been set up (data sets allocated and tapes mounted), the control data sets are reserved. When using RLS in a multihost environment, DFSMSHsm does an exclusive enqueue rather than a reserve. The reserves, or enqueues, prevent other DFSMSHsm functions that require the control data sets from running.

DFSMSHsm removes the CDS serialization after the following actions have been done:

1. The journal has been backed up.
2. The journal has been nulled (emptied).
3. DFSMSdss indicates that it has established a concurrent copy session for each control data set to be backed up.

All current DFSMSHsm-supported backup DASD and tape devices are supported by the concurrent copy function.

Concurrent copy management class support

When using DFSMSdss as the data mover, the BACKUP COPY TECHNIQUE management-class attribute that is assigned to the control data sets informs DFSMSHsm whether to direct DFSMSdss to use the concurrent copy function when backing up those data sets. (The attribute is used for a similar purpose during automatic or volume backup processing.)

The BACKUP COPY TECHNIQUE attribute is used as follows:

- CONCURRENT PREFERRED (P) - specifies that the concurrent copy facility is preferred. If a concurrent copy session can be established, the data set is backed up using the concurrent copy facility. Otherwise, data set is backed up by DFSMSdss logical dump without concurrent copy.
- CONCURRENT REQUIRED (R) - specifies that the concurrent copy facility is required. If a concurrent copy session cannot be established, the data set will not be backed up.
- STANDARD (S) - specifies that the concurrent copy facility is not to be used, even though it may be available for the data set. Normal DFSMSdss logical dump backup processing is used without concurrent copy.
- VIRTUAL PREFERRED (VP) - specifies that the virtual concurrent copy is preferred. If a virtual concurrent copy session cannot be established the data set is backed up by DFSMSdss logical dump without concurrent copy.
- VIRTUAL REQUIRED (VR) - specifies that the virtual concurrent copy is required. If a virtual concurrent copy session cannot be established, the data set will not be backed up.
- CACHE PREFERRED (CP) - specifies that the cache-based concurrent copy is preferred. If a cache-based concurrent copy session cannot be established the data set is backed up by DFSMSdss logical dump without concurrent copy.
- CACHE REQUIRED (CR) - specifies that the cache-based concurrent copy is required. If a cache-based concurrent session cannot be established, the data set will not be backed up.

If the management class associated with a data set specifies that the concurrent copy BACKUP COPY TECHNIQUE be used, DFSMSdss is invoked specifying the CONCURRENT parameter.

Note: Use these additional considerations when using cache-based concurrent copy to process large data sets or volumes, or when using multiple tasks to process a large number of data sets:

- Use concurrent copy only during periods of light update activity for the data sets or volumes involved.
- Spread multiple concurrent copy jobs across as many LPARs as possible.

- Ensure that jobs and address spaces that will use concurrent copy are assigned a WLM service class with a high execution velocity. Never assign a discretionary goal to concurrent copy work.
- Ensure that volumes that will be processed will not be reserved by another system during the concurrent copy.

DFSMSHsm as data mover

When DFSMSHsm (IDCAMS) is used as the data mover, the control data sets are not validated during backup, and concurrent copy is not available. Thus you need to examine the number of records copied each day, because a broken VSAM index for a CDS will likely result in significant data loss in the backup copy. This loss can go unnoticed for a considerable period of time.

To specify DFSMSHsm as the datamover, add the following command to the ARCCMDxx member for processing unit 1: SETSYS CDSVERSIONBACKUP (DATAMOVER (HSM))

Using non-intrusive journal backup

There are two types of journal backup methods which should be considered: *quiesced* and *non-intrusive*.

During *quiesced* journal backup, all DFSMSHsm activity is quiesced while the journal and the control data sets are backed up.

During *non-intrusive* journal backup, all DFSMSHsm activity is allowed to continue while DFSMSHsm creates a backup of the preexisting journal records. After the initial backup of the journal completes, all DFSMSHsm activity is quiesced and DFSMSHsm completes the backup of the journal and backs up the control data sets using concurrent copy (this is a requirement of non-intrusive journal backup). The overall elapsed time for non-intrusive journal backup is approximately the same as quiesced journal backup.

Because all DFSMSHsm activity is quiesced during quiesced journal backup, user and production jobs that require recall or recovery resources wait until the entire CDS and journal backup is complete. Therefore, the impact of journal backup on DFSMSHsm availability and performance should be considered when planning a backup schedule. Non-intrusive journal backup can be used to reduce the impact on DFSMSHsm availability and performance.

Message ARC0750I indicates which method is in use and why non-intrusive journal backup was not performed. All requirements to use non-intrusive journal backup must be satisfied.

Enabling non-intrusive journal backup

To enable and use non-intrusive journal backup, the non-intrusive journal backup requirements must be satisfied. See [Requirements to use non-intrusive journal backup](#).

Disabling non-intrusive journal backup

There is no method of disabling non-intrusive journal backup. Non-intrusive journal backup will be used instead of quiesced journal backup as long as the non-intrusive journal backup requirements are satisfied.

Requirements to use non-intrusive journal backup

Requirements that must be satisfied to enable and use non-intrusive journal backup are:

- The SETSYS JOURNAL(RECOVERY) setting is in effect.
 - Add the SETSYS JOURNAL(RECOVERY) command to the ARCCMDxx parmlib member of SYS1.PARMLIB and restart DFSMSHsm.
 - Issue the SETSYS JOURNAL(RECOVERY) command after DFSMSHsm is started.
- The control data sets are configured to be backed up using concurrent copy.

Related reading

- For more information about using DFSMSdss as the data mover and configuring the use of concurrent copy, see [“DFSMSdss as data mover” on page 494](#).
- For more information about using the SETSYS command, see Chapter 65, [“SETSYS command: Establishing or changing the values of DFSMSHsm control parameters,” on page 1057](#).

Specifying how many backup versions to keep

DFSMSHsm keeps the backup copies of the control data sets as versions, where each version is a set of CDS backup data sets and a journal backup data set. The version number of each backup data set is shown in the low-level qualifier of the data set names. Unless all backups fail, the CDS backup version number is incremented by one, and the new backup data sets are created and cataloged each time you back up the control data sets.

Note: As a result of errors during backup of an individual CDS, you may have one or more invalid backup data sets in a backup version. If you back up your control data sets to DASD and fail to attend to any CDS backup failures, you can eventually lose the ability to recover the control data sets.

Whenever a new CDS backup version is created, the oldest backup version is eliminated from the system (rolled off). If you back up to tape, the oldest backup version is uncataloged. If you back up to DASD, the oldest backup version is reused and renamed to the new version.

You must decide how many versions to keep on your system, and then tell DFSMSHsm that number by using the BACKUPCOPIES subparameter of the SETSYS CDSVERSIONBACKUP command. You should keep a minimum of three CDS backup versions. Specify that number to DFSMSHsm with the following command:

```
SETSYS CDSVERSIONBACKUP(BACKUPCOPIES(3))
```

Specifying the names of the backup data sets

Use subparameters of the SETSYS CDSVERSIONBACKUP command to specify the data set names that are to be assigned to the backup data sets. You can use up to 35 characters in the data set name, including periods, but you must not end the name with a period. DFSMSHsm appends a qualifier to the data set name that you specify. The form of this qualifier depends on the data mover used to perform the backup:

- *DSy.Vnnnnnnn* — V specifies that IDCAMS was the data mover
- *DSy.Dnnnnnnn* — D specifies that DFSMSdss was the data mover
- *DSy.Xnnnnnnn* — X specifies that the backup failed, regardless of the data mover

Note: *nnnnnnn* is the version number. *y* is the volume for a multicluster CDS. *DSy* does not exist if the CDS is only one volume.

If you do not specify the data set names, DFSMSHsm generates names of *uid.BCDS.BACKUP*, *uid.MCDS.BACKUP*, *uid.OCDS.BACKUP*, and *uid.JRNL.BACKUP* for the data sets. DFSMSHsm substitutes the UID from the startup procedure for *uid*.

The following commands, used in the example system and added to the ARCCMDxx member in processing unit 1, demonstrate DFSMSHsm processing when the data set names are not specified:

```
SETSYS CDSVERSIONBACKUP(DATAMOVER(HSM) -  
  BACKUPCOPIES(3) -  
  BCDSBACKUPDSN(BHSM.BCDS.BACKUP) -  
  MCDSBACKUPDSN(BHSM.MCDS.BACKUP) -  
  OCDSBACKUPDSN(BHSM.OCDS.BACKUP) -  
  JRNLBACKUPDSN(BHSM.JRNL.BACKUP))
```

Specifying the device type for backup of the control data sets

The control data sets and journal data set can be backed up to either DASD or tape. Both DASD and tape have certain advantages in relation to each other. In deciding whether to use DASD or tape for backing up your control data sets and journal data set, consider the following factors:

- **Mounting:** You do not have to mount DASD. For tape backup, you must mount a tape for each control data set and the journal.
- **Allocation:** With DASD, you do not have allocation problems that are caused by no available drives. With tape, the allocation request for a scratch tape fails if no tape drives are available.
- **SMS-managed:** With DASD, the backup copies of your control data sets can be SMS managed.
- **Preallocation:** With tape, you need not preallocate backup data sets.

Whether you back up the control data sets to DASD or to tape, DFSMSHsm issues messages ARC0742I and ARC0743I for each data set that is backed up. If the backups are in nonparallel mode, the messages are issued in pairs. However, if the backups are in parallel mode, all of the ARC0742I messages may be issued before the first ARC0743I message is issued. Parallel processing makes it possible to start all the backups before the first backup is completed.

If you decide to back up the control data sets and journal data set to DASD, you must preallocate the data sets. Also, allocate the different versions of the backup data sets on different volumes. This better ensures that you can recover your backup versions.

In the example system, backup is shown going to DASD. Therefore, the command that is added to the ARCCMDxx member in processing unit 1 is modified as follows:

```
SETSYS CDSVERSIONBACKUP(DATAMOVER(DSS) -
  BACKUPCOPIES(3) -
  BACKUPDEVICECATEGORY(DASD) -
  BCDSBACKUPDSN(BHSM.BCDS.BACKUP) -
  MCDSBACKUPDSN(BHSM.MCDS.BACKUP) -
  OCDSBACKUPDSN(BHSM.OCDS.BACKUP) -
  JRNLBACKUPDSN(BHSM.JRNL.BACKUP))
```

Unlike backup of user data sets, backup of the control data sets must be to only one kind of I/O device. You cannot use a mixture of DASD and tape.

Specifying DASD for backup

If you specify BACKUPDEVICECATEGORY(DASD), parallel processing is always performed.

Because the backup of the control data sets to DASD is in parallel mode, all of the resources necessary for the backup are allocated before the control data sets and the journal are reserved. This means that DFSMSHsm cannot perform its other functions until either backup is complete or (if concurrent copy is used) concurrent copy sessions have been established and journal backup is complete.

Specifying tape for backup

Parallel backup CDS processing to tape allows the control data set and journal backups to be performed concurrently, thereby reducing the time required for the CDS backup function.

If you specify BACKUPDEVICECATEGORY(TAPE), your datamover is DFSMSHsm, and you want parallel backup processing, then you must specify PARALLEL, because NOPARALLEL is the default. When using DFSMSdss as the data mover and going to tape, parallel processing must be specified.

If CDS backup is invoked while the control data sets are accessed in RLS mode, DFSMSdss must be the datamover. If the backup is directed to tape, the PARALLEL parameter of the SETSYS CDSVERSIONBACKUP(BACKUPDEVICECATEGORY) must be specified.

When backing up to tape in parallel mode, one tape device for each data set to be backed up is required. For instance, if all three control data sets and the journal are to be backed up, then four tape drives are required.

When the backup of the control data sets is in parallel mode, all of the resources necessary for the backup are allocated before the control data sets and the journal are reserved.

Protecting CDS backup tapes

The DFSMSHsm CDS backup tapes are supported for expiration protection only, as specified by the EXPIRATIONDATE or RETENTIONPERIOD subparameters of the SETSYS CDSVERSIONBACKUP(BACKUPDEVICECATEGORY(TAPE)) command. The SETSYS TAPESECURITY command does not affect the CDS backup tapes, and cannot be used to assign RACF or password protection as it can with other DFSMSHsm-owned tapes. However, the DFSMSHsm ARCCBEXT installation exit can be used to assign RACF protection to the CDS backup tapes, and the DFSMSHsm ARCTVEXT installation exit can be used to remove RACF protection from the tapes when you want to return them to scratch.

Related reading

For more information about DFSMSHsm installation exits, see [z/OS DFSMS Installation Exits](#).

Invoking the CDS backup exit (ARCCBEXT)

After CDS backup completes, the *control data set backup exit* (ARCCBEXT) is invoked, if it is active.

Related reading

For more information about the ARCCBEXT exit, see [z/OS DFSMS Installation Exits](#).

Backing up to multiple DASD data sets

If you decide to back up the control data sets and journal data set to DASD, you must first allocate and catalog a backup data set for each backup version of the control data sets. If the CDS is multicluster, additional backup version data sets are required. See [“Considerations when using multicluster control data sets”](#) on page 502.

The following example describes the process of backing up the control data sets and journal data set to multiple DASD backup data sets. The example assumes you have single-cluster control data sets.

1. The following command has been specified to indicate the number of preallocated data sets for each control data set and the journal data set:

```
SETSYS CDSVERSIONBACKUP(DATAMOVER(DSS) -
  BACKUPCOPIES(3) -
  BACKUPDEVICECATEGORY(DASD) -
  MCDSBACKUPDSN(BHSM.MCDS.BACKUP) -
  BCDSBACKUPDSN(BHSM.BCDS.BACKUP) -
  OCDSBACKUPDSN(BHSM.OCDS.BACKUP) -
  JRNLBACKUPDSN(BHSM.JRNL.BACKUP))
```

BACKUPCOPIES(3) indicates the number of preallocated data sets for each backup data set.

2. Three backup data sets are allocated for each control data set and the journal data set backup copy. Assume the following 12 data sets are allocated:

Copy Number	Names of Allocated Backup Data Sets
1	BHSM.MCDS.BACKUP.V0000001 BHSM.BCDS.BACKUP.V0000001 BHSM.OCDS.BACKUP.V0000001 BHSM.JRNL.BACKUP.V0000001
2	BHSM.MCDS.BACKUP.V0000002 BHSM.BCDS.BACKUP.V0000002 BHSM.OCDS.BACKUP.V0000002 BHSM.JRNL.BACKUP.V0000002
3	BHSM.MCDS.BACKUP.V0000003 BHSM.BCDS.BACKUP.V0000003 BHSM.OCDS.BACKUP.V0000003 BHSM.JRNL.BACKUP.V0000003

Note:

- a. The final qualifier of each backup data set must start with V0000001 and increase by 1 for each required backup data set. Because you chose "DSS" as the data mover in the SETSYS CDSVERSIONBACKUP command, DFSMSHsm changes the final qualifier of its output data sets to begin with the letter D (D0000001). The renaming of the backup data set final qualifier happens automatically when you change data movers.
 - b. If the journal is allocated as a large format sequential data set and is larger than 64K tracks, when you preallocate the journal backup data set, you must allocate the journal backup data set as a large format sequential data set, which is large enough to contain a copy of the original large format sequential journal.
3. DFSMSHsm backs up the control data sets and journal data set by doing the following:
- a. It issues an exclusive enqueue against the control data set resource and, if it is in a multiple DFSMSHsm-host environment, reserves the volumes containing the journal data set and each control data set being used.

When using RLS in a multiple DFSMSHsm-host environment, DFSMSHsm does an exclusive enqueue rather than a reserve.

- b. It invokes DFSMSdss to logically dump each of the control data sets, using concurrent copy if available. DFSMSdss informs DFSMSHsm when a concurrent copy session has been established, or when it has finished the dump of a control data set.
- c. It copies the journal to the backup data set and nulls the journal data set. When the journal has been backed up and all the concurrent copy sessions have been established or all the control data sets have been backed up, DFSMSHsm releases the volume reserves (if using RLS there are no reserves), and dequeues the control data set resource.

When DFSMSHsm backs up the control data sets and journal data set, it determines the final qualifier of the backup data sets. If the version number in the final qualifier matches the version number in the final qualifier of an existing data set, DFSMSHsm uses the existing data set. In this example, DFSMSHsm finds an existing backup data set the first three times it backs up the control data sets, and changes the first letter of the last data set name qualifier from V to D (V0000001 becomes D0000001). The fourth time DFSMSHsm backs up the control data sets, it cannot find an existing version 4 backup data set. Therefore, DFSMSHsm backs up the control data sets to the backup data set with the final qualifier of D0000001.

- d. If DFSMSHsm backs up the control data sets to DASD volumes and needs to rename the backup data set, it does so. In this example, after DFSMSHsm successfully backs up these data sets for the fourth time, it renames the backup data set by changing the final qualifier of D0000001 to a final qualifier of D0000004. Even if the renaming fails, the backup copy is still valid.
- e. DFSMSHsm optionally calls the control data set backup user exit ARCCBEXT, allowing you to process the backup version after DFSMSHsm creates it.

Note: If you change the specification for the number of backup copies kept to *reduce* the number of copies, DFSMSHsm does not delete the excess older backup versions that were made before you reduced the number of copies.

If you change the specification for the number of backup copies kept to *increase* the number of copies, you must first allocate and catalog additional backup data sets. Start with a final qualifier that is one more than the last final qualifier of your backup data sets on DASD.

Backing up to multiple tape data sets

If you decide to back up the control data sets and journal data set to multiple tape data sets, the process is a little different. When you specify the following command, you do not have to allocate and catalog backup data sets:

```
SETSYS CDSVERSIONBACKUP(BACKUPCOPIES(copies) -
  BACKUPDEVICECATEGORY(TAPE))
```

You can choose to specify a unit name, density, and retention period or expiration date.

The following example describes the process of backing up the control data sets and journal data set to multiple tape backup data sets.

1. The following command is specified:

```
SETSYS CDSVERSIONBACKUP (BACKUPCOPIES(3) -
  DATAMOVER(DSS) -
  BACKUPDEVICECATEGORY(TAPE))
```

BACKUPCOPIES(3) indicates the maximum number of cataloged backup data sets for each control data set and the journal data set.

2. DFSMSHsm backs up the control data sets and the journal data set. DFSMSHsm puts only one backup data set on a specific tape. Because you do not have to preallocate backup data sets when you use tape, DFSMSHsm dynamically allocates a new backup data set. The default backup data set name is the same for tape as for DASD. Therefore, if you have not specified the backup data set name with the SETSYS CDSVERSIONBACKUP command, DFSMSHsm uses the default backup data set name and the correct final qualifier for the new backup data set. In this case—the first time DFSMSHsm backs up the four data sets—the backup data sets have the following names:

```
HSM.MCDS.BACKUP.D0000001
HSM.BCDS.BACKUP.D0000001
HSM.OCDS.BACKUP.D0000001
HSM.JRNL.BACKUP.D0000001
```

The second time DFSMSHsm backs up the four data sets, it uses a final qualifier of D0000002.

```
HSM.MCDS.BACKUP.D0000002
HSM.BCDS.BACKUP.D0000002
HSM.OCDS.BACKUP.D0000002
HSM.JRNL.BACKUP.D0000002
```

3. The third time DFSMSHsm backs up the four data sets, it dynamically allocates a third set of backup data sets and uses a final qualifier of D0000003.

After DFSMSHsm successfully backs up the control data sets and the journal data set for the fourth time, it uncatalogs the set of backup data sets whose final qualifier is D0000001 and invokes installation exit ARCTVEXT for the rolled-off version of each successfully backed-up data set.

Note: If the backup is not successful for a particular data set, the oldest version of that data set is not rolled off, and DFSMSHsm invokes the tape installation exit, ARCTVEXT, that allows you to reuse the bad backup tapes.

4. DFSMSHsm optionally invokes the control data set backup user exit ARCCBEXT, allowing you to process the backup version after DFSMSHsm creates it.

Note:

1. The maximum number of tapes DFSMSHsm uses for one backup version of one control data set or the journal is 18.
2. If you change the specification for the number of backup copies kept to reduce the number of copies, DFSMSHsm does not delete or uncatalog the excess older backup versions that were made before you reduced the number of copies.

Considerations in a multiple DFSMSHsm host environment

The following are considerations in a multiple DFSMSHsm-host environment:

- All hosts sharing DFSMSHsm control data sets must specify the same options for the SETSYS CDSVERSIONBACKUP command, as the information is stored in the MCDS. The last DFSMSHsm host to issue the SETSYS CDSVERSIONBACKUP command controls how all the DFSMSHsm hosts back up the control data sets.

An alternative to having all DFSMSHsm hosts specifying the same options for the SETSYS CDSVERSIONBACKUP command is to have only one DFSMSHsm host (typically the host identified as the primary DFSMSHsm host) specifying the command.

- The NOCDSVERSIONBACKUP parameter of the SETSYS command is no longer valid. If SETSYS NOCDSVERSIONBACKUP is specified, message ARC0103I is issued, indicating an unsupported parameter.
- If backing up the control data sets to DASD, make the preallocated data sets accessible to any DFSMSHsm host doing the backups.
- If backing up to tape, some of your tape data sets won't be rolled off if they were created on one z/OS image, deleted on another z/OS image, and cataloged other than on a shared user catalog.
- A CDSQ=RLS DFSMSHsm environment will use XCF to communicate to all hosts in an HSMPLX that CDS Backup is starting and needs the ARCENQG/ARCCAT resource.

Considerations when using multicluster control data sets

A multicluster MCDS or BCDS can be defined when the CDS size increases beyond one volume. If you have defined a multicluster CDS, you must make the following changes to your CDS backup procedure:

- When backing up your control data sets to DASD, preallocate each volume within the multicluster CDS using a different naming convention. Each low-level qualifier (version number) must be preceded by .DSy, where y is a number from 1 to 4 and represents the number of volumes in the multicluster CDS. For instance, if you have split the MCDS into four volumes, split the BCDS into two volumes, and are keeping only one backup copy, the following data sets would be preallocated (assuming the choice of DFSMSdss for the data mover):

```
HSM.MCDS.BACKUP.DS1.D0000001
HSM.MCDS.BACKUP.DS2.D0000001
HSM.MCDS.BACKUP.DS3.D0000001
HSM.MCDS.BACKUP.DS4.D0000001
HSM.BCDS.BACKUP.DS1.D0000001
HSM.BCDS.BACKUP.DS2.D0000001
HSM.OCDS.BACKUP.D0000001
HSM.JRNL.BACKUP.D0000001
```

- The interface to the ARCCBEXT installation exit has been extended to include the names of the backup data sets for the multicluster CDS.
- When you back up your control data sets to tape, the new naming convention (.DSy) applies to the created tape data set names.

Note: The CDS backup tapes created under the old naming convention are not rolled off automatically. Message ARC0747E is issued to indicate that roll-off processing cannot be performed.

- Messages ARC0742I, ARC0743I, and ARC0744E indicate which volume in the multicluster CDS was being processed.
- When you back up your control data sets to tape in parallel, a tape drive is needed for each cluster in the multicluster CDS. For instance, if you split the MCDS into four volumes, split the BCDS into two volumes, have defined an OCDS on one volume, and are journaling, eight tape drives are required to back up the control data sets and the journal.

Nulling the journal

If the journal data set fails to back up during the CDS version backup function, the journal will not be nulled. Conversely, the journal is always nulled if the backup of the journal data set is successful, regardless of the success or failure of the backup of the control data sets.

You can null the journal by using the following command: `BACKVOL CDS(NULLJOURNALONLY)`

`NULLJOURNALONLY` is an optional subparameter telling the CDS version backup function to only null the journal. No backup copies of the control data sets or journal are made.

Changing the names of the backup data sets

You can change the naming conventions for the backup data sets by performing the following steps:

- Issue the `SETSYS CDSVERSIONBACKUP` command using the subparameter for the data set names assigned to the backup data sets. Specify the new naming convention used to back up the control data sets.

Rule: You must change the naming convention for the backup data sets in all procedures that DFSMSHsm uses. For example, update the `ARCCMDxx` member of the DFSMSHsm startup procedure if you have specified the `SETSYS CDSVERSIONBACKUP` command.

- Rename any current backup versions of the control data sets to the new naming convention if the backup data sets are on DASD. Also, you must rename any “unused” backup versions.
- Uncatalog the old backup data sets so the tape management function can reuse the tape if the backup data sets are on tape. During backup of the control data set, you might receive message `ARC0747E`, which indicates DFSMSHsm could not uncatalog the oldest version using the new backup names. The tape backup copies are successfully made.

Changing backup device from tape to DASD

If you started your backup of the control data sets and the journal data set to tape and want to change to DASD, do the following:

1. Uncatalog the backup versions that reside on tape. If this is not done, attempts to back up the control data sets to DASD will fail.

The expiration date specified by the `EXPIRATIONDATE` or `RETENTIONPERIOD` parameter is still in effect on your backup tapes. Your tape management system returns the tapes to scratch according to the expirations date. Note that some expiration dates, such as 99365 (which prevents the tape from ever expiring), may require manual deletion through your tape management system.

2. Specify the following command:

```
SETSYS CDSVERSIONBACKUP(BACKUPDEVICECATEGORY(DASD))
```

You can also change the number of backup copies. However, this example uses the same number as in the tape example; that is, three backup copies.

3. Allocate your backup data sets on DASD. The sample job `ALLOCBK1`, which is located in the DFSMSHsm starter set, allocates and catalogs the control data set backup version data sets on DASD volumes.

The final qualifier must again increase by 1 for each set of backup data sets. However, do not start with a final qualifier of D0000001. Instead, start with a final qualifier that is 1 more than the last final qualifier of your backup data sets on tape.

Issue the following command to determine the last final qualifier for the backup data sets:

```
QUERY CDSVERSIONBACKUP
```

In this example, the last final qualifier is D0000050.

When you allocate your backup data sets, you decide to use the default backup data set names. Because you are backing up all three control data sets and the journal data set, you must allocate 12 backup data sets:

Data Set	Names of Allocated Backup Data Sets
MCDS	HSM.MCDS.BACKUP.D0000051 HSM.MCDS.BACKUP.D0000052 HSM.MCDS.BACKUP.D0000053
BCDS	HSM.BCDS.BACKUP.D0000051 HSM.BCDS.BACKUP.D0000052 HSM.BCDS.BACKUP.D0000053
OCDS	HSM.OCDS.BACKUP.D0000051 HSM.OCDS.BACKUP.D0000052 HSM.OCDS.BACKUP.D0000053
Journal	HSM.JRNL.BACKUP.D0000051 HSM.JRNL.BACKUP.D0000052 HSM.JRNL.BACKUP.D0000053

DFSMShsm now backs up the control data sets and journal data set to backup data sets on DASD volumes.

Changing backup device from DASD to tape

If you started your backup of the control data sets and journal data set to DASD and want to change to tape, specify the following command:

```
SETSYS CDSVERSIONBACKUP(BACKUPDEVICECATEGORY(TAPE))
```

If you are using DFSMSdss as the data mover, specify:

```
SETSYS CDSVERSIONBACKUP(BACKUPDEVICECATEGORY(TAPE(PARALLEL)))
```

You may change the number of backup copies. If you do not change the number of backup copies, the backup copies that are currently cataloged on DASD are uncataloged by DFSMShsm.

Note: DFSMShsm does not delete the DASD backup copies. The only function performed by DFSMShsm is to uncatalog these data sets. If you feel that you do not need the backup copies on DASD, you may scratch these data sets from your system after the appropriate number of backup copies have been made on a tape device media.

If you have already uncataloged the DASD backup copies, or if you change the number of backup copies, the attempt to uncatalog the DASD backup copies may fail during the backup of the control data sets and journal data set. An ARC0747E message is issued for each data set that could not be uncataloged, and the ARC0741I message at the completion of the backup of the control data sets and journal data set indicates that the backup was UNSUCCESSFUL. However, this unsuccessful status indicates only that backup versions were not successfully uncataloged. The tape backup copies will have been successfully

made, and the final qualifier for these backup copies will have been successfully saved to be used for the next backup of the control data sets and journal data set. This scenario requires no action on your part.

Using the QUERY command to get CDS information

Issue the DFSMSHsm QUERY CDSVERSIONBACKUP or the QUERY SETSYS commands to determine whether DFSMSHsm or DFSMSdss is being used to back up the control data sets.

Issue the QUERY CONTROLDATASETS command to display the CDS serialization technique in use, and the key boundaries being used for non-key-range multicluster control data sets.

Backing up the control data sets manually

Occasionally, it may become necessary for you to manually back up the control data sets. This manual backup could be needed if CDS version backup fails to get a good copy of the control data sets, or if you receive a message that the journal is full. DFSMSHsm provides parameters for the BACKVOL command that allow you to back up all the control data sets manually:

```
BACKVOL CDS(DATAMOVER(HSM | DSS)
  BACKUPDEVICECATEGORY(DASD | TAPE(NOPARALLEL | PARALLEL)))
```

where:

DATAMOVER(HSM | DSS)

specifies which CDS backup data mover should be used when backing up the control data sets.

BACKUPDEVICECATEGORY(TAPE | DASD)

specifies the device on which the backup copies are recorded.

TAPE(NOPARALLEL | PARALLEL)

specifies whether one or more tape devices are allocated. If DATAMOVER(DSS) is specified, TAPE(NOPARALLEL) cannot be specified.

Note:

1. If you do not specify DATAMOVER with the BACKVOL CDS command, the last DATAMOVER specified by SETSYS CDSVERSIONBACKUP is the default.
2. If you do not specify BACKUPDEVICECATEGORY with the BACKVOL CDS command, the last BACKUPDEVICECATEGORY specified by SETSYS CDSVERSIONBACKUP is the default.
3. If you specify BACKVOL CDS DATAMOVER(DSS) without BACKUPDEVICECATEGORY, and the DFSMSHsm CDS version backup environment indicates TAPE(NOPARALLEL), the BACKVOL command terminates with an error message indicating that the CDSVERSIONBACKUP options of DATAMOVER(DSS) and TAPE(NOPARALLEL) are in conflict.
4. Use caution if you change device types with the BACKUPDEVICECATEGORY parameter. See the topics on [“Changing backup device from tape to DASD”](#) on page 503 and [“Changing backup device from DASD to tape”](#) on page 504.
5. Using DATAMOVER(DSS) provides advantages of validation during backup as well as (with the concurrent copy function) reduced serialization of the control data sets. DATAMOVER(HSM) is retained as an option for purposes of coexistence with previous releases.
6. In a single DFSMSHsm host environment, DFSMSHsm obtains an exclusive enqueue on the control data sets. In a multiple DFSMSHsm host environment, DFSMSHsm reserves the volumes, or if using RLS, does an exclusive enqueue on a SYSTEMS wide global resource which will prevent other HSMs in an HSMplex from accessing the control data sets.

Possible failures during CDS and journal backup

If a CDS or journal backup fails, DFSMSHsm documents the failure with message ARC0744E. This topic explains how to proceed after the most likely type of error, and more general suggestions for other error conditions.

Growth of your control data sets

Over time, the number of data sets migrated and backed up, the number of tape volumes owned by DFSMSHsm, and so on, typically increase, causing your control data sets to grow in size. A control data set may grow such that the space allocated to its DASD backup copy is no longer enough, producing return code 12, 13, 18, 47, or 48 in message ARC0744E during an attempted backup.

Assuming from analyzing messages from DFSMSdss or Access Method Services that a backup copy is full, proceed as follows:

1. Issue the QUERY CDSVERSIONBACKUP command. The resulting message ARC0376I, for example,

ARC0376I

```
BACKUPCOPIES=3,
BACKUPDEVICECATEGORY=DASD,
LATESTFINALQUALIFIER=V0000170,
DATAMOVER=HSM
```

gives you the latest version qualifier, and how many backup copies need to be reallocated.

2. Examine the message for the control data set that is identified in the ARC0744E message and determine which backup copies (MCDS, BCDS, OCDS, or JRNL) must be made larger. Assume that the backup copies of the BCDS must be reallocated.
3. Rename the backup data sets *uid.BCDS.BACKUP.V0000168* through *uid.BCDS.BACKUP.V0000170* so they can be kept until there are successful backups.
4. Compare the (used) size of the current BCDS to its size when the backup data sets for the BCDS were last allocated. This allows you to get a rough idea of how much larger the backup data sets must be.
5. Use the ratio from step “4” on page 506, and reallocate backup data sets *uid.BCDS.BACKUP.V0000168* through *uid.BCDS.BACKUP.V0000170* to their new larger sizes.
6. Issue the commands

```
RELEASE BACKUP
BACKVOL CDS
```

If the failed backup was for the journal, DFSMSHsm will have inhibited journaling. A successful BACKVOL CDS command should back up the journal, then null the online journal.

7. Issue commands to RELEASE the other DFSMSHsm functions that you are using once the BACKVOL command is successful.
8. Delete the backup data sets that were renamed in step “3” on page 506 when DFSMSHsm makes three successful backups. A successful backup generates the following message as part of the output from a QUERY CDSV:

ARC0376I

...

```
LATESTFINALQUALIFIER=V0000173,
```

Other failures

By considering the return code in message ARC0744E, you can determine which type of failure occurred:

- If there is an indication of an error in the structure or contents of the control data set itself, perform the following steps:
 1. Take the action to correct the error as indicated by the error message number and the associated return code. This information is contained in the message documentation.
 2. You might need to recover the CDS to a previous level.
- If there is an indication of an error in the system environment outside of the control data set (for example, an output tape could not be allocated), perform the following steps:

1. Stop DFSMSHsm if necessary (if, for example, the error was fragmented storage such that IDCAMS could not be loaded).
 2. Correct the environmental condition, if necessary.
 3. Restart DFSMSHsm, if you stopped it.
 4. Issue the BACKVOL CDS command to make up for the backup that failed.
- If the non-intrusive journal backup method was intended, but was not used, perform the following steps:
 1. Review the output of message ARC0750I, which is issued at the start of journal backup. This message will indicate which journal backup method was used and why non-intrusive journal backup was not used.
 2. Verify all requirements to use non-intrusive journal backup are satisfied. For a list of requirements, see [“Using non-intrusive journal backup”](#) on page 496.

When the conditions preventing non-intrusive journal backup are corrected, future CDS backup processing will use non-intrusive journal backup.

- If there is an indication of a probable program error, gather the necessary data for contacting the IBM Support Center.

Related reading:

- For more information about the action to take regarding error messages and return codes, see [z/OS MVS System Messages, Vol 2 \(ARC-ASA\)](#).
- For more information about how to recover the CDS to a previous level, see [“Recovering control data sets using the enhanced CDS recovery function”](#) on page 508).

Reasons for recovering the control data sets

Occasionally a control data set becomes unusable by DFSMSHsm. For example, a hardware failure or a software logical failure may occur after which DFSMSHsm is unable to use a control data set.

When the control data sets are backed up, they constitute a snapshot of the conditions in the system at that time. After the control data sets are backed up, as DFSMSHsm continues to process data sets and volumes, the control data sets are continually changing. To make it possible for you to return the control data sets to their condition just before the error, DFSMSHsm makes a journal record of each transaction that occurs in the control data sets. If a control data set becomes lost or damaged, you can return it to its correct condition by recovering a backup version of the control data set and applying the appropriate journal.

The CDS recovery process has variations based on which data mover has been used to back up the control data sets. The low-level (final) qualifier of the name of the control data set backup data set indicates which data mover has been used to back it up. A low-level qualifier of Vnnnnnnn indicates that DFSMSHsm backed up the data set. A low-level qualifier of Dnnnnnnn indicates that DFSMSdss backed up the data set, and a low-level qualifier of Xnnnnnnn indicates that CDS version backup of the data set failed, regardless of whether DFSMSHsm or DFSMSdss was doing the backup.

I/O errors

When an I/O error occurs on the control data sets, the following situations can exist:

- If the I/O error is caused by an equipment check on the real DASD containing the affected data set, recover the data set to a different volume. Call your service representative to repair the drive on which the equipment check has occurred.
- If the I/O error is caused by a data check on the real DASD containing any control data set, you can use the enhanced CDS recovery function to recover the backup version of the affected data set to a different volume. You can use Device Support Facilities (a program to perform operations on disk volumes) to analyze, inspect, and assign alternate tracks and then recover the affected control data set to the same

volume. Or, you can rename the affected control data set and define a new control data set on the same volume.

Recovering control data sets using the enhanced CDS recovery function

The recommended procedure for recovery is called the "enhanced CDS recovery function", which allows you to recover a control data set to the point of failure (to the point where the hardware failure occurred or to the point where the software failure was recognized).

The enhanced CDS recovery function consists of the following two utility programs:

ARCBJRNL

The journal copy utility that backs up the journal—using as input either the active journal or the active journal plus multiple journal backup copies—and prepares the resultant backed up copy that is sorted and used as input to the import utility.

Rule: Because there may still be residual data in the journal, you must run the sort job regardless of how many records that ARCBJRNL reports were processed.

ARCIMPRT

The import utility that uses a sorted version of the backed up and sorted journal or journals from the journal copy utility and an exported control data set to recover the control data set to the point of failure.

Requirements for using the enhanced CDS recovery function

To successfully use the enhanced CDS recovery function, you must be sure that:

- You have sufficient DASD to contain the rebuilt control data set and the backed up journal.
- DFSMSHsm is not active on any z/OS image in the complex while the control data set is being recovered.
- You have specified SETSYS JOURNAL for normal DFSMSHsm operation, because an up-to-date journal is necessary for the enhanced CDS recovery function.
- You run the ARCIMPRT utility separately for each specific control data set to be recovered because the parameter passed to ARCIMPRT is for a specific control data set to be recovered. Also, the EXPORT DD statement must be changed to the particular exported control data set being used.

If you are recovering a multicluster CDS, you need recover only the specific volume which failed; you do not need to recover all the volumes within the multicluster CDS.

In other words, if a migration control data set is to be recovered, then the parameter passed to ARCIMPRT must be MCDS or MIGRATIONCONTROLDATASET, and the EXPORT DD statement *dsname* must refer to the portable-exported-migration CDS (your backup copy of the control data set).

Implementing enhanced CDS recovery using JCL

This topic describes the steps necessary to recover a CDS. You can recover a CDS either from the most recent backup copy or from an older backup copy. An older backup copy is needed if your most recent backup copy is unusable. Both types of recoveries are essentially the same except for Step 1 (Create the Backup Journal).

DFSMSHsm should be down when processing this procedure.

If multiple journal backup copies are needed to recover the journal, and therefore recover a control data set, the following procedure should be used, because it minimizes the time DFSMSHsm is down:

1. Use the ARCBJRNL utility (with multiple backup copies as input) and the ARCIMPRT utility to recover the control data set to a point just before what the active journal contains.
2. Bring down DFSMSHsm.

3. Use the ARCBJRNL utility (with only the active journal as input) and the ARCIMPRT utility to finish recovering the control data set. When you run this step you need to make an exported copy of the MCDS created by ARCIMPRT in step 1 as the input to ARCIMPRT in this step.
4. Bring DFSMSHsm up.

Steps 1, 2, and 4 can be run separately as shown or can be combined into one job.

The following sample JCL shows the steps required to recover a control data set:

1. Create the backup journal.

The backup journal can be created by using either of the two following JCL examples.

This example uses only the active journal as input and is used if recovering from the most recent backup copy of your CDS. If the most recent backup copy is a failed copy (last qualifier is Xnnnnnnn), follow the procedures which use an active journal and one or more backup journals.

```
//ARCBJRNL JOB ,MSGLEVEL=(1,1),MSGCLASS=A,REGION=1024K
//* -----
//* CREATE DATA SET CONTAINING RECORDS FROM THE
//* ACTIVE JOURNAL
//* -----
//STEP01 EXEC PGM=ARCBJRNL
//STEPLIB DD DSN=location where program ARCBJRNL resides,
//          DISP=SHR
//SYSPRINT DD SYSOUT=*
//JRNLO DD DSN=online journal data set name,
//        DISP=OLD
//JRNLBK DD DSN=backup journal name,
//          UNIT=unit name,
//          VOL=SER=volume where backup journal will reside,
//          SPACE=adequate space to hold journal,
//          DISP=(,CATLG,DELETE)
```

Note:

- a. You can indicate what input—the active journal, journal backup copies, or both—is used during ARCBJRNL utility processing by using the PARM keyword on the EXEC statement. The keywords and their meanings are:
 - JRNLOONLY — Only the active journal is used as input
 - JRNLBKBACKUP — Only journal backup data sets are used as input
 - JRNLBKBACKUPS — Only journal backup data sets are used as input
 - BOTH — Both the active journal and journal backup data sets are used as input
- b. If PARM is not specified, only the active journal is used as input to ARCBJRNL processing.
- c. When using multiple journal backup data sets for input to ARCBJRNL processing, list these data sets in ascending version order in the ARCBJRNL BKUPJRNL DD DSN= statements.
- d. The following DD statements are required:
 - i) JRNLO DD statement pointing to the current online journal being used by DFSMSHsm.
 - ii) BKUPJRNL DD statement pointing to the journal backup copies. If recovering using multiple journal backup copies you must concatenate them in ascending order. In addition if the journal backups were written to tape you must ensure you have enough tape drives available for the number of journal backup copies you will be concatenating as DFSMSHsm will allocate all of these data sets at the same time.
 - iii) JRNLBK dd statement pointing to the merged journal dataset created by ARCBJRNL which will be used as input to step 2. The following example uses the active journal and three existing journal backup copies as input. This example is used if recovering from an older backup copy of your CDS. In this case, the backup CDS is from 4 backups ago.

The following example uses the active journal and three existing journal backup copies as input. This example is used if recovering from an older backup copy of your CDS. In this case, the backup CDS is from 4 backups ago.

```
//ARCBJRNL JOB ,MSGLEVEL=(1,1),MSGCLASS=A,REGION=1024K
//* -----
//* CREATE DATA SET CONTAINING JOURNAL FROM JOURNAL
//* BACKUP COPY DATA SETS AND THE ACTIVE JOURNAL
//* -----
//STEP01 EXEC PGM=ARCBJRNL,PARM='BOTH'
//STEPLIB DD DSN=location where program ARCBJRNL resides,
// DISP=SHR
//SYSPRINT DD SYSOUT=*
//JRNLO DD DSN=online journal data set name,
// DISP=SHR
//BKUPJRNL DD DSN=backup copy name and version,DISP=SHR
// DD DSN=backup copy name and version,DISP=SHR
// DD DSN=backup copy name and version,DISP=SHR
//JRNLBK DD DSN=backup journal name,
// UNIT=unit name,
// VOL=SER=volume where backup journal will reside,
// SPACE=adequate space to hold journal,
// DISP=(,CATLG,DELETE)
```

2. Sort the journal backup file.

After you have created the journal backup file using the JCL in step 1, sort the file by KEY using the EQUALS parameter, as in the following JCL.

Note: The following JCL assumes you have a SORTD cataloged procedure. The SORTD cataloged procedure can be created by running the DFSORT SORTPROC job that DFSORT distributes in SYS1.SAMPLIB. If you do not have a SORTD procedure, modify the EXEC card in the JCL to identify the sort program you want to use. Ensure that the program is logically equivalent to DFSORT.

```
//SORT JOB
//* -----
//* SORT THE BACKED UP JOURNAL
//* -----
//STEP02 EXEC SORTD
//SORTLIB DD .....
//SYSOUT DD SYSOUT=*
//SORTWK01 DD .....
//SORTWK02 DD .....
//SORTWK03 DD .....
//SORTWKnn DD .....
//SORTIN DD DSN=backup journal name from STEP 1,
// DISP=SHR
//SORTOUT DD DSN=sorted backup journal name,
// UNIT=unit name,
// VOL=SER=volume where sorted backed up journal will reside,
// SPACE=adequate space to hold sorted backed up journal,
// DCB=(RECFM=VBS,BLKSIZE=0,LRECL=6560),
// DISP=(,CATLG,DELETE)
//SYSIN DD *
SORT FIELDS=(17,44,CH,A)
OPTION EQUALS
/*
```

3. The next step depends on the data mover used to create the backup copy. If the backup copy was made by DFSMSHsm, that backup copy is already in the form of a portable exported data set. If this is the case, step 3 is not required.

If the backup copy has been made by DFSMSdss:

- a. Restore the backup version (either the most recent backup version or the last good backup version) using the following example JCL:

```
//JOB1 JOB accounting information,REGION=nnnK
//STEP1 EXEC PGM=ADRDSSU
//SYSPRINT DD SYSOUT=*
//TAPE DD DSN=uid.CDS.BACKUP.D0000106,DISP=(OLD,KEEP)
//DASD DD UNIT=3390,VOL=SER=222222,DISP=OLD
//SYSIN DD *
RESTORE DATASET(-
INCLUDE(uid.dsname))-
INDDNAME(TAPE)-
OUTDDNAME(DASD)-
REPLACE
/*
```

- b. Export the data set restored in step “3.a” on page 510 using the following example JCL:

```
//EXPORT JOB accounting information,REGION=nnnnK
//STEP1 EXEC PGM=IDCAMS
//SYSPRINT DD SYSOUT=*
//OUTDD1 DD DISP=(,CATLG,DELETE),BUFNO=26,BLKSIZE=28332,
//        SPACE=(CYL,(200,20),RLSE),
//        UNIT=3390,VOL=SER=222222,
//        DSN=temp_dsname
//SYSIN DD *
EXPORT dsname -
OUTFILE(OUTDD1) -
TEMPORARY
/*
```

4. Import and merge the control data set.

After you have sorted the journal backup file by doing step 2 and you have an exported copy of the subject CDS, run ARCIMPRT to create a control data set by using the following JCL.

Note:

- If you need to increase the size of the control data set, issue the DEFINE command before the IMPORT command.
- Any valid IDCAMS command may be specified in the SYSIN stream. These commands are passed directly to IDCAMS (program ARCIMPRT does not modify these commands). Therefore, the DELETE command is used to delete the control data set before the data set is imported.
- The IMPORT command must use the INFILE parameter; using the INDATASET parameter will result in an error return.

The following sample shows how to re-create a migration control data set. To re-create a backup control data set or an offline control data set, make changes to the "PARM=" in the EXEC statement and to the EXPORT DD statement *dsname* that reflects which control data set exported copy to use. Also make changes to the OUTDATASET name in the IDCAMS control statement that reflects which control data set is to be re-created.

```
//ARCIMPRT JOB
/* -----
/* RE-CREATE THE MCDS
/* Note the parameter in the following execute statement
/* specifying which CDS to recover.
/* Also, any valid IDCAMS command may be specified in the
/* SYSIN stream below.
/* -----
//STEP03 EXEC PGM=ARCIMPRT,PARM='MCDS'
//STEPLIB DD DSN=where ARCIMPRT resides,
//        DISP=SHR
//SYSPRINT DD SYSOUT=*
//AMSDUMP DD SYSOUT=*
//JOURNAL DD DSN=name of sorted backup journal from STEP 2,
//        DISP=SHR
//EXPORT DD DSN=name of portable exported MCDS from STEP 3,
//        DISP=SHR
//SYSIN DD *
DELETE (MCDS cluster name) CLUSTER PURGE
IMPORT INFILE(EXPORT) OUTDATASET(MCDS cluster name)
/*
```

- Restart DFSMSHsm from the processing unit from which you issued ARCIMPRT.
- Verify that the control data sets are correct. See [“Determining if control data sets are accurate”](#) on page 517.
- Fix any errors in the control data sets. See [“Repairing errors in the control data sets”](#) on page 517.
- If you are recovering the MCDS, issue a QUERY CDSVERSIONBACKUP to ensure that the latest final qualifier is correct. You can determine the final qualifier of the latest backup copy from your catalog using the LISTCAT LEVEL command, as shown in the following example:

```
LISTCAT LEVEL(uid)
```

If these qualifiers do not match, use the FIXCDS patch command to correct the field at offset X'B1' in the MHCR record to reflect the latest version in the catalog, as shown in the following example:

```
FIXCDS S MHCR PATCH(X'B1' 0000007)
```

9. Use the CONTROLDATASETS parameter of the BACKVOL command to get a current backup copy of the control data sets and journal data set.
10. Restart DFSMSHsm in the other processing units.

ARCBJRNL and ARCIMPRT return codes

Table 49 on page 512 and Table 50 on page 512 describe the return codes that are returned by the ARCBJRNL and ARCIMPRT utilities. These codes are returned in general register 15 and can be referred to in your JCL.

Table 49. ARCBJRNL Return Codes

Return code	Meaning
0	Normal return.
4	No journal ARCCR control record (MSGARC0461I).
8	Only journal ARCCR control record (MSGARC0461I).
28	Get macro I/O error.
32	Put macro I/O error.
40	Online journal OPEN error.
42	The online journal data set has a format 8 DSCB.
44	Backup journal OPEN error.
46	The journal backup input data set has a format 8 DSCB.
48	EOV or abend error.
50	I/O error occurred on journal backup input data set.
52	OBTAIN macro failed for the journal backup input data set.
54	Open error occurred on journal backup input data set.
56	RDJFCB macro failed for the journal backup input data set.
58	ABEND error occurred processing journal backup input data set.
64	JRNLO DD DUMMY record was found for the online journal data set.
68	RDJFCB macro failed.
72	OBTAIN macro failed.
80	Journal control record and data set type are inconsistent.
84	Insufficient level of DFSMSdfp product is installed.
99	Input parameter error (invalid value specified on PARM keyword).

Table 50. ARCIMPRT Return Codes

Return code	Meaning
0	Normal return.
4	IDCAMS message: minor problems but function completed.
8	IDCAMS message: function completed but some processing bypassed.
12	IDCAMS message: entire function could not be performed.
16	IDCAMS message: severe error or problem encountered.

Table 50. ARCIMPRT Return Codes (continued)

Return code	Meaning
18	Invalid backup journal used as input to ARCIMPRT (MSGARC0463I).
20	Invalid or no parameter passed to ARCIMPRT (MSGARC0462I).
22	Backup journal file open error.
23	Backup journal file has a format 8 DSCB.
24	Backup journal file I/O error.
25	Export file has a format 8 DSCB.
26	Export file open error.
27	No CDS records found in exported CDS.
28	Export file I/O error.
30	Sysprint file open error.
32	Sysprint file I/O error.
34	Did not read a header record preceding the CDS backup copy (this can occur if the IMPORT command uses the INDATASET parameter instead of INFILE).
68	RDJFCB macro failed.
72	OBTAIN macro failed.

Recovering multicluster non-key range control data sets

ARCIMPRT has been enhanced to recover multicluster non-key-range data sets. It uses the key boundaries to determine which journal records need to be applied to the cluster being recovered.

If you reorganize your control data sets, you should immediately back them up. If you do not, and you attempt to perform a CDS recovery using a CDS backup version created before the CDS was reorganized, the recovery fails with message ARC0466I. Then the following steps must be taken to restore your multicluster non-key-range CDS:

1. The cluster being recovered must be returned to the state in which it existed after the reorganization. For example, if the control data sets were split from two to three, then the job or jobs used to perform the split should be rerun. Only the cluster or clusters being recovered should be returned to the state they were in following the reorganization.
2. Reissue the ARCIMPRT job using the new FORCE parameter. The FORCE parameter causes ARCIMPRT to use the latest key boundaries in use, instead of those that existed at the time of the CDS version backup. To use the FORCE parameter on the MCDS, you would issue:

```
PARM= ' MCDS , FORCE '
```

After the recovery, message ARC0467I is issued identifying the cluster that was recovered.

Control data set recovery procedure using CDSVERSIONBACKUP with UPDATEC

For performance reasons, you should use the enhanced CDS recovery function instead of the UPDATEC command to recover your control data sets. However, if you want to use UPDATEC, use the following procedure:

1. Use the CDSVERSIONBACKUP parameter of the QUERY command to find out the initial characters and the final qualifier of the backup data set name. Save the QUERY information for use in steps [“5” on page 514](#) and [“11” on page 515](#). You will receive the following messages from the query:

ARC0375I

```
CDSVERSIONBACKUP,

MCDSBACKUPDSN=uid.MCDS.BACKUP,

BCDSBACKUPDSN=uid.BCDS.BACKUP,

OCDSBACKUPDSN=uid.OCDS.BACKUP,

JRNLBACKUPDSN=uid.JRNL.BACKUP
```

ARC0376I

```
BACKUPCOPIES=3,

BACKUPDEVICECATEGORY=DASD,

LATESTFINALQUALIFIER=V0000007,

DATAMOVER=HSM
```

Recommendation: If DFSMSHsm is not active, you should issue the following IDCAMS LISTCAT command to determine the latest version: LISTCAT LEVEL(*uid*)

Also note whether DFSMSHsm or DFSMSdss was the data mover (by looking at the prefix letter of the low-level qualifier).

2. Stop DFSMSHsm in all processing units.
3. Use the Access Method Services DELETE command to delete the control data set that has the error. The following example shows the DELETE command using one of several parameters that are available.

```
DELETE CLUSTER(uid.MCDS)
```

4. Re-create the control data set that was deleted in step “3” on page 514. When you re-create the control data set, increase the space allocation for that control data set if more space is required. For more information, refer to the *z/OS DFSMSHsm Implementation and Customization Guide*.
5. The next step depends on the data mover used to create the backup version.

- If the data mover was DFSMSdss, restore the latest backup version into the re-created data set using the following JCL example:

```
//JOB1 JOB accounting information,REGION=nnnK
//STEP1 EXEC PGM=ADRDSSU
//SYSPRINT DD SYSOUT=*
//TAPE DD DSN=uid.MCDS.BACKUP.D0000106,DISP=(OLD,KEEP)
//DASD DD UNIT=3390,VOL=SER=222222,DISP=OLD
//SYSIN DD *
        RESTORE DATASET(-
        INCLUDE(uid.dsname))-
        INDDNAME(TAPE)-
        OUTDDNAME(DASD)-
        REPLACE
/*
```

- If the data mover was DFSMSHsm, use the Access Method Services IMPORT command to recover the latest backup version of the affected control data set by using the following JCL example:

```
//IMPORT JOB , 'USERID' MSGCLASS=A,REGION=768K
//STEP1 EXEC PGM=IDCAMS
//DEST DD DSN=uid.MCDS,DISP=OLD
//SOURCE DD DSN=uid.MCDS,DISP=OLD,AMP=AMORG
//DASD DD DSN=uid.MCDS.BACKUP.V0000106,
// DISP=OLD
//SYSPRINT DD SYSOUT=*
//SYSIN DD *
IMPORT-
INFILE(DASD)-
OUTFILE(SOURCE)-
INTOEMPTY-
PURGE
/*
```

6. Restart DFSMSHsm in emergency mode, EMERG=YES, in the processing unit from which you will issue the UPDATEC command.

Recommendation: On the restart, ensure that your ARCCMDxx parmlib member is set correctly with either of the following specification:

- SETSYS EMERG is specified.
- Neither SETSYS EMERG nor SETSYS NOEMERG is specified.

If you follow either of the above recommendations, then the EMERG=YES specification will not be overridden by your ARCCMDxx member.

7. Use the UPDATEC command to combine the entries from the journal data set with the entries from the recovered control data set. (See [“Updating recovered control data sets using UPDATEC”](#) on page 516.) When you use this command, the backup version number of the journal data set is one greater than that of the backup version control data set used in step [“5”](#) on page 514. You must concatenate the journal backup data set name that you received in the ARC0375I message in step [“1”](#) on page 513 with the version number, and use that as the journal parameter of the UPDATEC command.

If you need to use multiple backup versions of the journal data set to recover a control data set, be sure you apply the backup versions in the correct order (oldest to newest).

8. Stop and restart DFSMSHsm in emergency mode, EMERG=YES, from the processing unit from which you issued the UPDATEC command.

Recommendation: On the restart, ensure that your ARCCMDxx parmlib member is set correctly with either of the following specification:

- SETSYS EMERG is specified.
- Neither SETSYS EMERG nor SETSYS NOEMERG is specified.

If you follow either of the above recommendations, then the EMERG=YES specification will not be overridden by your ARCCMDxx member.

9. Verify that the control data sets are correct. (See [“Determining if control data sets are accurate”](#) on page 517.)
10. Fix any errors in the control data sets. (See [“Repairing errors in the control data sets”](#) on page 517.)
11. If you are recovering the MCDS, issue a QUERY CDSVERSIONBACKUP to ensure that the latest final qualifier is the same as that shown in step 1. If you do not have the output from the QUERY command in step 1, you can determine the final qualifier of the latest backup copy from your catalog using the LISTCAT LEVEL command, as shown in the following example:

```
LISTCAT LEVEL(uid)
```

If these qualifiers do not match, use the FIXCDS patch command to correct the field at offset X'B1' in the MHCR record to reflect the latest version in the catalog, as shown in the following example:

```
FIXCDS S MHCR PATCH(X'B1' 0000007)
```

12. Use the CONTROLDATASETS parameter of the BACKVOL command to get a current backup copy of the control data sets and journal data set.

13. If the backup of the control data sets was successful, you can issue a SETSYS NOEMERG command, and release DFSMSHsm's automatic functions with a RELEASE ALL command.
14. Restart DFSMSHsm in the other processing units.

Updating recovered control data sets using UPDATEC

For performance reasons, you should use the enhanced CDS recovery function instead of the UPDATEC command to recover your control data sets. If you do use UPDATEC, the forms of the command are:

UPDATEC BACKUPCONTROLDATASET

UPDATEC BACKUPCONTROLDATASET JOURNAL(*dsname*)

UPDATEC MIGRATIONCONTROLDATASET

UPDATEC MIGRATIONCONTROLDATASET JOURNAL(*dsname*)

UPDATEC OFFLINECONTROLDATASET

UPDATEC OFFLINECONTROLDATASET JOURNAL(*dsname*)

UPDATEC ALL

UPDATEC ALL JOURNAL(*dsname*)

The forms with no journal specified use the current (active) journal data set to update the specified data set. The forms with a journal specified use a backed up journal data set requested by *dsname* to update the specified data set. For example, the command UPDATEC BACKUPCONTROLDATASET applies the transactions recorded in the active journal data set to the backup control data set. Thus, if the backup control data set were a copy of the last backup version of the backup control data set, the UPDATEC command would modify it to the state of the backup control data set before it was lost or damaged.

If the most-recent backup version of a control data set is also damaged, you can still recover the control data set by a three-step process:

1. Import the next-most-recent backup version of the data set.
2. Run UPDATEC with the journal that corresponds to the next-most-recent backup version. This journal is the most-recent *backed up* journal.
3. Run UPDATEC with the current journal.

Note: The UPDATEC command may be used to recover a damaged control data set. However, UPDATEC can take a long time to run. Because the process holds an exclusive enqueue and reserve on all the control data sets, no other DFSMSHsm functions (such as RECALL) can be run when UPDATEC is running. Therefore, a complex will not be able to do any DFSMSHsm work until UPDATEC finishes. In a JES3 environment, the whole complex may be unavailable until UPDATEC finishes processing.

VSAM considerations for the control data sets

The three control data sets are VSAM data sets and as such need to be periodically compressed and reorganized. To redistribute records or compress the control data sets, use the Access Method Services EXPORT and IMPORT commands. To move the control data sets to another volume or to increase their space allocations, use the Access Method Services REPRO, DELETE, and DEFINE commands.

Immediately after you reorganize your control data sets you should back them up.

Related reading

For more information about VSAM control data sets, see the topic about VSAM considerations for control data sets in [*z/OS DFSMSHsm Implementation and Customization Guide*](#).

Determining if control data sets are accurate

During recovery processing, a control data set can lose synchronization with the actual conditions in the system. DFSMSHsm provides a command allowing you to determine how closely the control data sets match the actual system conditions and to repair minor discrepancies.

The AUDIT command detects and reports discrepancies about data set information from:

- Computing system catalogs
- DFSMSHsm control data set records
- The VTOC of the DASD storage volume on which the data set resides

An example of the AUDIT command is:

```
AUDIT DATASETCONTROLS(MIGRATION) -  
      NOFIX OUTDATASET(outputname) REPORT(ERRORS)
```

In processing this command, DFSMSHsm reads each data set record in the MCDS. DFSMSHsm compares the information about each data set to the information contained in the system catalogs and in the VTOCs of any DASD volumes that the catalogs or the MCDS indicates the data set resides on. DFSMSHsm does not try (because of the NOFIX parameter) to reconcile any differences that it finds. Instead, DFSMSHsm sends a report of any errors to the data set specified by the OUTDATASET parameter.

Recommendation: The OUTDATASET contains executable FIXCDS commands to create or correct CDS records, but those CDS changes are only a subset of the corrective actions taken by AUDIT. In addition, the CDS records may be read multiple times during the course of an audit. If the NOFIX option is specified, the changes to a record generated on its initial read are not reflected in that record when it is read a subsequent time, which may result in incorrect actions being taken. For these reasons, the later submission of output from an AUDIT NOFIX as a substitute for an AUDIT FIX is generally discouraged.

The AUDIT command helps determine how closely the control data sets match the actual system conditions. There are Access Method Services commands that verify the structure of the CDS. The Access Method Services DIAGNOSE and EXAMINE commands can be used to validate the VSAM volume data set data structures and analyze the structural consistency of the index and data component of a key-sequenced data set.

Related reading

For more information about the AUDIT command, see [Chapter 30, “AUDIT command: Auditing DFSMSHsm,”](#) on page 737.

Repairing errors in the control data sets

For various reasons, the records in the control data set may occasionally need to be changed. You use the FIXCDS command to display or change control data set records. With the FIXCDS command, you can specify a specific record type, a specific data set, and a specific kind of change to make.

Related reading

For more information about the FIXCDS command, see [z/OS DFSMSHsm Diagnosis](#).

Procedures for handling a journal EOV error

DFSMSHsm issues message ARC0026E specifying EOV ERROR ON JOURNAL when the Journal data set becomes full. If this error is received, begin CDS backup processing by using the BACKVOL CDS command or the SETSYS command with the AUTOBACKUPSTART parameter. It is preferable that the backup of the control data sets be initiated on the system that encountered the error. This creates backup copies of the MCDS, BCDS, OCDS and nulls the journal data set so that all the space in it becomes available. If you are in a multiple DFSMSHsm-host environment, issue the RELEASE ALL command on each system that received the ARC0026E message after the completion of the backup of the data set.

Recovering from a journal I/O error

A journal I/O error may have two causes. The first cause is a corrupted journal record header (MLOG). To recover from this type of error, do the following:

Action	Command
1. Put DFSMSHsm in emergency mode.	SETSYS EMERGENCY
2. Issue the CONTROLDATASETS parameter of the BACKVOL command to back up the control and journal data sets.	BACKVOL CONTROLDATASETS
Note: This step may fail with another I/O error. If it does, see “Example 2: Replacing a damaged journal” on page 522 for more information on how to replace a damaged journal.	
3. Stop DFSMSHsm.	F DFSMSHSM,STOP
4. Use IEBGENER to copy some data into the journal data set to overwrite the existing control record.	
5. Start DFSMSHsm.	S DFSMSHSM

The second cause of a journal I/O error is a hardware error. If overwriting the journal record header does not correct the journal I/O error, a hardware malfunction probably caused the error.

To correct a hardware-caused journal I/O error, you may have to either 1) allocate a new journal data set on the same volume in a different location or 2) allocate a new journal data set on a different volume.

To allocate a new journal data set on the same DASD volume, do the following:

Action	Command
1. Put DFSMSHsm in emergency mode.	SETSYS EMERGENCY
2. Issue the CONTROLDATASETS parameter of the BACKVOL command to back up the control and journal data sets.	BACKVOL CONTROLDATASETS
Note: This step may fail with another I/O error. If it does, see “Example 2: Replacing a damaged journal” on page 522 for more information about how to replace a damaged journal.	
3. Stop DFSMSHsm.	F DFSMSHSM,STOP
4. Rename the old journal data set	
5. Allocate a new journal data set	
6. Delete the old journal data set	
7. Start DFSMSHsm.	S DFSMSHSM

To allocate a new journal data set on a different DASD volume, follow the instructions in the next topic [“Moving the journal” on page 518](#).

Moving the journal

To move the journal data set from one DASD device to another, do the following:

Action	Command
1. Put DFSMSHsm in emergency mode.	SETSYS EMERGENCY
2. Issue the CONTROLDATASETS parameter of the BACKVOL command to back up the control and journal data sets.	BACKVOL CONTROLDATASETS
3. Stop DFSMSHsm.	F DFSMSHSM,STOP
4. Delete the old journal data set	
5. Allocate a new journal data set on a different DASD device.	
6. Start DFSMSHsm.	S DFSMSHSM

Steps to ensure that the control data sets are accurate

After you recover the control data sets, you can do the following to ensure that they are accurate:

1. Issue the AUDIT commands to determine if any discrepancies exist between the data set records in the recovered control data sets and the data set records in the computing system catalog.
2. Issue the AUDIT commands with the FIX parameter to fix any errors that AUDIT can correct.
3. Issue the FIXCDS command to fix any minor problems encountered in the recovered control data sets.

Control data set backup and recovery examples

This topic provides some examples of recovering your control data sets and journal data set.

Recovery examples using the enhanced CDS recovery function

The following examples help you recover your control data sets or journal data sets using the enhanced CDS recovery function.

Example 1: Recovering the MCDS from DASD

This example shows how you set up your environment, how to recover the MCDS, and the messages that are issued during the backup and recovery processing.

Set up your environment with the following SETSYS command:

```
SETSYS CDSVERSIONBACKUP(BACKUPCOPIES(3) -
    BACKUPDEVICECATEGORY(DASD))
```

Issue the QUERY CDSVERSIONBACKUP command to find out what the last final qualifier was for the backup data sets. DFSMSHsm issues the following messages:

ARC0375I

CDSVERSIONBACKUP,

MCDSBACKUPDSN=*uid*.MCDS.BACKUP,

BCDSBACKUPDSN=*uid*.BCDS.BACKUP,

OCDSBACKUPDSN=*uid*.OCDS.BACKUP,

JRNBACKUPDSN=*uid*.JRNL.BACKUP

ARC0376I

BACKUPCOPIES=3,

BACKUPDEVICECATEGORY=DASD,

LATESTFINALQUALIFIER=V0000000,

DATAMOVER=HSM

Note: Since the LATESTFINALQUALIFIER begins with a V, the last data mover was DFSMSHsm.

Because no backup data sets are preallocated, you preallocate the following backup data sets:

uid.MCDS.BACKUP.V0000001 through *uid*.MCDS.BACKUP.V0000003

uid.BCDS.BACKUP.V0000001 through *uid*.BCDS.BACKUP.V0000003

uid.OCDS.BACKUP.V0000001 through *uid*.OCDS.BACKUP.V0000003

uid.JRNL.BACKUP.V0000001 through *uid*.JRNL.BACKUP.V0000003

Now you let DFSMSHsm execute to a point where DFSMSHsm has successfully backed up the control data sets and the journal data set ten times. The backup data sets have the final qualifiers of V0000008, V0000009, and V0000010.

As DFSMSHsm processes the MCDS, an I/O error occurs, so a part of the MCDS is no longer usable. To recover the MCDS, you would:

1. Issue QUERY CDSVERSIONBACKUP to find out what was the latest backup version. DFSMSHsm issues the following messages:

ARC0375I

CDSVERSIONBACKUP,

MCDSBACKUPDSN=*uid*.MCDS.BACKUP,

BCDSBACKUPDSN=*uid*.BCDS.BACKUP,

OCDSBACKUPDSN=*uid*.OCDS.BACKUP,

JRNLBKUPDSN=*uid*.JRNL.BACKUP

ARC0376I

BACKUPCOPIES=3,

BACKUPDEVICECATEGORY=DASD,

LATESTFINALQUALIFIER=V0000010,

DATAMOVER=HSM

Recommendation: If the QUERY CDSVERSIONBACKUP command is not successful or if DFSMSHsm is not active, issue the following IDCAMS LISTCAT command to determine the latest version: LISTCAT LEVEL(*uid*)

2. Issue a IDCAMS LISTCAT(*uid*) to determine if the backup copy is good. This determination is made by checking the low-level qualifier for a V or an X.

3. Stop DFSMSHsm in all processing units.
4. See [“Requirements for using the enhanced CDS recovery function”](#) on page 508 for information on using the enhanced CDS recovery function to recover the MCDS.
5. Restart DFSMSHsm in the processing unit.
6. Verify that the control data sets are correct (see [“Determining if control data sets are accurate”](#) on page 517).
7. Fix any errors in the control data sets (see [“Repairing errors in the control data sets”](#) on page 517).
8. Because you are recovering the MCDS, issue a QUERY CDSVERSIONBACKUP command to ensure that the latest final qualifier is the same as that shown in step 1. If you do not have the output from query command in step 1, you can determine the final qualifier of the latest backup copy from your catalog using the LISTCAT LEVEL command, as shown in the following example:

```
LISTCAT LEVEL(uid)
```

If these qualifiers do not match, use the FIXCDS patch command to correct the field at offset X'B1' in the MHCR record to reflect the latest version in the catalog, as shown in the following example:

```
FIXCDS S MHCR PATCH(X'B1' 0000010)
```

9. Issue the BACKVOL CDS command to ensure that all copies of the control data sets and the journal data set are current. During backup of the control data sets and the journal data set, DFSMSHsm issues the following messages:

ARC0740I

CDS BACKUP STARTING AT 04:15:35 ON 95/05/24 ON SYSTEM 381A TO DASD IN PARALLEL MODE, DATAMOVER=HSM

ARC0742I

BACKUP FOR MCDS STARTING AT 04:15:55 ON 95/05/24, BACKUP COPY TECHNIQUE IS UNDEFINED

ARC0743I

MCDS SUCCESSFULLY BACKED UP TO *uid*.MCDS.BACKUP.V0000008, ON VOLUMES VOL001,VOL002, TIME=04:20:03, DATE=95/05/24

ARC0742I

BACKUP FOR BCDS STARTING AT 04:25:55 ON 95/05/24, BACKUP COPY TECHNIQUE IS UNDEFINED

ARC0743I

BCDS SUCCESSFULLY BACKED UP TO *uid*.BCDS.BACKUP.V0000008, ON VOLUMES VOL003,VOL004, TIME=04:30:13, DATE=95/05/24

ARC0742I

BACKUP FOR OCDS STARTING AT 04:35:55 ON 95/05/24, BACKUP COPY TECHNIQUE IS UNDEFINED

ARC0743I

OCDS SUCCESSFULLY BACKED UP TO *uid*.OCDS.BACKUP.V0000008, ON VOLUME VOL005,
TIME=04:40:44, DATE=95/05/24

ARC0750I

BACKUP FOR JRNL STARTING AT 04:40:55 ON 95/05/24

ARC0743I

JRNL SUCCESSFULLY BACKED UP TO *uid*.JRNL.BACKUP.V0000008, ON VOLUME VOL006,
TIME=04:45:26, DATE=95/05/24

ARC0748I

LAST SUCCESSFUL CDS BACKUP-SET QUALIFIER IS V0000011

ARC0741I

CDS BACKUP ENDING AT 04:45:35 ON 95/05/24, STATUS=SUCCESSFUL

Note: Because you have specified three backup copies and you are backing up to DASD, DFSMSHsm replaces the V0000008 version of the backup data sets with V0000011.

If you issue the QUERY CDSVERSIONBACKUP command again, DFSMSHsm issues the following messages:

ARC0375I

CDSVERSIONBACKUP,

MCDSBACKUPDSN=*uid*.MCDS.BACKUP,

BCDSBACKUPDSN=*uid*.BCDS.BACKUP,

OCDSBACKUPDSN=*uid*.OCDS.BACKUP,

JRNLBKUPDSN=*uid*.JRNL.BACKUP

ARC0376I

BACKUPCOPIES=3,

BACKUPDEVICECATEGORY=DASD,

LATESTFINALQUALIFIER=V0000011,

DATAMOVER=HSM

10. Restart DFSMSHsm in the other processing units.

Example 2: Replacing a damaged journal

This example shows how you set up your environment, how to recover the journal, and some of the messages that are issued during the backup and recovery processing.

Set up your environment with the following SETSYS command:

```
SETSYS CDSVERSIONBACKUP(DATAMOVER(DSS) -
  BACKUPCOPIES(4) -
  MCDSBACKUPDSN(BHSM.MCDS.BACKUP) -
  BCDSBACKUPDSN(BHSM.BCDS.BACKUP) -
  OCDSBACKUPDSN(BHSM.OCDS.BACKUP) -
  JRNLBACKUPDSN(BHSM.JRNL.BACKUP) -
  BACKUPDEVICECATEGORY(DASD))
```

You preallocate the following backup data sets:

```
BHSM.MCDS.BACKUP.D0000001
BHSM.BCDS.BACKUP.D0000001
BHSM.OCDS.BACKUP.D0000001
BHSM.JRNL.BACKUP.D0000001
```

```
BHSM.MCDS.BACKUP.D0000002
BHSM.BCDS.BACKUP.D0000002
BHSM.OCDS.BACKUP.D0000002
BHSM.JRNL.BACKUP.D0000002
```

```
BHSM.MCDS.BACKUP.D0000003
BHSM.BCDS.BACKUP.D0000003
BHSM.OCDS.BACKUP.D0000003
BHSM.JRNL.BACKUP.D0000003
```

```
BHSM.MCDS.BACKUP.D0000004
BHSM.BCDS.BACKUP.D0000004
BHSM.OCDS.BACKUP.D0000004
BHSM.JRNL.BACKUP.D0000004
```

Assume DFSMSHsm has successfully backed up the control data sets and the journal data set ten times. The backup data sets have the final qualifiers of D0000007, D0000008, D0000009, and D0000010.

As DFSMSHsm processes the journal data set, an I/O error occurs. DFSMSHsm disables the journal data set and issues the following message:

```
ARC0026A JOURNALING DISABLED DUE TO I/O ERROR.
          MIGRATION, BACKUP, DUMP, AND RECYCLE HELD.
```

Issue a BACKVOL CDS command to back up the control data sets and the journal data set. DFSMSHsm successfully backs up the control data sets and issues message ARC0743I for each backup. The message indicates that DFSMSHsm made the backup to the backup data set whose final qualifier is D0000007 (oldest version).

When DFSMSHsm tries to back up the journal, another I/O error occurs. Because DFSMSHsm cannot successfully complete the journal data set backup function, it renames the journal backup data set to X0000011. Then DFSMSHsm issues the following message:

```
ARC0744E JRNL COULD NOT BE BACKED UP,
          RC=retcode, REASON=reascode
          MIGRATION, BACKUP, DUMP, AND RECYCLE HELD.
```

In addition, DFSMSHsm issues the following message to indicate the latest final backup data set qualifier (D0000011). DFSMSHsm waits for the completion of the CDS backups and then nulls (empties) the journal data set if no CDS backup failures occur.

```
ARC0748I LAST SUCCESSFUL CDS BACKUP-SET QUALIFIER IS
          D0000011
```

At this point, assume the following conditions exist:

- The latest backup versions of the control data sets are backup data sets whose final qualifier is D0000011.
- The latest good backup version for the journal data set is a backup data set whose final qualifier is D0000010.
- The current control data sets are usable.

If you want to continue processing with the journal, you must stop DFSMSHsm, delete and reallocate the journal data set to avoid getting another I/O error during processing of the data set. This process is described in “Reasons for recovering the control data sets” on page 507. A hardware problem could be causing the I/O error on the journal data set, so be sure you do not re-allocate the journal data set to where it was allocated before the I/O error occurred.

After you restart DFSMSHsm, issue BACKVOL CDS to back up the control data sets and the new, empty journal data set. DFSMSHsm backs up the control data sets and the journal data set to the backup data sets whose final qualifiers are D0000008. If DFSMSHsm successfully backs up the control data sets and the journal data set, DFSMSHsm renames the backup data sets with the final qualifier of D0000012 (or V0000012 if IDCAMS is the data mover).

Example 3: Recovering the MCDS from tape when the latest MCDS backup version is unusable

This example shows how to set up your environment, how to recover the MCDS when the most recent backup version is unusable, and the processing that occurs when recovering the MCDS.

Set up your environment with the following SETSYS command:

```
SETSYS CDSVERSIONBACKUP(DATAMOVER(DSS) -  
  BACKUPCOPIES(6) -  
  MCDSBACKUPDSN(BHSM.MCDS.BACKUP) -  
  BCDSBACKUPDSN(BHSM.BCDS.BACKUP) -  
  OCDSBACKUPDSN(BHSM.OCDS.BACKUP) -  
  JRNBACKUPDSN(BHSM.JRNL.BACKUP) -  
  BACKUPDEVICECATEGORY(TAPE))
```

Assume DFSMSHsm has successfully backed up the control data sets and the journal data set six times, and the latest final qualifier is D0000006. Therefore, backup data sets with final qualifiers of D0000001 through D0000006 exist on tape volumes.

If an error occurs so DFSMSHsm cannot access the MCDS, you:

1. Issue QUERY CDSVERSIONBACKUP and observe that the latest final qualifier is D0000006.
2. Using DFSMSdss, restore the MCDS backup version of D0000006. Assume that, when you attempt this restore, the restore fails. You must now use MCDS backup version BHSM.MCDS.BACKUP.D0000005.
3. Using DFSMSdss, restore the MCDS backup version of D0000005.
4. Using IDCAMS, export the D0000005 backup version of the MCDS that was restored in step 3. The following example shows JCL that can be used to do the export:

```
//EXPORT JOB ,MSGLEVEL=(1,1),MSGCLASS=A,REGION=1024K  
//STEP1 EXEC PGM=IDCAMS  
//SYSPRINT DD SYSOUT=*  
//OUTDD1 DD DISP=(,CATLG,DELETE),BUFNO=26,BLKSIZE=28332,  
//          SPACE=(CYL,(200,20),RLSE),  
//          UNIT=3390,VOL=SER=333333,  
//          DSN=BHSM.MCDS.BACKUP.TEMP  
//SYSIN DD *  
EXPORT BHSM.MCDS.BACKUP.D0000005 -  
  OUTFILE(OUTDD1) -  
  TEMPORARY  
/*
```

Where:

BHSM.MCDS.BACKUP.TEMP is the data set name of the exported copy being created.

BHSM.MCDS.BACKUP.D0000005 is the data set name of the control data set being exported.

BLKSIZE=28332 is the capacity of half a track on a 3390 device.

5. Stop DFSMSHsm in all processing units.
6. Create the backup journal file using the online journal and the latest backup copy of the journal. Use ARCBJRNL and PARM=' BOTH ', JRNLO DD for the online journal, and BKUPJRNL DD for the journal backup copy version D0000006 to create the backup journal file. See [“Implementing enhanced CDS recovery using JCL” on page 508](#) for an example of the JCL needed to create the backup journal file.
7. Sort this newly created backup journal file. See [“Implementing enhanced CDS recovery using JCL” on page 508](#) for an example of the JCL needed to sort the backup journal file.
8. Import and merge the exported MCDS from step 4 and the sorted backup journal file from step 7 using ARCIMPRT. Again, see [“Implementing enhanced CDS recovery using JCL” on page 508](#) for an example of the JCL needed to do the import and merge.
9. Use the PATCH parameter of the FIXCDS command to update the MHCR to version 6, the latest control data set backup version.
10. Issue the BACKVOL CDS command to obtain a new set of backup copies of the control data sets and journal data set. When DFSMSHsm successfully backs up these data sets, the latest backup copies are those data sets whose final qualifier is D0000007.

DFSMSHsm uncatalogs the D0000001 backup version. Only versions D0000002 through D0000007 remain cataloged.

Performance considerations in a multiple DFSMSHsm host environment

Review the following performance consideration if you have configured your system to use a multiple DFSMSHsm host environment:

- ARCGPA and ARCCAT resources are held when a DFSMSHsm function requires an update to or read of a control data set (CDS) record. While the resources are held, all other functions must wait for the controlling function to complete its task. In some cases, the wait is long and can delay new DFSMSHsm request or functions from starting. For example, when a CDS backup task appears to be hung, it might be waiting for a large data set recall task to complete. Furthermore, new recall requests wait for both the original recall request and the CDS backup to complete before being processed. Specifically:
 - In a record level sharing (RLS) environment, a CDS backup must wait for all DFSMSHsm functions across the HSMplex to complete.
 - In a non-RLS environment, a CDS backup must wait for all DFSMSHsm functions within the same LPAR as the DFSMSHsm host performing the CDS backup to complete.

To minimize this delay, DFSMSHsm hosts in the same HSMplex (RLS environment) or within the same LPAR (non-RLS environment) allow CDS backup to begin immediately after all pending CDS updates are complete. The host performing the CDS backup sends a notification to the other hosts using cross-system coupling facility (XCF) services. All hosts processing functions and tasks that might delay CDS backup complete pending CDS updates, suspend new CDS updates, and release all resources (such as ARCGPA and ARCCAT) necessary for CDS backup to begin. After CDS backup is complete, suspended functions and tasks resume.

- Because all DFSMSHsm activity is quiesced during quiesced journal backup, user and production jobs that require recall or recovery resources wait until the entire CDS and journal backup is complete. Therefore, the impact of journal backup on DFSMSHsm availability and performance should be considered when planning a backup schedule.

Non-intrusive journal backup can be used to reduce the impact on DFSMSHsm availability and performance when concurrent copy is available for CDS backup and the SETSYS JOURNAL(RECOVERY) setting is in effect. This method of journal backup does not hold resources during journal backup, which allows DFSMSHsm activity to continue. Resources are held only at the end of journal backup while changes to the journal that occurred during creation of the initial backup copy are appended to the

backup copy. The control data sets are then backed up using concurrent copy. For more information about the non-intrusive journal backup method, see the topic [“Using non-intrusive journal backup”](#) on page 496.

- When there are multiple HSMplexes within a z/OS sysplex, the startup procedure keyword PLEXNAME should be specified. For more information about the SETSYS PLEXNAME command, see [Chapter 65, “SETSYS command: Establishing or changing the values of DFSMSHsm control parameters,”](#) on page 1057.

MASH configuration considerations

When running in a multiple address space DFSMSHsm (MASH) configuration where XCF services are not available, the following should be considered:

- Long running functions on other DFSMSHsm hosts (including those that start before automatic CDS backup) will not release the resources required to allow CDS backup to obtain an exclusive lock. This prevents starting CDS backup.
- The enqueue prevents all data set or volume-type functions from accessing the control data sets while they are being backed up. Therefore, you should carefully consider the best time to start backup of the control data sets.

Chapter 13. Managing DFSMSHsm media

As time passes, conditions in your computer system change such that you will need to manage the DFSMSHsm-owned storage media in your system. For example:

- When the data on backup or ML2 tapes expires, you then want to consolidate the valid data scattered over many tapes.
- You may expect many data sets to be migrated and want to make room on the migration volumes for the new data sets before it is done automatically.
- You may be replacing one DASD device type with another DASD or tape device type and want to move the data sets that are on level 0, level 1, and level 2 volumes to the new device types.
- You may want to remove volumes from DFSMSHsm management or ownership.

Moving all data sets from one level 0 volume to other level 0 volumes

Device conversion of level 0 volumes is performed expeditiously by DFSMSdss. However, the following capabilities exist and are useful under some conditions.

You can use DFSMSHsm to move single data sets or all data sets from one level 0 volume to other level 0 volumes. The processing for non-SMS-managed data sets differs from that for SMS-managed data sets.

To move BDAM data sets between volumes of different track sizes, you might consider migrating and then recalling that data set using the DAOPTION.

The commands for moving SMS-managed data sets are:

```
MIGRATE DATASETNAME(dsname) CONVERT
MIGRATE DATASETNAME(dsname) CONVERT(volser2)
MIGRATE VOLUME(volser1 MIGRATE(0)) CONVERT
MIGRATE VOLUME(volser1 MIGRATE(0)) CONVERT(volser2)
```

The commands for moving all non-SMS-managed data sets from one level 0 volume to one or more other level 0 volumes are:

```
MIGRATE DATASETNAME(dsname) CONVERT
MIGRATE DATASETNAME(dsname) -
  CONVERT(volser2 unittype2)
MIGRATE VOLUME(volser1 MIGRATE(0)) CONVERT
MIGRATE VOLUME(volser1 MIGRATE(0)) -
  CONVERT(volser2 unittype2)
MIGRATE VOLUME(volser1 MIGRATE(0)) CONVERT -
  UNIT(unittype1)
MIGRATE VOLUME(volser1 MIGRATE(0)) -
  CONVERT(volser2 unittype2) UNIT(unittype1)
```

Processing SMS-managed data sets

The main difference in the processing of SMS-managed data sets is that you cannot direct the movement to a specific volume. Although you can specify a volume, SMS-processing determines the actual volume that the data set resides on after being moved. The process for moving data sets migrates the data sets

to ML1 volumes and recalls them to level 0 volumes. At the beginning of processing for MIGRATE VOLUME commands, DFSMSShsm obtains a list of the management classes active in the system. See [“DFSMSShsm retrieval of management classes and storage groups”](#) on page 154 for a discussion of the exception. DFSMSShsm does not obtain a list of management classes for MIGRATE DATASETNAME commands. As it processes each data set, DFSMSShsm checks the value specified for the data set by the COMMAND OR AUTOMIGRATE attribute in the management class. If the value of the attribute is BOTH, DFSMSShsm processes the data set.

In recalling each data set, DFSMSShsm invokes the automatic class selection (ACS) services of DFSMSdftp and passes the information described in [“Automatic recall”](#) on page 83.

If SMS is installed and active, the ACS routine may return to DFSMSShsm a storage class and, optionally, a management class. If the ACS routine returns a storage class, DFSMSShsm passes the data set name to DFSMSdftp, along with its storage class name and management class name (if present). DFSMSdftp selects a volume and places the data set on it. The volume selected is not necessarily the target volume specified by the MIGRATE command. The catalog entry is updated to reflect the current status.

To prevent SMS from selecting the source volume as the target volume for the recall, change the status attribute for the volume in the storage group. Suitable status attributes are DISABLENEW and QUIESCENEW.

If all the data sets on a volume are being processed (MIGRATE VOLUME is specified), any data set that should be expired is expired without being migrated.

Processing non-SMS-managed data sets

There are two differences in processing for non-SMS-managed data sets:

- No storage class, management class, and data class are received.
- Data sets are recalled to the volume specified.

The target unit type need not be specified if the volume has been added to DFSMSShsm by an ADDVOL command.

For non-SMS-managed data sets, DFSMSShsm migrates the data sets to an ML1 volume and then recalls them to the volume specified by *volser2*. If *volser2* is not specified, DFSMSShsm selects the level 0 volumes to recall the data sets to in the manner specified in [“Recall”](#) on page 119. If *volser2* has not been identified to DFSMSShsm, use *unitttype2* to specify the type of unit that *volser2* can be mounted on. If *volser1* has not been identified to DFSMSShsm, use the UNIT(*unitttype1*) parameter to specify the type of unit that *volser1* can be mounted on. To prevent selection of the source volume as the target volume for the recall, you must do two things:

- Specify the volume to DFSMSShsm with NOAUTORECALL in the ADDVOL command
- Remove the volume from any pools of which it is a member

With BDAM data sets, when you specify a target volume on a different device type during DASD conversion, DFSMSShsm recalls the data set you specify if the data on a track of the source volume fits on a track of the target volume. However, you are responsible for data addressability.

DFSMSShsm maintains the same number of tracks for BDAM data set space during DASD conversion to a different device type. There is no change in the number of records per track, so space is wasted when you convert a BDAM data set to a DASD with a larger track size. DFSMSShsm assumes that any user program accessing BDAM data depends on having the same relative track address.

DFSMSShsm does not compact data sets or migrate them to SDSP data sets when it does DASD conversion.

If you specify the CONVERT parameter in a direct-to-tape environment, the command fails.

Examples of moving data sets between level 0 volumes

Consider what happens if you use the MIGRATE CONVERT command in the system shown in [Figure 83](#) on page 529.

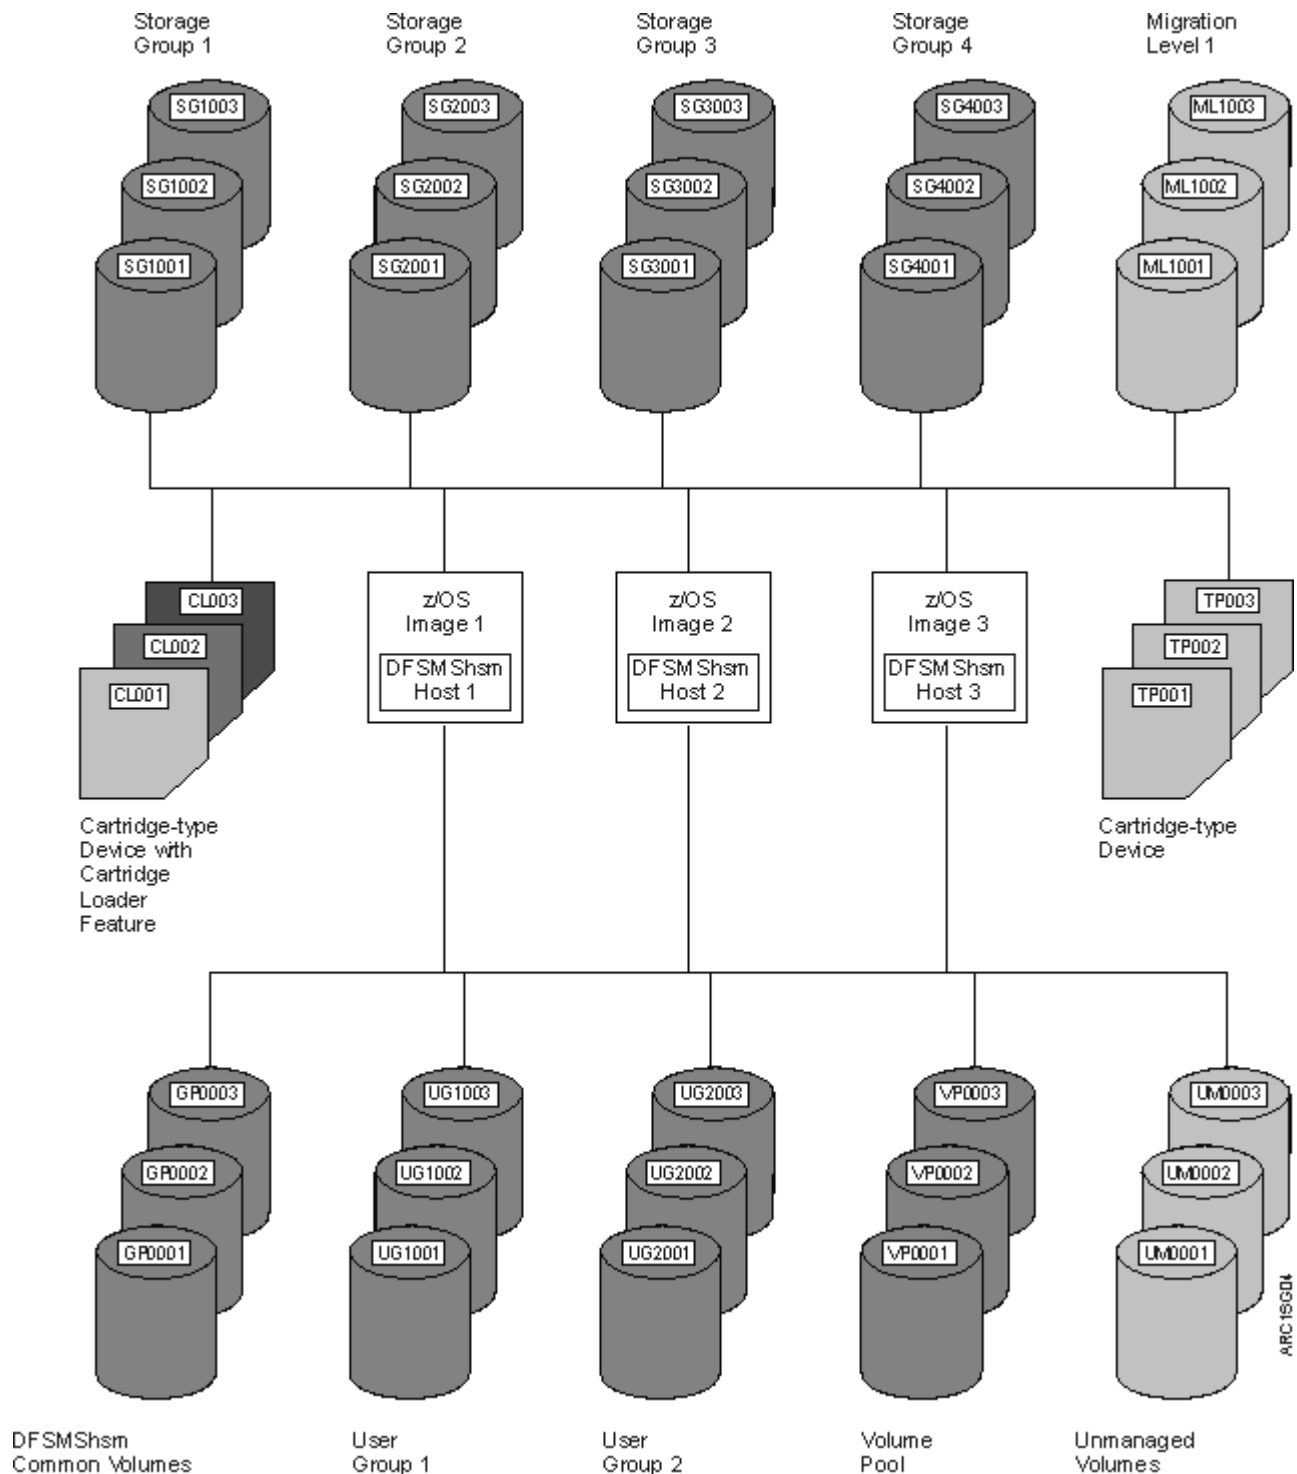

Figure 83. Example System for MIGRATE CONVERT

SMS-managed volume

Assume that you want to remove volume SG2002 from the system and replace it with a new volume. You must do three things:

- Prevent new allocations to volume SG2002
- Remove the data sets that DFSMSHsm can process from the volume
- Remove the data sets that DFSMSHsm cannot process from the volume

To prevent new allocations to the volume, you must change the status of the volume in the storage group. For example, you can establish the volume status in the storage group definition as shown in [Figure 84](#) on [page 530](#).

```
STORAGE GROUP NAME: STGGP2
VOLUME SERIAL NUMBER: SG2002
```

SYSTEM NAME		SMS VOL STATUS
-----		-----
PROCUN1	====>	DISNEW
PROCUN2	====>	DISNEW
PROCUN3	====>	DISNEW

Figure 84. SMS Volume Status

To remove the data sets that DFSMSHsm can process, you can issue the following command:

```
MIGRATE VOLUME(SG2002 MIGRATE(0)) CONVERT
```

DFSMSHsm migrates all of the data sets that it can process off of volume SG2002 and recalls them to other SMS-managed volumes. The DFSMSdfp automatic class selection routine selects the volume for data set recall.

To move any data sets that DFSMSHsm cannot process, you can use DFSMSdss.

Non-SMS-managed volume

Assume that you want to remove all data sets from volume UG2003. You still must prevent allocations to the volume, remove data sets that DFSMSHsm can process from the volume, and remove any data sets that DFSMSHsm cannot process from the volume.

Preventing users other than DFSMSHsm from allocating to the volume is a normal MVS process. You can prevent DFSMSHsm from selecting the volume for recall of data sets by removing UG2003 from the user group with the following command in all z/OS images:

```
DEFINE POOL(GROUP2 VOLUMES(UG2001 UG2002))
```

Because you have volume UG2003 dedicated to GROUP2, you have specified the NOAUTORECALL parameter of the ADDVOL command. Thus, because the volume does not belong to any pool and has the attribute of NOAUTORECALL, DFSMSHsm cannot recall any data sets to it.

To move the data sets that DFSMSHsm can process, issue the following command:

```
MIGRATE VOLUME(UG2003 MIGRATE(0)) CONVERT
```

Notice that this is the same command used for the SMS-managed volume. DFSMSHsm again migrates and recalls all of the data sets on the volume that it can process. However, because the volume is not SMS managed (because the ACS routines indicate the data sets should be non-SMS-managed), DFSMSHsm selects the volumes to which the data sets are recalled. Because, presumably, all of the data sets on volume UG2003 belong to GROUP2, DFSMSHsm recalls them to either UG2001 or UG2002.

To move any data sets that DFSMSHsm cannot process, you can use DFSMSdss.

Moving some data sets from migration level 1 volumes

Two commands, FREEVOL and MIGRATE, are available to move data from ML1 volumes. You can move data sets from individual ML1 volumes with the FREEVOL command, or you can move or delete data sets from all ML1 volumes with the MIGRATE command. If you intend to make more space available on ML1 volumes, use the MIGRATE ML1 command.

Note: The "data" and "data sets" mentioned here and in the next few topics refer to data sets that have been created by DFSMSHsm. If your installation stores non-SMS-managed user or system data on ML1 volumes (refer to *z/OS DFSMSHsm Implementation and Customization Guide* for further restrictions), this data is not affected by FREEVOL and MIGRATE commands.

Use the FREEVOL AGE(0) command to empty DASD migration or DASD backup volumes in preparation for movement to new equipment or to replace partially damaged volumes. If you are attempting to empty an ML1 volume, there can be two types of data that need to be moved off the volume: backup versions and migrated data that must remain until it is backed up. Since backup of the migrated data only occurs when automatic backup is run on the primary DFSMSHsm host, ensure that all data sets are removed from the ML1 volume by running automatic backup on your primary DFSMSHsm host shortly before issuing the FREEVOL AGE(0) command.

Using the FREEVOL command for migration level 1 volumes

The FREEVOL command allows you to move data sets from a single ML1 volume to other ML1 volumes or to ML2 volumes. This command can be useful when converting to or from the use of SDSPs when the target is level 1. Selection of the target volumes can be manipulated by using the DRAIN parameter of the ADDVOL command. You can use the following commands to move data sets that exceed a certain age:

```
FREEVOL MIGRATIONVOLUME(volser) AGE(days)
FREEVOL MIGRATIONVOLUME(volser) AGE(days) -
  TARGETLEVEL(MIGRATIONLEVEL1)
FREEVOL MIGRATIONVOLUME(volser) AGE(days) -
  TARGETLEVEL(MIGRATIONLEVEL2)
FREEVOL MIGRATIONVOLUME(volser) AGE(days) -
  TARGETLEVEL(MIGRATIONLEVEL2(DASD))
FREEVOL MIGRATIONVOLUME(volser) AGE(days) -
  TARGETLEVEL(MIGRATIONLEVEL2(TAPE))
```

If you use the data set backup functions BACKDS, HBACKDS, ARCINBAK, or ARCHBACK and run short of ML1 space, you can move BACKDS versions from all ML1 volumes to daily backup volumes by using the FREEVOL ML1BACKUPVERSIONS command.

In all forms of the command used in this topic, the value for the AGE parameter must be greater than zero. Processing of the commands is different for SMS-managed and non-SMS-managed data sets.

Processing for SMS-managed data sets

At the beginning of processing, DFSMSHsm obtains a list of the active management classes in the system. See [“DFSMSHsm retrieval of management classes and storage groups” on page 154](#) for a discussion of the exception. DFSMSHsm then calculates the inactive age of each data set and compares it to the value of the LEVEL 1 DAYS NON-USAGE attribute in the management class with which the data set is associated. If the inactive age is greater than or equal to the value of the LEVEL 1 DAYS NON-USAGE attribute, the data set migrates to an ML2 volume, unless the value of the attribute is NOLIMIT. If the attribute value is NOLIMIT, the data set does not migrate.

The TARGETLEVEL parameter does not determine the level to which SMS-managed data sets migrate. However, if the MIGRATIONLEVEL2 subparameter is specified with a device category of TAPE or DASD, the data set migrates to an ML2 volume of the category specified. If the MIGRATIONLEVEL2 subparameter does not specify a device category, the data set migrates to a level 2 volume of the category specified by the TAPEMIGRATION parameter of the SETSYS command.

Processing for non-SMS-managed data sets

For non-SMS-managed data sets, DFSMSHsm compares the time since the data set was last opened against the value specified with the AGE parameter. If the time since the data set was last opened is equal to or more than the value specified with the AGE parameter, DFSMSHsm migrates the data set to a volume of the level specified by the TARGETLEVEL parameter. If the MIGRATIONLEVEL2 subparameter

of the TARGETLEVEL parameter specifies a device category, the data set migrates to an ML2 volume of the category specified. If the MIGRATIONLEVEL2 subparameter does not specify a device category, the data set migrates to an ML2 volume of the category specified by the TAPEMIGRATION parameter of the SETSYS command.

Using the MIGRATE command for migration level 1 volumes

With the MIGRATE command you can either migrate data sets from all the ML1 volumes or delete migrated data sets from individual ML1 volumes. The commands to delete the migrated data sets do not affect SMS-managed data sets.

Migrating data sets

The commands to migrate data sets are:

```
MIGRATE MIGRATIONLEVEL1
MIGRATE MIGRATIONLEVEL1 DAYS(days)
```

For each form of the command, SMS-managed data sets and non-SMS-managed data sets are processed differently.

Processing for SMS-managed data sets

For SMS-managed data sets, DFSMSHsm obtains a list of the management classes that are active in the system, unless a volume function is processing or has just completed. See [“DFSMSHsm retrieval of management classes and storage groups”](#) on page 154 for a discussion of the exception. It then compares the time since the data set was last opened to the value of the LEVEL 1 DAYS NON-USAGE attribute in the appropriate management class for each data set. If the time since the data set was last opened is equal to or more than the value in the LEVEL 1 DAYS NON-USAGE parameter, the data set migrates to ML2. Otherwise, the data set remains on the ML1 volume. If the value of the LEVEL 1 DAYS NON-USAGE attribute is NOLIMIT, the data set remains on the ML1 volume.

Processing for non-SMS-managed data sets

For non-SMS-managed data sets, the processing depends on whether the DAYS parameter is specified on the MIGRATE command.

If the DAYS parameter is *not* specified on the MIGRATE command, DFSMSHsm checks the time since the data set was last opened against the value of the MIGRATIONLEVEL1DAYS parameter of the SETSYS command. If the data set has not been opened for a number of days more than or equal to the value specified by MIGRATIONLEVEL1DAYS, the data set migrates to ML2.

If the DAYS parameter is specified on the MIGRATE command, DFSMSHsm checks the time since the data set was last opened against the value specified with the DAYS parameter. If the data set has not been opened for a number of days more than or equal to the value specified by the DAYS parameter, the data set migrates to ML2.

Deleting non-SMS-managed data sets from migration volumes

You can use the MIGRATE command to delete obsolete non-SMS-managed data sets from migration volumes. The forms of the command to delete data sets are:

```
MIGRATE VOLUME(volser DELETEBYAGE(days))
MIGRATE VOLUME(volser DELETEIFBACKEDUP(days))
```

If you specify DELETEBYAGE, DFSMSHsm deletes any non-SMS-managed data set that has not been opened for more days than is specified by DELETEBYAGE(*days*) from the migration volume. It does not delete any data set that has not passed the expiration date indicated in the data set's VTOC entry.

If you specify `DELETEIFBACKEDUP`, DFSMSHsm deletes any non-SMS-managed data set that has a valid backup version and that has not been opened for more days than is specified by `DELETEIFBACKEDUP(days)`. DFSMSHsm also marks the latest valid backup copy as a retired version. This command deletes the data set regardless of whether the data set has passed the expiration date indicated in the data set's VTOC entry.

Moving all the data sets from a migration level 1 volume

You can move all the data sets from an ML1 volume either to other ML1 volumes or to ML2 volumes. Use the following commands to move all data sets:

```
FREEVOL MIGRATIONVOLUME(volser)
FREEVOL MIGRATIONVOLUME(volser) AGE(0)
FREEVOL MIGRATIONVOLUME(volser) -
  TARGETLEVEL(MIGRATIONLEVEL1)
FREEVOL MIGRATIONVOLUME(volser) AGE(0) -
  TARGETLEVEL(MIGRATIONLEVEL1)
FREEVOL MIGRATIONVOLUME(volser) -
  TARGETLEVEL(MIGRATIONLEVEL2)
FREEVOL MIGRATIONVOLUME(volser) AGE(0) -
  TARGETLEVEL(MIGRATIONLEVEL2)
FREEVOL MIGRATIONVOLUME(volser) -
  TARGETLEVEL(MIGRATIONLEVEL2(DASD))
FREEVOL MIGRATIONVOLUME(volser) AGE(0) -
  TARGETLEVEL(MIGRATIONLEVEL2(DASD))
FREEVOL MIGRATIONVOLUME(volser) -
  TARGETLEVEL(MIGRATIONLEVEL2(TAPE))
FREEVOL MIGRATIONVOLUME(volser) AGE(0) -
  TARGETLEVEL(MIGRATIONLEVEL2(TAPE))
```

For this operation, the AGE parameter must be omitted or must be zero. Processing is different for SMS-managed data sets and for non-SMS-managed data sets. For either type of data set, DFSMSHsm moves all the migration copies on the volume. Small data sets that move to an ML1 volume can go to SDSP data sets.

Processing for SMS-managed data sets

At the beginning of processing, DFSMSHsm obtains a list of the management classes that are active in the system, unless a volume function is processing or has just completed. See [“DFSMSHsm retrieval of management classes and storage groups”](#) on page 154 for a discussion of the exception. DFSMSHsm then compares the time since each data set was last opened to the value specified with the LEVEL 1 DAYS NON-USAGE attribute in the management class with which the data set is associated. If the time since the data set was last opened is equal to or more than the value specified with the LEVEL 1 DAYS NON-USAGE attribute, the data set migrates to an ML2 volume. If either the time since the data set was last opened is less than the value specified with the LEVEL 1 DAYS NON-USAGE attribute or the attribute value is NOLIMIT, the data set migrates to another ML1 volume.

DFSMSHsm does not use the TARGETLEVEL parameter to determine the migration level to which to migrate an SMS-managed data set. However, if the TARGETLEVEL parameter specifies MIGRATIONLEVEL2 with a device category, any SMS-managed data set that migrates to ML2 migrates to a device of the category specified by the MIGRATIONLEVEL2 subparameter. If the MIGRATIONLEVEL2 subparameter does not specify a device category, any SMS-managed data set that migrates to ML2 migrates to a device of the category specified by the TAPEMIGRATION parameter of the SETSYS command.

Processing for non-SMS-managed data sets

For non-SMS-managed data sets, DFSMSHsm migrates all data sets from the ML1 volume to either:

- ML2 volumes if TARGETLEVEL is not specified
- The level of volumes specified by the TARGETLEVEL parameter

If a device category is specified by the MIGRATIONLEVEL2 subparameter of the TARGETLEVEL parameter, DFSMSHsm migrates the data sets to the category of device specified by the MIGRATIONLEVEL2 subparameter. If the MIGRATIONLEVEL2 subparameter does not specify a device category, DFSMSHsm migrates the data sets to the category of device specified by the TAPEMIGRATION parameter of the SETSYS command.

Moving data sets from a DASD migration level 2 volume to other migration level 2 volumes

You can use DFSMSHsm to move data sets from one DASD ML2 volume to other ML2 volumes. The FREEVOL command is used to move the data sets.

Use the following commands to move data sets between ML2 volumes:

```
FREEVOL MIGRATIONVOLUME(volser)
FREEVOL MIGRATIONVOLUME(volser) -
  TARGETLEVEL(MIGRATIONLEVEL2)
FREEVOL MIGRATIONVOLUME(volser) -
  TARGETLEVEL(MIGRATIONLEVEL2(DASD))
FREEVOL MIGRATIONVOLUME(volser) -
  TARGETLEVEL(MIGRATIONLEVEL2(TAPE))
FREEVOL MIGRATIONVOLUME(volser) AGE(0)
FREEVOL MIGRATIONVOLUME(volser) -
  TARGETLEVEL(MIGRATIONLEVEL2) AGE(0)
FREEVOL MIGRATIONVOLUME(volser) -
  TARGETLEVEL(MIGRATIONLEVEL2(DASD)) AGE(0)
FREEVOL MIGRATIONVOLUME(volser) -
  TARGETLEVEL(MIGRATIONLEVEL2(TAPE)) AGE(0)
FREEVOL MIGRATIONVOLUME(volser) AGE(days)
FREEVOL MIGRATIONVOLUME(volser) -
  TARGETLEVEL(MIGRATIONLEVEL2) AGE(days)
FREEVOL MIGRATIONVOLUME(volser) -
  TARGETLEVEL(MIGRATIONLEVEL2(DASD)) AGE(days)
FREEVOL MIGRATIONVOLUME(volser) -
  TARGETLEVEL(MIGRATIONLEVEL2(TAPE)) AGE(days)
```

For the forms of the command with no AGE specified or with AGE(0) specified, DFSMSHsm migrates all SMS-managed and non-SMS-managed data sets to other ML2 volumes. For the forms of the command with an age greater than 0 specified, DFSMSHsm moves only the data sets that are equal to or exceed the specified inactive age. The category of volume is specified by the TARGETLEVEL(MIGRATIONLEVEL2) parameter. If a device category is specified with the MIGRATIONLEVEL2 subparameter, the data sets migrate to volumes of that device category. If no device category is specified with the MIGRATIONLEVEL2 subparameter, the data sets migrate to the device category specified by the TAPEMIGRATION parameter of the SETSYS command.

Removing residual dump and backup VTOC copy data sets from migration level 1 volumes

During dump or backup (volume) processing, DFSMSHsm creates a data set (the VTOC copy data set), that contains selected information from the VTOC of the volume DFSMSHsm is dumping or backing up. These data sets are created on ML1 volumes. The VTOC copy data set drives the recovery of backed up data sets. Occasionally, VTOC copy data sets that are no longer needed remain as residual data sets on ML1 volumes. This happens when the primary volume that was dumped or backed up is removed from the system, and there is no longer a need to recover that volume.

To delete the VTOC copy data sets, use the DATA SET option from the ISMF primary option menu. This option can give you a list of the data sets associated with the primary volume that has been removed from the system. The DELETE command can then be used to remove the VTOC copy data sets.

The following search argument assumes that the SETSYS BACKUPPREFIX is (DFHSM) and that the volume serial number identifies the volume of interest. A data set name search argument of

```
'DFHSM.VTOC.*.%volser.*'
```

on the data set selection entry panel lists all the backup VTOC copy data sets. To find the dump VTOC copy data sets, change the second qualifier from VTOC to DUMPVTOC. Enter DELETE (on the data set list panel) in the line operator column next to the VTOC copy data sets you want to remove.

Preventing further migration to a DASD migration volume

Although the FREEVOL and MIGRATE commands can be used to empty migration volumes, the command does not prevent further use of the volumes. To prevent a migration volume from accepting any further migration copies, issue the following command:

```
ADDVOL volser UNIT(unittype) MIGRATION(DRAIN)
```

The DRAIN parameter prevents an ML2 volume from being associated with a key range, thus preventing the volume from being used for migration output. However, if an ML2 volume that has already been associated with a key range is given the DRAIN parameter in an ADDVOL command, that volume remains eligible to be used for migration output.

If you want to prevent such a volume from being used, you must first issue a DELVOL command with the UNASSIGN parameter; then issue an ADDVOL command with the DRAIN parameter. To determine which DASD ML2 volumes are associated with key ranges, use the QUERY MIGRATIONLEVEL2 command.

Moving data sets from DASD backup volumes

You can move all backup versions of SMS and non-SMS-managed data sets that meet a specified age criterion from DFSMSHsm daily backup volumes. Backup versions are moved from a specified daily backup volume to spill DASD or tape volumes. A parameter can be specified to prevent the movement of the most recent backup version for each data set.

Backup versions can be moved from a specific backup volume to spill tape volumes by using the following command:

```
FREEVOL BACKUPVOL(volser) TARGETLEVEL(SPILL(TAPE))
```

You can selectively move backup versions from a specific backup volume to the type of volumes set up by the SETSYS SPILL parameter where the AGE parameter is greater than zero. The command to move the data set is:

```
FREEVOL BACKUPVOL(volser) AGE(days) RETAINNEWEST
```

Removing volumes from DFSMSHsm management or control

You can use the DELVOL command to remove volumes that have been made known to DFSMSHsm by the ADDVOL command, or have automatically been made known to DFSMSHsm. Volumes are automatically ADDVOLed to DFSMSHsm in several ways; for example, an assignment of a scratch tape volume from DFSMSHsm management or control, or the use of an SMS-managed primary volume.

The recycle function and the DELVOL PURGE command are the only two ways to reuse a tape volume that has been written by DFSMSHsm.

When SMS storage groups are changed, use the DELVOL command to remove, from DFSMSHsm control, volumes that were removed from the SMS storage groups before daily automatic functions started. DELVOL these volumes on all DFSMSHsm systems that know about them. Do this so that the MVT entries will not be present.

For more information, see Chapter 42, “DELVOL command: Removing a volume from DFSMSHsm management,” on page 841.

Removing dump copies and dump VTOC copy data sets from DFSMSHsm

Attention: If the dump copy you are removing is on a stacked dump tape and there are valid dump copies for other primary volumes on the tape, you cannot delete the dump tape (step 2) and you cannot delete the MCP record (step 3) without removing valid dump copies and losing data. The MCP record cannot be deleted until the dump tape expires.

Perform the following steps to discard dump copies associated with a volume that has been removed from the control of DFSMSHsm.

1. Obtain a list of the dump information associated with the DFSMSHsm-managed volume by issuing the following command. For *volser*, use the level 0 or ML1 volume that was dumped.

```
LIST VOLUME(volser) BCDS ALLDUMPS
```

2. Discard each dump copy by issuing the following command. For *volser*, use one of the dump volumes that is part of the dump copy. The PURGE, REASSIGN, UNASSIGN, and LASTCOPY parameters of the DELVOL DUMP command can be specified. You must specify COPYPOOLCOPY if the dump is part of a copy pool copy.

```
DELVOL volser DUMP
```

During DELVOL processing, when the last dump copy that requires the dump VTOC copy data set is deleted from the dump generation, the dump VTOC copy data set is deleted.

3. After you have removed all dump copies associated with a DFSMSHsm-managed volume, you can delete the MCP record. This BCDS record is deleted by issuing the following command. For *volser*, use the level 0 or ML1 volume that was dumped.

```
FIXCDS P volser DELETE
```

Note: The MCP record also contains information that is related to the backup VTOC copy data set. This data set drives the recovery of backed-up data sets. Therefore, do not delete the MCP record if you still want to recover the data that was backed up from the level 0 volume.

JES3 considerations

These considerations apply only to non-SMS-managed volumes.

A DELVOL command for a volume is accepted at any time after initialization. However, use this command only when absolutely necessary. When you must delete a DFSMSHsm primary volume that JES3 setup might have reserved for use, leave the volume online if possible. This allows jobs to run that have already been set up to use the deleted volume as one of a pool. If the required data set is actually on another primary volume or if the data set is still migrated, the job can complete successfully. The volume is not selected for subsequent automatic recall of a data set because the volume has been deleted from DFSMSHsm.

Avoid the use of the DELVOL command unless you are certain that JES3 has not and will not associate or set up any migrated data sets for recall to the primary volume to be deleted. You cannot readily use the ADDVOL command to return the volume to DFSMSHsm's control because the ADDVOL command is processed only during initialization of DFSMSHsm in a JES3 environment.

An inadvertently used DELVOL command could prevent a job from running. If a migrated data set is associated with five or fewer pool volumes and one of the volumes is deleted from DFSMSHsm's control, the recall is directed to one of the remaining four volumes.

Consolidating valid data on tape volumes

As time goes by, data on your backup and ML2 tape volumes becomes invalid. Migrated data sets expire or are marked for deletion by DELETE and HDELETE commands. Backup versions roll off or are marked for deletion by BDELETE, HBDELETE, and EXPIREBV commands. To consolidate the valid data on fewer tapes, you can use the DFSMSHsm recycle process. You must perform two actions to use the recycle process:

1. You must define the parameters of the recycle process to DFSMSHsm. You perform the definition only once.
2. You must direct DFSMSHsm to begin the recycle process. You do this each time that you want recycle to run.

Defining the parameters of the recycle process

To define the parameters of the recycle process, you must specify the following information:

- The maximum percent of data remaining valid on a full (backup or ML2) or partial (nonassociated ML2) tape volume and its connected set before the volume is recycled
- The desired number of ML2 partial tape volumes not associated with any migration or recycle output task that remain after the recycle process
- The kind of unit used for output in recycling tape volumes
- Whether the recycle process waits for a tape allocation
- How many recycle tasks can run concurrently
- Whether to duplex recycle output. For ML2 tapes, specify SETSYS DUPLEX(MIGRATION(Y | N)). For backup tapes, specify SETSYS DUPLEX(BACKUP(Y | N)).

The SETSYS command is used for defining the default parameters of the recycle process. The command that is added to the ARCCMDxx member in each DFSMSHsm host for the example system is:

```
SETSYS ML2RECYCLEPERCENT(25) RECYCLEPERCENT(25) -
RECYCLEOUTPUT(BACKUP(ACL),MIGRATION(ACL)) -
MAXRECYCLETASKS(3) ML2PARTIALSNOTASSOCIATEDGOAL(8)
```

The following discussions of the SETSYS parameters related to recycle processing use the term *connected set*. A connected set is a single tape or a group of 2 or more tapes that has the following properties:

- The first tape has no valid data set spanning to a previous tape. (A spanning data set is a data set that is contained on more than one tape, and can span from 2 to 254 tape volumes.)
- The last tape has no valid data set spanning to a successive tape.
- All tapes have either a valid data set spanning to their previous tape, to their successive tape, or to both.
- All tapes are of one function type (for instance, all migration tapes).
- All tapes can be read on the same tape drive (for instance, a 3480X 18-track drive with IDRC compaction).
- A valid data set is contained entirely in only one connected tape set.
- DFSMSHsm recycles only those that are 254 or fewer volumes long. For an ML2 partial tape to be considered, it must be the only tape in its connected set.

Input tape drives that are allocated for connected sets remain allocated until all input tapes have been processed.

ML2RECYCLEPERCENT and **RECYCLEPERCENT** control the maximum amount of data that is *valid* on ML2 volumes and backup volumes, respectively, when DFSMSHsm automatically selects the volume for processing during recycling. In the example system, when DFSMSHsm detects that it has invalidated enough data to bring the amount of valid data on a volume and its connected set to 25% or less, it writes an informational message in the command activity log. When the RECYCLE command is issued for the appropriate category of volume, DFSMSHsm automatically selects each connected set of that category that has 25% or less valid data and recycles the complete connected set.

Note: For reel tapes, the percentage is valid blocks divided by total blocks written to this tape. For cartridge tapes, the percentage is valid blocks divided by estimated reuse capacity. This reuse capacity is estimated as the average total blocks written for each cartridge type.

The percentages for tapes can be displayed using either RECYCLE DISPLAY or LIST TTOC commands. (If you use the RECYCLE DISPLAY command, volumes which have 0 percent valid will not be listed. When such a volume is recycled, it will not be mounted, thus the volume does not have to be retrieved to be recycled.)

ML2PARTIALSNOTASSOCIATEDGOAL controls the desired number of partial ML2 tape volumes that are available. The recycle process considers all the ML2 partial tape volumes in the HSMplex that are not associated as output for any migration or recycle task and are not connected to a predecessor tape. If the number of those volumes is greater than eight, the excess volumes over eight are recycled. The tapes with the least amount of valid data (and that meet the other recycling criteria specified for the installation) are selected for recycling.

RECYCLEOUTPUT restricts the category of output device used by DFSMSHsm for writing the tape volume that consolidates the data from the tape volumes being recycled. Because you want the output tapes mounted on the 3490 devices with the automatic cartridge loader feature, you use the esoteric name that was specified with the USERUNITTABLE parameter of the SETSYS command.

MAXRECYCLETASKS specifies the maximum number of tape processing subtasks that DFSMSHsm will run. The default value is 2, and this value can be dynamically changed even while RECYCLE is running by using the SETSYS MAXRECYCLETASKS(*nn*) command (the minimum number of tasks is 1, the maximum number is 15). In the example system, MAXRECYCLETASKS is set to 3 subtasks (6 tape drives involved).

Note:

1. Each subtask requires two tape drives. If duplexing, each task requires three tape drives. One drive for the input tape, one for the original tape, and one for the alternate tape.

- Each subtask, when dealing with single-file-format tape cartridges, keeps the input tape drive allocated for as long as possible (certain error conditions will cause the drive to be deallocated).

RECYCLETAPEALLOCATION specifies whether DFSMSHsm is to wait for tape allocation to complete or is to proceed to process other requests. You have already specified NOWAIT in the initial overall SETSYS command.

Related reading

For more information about how to periodically deallocate an input unit during recycle processing and the effect of the SETSYS parameter RECYCLEINPUTDEALLOCFREQUENCY, see [“RECYCLEINPUTDEALLOCFREQUENCY: Allowing periodic deallocation of input unit during recycle processing” on page 1174.](#)

Initiating recycle processing

You can direct DFSMSHsm to recycle a single connected set or to recycle entire categories of volumes. Some commands that recycle tape volumes are:

```
RECYCLE ALL EXECUTE
RECYCLE ALL EXECUTE LIMIT(nnnn)
RECYCLE ALL EXECUTE PERCENTVALID(pct)
RECYCLE ALL EXECUTE SELECT(INCLUDE(RANGE(include_range_list))
    - EXCLUDE(RANGE(exclude_range_list)))
RECYCLE ML2 EXECUTE
RECYCLE ML2 EXECUTE PERCENTVALID(pct)
RECYCLE ML2 VERIFY TAPELIST(FULLDSNAME(tapelist_dsn))
RECYCLE DAILY EXECUTE
RECYCLE DAILY EXECUTE PERCENTVALID(pct)
RECYCLE DAILY EXECUTE PERCENTVALID(pct) CHECKFIRST(N)
RECYCLE DAILY(day) EXECUTE
RECYCLE DAILY(day) EXECUTE PERCENTVALID(pct)
RECYCLE BACKUP EXECUTE
RECYCLE BACKUP DISPLAY TAPELIST (PREFIX(tapelist_prefix))
RECYCLE SPILL EXECUTE
RECYCLE SPILL EXECUTE PERCENTVALID(pct)
RECYCLE VOLUME(volser) EXECUTE
RECYCLE ALL OUTDATASET(dsname) EXECUTE
```

The BACKUP parameter allows both daily and spill backup tapes to be selected for input.

The EXECUTE parameter causes DFSMSHsm to perform the recycle function of moving valid data sets onto other tape volumes.

The LIMIT parameter quiescs the recycle process after the specified number of tapes are returned to scratch. DFSMSHsm calculates the total number of tapes returned by subtracting the number of output tapes used from the number of input tapes freed.

The SELECT parameter adds increased granularity to the RECYCLE eligibility tests. The *include_range_list* and *exclude_range_list* values help determine which tape volumes are candidates to be recycled. These values may be useful whenever you are addressing tape media conversion issues.

When a large number of tapes need to be manually pulled from shelves, the optional `TAPELIST` parameter produces a list of those tapes. The list is composed of pull groups, which are subsets of tapes, with each group in volume-serial sequence. The pull groups are listed in the sequence in which recycle processing will most likely request them. This projected sequence may differ from the actual processing sequence due to other factors affecting recycle processing, including, but not limited to: running more than one recycle task, unrecoverable errors, a mixture of device types or connected sets containing more than five volumes.

An alternative `VERIFY` parameter specifies the same lists as `EXECUTE TAPELIST`, but does not move any data sets. An alternative `DISPLAY` parameter specifies a single list in volume-serial sequence, but does not move any data sets.

The `OUTDATASET` parameter allows you to send `RECYCLE` messages and, if specified, the `DISPLAY` output to an output DASD data set rather than to `SYSOUT`.

The `PREFIX` and `FULLDSNAME` parameters allow you to send the tape list output to a DASD data set, rather than to `SYSOUT`.

For the `RECYCLE VOLUME` form of the command, `DFSMSHsm` does not check the volume to see whether the amount of valid data is equal to or less than the percent of valid data or any other selection criteria specified in either the `RECYCLE` command or the `SETSYS` command; `DFSMSHsm` recycles the volume's connected set, no matter how much of the data on the volume is invalid.

For the forms of the command using recycle categories of volumes (or all `DFSMSHsm`-owned tape volumes), `DFSMSHsm` automatically checks each connected set to determine whether it is eligible to be recycled. A volume is eligible for recycling only if the following conditions are met:

- The tape volume is an ML2 tape or a backup tape, but not an unassigned backup tape.
- A backup tape volume is marked full, or an ML2 volume is either marked full or is a partial tape not associated with any migration or recycle task and not connected to a predecessor tape.
- The percentage of valid data on the volume's connected set is equal to or less than the applicable value. This percentage is specified with the `PERCENTVALID` parameter, the `SETSYS ML2RECYCLEPERCENT` parameter, or the `SETSYS RECYCLEPERCENT` parameter. When these parameters are not specified, the `DFSMSHsm` default is 20%.
- The `SELECT` criteria, if specified, must be met. That is, all tapes of a connected set must be within the `INCLUDE RANGE` and none in the `EXCLUDE RANGE`.
- The volume has not previously failed recycle processing, or if it has failed, now contains no valid data.
- The `TTOC` for the volume is complete.
- The volume does not have a disaster alternate volume that has been flagged as a disaster alternate volume.

Each volume in an eligible connected set containing data is mounted, and all valid data is transferred to other tape volumes. When the first volume has had all of its valid data transferred, the next volume processed from that category has all of its valid data transferred to the same target volume until the target volume becomes full.

`DFSMSHsm` recycles ML2 volumes to ML2 volumes. It recycles both daily backup volumes and spill backup volumes to spill backup volumes.

`DFSMSHsm` selects and maintains different target tape volumes for recycle, data set migration, volume backup, and volume migration processing. This allows you to run migration, backup, and recycle at the same time.

If you specify `PERCENTVALID(0)`, `DFSMSHsm` selects only those tapes that are already empty but have not yet been returned to scratch. You may want to use `PERCENTVALID(0)` at those times when tape operators are not available.

Note: Tape drives will not be allocated if you specify `PERCENTVALID(0)`.

PERCENTVALID calculation

The PERCENTVALID calculation determines the valid data that exists within an entire connected set; it doesn't determine valid data for an individual volume within that set (unless the connected set consists of a single volume).

In determining whether to recycle a connected set, DFSMSHsm by default requires the first tape within the connected set to meet the current PERCENTVALID specification before continuing with the calculation. To allow connected sets to be recycled sooner, and possibly free up more volumes to scratch or tape pools, you can bypass this first volume check by entering the RECYCLE command with the CHECKFIRST parameter specified as N (no). When you specify CHECKFIRST(N), DFSMSHsm calculates the percent valid of the entire connected set, regardless of how much valid data is on the first volume of the connect set.

Note that CHECKFIRST(N) causes recycle processing to always determine the average percentage valid for a connected set, which can slow recycle performance if your installation has many large connected sets. Also, if you enter the RECYCLE command with the VOLSER parameter, the system ignores the CHECKFIRST parameter.

Examples

Volser	% Valid	Predecessor	Successor
-----	-----	-----	-----
TAPEA	35	-NONE-	TAPEB
TAPEB	5	TAPEA	-NONE-

If RECYCLE ALL PERCENT(30) EX is issued, the TAPEA–TAPEB connected set will not be selected, since the first tape in the set does not meet the PERCENTVALID criterion and CHECKFIRST(N) was not specified.

Volser	% Valid	Predecessor	Successor
-----	-----	-----	-----
TAPEC	25	-NONE-	TAPED
TAPED	75	TAPEC	-NONE-

If RECYCLE ALL PERCENT(30) EX is issued, the TAPEC–TAPED connected set will not be selected. Even though the first tape in the set meets the PERCENTVALID criterion, the entire connected set does not meet the criterion.

Volser	% Valid	Predecessor	Successor
-----	-----	-----	-----
TAPEE	5	-NONE-	TAPEF
TAPEF	45	TAPEE	-NONE-

If RECYCLE ALL PERCENT(30) EX is issued, the TAPEE–TAPEF connected set will be selected: the first tape volume in the set meets the PERCENTVALID criterion, and the entire connected set meets the criterion.

Volser	% Valid	Predecessor	Successor
-----	-----	-----	-----
TAPEG	55	-NONE-	TAPEH
TAPEH	1	TAPEG	-NONE-

If RECYCLE ALL PERCENT(30) EX CHECKFIRST(N) is issued, the TAPEG–TAPEH connected set will be selected. Although the first tape, TAPEG, does not meet the PERCENTVALID criterion, CHECKFIRST(N) was specified, and the entire connected set meets the PERCENTVALID criterion.

Selecting tape volumes during recycling

When you recycle tape volumes, DFSMSHsm selects the target tape volume to receive the valid data sets. No other task can be using this tape volume. (See [Table 13 on page 138](#) for volume contention information.)

Making cartridge-type, single-file-format tapes from reel-type or multiple-file-format tapes

Many of DFSMSHsm's advanced tape operations can be performed only on cartridge-type, single-file-format tape volumes. If you have reel-type or cartridge-type, multiple-file-format, DFSMSHsm-owned volumes in your system, you can transfer the data to cartridge-type, single-file format tapes by using the recycle function. Ensure that your RECYCLEOUTPUT parameter specifies a unit type that uses the magnetic tape cartridge. Then you can issue RECYCLE commands either to recycle individual volumes or to recycle categories of volumes. If you recycle categories of volumes, you will want to use the PERCENTVALID parameter to specify a high percentage so that all of the volumes in the category are recycled.

Limiting data that is written to a cartridge-type device

When you want to direct data to a cartridge-type tape volume within a single-file-format tape environment, you can specify the percent full from 1 to 9999 on the SETSYS TAPEUTILIZATION(UNITTYPE(unit) PERCENTFULL(pct)) command. When the percent full is reached, DFSMSHsm forces end-of-volume function on that volume. This command limits the amount of data that is written on a cartridge-type tape volume, which ensures that the tape can be copied with the TAPECOPY command. This also ensures that the original and the alternate tapes are identical when they are duplexed.

If your installation is backing up or migrating many small data sets, you might not be making full use of newer high capacity tape volumes. Here, it is recommended that your installation use extended tape table of contents (TTOCs). Doing so allows DFSMSHsm to write as many as 1,060,000 data sets on a single migration tape or backup tape, if the data sets will fit. In previous releases of z/OS, this number was limited to 330,000 data sets.

To use extended TTOCs, you must:

- Define the offline control data set (OCDS) with a maximum record size of 6144 bytes
- Specify the use of extended TTOCs by entering the SETSYS command with the EXTENDEDTTTOC(Y) parameter specified.

For information about defining the OCDS, see [z/OS DFSMSHsm Implementation and Customization Guide](#).

Note:

1. When you specify SETSYS DUPLEX for either backup or migration, or both, and you specify the NOLIMIT parameter for your tapes, PERCENTFULL is automatically set to 97%. If you designate a specific percentage, such as 100, DFSMSHsm uses the percentage that you specify.
2. Other effects of specifying the NOLIMIT parameter with the TAPEUTILIZATION command are that only one buffer is used for recycle processing rather than three, and no action is taken to reduce data set tape volume spanning.
3. You can use the following table to determine the PERCENTFULL value on the SETSYS TAPEUTILIZATION(UNITTYPE(unit)PERCENTFULL(pct)) command.

Table 51. Cartridge Percentages, by Output Device and Length			
Output Device	IBM Standard Length Cartridge Percentages	IBM Enhanced Length Cartridge Percentages	Other Cartridge Length Percentages
3490E native attached drive	1–100	1–100	1–9999, when compared to the IBM 3490E cartridge
3590B native attached drive	1–100	1–100	1–9999, when compared to the IBM 3590 cartridge
3590B emulating 3490E	1–100	1–100	1–9999, when compared to the IBM 3590 cartridge

Table 51. Cartridge Percentages, by Output Device and Length (continued)			
Output Device	IBM Standard Length Cartridge Percentages	IBM Enhanced Length Cartridge Percentages	Other Cartridge Length Percentages
3590E emulating 3490E or 3590B	1–100	1–100	1–9999, when compared to the IBM 3590 cartridge
3590 Model H emulating a 3590 Model B or 3490E	1–100	1–100	1–9999, when compared to the IBM 3590 cartridge
3592 Model J emulating 3490E or 3590B	1–100	N/A	N/A
3592 Model E-05 emulating 3590B	1–100	N/A	N/A
3592 Model E-06 emulating 3590B	1–100	N/A	N/A

Note: If your environment consists of different technology 3590 tape devices configured as stand-alone (non-SMS tape), you must associate an esoteric name with each type of device. You also must request that DFSMSHsm use the esoteric names rather than the generic names. This also applies to a mixed 3490 environment.

4. If backup or migration is using a system-managed tape library, specify the LIBRARYBACKUP or LIBRARYMIGRATION parameters with the SETSYS TAPEUTILIZATION command.
5. Virtual tape systems should generally use a PERCENTFULL value of 97%, unless a bigger value is needed to account for virtual tapes larger than the nominal 400 MB standard capacity MEDIA1 or 800 MB enhanced capacity MEDIA2 tapes. In the case of the newer virtual tape systems (TS7700 Release 1.4 and above), where DFSMSHsm derives media capacity by checking the mounted virtual tape, DFSMSHsm allows a PERCENTFULL value up to 110%. Anything larger is reduced to 100%. For older virtual tape systems, where DFSMSHsm cannot dynamically determine virtual tape capacity, PERCENTFULL values larger than 110% are honored. For example, to use virtual tapes for backup and migration volumes, you could enter the following commands:

```
SETSYS TAPEUTILIZATION(LIBRARYBACKUP PERCENTFUL(97))
SETSYS TAPEUTILIZATION(LIBRARYMIGRATION PERCENTFUL(97))
```

Specifying capacity utilization

On a CAPACITYMODE-switchable 3590 or 3592 device that is emulating a 3490 device, you have an option when you specify tape capacity. You can specify either to fill tapes to their full capacity or to stop at a point compatible with non-CAPACITYMODE-switchable devices. You specify whether to fill tapes to their full capacity using the SETSYS TAPEUTILIZATION (UNITTYPE(unittype)...CAPACITYMODE(COMPATIBILITY|EXTENDED)) command.

Note: CDS backup, ABARS output, and DUMP tapes do not support this function because they do not have the same block limitation as the supported functions.

DFSMSHsm writes to 97% of the capacity of MEDIA5, MEDIA6, MEDIA7, MEDIA8, MEDIA9, MEDIA10, MEDIA11, MEDIA12, and MEDIA13 tapes unless you specify otherwise through the SETSYS

TAPEUTILIZATION command. DFSMSHsm uses the reported cartridge type on the physical device to determine the tape capacity.

Considerations for using the 3592 Model J tape drive

Here are some tips you might find helpful when using the 3592 Model J tape drive.

- If your installation has an excessive number of spanning data sets, consider specifying a larger value in the SETSYS TAPESPANSIZE command. A larger absolute value is needed to represent the same amount of unused capacity on a percentage basis when the tape has a larger total capacity. For example, if you allow 2% of unused tape to avoid tape spanning for a 3590-Hxx device using enhanced media, you specify a TAPESPANSIZE of 1200 MB. To allow 2% unused tape for a MEDIA5 tape on a 3592 Model J device (no performance scaling), you specify a TAPESPANSIZE of 6000 MB. All size calculations for scaled tapes are based upon the scaled size and not the unscaled size.
- If the speed of data access on MEDIA5 tape is more important than full use of capacity, consider using performance scaling. Performance scaling allows 60 GB of physical (and more logical) data on each tape and keeps all data sets closer together and closer to the initial tape load point. If you use performance scaling with the DFSMSHsm duplex function, ensure that the original tape and the alternate tape both use performance scaling. Similarly make sure that Tapecopy input tapes and output tapes have the same performance scaling attributes.

Note: Performance scaling is not available on MEDIA6, MEDIA7, or MEDIA8 tape cartridge media.

- If your installation is using MEDIA5 tapes with performance scaling, consider using MEDIA7 tapes for high performance functions. The available MEDIA5 tapes could then be used to their full capacity. DFSMSHsm recycle processing of 3592 tapes can take significantly longer than the recycle of smaller tapes because the amount of data moved at the same RECYCLEPERCENT can be much larger. Besides moving more data, the likelihood of a tape takeaway for recall processing increases with the number of data sets still remaining on the tape.

One option for controlling overall recycle run time is the LIMIT(nnnn) parameter of recycle. Recycle returns no more than the specified number of tapes to scratch during the current recycle run. Because recycle sorts the tapes based on the amount of valid data still on each volume, the tapes recycled require the least processing time.

Another option to consider is decreasing the ML2RECYCLEPERCENT parameter, the RECYCLEPERCENT parameter, or both. For example, if your installation uses performance scaling (60 GB) for ML2, and you would like to move no more than 6 GB of data when an ML2 tape is recycled, set ML2RECYCLEPERCENT(10). If your installation uses full capacity (300 GB) for backup tapes and you would like to move no more than 6 GB of data when a backup tape is recycled, set RECYCLEPERCENT(2). These examples assume that the ML2 and Backup tapes in the installation are filled to capacity because the calculations are based upon the average fullness of marked full tapes on your system (the reuse capacity.)

To determine how much data your current recycle threshold implies, use the reuse capacity associated with the tapes. The current recycle threshold percent multiplied by the reuse capacity gives the maximum amount of data on any of the tapes when they are recycled.

While lowering the recycle threshold reduces recycle processing time and decreases the number of times each tape must be recycled, it may also increase the overall number of tapes needed in your installation. Also, if you have a mix of ML2 or Backup tape capacities in need of recycle processing, you may want to recycle tapes with the RANGE parameter and use the appropriate recycle threshold for the tape capacities in the range.

In an SMS tape environment, and optionally in a non-SMS tape environment, the SMS data class construct can be used to select WORM tapes for ABACKUP processing. The output data set prefix

specified in the aggregate group definition can be used by the ACS routines to select a WORM data class. Set up the ACS routine and the output data set name to uniquely identify the ABARS output files that must go to WORM tape.

In a non-SMS tape environment, the default is to allow tape pooling to determine if ABARS data sets go to WORM or R/W media. Optionally, if the DEVSUP parameter ENFORCE_DC_MEDIA=ALLMEDIATY or ENFORCE_DC_MEDIA=MEDIA5PLUS is used, then the data class must request the appropriate media type for it to be successfully mounted.

- If your installation is running z/OS in a Sysplex environment, consider using the Common Recall Queue to optimize mounts of migration tapes.
- AUDIT MEDIACONTROLS for a FAILEDCREATE situation typically only needs to look at the last few files on a tape. If it is available for your system level, make sure Audit APAR OA04419 is applied.
- To fully use MEDIA5 tapes, unless you have a specific need to run in 22-bit FBID mode, operate 3592 Model J tape drives emulating device type 3490 in 32-bit FBID mode. MEDIA6, MEDIA7, and MEDIA8 tapes cannot be used on a 3592 Model J emulating device type 3490. The 3592 Model J tape drive always operates in 32-bit FBID mode when it is emulating device type 3590.
- If you decide to change the performance scaling attribute for a particular function and partially full MEDIA5 tapes already exist, mark full the partial MEDIA5 tapes for that function. This is necessary because OPEN processing carries over the performance scaling attribute from partial tapes to the next mounted empty tape as long as the tape is mounted under the same allocation. When the function runs the next time, it will need to mount an empty tape and the performance scaling change can take effect.

Considerations for using the 3592 Model E05 tape drive

Here are some tips you might find helpful when using DFSMSHsm with the 3592 Model E05 tape drive.

- In a non-SMS mixed tape hardware environment, where multiple types of tape hardware are used to emulate 3590 devices, it is recommended that you define unique esoterics for each type of tape hardware. This action is necessary to avoid mixing incompatible recording technologies. You can define an esoteric to DFSMSHsm through the SETSYS USERUNITTABLE command, for example:

```
SETSYS UUT(3592E05:3592E05 3590H:3590H)
```

With esoterics defined, you can then direct output to the desired set of drives through the SETSYS command, for example:

```
SETSYS BACKUP(TAPE(3592E05))
```

- If your installation has an excessive number of spanning data sets, consider specifying a larger value in the SETSYS TAPESPANSIZE command. A larger absolute value is needed to represent the same amount of unused capacity on a percentage basis when the tape has a larger total capacity. For example, if you allow 2% of unused tape to avoid tape spanning for a 3590-Hxx device using enhanced media, specify a TAPESPANSIZE of 1200 MB. To allow 2% unused tape for a MEDIA5 tape on a 3592 Model E05 tape drive (no performance scaling), specify a TAPESPANSIZE of 9999 MB. All size calculations for scaled tapes are based upon the scaled size and not the unscaled size.
- If the speed of data access on a MEDIA5 or MEDIA9 tape is more important than full use of capacity, consider using performance scaling. Performance scaling uses 20% of the physical capacity on each tape and keeps all data sets closer together and closer to the initial tape load point. If you use performance scaling with the DFSMSHsm duplex function, be sure the original tape and the alternate tape both use performance scaling. Similarly make sure that TAPECOPY input tapes and output tapes have the same performance scaling attributes.

Note: Performance scaling is not available on the following tape cartridge media: MEDIA6, MEDIA7, MEDIA8, or MEDIA10.

- If your installation is using MEDIA5 tapes with performance scaling, consider using MEDIA7 tapes for high performance functions. The available MEDIA5 tapes could then be used to their full capacity.

Consider performance segmentation as a compromise solution. Performance segmentation increases the performance of data sets in the first twenty percent of the tape's capacity, but also uses the remaining capacity as a slower access segment. Average performance for the tape is increased at the expense of losing a percentage of the MEDIA5 or MEDIA9 overall tape capacity. (You cannot determine which data sets reside in which segment.)

DFSMSHsm recycle processing of 3592 Model E05 tapes can take significantly longer than with smaller tapes because the amount of data moved at the same RECYCLEPERCENT can be much larger. Besides moving more data, the likelihood of a tape takeaway for recall processing increases with the number of data sets still remaining on the tape.

One option for controlling overall recycle run time is the LIMIT(*nnnn*) parameter of recycle. Recycle returns no more than the specified number of tapes to scratch during the current recycle run. Because recycle sorts the tapes based on the amount of valid data still on each volume, the tapes recycled require the least processing time.

Another option to consider is decreasing the ML2RECYCLEPERCENT parameter, the RECYCLEPERCENT parameter, or both. Assume, for example, that your installation uses MEDIA7 tape for ML2 and MEDIA5 tape for backup. If the EFMT1 format is used and you would like no more than 6 GB of data to be moved when an ML2 tape is recycled, set ML2RECYCLEPERCENT(10) because a MEDIA7 tape can hold 60 GB of data in EFMT1. If your installation uses full capacity for backup tapes and you want no more than 6 GB of data to be moved when a backup tape is recycled, set RECYCLEPERCENT(2) because a MEDIA5 tape can hold 300 GB of data in EFMT1. These examples assume that the ML2 and backup tapes in the installation are filled to capacity because the calculations are based upon the average fullness of marked full tapes on your system (the reuse capacity.)

To determine how much data your current recycle threshold implies, use the reuse capacity associated with the tapes. The current recycle threshold percent multiplied by the reuse capacity gives the maximum amount of data on any of the tapes when they are recycled.

While lowering the recycle threshold reduces recycle processing time and decreases the number of times each tape must be recycled, it may also increase the overall number of tapes needed in your installation. Also, if you have a mix of ML2 or backup tape capacities in need of recycle processing, you may want to recycle tapes with the RANGE parameter and use the appropriate recycle threshold for the tape capacities in the range.

In an SMS tape environment, and optionally in a non-SMS tape environment, the SMS data class construct can be used to select WORM tapes for ABACKUP processing. The output data set prefix specified in the aggregate group definition can be used by the ACS routines to select a WORM data class. Set up the ACS routine and the output data set name to uniquely identify the ABARS output files that must go to WORM tape.

In a non-SMS tape environment, the default is to allow tape pooling to determine if ABARS data sets go to WORM or R/W media. Optionally, if the DEVSUP parameter ENFORCE_DC_MEDIA=ALLMEDIATY or ENFORCE_DC_MEDIA=MEDIA5PLUS is used, the data class must request the appropriate media type for it to be successfully mounted.

- Consider using the Fast Subsequent Migration function to reduce the need to RECYCLE these high-capacity tapes.
- For a Sysplex environment, consider using the Common Recall Queue to optimize mounts of migration tapes.
- AUDIT MEDIACONTROLS for a FAILEDCREATE situation typically only needs to look at the last few files on a tape. If it is available for your system level, ensure that Audit APAR OA04419 is applied.
- The 3592 Model E05 tape drive is used in 3590 emulation mode only; never 3490.

Considerations for using the 3592 Model E06 tape drive

Here are some tips you might find helpful when using DFSMSHsm with the 3592 Model E06 tape drive.

- In a non-SMS mixed tape hardware environment, where multiple types of tape hardware are used to emulate 3590 devices, it is recommended that you define unique esoterics for each type of tape

hardware. This action is necessary to avoid mixing incompatible recording technologies. You can define an esoteric to DFSMSHsm through the SETSYS USERUNITTABLE command, for example:

```
SETSYS UUT(3592E06:3592E06 3590H:3590H)
```

With esoterics defined, you can then direct output to the desired set of drives through the SETSYS command, for example:

```
SETSYS BACKUP(TAPE(3592E06))
```

- If your installation has an excessive number of spanning data sets, consider specifying a larger value in the SETSYS TAPESPANSIZE command. A larger absolute value is needed to represent the same amount of unused capacity on a percentage basis when the tape has a larger total capacity. For example, if you allow 2% of unused tape to avoid tape spanning for a 3590-Hxx device using enhanced media, specify a TAPESPANSIZE of 1200 MB. To allow 2% unused tape for a MEDIA5 tape on a 3592 Model E06 tape drive (no performance scaling), specify a TAPESPANSIZE of 9999 MB. All size calculations for scaled tapes are based upon the scaled size and not the unscaled size.
- If the speed of data access on a MEDIA5 or MEDIA9 tape is more important than full use of capacity, consider using performance scaling. Performance scaling uses 20% of the physical capacity on each tape and keeps all data sets closer together and closer to the initial tape load point. If you use performance scaling with the DFSMSHsm duplex function, be sure the original tape and the alternate tape both use performance scaling. Similarly make sure that TAPECOPY input tapes and output tapes have the same performance scaling attributes.

Note: Performance scaling is not available on the following tape cartridge media: MEDIA6, MEDIA7, MEDIA8, or MEDIA10.

- If your installation is using MEDIA5 tapes with performance scaling, consider using MEDIA7 tapes for high performance functions. The available MEDIA5 tapes could then be used to their full capacity.

Consider performance segmentation as a compromise solution. Performance segmentation increases the performance of data sets in the first twenty percent of the tape's capacity, but also uses the remaining capacity as a slower access segment. Average performance for the tape is increased at the expense of losing a percentage of the MEDIA5 or MEDIA9 overall tape capacity. (You cannot determine which data sets reside in which segment.)

One option for controlling overall recycle run time is the LIMIT(*nnnn*) parameter of recycle. Recycle returns no more than the specified number of tapes to scratch during the current recycle run. Because recycle sorts the tapes based on the amount of valid data still on each volume, the tapes recycled require the least processing time.

Another option to consider is decreasing the ML2RECYCLEPERCENT parameter, the RECYCLEPERCENT parameter, or both. Assume, for example, that your installation uses MEDIA7 tape for ML2 and MEDIA5 tape for backup. If the EFMT1 format is used and you would like no more than 6 GB of data to be moved when an ML2 tape is recycled, set ML2RECYCLEPERCENT(10) because a MEDIA7 tape can hold 60 GB of data in EFMT1. If your installation uses full capacity for backup tapes and you want no more than 6 GB of data to be moved when a backup tape is recycled, set RECYCLEPERCENT(2) because a MEDIA5 tape can hold 300 GB of data in EFMT1. These examples assume that the ML2 and backup tapes in the installation are filled to capacity because the calculations are based upon the average fullness of marked full tapes on your system (the reuse capacity.)

To determine how much data your current recycle threshold implies, use the reuse capacity associated with the tapes. The current recycle threshold percent multiplied by the reuse capacity gives the maximum amount of data on any of the tapes when they are recycled.

While lowering the recycle threshold reduces recycle processing time and decreases the number of times each tape must be recycled, it may also increase the overall number of tapes needed in your installation. Also, if you have a mix of ML2 or backup tape capacities in need of recycle processing, you may want to recycle tapes with the RANGE parameter and use the appropriate recycle threshold for the tape capacities in the range.

In a non-SMS tape environment, the default is to allow tape pooling to determine if ABARS data sets go to WORM or R/W media. Optionally, if the DEVSUP parameter ENFORCE_DC_MEDIA=ALLMEDIATY or ENFORCE_DC_MEDIA=MEDIA5PLUS is used, the data class must request the appropriate media type for it to be successfully mounted.

- DFSMSShsm recycle processing of 3592 Model E06 tapes can take significantly longer than with smaller tapes because the amount of data moved at the same RECYCLEPERCENT can be much larger. Besides moving more data, the likelihood of a tape takeaway for recall processing increases with the number of data sets still remaining on the tape.
- In an SMS tape environment, and optionally in a non-SMS tape environment, the SMS data class construct can be used to select WORM tapes for ABACKUP processing. The output data set prefix specified in the aggregate group definition can be used by the ACS routines to select a WORM data class. Set up the ACS routine and the output data set name to uniquely identify the ABARS output files that must go to WORM tape.
- Consider using the Fast Subsequent Migration function to reduce the need to RECYCLE these high-capacity tapes.
- For a Sysplex environment, consider using the Common Recall Queue to optimize mounts of migration tapes.
- The 3592 Model E06 tape drive is used in 3590 emulation mode only; never 3490.

Considerations for using the 3592 Model E07 tape drive

Here are some tips you might find helpful when using DFSMSShsm with the 3592 Model E07 tape drive.

- In a non-SMS mixed tape hardware environment, where multiple types of tape hardware are used to emulate 3590 devices, it is recommended that you define unique esoterics for each type of tape hardware. This action is necessary to avoid mixing incompatible recording technologies. You can define an esoteric to DFSMSShsm through the SETSYS USERUNITTABLE command, for example:

```
SETSYS UUT(3592E07:3592E07 3590H:3590H)
```

With esoterics defined, you can then direct output to the desired set of drives through the SETSYS command, for example:

```
SETSYS BACKUP(TAPE(3592E07))
```

- If your installation has an excessive number of spanning data sets, consider specifying a larger value in the SETSYS TAPESPANSIZE command. A larger absolute value is needed to represent the same amount of unused capacity on a percentage basis when the tape has a larger total capacity. For example, if you allow 2% of unused tape to avoid tape spanning for a 3590-Hxx device using enhanced media, specify a TAPESPANSIZE of 1200 MB. To allow 2% unused tape for a MEDIA11 tape on a 3592 Model E07 tape drive (no performance scaling), specify a TAPESPANSIZE of 9999 MB. All size calculations for scaled tapes are based upon the scaled size and not the unscaled size.
- If the speed of data access on a tape is more important than full use of capacity, consider using performance scaling, if the media you are using supports it. Performance scaling uses 20% of the physical capacity on each tape and keeps all data sets closer together and closer to the initial tape load point. If you use performance scaling with the DFSMSShsm duplex function, be sure the original tape and the alternate tape both use performance scaling. Similarly make sure that TAPECOPY input tapes and output tapes have the same performance scaling attributes.

Note: Performance scaling is not available on the following tape cartridge media: MEDIA6, MEDIA7, MEDIA8, MEDIA10, MEDIA12, and MEDIA13.

- If you are using MEDIA5, MEDIA9, or MEDIA11 tapes with performance scaling, consider using MEDIA7 or MEDIA13 tapes for high performance functions. The available MEDIA5, MEDIA9, or MEDIA11 tapes could then be used to their full capacity.

Consider performance segmentation as a compromise solution. Performance segmentation increases the performance of data sets in the first twenty percent of the tape's capacity, but also uses the

remaining capacity as a slower access segment. Average performance for the tape is increased at the expense of losing a percentage of the overall tape capacity. (You cannot determine which data sets reside in which segment.)

One option for controlling overall recycle run time is the `LIMIT(nnnn)` parameter of `recycle`. `Recycle` returns no more than the specified number of tapes to scratch during the current recycle run. Because `recycle` sorts the tapes based on the amount of valid data still on each volume, the tapes recycled require the least processing time.

Another option to consider is decreasing the `ML2RECYCLEPERCENT` parameter, the `RECYCLEPERCENT` parameter, or both. Assume, for example, that your installation uses lower capacity tapes for ML2 and higher capacity tapes for backup. If you want to move only 100 GB of data from each recycled tape, calculate the percent that 100 GB represents of each of the two tape media. Then set `RECYCLEPERCENT()` to the calculated percent 100 GB represents of the backup media and set `ML2RECYCLEPERCENT()` to the calculated percent 100 GB represents of the smaller migration tapes. These examples assume that the ML2 and backup tapes in the installation are filled to capacity because the calculations are based upon the average fullness of marked full tapes on your system (the reuse capacity.)

To determine how much data your current recycle threshold implies, use the reuse capacity associated with the tapes. The current recycle threshold percent multiplied by the reuse capacity gives the maximum amount of data on any of the tapes when they are recycled.

While lowering the recycle threshold reduces recycle processing time and decreases the number of times each tape must be recycled, it may also increase the overall number of tapes needed in your installation. Also, if you have a mix of ML2 or backup tape capacities in need of recycle processing, you may want to recycle tapes with the `RANGE` parameter and use the appropriate recycle threshold for the tape capacities in the range.

In a non-SMS tape environment, the default is to allow tape pooling to determine if ABARS data sets go to WORM or R/W media. Optionally, if the `DEVSUP` parameter `ENFORCE_DC_MEDIA=ALLMEDIATY` or `ENFORCE_DC_MEDIA=MEDIA5PLUS` is used, the data class must request the appropriate media type for it to be successfully mounted.

- DFSMSShm recycle processing of 3592 Model E07 tapes can take significantly longer than with smaller tapes because the amount of data moved at the same `RECYCLEPERCENT` can be much larger. Besides moving more data, the likelihood of a tape takeaway for recall processing increases with the number of data sets still remaining on the tape.
- In an SMS tape environment, and optionally in a non-SMS tape environment, the SMS data class construct can be used to select WORM tapes for `ABACKUP` processing. The output data set prefix specified in the aggregate group definition can be used by the ACS routines to select a WORM data class. Set up the ACS routine and the output data set name to uniquely identify the ABARS output files that must go to WORM tape.
- Consider using the Fast Subsequent Migration function to reduce the need to `RECYCLE` these high-capacity tapes.
- For a Sysplex environment, consider using the Common Recall Queue to optimize mounts of migration tapes.
- The 3592 Model E07 tape drive is used in 3590 emulation mode only; never 3490.

Limiting the number of ML2 and backup data sets that span tape volumes

The `TAPESPANSIZE` optional parameter of the `SETSYS` command can be used to reduce the occurrences of data sets spanning tape volumes. This is of benefit when running certain functions such as recall, recover, and recycle. When a data set spans tape volumes, a recall or recovery of that data set requires two tape mounts rather than one.

If you are recycling a connected set of tape volumes, recycle processing determines whether the average of all the tapes in the connected set meets the selection criteria and optionally whether the first volume

in the connected set also meets the selection criteria. If not, no tapes in the connected set are recycled, potentially leaving some tapes with very little data on them. You can modify your installation's use of recycling for connected sets through the CHECKFIRST parameter.

With the SETSYS TAPESPANSIZE command, you can specify a value between 0 and 4000. This value represents the maximum number of megabytes of tape that DFSMSHsm can leave unused while trying to eliminate spanning data sets. To state this differently, this value is the minimum size of a data set that is allowed to span tape volumes. Data sets whose size is less than the value do not normally span volumes. Only those data sets whose size is greater than or equal to the specified value are allowed to span volumes. The data written to tape results from compression by the tape subsystem, so predictions of that resultant size are not always correct. Therefore, spanning can occur for some data sets that do not compress as expected.

When data is being written to tape, DFSMSHsm estimates whether the space remaining on a tape can contain the entire data set, based on the following criteria:

- The limit that is specified with the SETSYS TAPEUTILIZATION command
- Whether the data set is already compressed on DASD
- The compression ratio that is assumed for your data sets
- Whether (for a logical 3490 device) the new data set would exceed the architected block count

If TAPEUTILIZATION specifies the NOLIMIT parameter, no action is taken to reduce the spanning of the data set tape volume.

Note: The use of the NOLIMIT parameter is not recommended.

How to handle inconsistencies between tape media contents and OCDS TTOC records

When DFSMSHsm detects an inconsistency between the TTOC record and the content of the tape media, an ARC0378I message is issued during the DFSMSHsm startup to notify the system programmer that the missing TTOC record data set entries need to be resolved.

To get a list of all the volumes whose TTOC records are missing data set entries:

1. Issue a LIST TAPETABLEOFCONTENTS command with the SELECT(FAILEDCREATE) parameter. Inconsistent TTOC records for a failing DFSMSHsm host will not be listed until DFSMSHsm is restarted in that z/OS image because the records appear to still be in use.
2. Use the extended AUDIT MEDIACONTROLS function to reconstruct the missing TTOC data set entries for the indicated tape volume.

If data checks occur or invalid file block identifiers are encountered during AUDIT MEDIACONTROLS processing, a RECYCLE FORCE command can be issued to recycle the known valid data set entries on a tape volume. A warning message (ARC0378I) is issued, and the recycled tape volume is not deleted.

In general, you should *not* use the RECYCLE FORCE command to recycle a tape volume before using the AUDIT MEDIACONTROLS command to resolve the missing TTOC data set entries. If you do use it, you must *immediately* perform the following steps to avoid losing the valid data sets on the just-recycled tape volume:

- a. Issue a LIST DSN MCDS SELECT(VOLUME(volume serial number of recycled migration tape)) command, or a LIST DSN BCDS SELECT(VOLUME(volume serial number of recycled backup tape)) command to list the data set names of the data sets that DFSMSHsm indicates still reside on the tape volume.

- b. Recall or recover the indicated data sets that do not have TTOC data set entries associated with valid data sets residing on the tape volume.
- c. Issue a DELVOL command for the recycled tape volume.

When an ML2 tape volume cannot be deleted because an ARC0260I message indicates that valid data may exist on a volume, it is because the OCDS TTOC record indicates that the volume may contain valid migration copies. This condition occurs when an inconsistency exists between the TTOC record and the content of the tape media. Inconsistencies are created whenever TTOC creation or TTOC invalidation information is lost because of a DFSMSHsm cancel, a system failure due to a power outage, or an I/O error on the OCDS.

A TTOC creation inconsistency is present when the ARC0260I message is preceded by an ARC0378I message that relates to the same volume. TTOC creation inconsistencies are resolved by running the extended AUDIT MEDIACONTROLS function to reconstruct missing data set entries on the OCDS TTOC record that relates to the tape volume. After the extended AUDIT MEDIACONTROLS function is completed for the inconsistent tape volume, the normal generic RECYCLE function established by the installation will DELVOL the tape volume after all valid data is moved to another ML2 tape volume. If an immediate DELVOL of the tape volume is necessary, the single volume RECYCLE function will DELVOL the tape volume after all valid data is moved to another ML2 tape volume.

A TTOC invalidation inconsistency is present when the ARC0260I message is not preceded by an ARC0378I message that relates to the same volume. TTOC invalidation inconsistencies are resolved by the normal generic RECYCLE function established by the installation. If an immediate DELVOL of the tape volume is necessary, the single volume RECYCLE function can be used. Either way, the RECYCLE function will DELVOL the tape volume after all valid data is moved to another ML2 tape volume.

Recovering a damaged DFSMSHsm single-file migration level 2 volume

For information on recovering the undamaged remains of a single-file tape after it has been partially overwritten, see Chapter 60, “RECOVER command: Recovering a backup version or dump copy of a data set, or UNIX file, or a volume,” on page 997.

Making migration level 2 key range volumes available

When the ML2 volume for a specific key range becomes full during migration, DFSMSHsm tries to assign a new volume to the key range. If no ML2 volumes are available, you can do one of the following to make volumes available:

- Use the ADDVOL command to add more ML2 volumes to DFSMSHsm.
- Use the UNASSIGN parameter of the DELVOL command for each ML2 volume you want to be made available for reuse. When you use this parameter, specify DASD ML2 volumes that have been used before and that you want to reuse now. Ensure that space is available on these volumes because of subsequent recalls and deletions.
- Use a DEFINE command to assign a volume to a key range. To associate a specific volume with a key range, use the DEFINE command. Issue a QUERY ML2 command to determine the current association of volumes to key ranges. Then enter a DEFINE command specifying the same set of volumes but with the new volume replacing the old volume associated with the key range.

These three commands (DELVOL, ADDVOL, and DEFINE) allow you to reuse the current level 2 volumes.

Recovering a migrated data set

A restriction was noted in the discussion on recovering backup versions of data sets: DFSMSHsm cannot recover a data set to a migration volume.

Note: DFSMSHsm can recover a non-VSAM data set that is currently marked as migrated in the computing system catalog if a recover data set name is issued with NEWNAME specified, and the NEWNAME data set is not a migrated data set.

To recover a backup version of a migrated data set, use one of the following procedures:

- Recall the migrated data set and recover a backup version of that data set. You can use the REPLACE parameter if necessary.
- Delete the migrated data set and recover a backup version of the data set you just deleted.
- Issue a recover data set name with NEWNAME(*newdsname*) specified. If the NEWNAME(*newdsname*) is not a migrated data set, it will successfully recover.

Recovering a migration volume

You can use the RECOVER command to recover a data set to a level 0 volume. The RECOVER command recovers a data set in its original format. Because the migrated copy of a data set is stored in a different format from the original user's data set, you cannot use the RECOVER command to recover a data set to a migration volume. Depending on whether you use DFSMSHsm commands to periodically dump your DASD migration volumes, you can use one of the following procedures to recover an entire migration volume.

Note: These procedures assume that you have been using DFSMSHsm to back up data sets because the procedures recover the latest backup version of each data set that was on the migration volume.

Be aware that the latest backup version of each data set might not be identical to the data set that DFSMSHsm migrated. For example, the data set might have needed backup when DFSMSHsm migrated it, but DFSMSHsm did not have a chance to back up the migrated data set before the migration volume became inaccessible.

If you use DFSMSHsm's BACKVOL command to periodically dump your DASD ML2 volumes and use the automatic dump facility to periodically dump your ML1 volumes, perform [“Procedure 1” on page 552](#) to recover the data, mostly to a DASD migration volume.

If you do not dump your DASD migration volumes or need to recover the data sets that were on a tape migration volume and have no alternate tape, perform [“Procedure 2” on page 553](#) to recover all the data to primary volumes. For a discussion of alternate volumes, see [Chapter 9, “Making disaster backup copies of DFSMSHsm-owned tape volumes,” on page 435](#).

Procedure 1

1. To ensure that DFSMSHsm does not select the volume being recovered as a target volume for migration, issue the DFSMSHsm ADDVOL command with the DRAIN parameter. Issue the command in all DFSMSHsm hosts.
2. Restore the latest dump copy of the volume. This restores the DASD migration volume to its level when the dump copy was created. Issue the following DFSMSHsm command to request a full volume restore of the volume.

```
RECOVER * TOVOLUME(valid) UNIT(unittype) FROMDUMP
```

3. If the migration volume contains SDSP data sets and you have your own procedures to back up these data sets more frequently than you dump the volume, recover the most recent backup of the SDSP data set to the migration volume being recovered.
4. After the volume has been successfully restored, issue the FREEVOL command. This leaves data on the migration volume that is no longer valid, migrated data. It also enables you to easily obtain a list of the data sets that still need to be recovered (those that the MCDS indicates are still on the migration volume). The FREEVOL command process is driven off of the volume table of contents (VTOC) and includes all data sets in an SDSP data set on the volume that are currently migrated. Use the AGE(0) parameter to indicate that all data sets must be migrated. You can specify either ML1 or ML2 as the target migration level when you want to process a ML1 volume. Use the following command as an example:

```
FREEVOL MIGRATIONVOLUME(volser) TARGETLEVEL(MIGRATIONLEVEL1) AGE(0)
```

- Request from DFSMSHsm a list of all the migrated data sets that are indicated as being on the volume being recovered. These data sets represent the data sets that were migrated to the volume after the most recent dump copy was created. The migration copies of the data sets have been lost, so the data sets must be recovered from backup versions. Use the following LIST command to request this list of data sets:

```
LIST DATASETNAME MIGRATIONCONTROLDATASET -  
SELECT(VOLUME(volser)) OUTDATASET(dsname)
```

The OUTDATASET parameter is highly recommended so that the output from the LIST command is written to the data set whose name is given by *dsname*. This allows you to use a text editor to modify the output to easily perform the remaining steps:

- Make one more copy of the output data set, *dsname*.
- For each data set in the output from “5” on page 553, perform steps “8” on page 553 and “9” on page 553. You cannot perform these steps concurrently for the same data set. By using two copies of the list of data sets from step “5” on page 553, you can modify each of the two lists to perform steps “8” on page 553 and “9” on page 553 for all of the data sets at one time. Use a text editor and its global change command to add and remove the necessary text around each data set name.
- Delete the migrated data set. This uncatalogs the data set and deletes the MCDS data set record and any associated MCL, MCA, and MCO records. Do this with the following DFSMSHsm command:

```
DELETE dsname
```

- Recover the latest backup version for each data set. Do this with the following DFSMSHsm command:

```
RECOVER dsname REPLACE
```

Note: The backup copy that is recovered may not be the most current version of a data set if the data set was migrated to the ML1 volume before it was backed up.

- If the recovered volume is an ML1 volume, there might be backup versions that were restored to the migration volume. Some of these may represent valid backup versions. These can exist if data set backup requests were processed between the time automatic backup last ran on the primary DFSMSHsm host before the volume was dumped and the time when the volume was dumped. You can use the following procedure to assist you in recovering the backup versions, see “[Recovering backup versions from a damaged migration level 1 volume](#)” on page 554.
- After all valid, DFSMSHsm-owned data sets have been removed from the volume, you can reinitialize the volume. DFSMSHsm no longer requires access to it. You can also remove the volume from DFSMSHsm’s control with the DELVOL command.

The data sets will probably migrate the next time automatic primary space management occurs on the DFSMSHsm-managed volumes. This happens because when DFSMSHsm recovers a data set, the data set VTOC entry is restored exactly as it was when the backup version being recovered was created. DFSMSHsm does not reset the date-last-referenced field to the current date when it recovers the data set unless you rename the data set. Therefore, the recovered data sets will probably have a high inactive age.

Procedure 2

Rule: Do not start any step until the previous steps have completed.

- Determine which data sets were on the migration volume. To do this, use the following command:

```
LIST DSN MCDS SELECT(VOLUME(volser)) -  
OUTDATASET(dsname)
```

For *volser*, specify the volume serial number of the migration volume. DFSMSHsm writes the list in the data set whose name is *dsname*. You can issue this command from a console, terminal, or batch job.

2. Do a LISTCAT command if you want to save information about the data sets that you are going to delete in the next step. You may want to know, for example, whether the status of a generation data set (GDS) is DEFERRED or ACTIVE before it is deleted, because after being deleted it is always recovered with a status of DEFERRED.
3. Delete the MCDS data set record. This uncatalogs the data set and deletes the MCDS data set record and any associated MCL, MCA, and MCO records. To do this, use the following command for each data set on the migration volume:

```
DELETE dsname
```

When you use a text editor such as ISPF, you can edit the data set produced by the LIST command (step 1) so it contains one line for each data set. Each line contains the data set name. Replicate this data set once because you will need a copy for the next step. Then, use a global change command to precede each data set name with the characters HSEND CMD DELETE. A DFSMSHsm-authorized user can then run the data set as a command procedure (CLIST). However, if you have many data sets, include the necessary JCL in the data set and submit the data set as a batch job.

4. Recover the latest backup version for each data set that migrated to the migration volume. To do this, issue the following DFSMSHsm command:

```
RECOVER dsname
```

When you use a text editor such as ISPF, you can edit the copy of the data set containing the name of each data set on a separate line. Then, use a global change command to precede each data set name with the characters HSEND CMD RECOVER. A DFSMSHsm-authorized user can then run the data set as a command procedure (CLIST). If you have many data sets, include the necessary JCL in the data set and submit the data set as a batch job.

5. Issue the IDCAMS ALTER ROLLIN command if you want to change the status of a recovered GDS from DEFERRED to ACTIVE.

The catalog status of a recovered GDS is dependent upon its catalog status before being recovered. If the GDS is not cataloged before recovery, its catalog status after recovery is DEFERRED. If the GDS is cataloged before recovery, its catalog status after recovery remains the same, with the following exception: when DFSMSHsm is used as a data mover to recover a rolled-off GDS, the cataloged status of the GDS, after it is recovered, is DEFERRED.

6. Follow the procedure titled [“Recovering backup versions from a damaged migration level 1 volume”](#) on [page 554](#) if the volume being recovered is an ML1 volume and there are backup versions that must be recovered or replaced.

The data sets will probably migrate the next time automatic space management occurs on the DFSMSHsm-managed volumes. This happens because when DFSMSHsm recovers a data set, the data set VTOC entry is restored exactly as it was when the backup version being recovered was created. DFSMSHsm does not reset the date-last-referenced field to the current date when it recovers the data set. Therefore, the recovered data sets will probably have a high inactive age.

For more information about the LISTCAT command, see [z/OS DFSMS Access Method Services Commands](#).

Recovering backup versions from a damaged migration level 1 volume

Use the following steps to recover backup versions from a damaged migration level 1 volume.

1. Issue the following Access Method Services command to print a list of MCM records. Use this list to determine if any of the backup versions on a damaged or restored ML1 volume are still valid.

```
PRINT IDS(bcds-dsname) FROMKEY(X'26') -
TOKEY(X'26') OUTFILE(ddname)
```

For *bcds-dsname*, substitute the fully qualified data set name of the DFSMSHsm backup control data set. For *ddname*, substitute the DDname of a preallocated data set that contains the output from the PRINT command.

2. Examine each MCM record that was printed to see if it represents a backup version that resides on the migration volume being recovered. To do this, look at offset 152 (X'98') in the record for the ML1 volume serial number. For all MCM records that have the volume serial number of the volume being recovered, you should perform the following. For *dsname* in the following commands, use the original data set name found at offset 64 (X'40') of the MCM record.
 - a. Use the following DFSMSHsm command to find out the version number of the backup version indicated as being on the volume being recovered:

```
LIST DATASETNAME(dsname) BACKUPCONTROLDATASET
```

- b. Using the version number found in the previous step, issue the following DFSMSHsm command to delete that backup version:

```
BDELETE dsname VERSIONS(bvn)
```

- c. Issue the following DFSMSHsm command to create a replacement backup version of the data set:

```
BACKDS dsname
```

An optional first step might be appropriate if the number of backup versions on the migration volume is large or if the original data sets no longer exist from which to create new backup versions. The movement of the backup versions phase of automatic backup, run in the primary DFSMSHsm host, moves all of the valid backup versions to backup volumes. Allowing automatic backup to run first moves all backup versions off all ML1 volumes so that only the MCM records for the damaged volume must be examined. The remainder of the procedure must still be followed for lost backup versions. If the migration volume was dumped, backup versions might have been lost if placed on the migration volume after the dump copy was created. If the migration volume was not restored from a dump copy, backup versions could still be lost if they resided on the parts of the volume that were damaged.

Returning dump tapes to use

Dump tapes in dump classes with the NOAUTOREUSE parameter specified are not automatically returned to usability when their generation is rolled off or expires. To return these tapes to use:

1. Physically return the tape volumes to the computer site.
2. Issue the following command for each tape volume:

```
DELVOL volser DUMP(REASSIGN)
```

3. Determine if the volumes are ready for reuse. If you have specified the TAPEDELETION(HSMTAPE) parameter of the SETSYS command, the volumes are ready for reuse. If you have specified the TAPEDELETION(SCRATCH) parameter, you might be required to reinitialize the volumes before they are returned to the scratch pool.

Managing SDSP data sets

Three procedures must be considered in managing SDSP data sets:

- Reorganizing the data sets
- Backing up and recovering the data sets
- Removing the data sets

Reorganizing SDSPs

Migration of user data sets into an SDSP causes VSAM CI and CA splits. Erasing the VSAM records of recalled and deleted data sets in an SDSP makes space reusable. However, these dynamics cause a redistribution of the free space in the SDSP. The SDSP will eventually appear to be full even though some free space may exist within the SDSP. When the high-used relative byte address equals the high-allocated relative byte address, the SDSP can appear to be full to a migration request if the SDSP cannot be extended. If DFSMSHsm fails in migrating to an SDSP, it issues a message to the migration activity log, and stops directing migrations to that SDSP.

For discussions of selecting SDSPs and the causes of out-of-space conditions, see [“SDSP selection”](#) on page 77 and [“Out-of-space condition during migration”](#) on page 77.

In this case, and after migration cleanup has run, you should consider reorganizing the SDSP. The frequency of reorganization depends on the size and number of SDSPs and on the number of data sets that regularly migrate to SDSPs in your environment. You should have enough SDSPs so that when one becomes full, the migrations occur to other SDSPs while you schedule and perform the SDSP reorganization. Use the TSO LISTC command once per week to determine the status of SDSPs as reported by the high-used and high-allocated relative byte addresses. After observing the SDSP status for several weeks, you can establish an appropriate frequency for SDSP reorganization in your environment. You may also choose to expand the SDSP, should you encounter an out-of-space condition. Alternatively, a reorganization of the SDSP can be automatically triggered when DFSMSHsm issues message ARC0542I to the console.

The format of the SDSP data set name is `uid.SMALLDS.Vvolser`. Where

- `uid` is a high-level qualifier that is the DFSMSHsm-authorized user ID from the startup procedure.
- `SMALLDS` and `V` are constants.
- `volser` is the volume serial number of the volume where the SDSP resides.

Note: An SDSP data set name is essentially a fixed name relating to a specific volume serial number in your environment and, once established, should not be changed.

You can reorganize the SDSP data set by using the Access Method Services EXPORT and IMPORT commands. Then, use the DFSMSHsm ADDVOL command to add the ML1 volume to DFSMSHsm again and specify the SMALLDATASET PACKING parameter to make the volume eligible for SDSP data set selection again.

Related reading

- For more information about the SDSP data set name is generated, see [z/OS DFSMSHsm Implementation and Customization Guide](#).
- For more information about the EXPORT and IMPORT commands and how to use them, see [z/OS DFSMS Access Method Services Commands](#).

SDSP backup and recovery

You should back up your SDSP data sets daily, such as at the end of automatic space management. The frequent backup is desirable because of the large number of user data sets whose data is stored in an SDSP data set. An SDSP data set is an active data set and is dynamically changing. The more frequently you back it up, the more current it will be if it must be recovered.

Example: If there are 50,000 data sets in an SDSP data set and it is lost, DFSMSHsm has to do 50,000 data set recovers. If you have backed up the SDSP, you can recover the SDSP from your latest backup and then recover only a few user data sets that have migrated to it since your latest backup of the SDSP.

DFSMSHsm does not automatically back up an SDSP data set as a single entity, but it can back up the individual data sets that the SDSP data set contains. However, you can use DFSMSHsm commands to back up and recover an SDSP data set. To back up an SDSP data set, issue the BACKDS command and include only the data set name of the SDSP.

To recover an SDSP that has been backed up by DFSMSHsm, do the following:

1. Issue a DELVOL MIGRATION command for the ML1 volume on which the SDSP resides. DFSMSHsm's recovery function does not recover backup versions to migration volumes, so the ML1 volume must be temporarily removed from DFSMSHsm's inventory of migration volumes.
2. Issue a RECOVER command for the SDSP data set.
3. Issue an ADDVOL command for the ML1 volume after the RECOVER command has been processed successfully. This adds the volume back to DFSMSHsm's inventory of migration volumes.

Removing SDSPs

There are two different methods of removing SDSPs: removing an entire ML1 volume that contains the SDSP or removing the SDSP from the ML1 volume that it resides on.

Removing a migration level 1 volume that contains an SDSP

The following steps remove all data sets from an ML1 volume that includes an SDSP:

1. Remove all migrated data sets from the ML1 volume using the FREEVOL command. The data sets will select a target volume using the same selection process DFSMSHsm uses during migration. Small data sets that move to another ML1 volume may go into an SDSP data set. The FREEVOL process cleans up data sets in the SDSP in need of scratching.
2. Verify that all valid data sets are out of the SDSP by using the following command:

```
LIST dsname SEL(VOL(ml1volser) SDSP) TERM
```

If there are data sets in the SDSP that do not move and are no longer wanted, try to delete them. It is important that you do not leave the control records for a data set in DFSMSHsm's system when you delete the SDSP.

3. Delete the SDSP data set using IDCAMS.
4. Check the ML1 volume to verify the SDSP and all user data sets have been moved off the volume. Use ISPF 3.4 or the LIST VTOC command to display the data set list for the ML1 volume. If the ML1 volume contains BACKDS data sets, automatic backup should be run on the primary DFSMSHsm host to move them to a backup tape.
5. DELVOL the ML1 volume from each DFSMSHsm host and remove the ADDVOL for the ML1 volume from each startup parmlib. The DELVOL command is issued as follows:

```
HSEND DELVOL ml1volser MIGRATION
```

The former ML1 volume is no longer associated with DFSMSHsm.

Removing an SDSP from a migration level 1 volume

The steps for removing only the SDSP from an ML1 volume are:

1. Code the ARCMEXT user exit to select only the data sets in the SDSP that will be migrated during the FREEVOL. Use the FREEVOL command to move all the valid data sets in the SDSP to another volume. The data sets in the SDSP will select a target volume using the same selection process DFSMSHsm uses during migration. Small data sets that move to another ML1 volume may go into an SDSP data set.
2. Verify that all valid data sets are out of the SDSP by using the following command:

```
LIST dsname SEL(VOL(ml1volser) SDSP) TERM
```

If there are data sets in the SDSP that do not move and are no longer wanted, try to delete them. It is important that you do not leave the control records for a data set in DFSMSHsm's system when you delete the SDSP.

3. Delete the SDSP data set using IDCAMS.

4. Use ISPF 3.4 or the LIST VTOC command to display the data set list for the ML1 volume. Check this list to verify the SDSP has been moved off the volume.
5. Issue the following ADDVOL NOSDSP command for the source ML1 volume. Update all startup parmlibs with an ADDVOL command for the ML1 volume to reflect the NOSDSP status.

```
ADDVOL ml1volser UNIT(unitttype) MIGRATION(ML1 NOSDSP)
```

6. Update the SETSYS SDSP parameter to reflect a NOSDSP status if you are removing all SDSPs from the DFSMSHsm system.

Protecting DFSMSHsm-owned tape volumes

You can protect DFSMSHsm-owned tape volumes with password protection, RACF protection, expiration date protection, or a combination of the three.

Related reading

For more information about protecting DFSMSHsm-owned tape volumes, see [z/OS DFSMSHsm Implementation and Customization Guide](#).

Converting to a new tape technology

If you are converting from an old tape technology to a new tape technology, identify whether the old tapes have the same logical device type as the new ones. Then mark the old tapes full so that they are no longer available for output consideration. With DFSMSHsm support of the 3590E device, you do not have to perform this step, because DFSMSHsm can distinguish 3592, 3590E, 3590B, 3590H, and VTS tapes from other type cartridges. However, DFSMSHsm does not differentiate between other hardware that has a common logical device type.

Use the following command to identify the old backup tapes:

```
LIST TTOC SELECT (BACKUP NOTFULL)
```

Use the following command to mark the old tapes as full:

```
DELVOL volser BACKUP(MARKFULL)
```

Requesting DFSMSHsm service from your applications

DFSMSHsm has macros available that allow you to request DFSMSHsm service from your application programs. You provide information to the macro and execute it from your application program. The macro builds the required DFSMSHsm control information and issues the request for DFSMSHsm service.

Related reading

For more information about the macros, see [z/OS DFSMSHsm Managing Your Own Data](#).

Chapter 14. Obtaining information from DFSMSHsm

In using DFSMSHsm, you may have occasion to require information about what is happening in the processing. DFSMSHsm provides extensive facilities for determining what the conditions are in the product. The DFSMSHsm log and the activity logs have already been mentioned. In addition to the logs, you can obtain the following from DFSMSHsm:

- Information from the control data sets
- Information about the present operating conditions in the DFSMSHsm address space
- Information about availability of output tape volumes
- Statistical information about DFSMSHsm operations
- A trace of DFSMSHsm's processing
- Information about the conditions in the system if a specific error occurs
- Determining the results of volume space management data set selection without actually moving data sets

Related reading

For more information about using DCOLLECT for reporting, see [*z/OS DFSMSdfp Storage Administration*](#) and [“Running new reports with report generator”](#) on page 575 for running new reports.

Obtaining information from the control data sets

Use the LIST command to obtain information from the control data sets. Information can be about:

- Backup volumes
- Copy pools
- Data sets
- UNIX files
- Dump classes
- Dump volumes
- DFSMSHsm host serialization
- DFSMSHsm-managed volumes
- DFSMSHsm-owned volumes
- Tape volumes
- User authorization

In obtaining the information, you can receive it in any of three ways: as a printed listing, as a DASD data set, or as terminal output. For small amounts of data, such as DFSMSHsm host serialization information or user-authorization information, terminal output is satisfactory. However, the LIST command is capable of producing very large amounts of information, for example, when you request information about all migration volumes. For such requests, you want to be sure to direct the output to either a printed listing or a DASD data set that you can edit or print later.

The parameters that control the destination for the LIST command output are the same for any request. In showing the forms of the command for each type of output, all other parameters (such as request) are being identified.

The form of the command for obtaining terminal output is:

```
LIST (request) TERMINAL
```

The form of the command for obtaining a printed listing is:

```
LIST (request) SYSOUT
LIST (request) SYSOUT(class)
```

The first form of the command directs the printed output to the SYSOUT class specified with the SETSYS command. The second form of the command specifies a SYSOUT class to which the output is directed.

The form of the command to direct the output to a DASD data set is:

```
LIST (request) OUTDATASET(dsname)
```

dsname is the fully qualified name of the data set to which you want the LIST command output sent. If the data set exists, DFSMSHsm places the report at the end of the existing data set. If the data set does not exist, DFSMSHsm dynamically allocates and catalogs an output data set.

Related reading

For more information about the LIST command, see [Chapter 53, “LIST command: Listing information from the MCDS, BCDS, and OCDS,” on page 919](#).

Obtaining backup volume information

The forms of the requests for obtaining backup volume information are:

```
LIST BACKUPVOLUME
LIST BACKUPVOLUME SELECT(EMPTY)
LIST BACKUPVOLUME(volser)
```

The first request lists the information about all the backup volumes in the system. The second request lists the information about all the empty backup volumes in the system. The second request can be used to determine which DFSMSHsm tapes can be placed in the cartridge loader. The third request lists the information about a specific backup volume.

Obtaining data set information

You can obtain information about a single data set or about every data set for which DFSMSHsm has any record. You can also select groups of data sets. Optional parameters allow you to select:

- Information from the backup control data set
- Information from the migration control data set
- Information from both the backup and the migration control data sets
- Information about data sets that have been recalled
- Information about data sets with a certain minimum age, maximum age, or between a minimum and a maximum age
- Information about data sets on ML1 volumes
- Information about data sets on ML2 volumes
- Information about the designated data sets on a specific migration volume
- A list of all of the migrated data sets that were empty at the time of migration
- Information about the data sets in SDSP data sets
- Information about the data sets not in SDSP data sets
- Information about VSAM data sets
- A summary of the information about the data sets

Many permutations exist for requesting information about data sets and levels. Some of them are shown here.

Sample requests for information about data sets are:

This request obtains information about all data sets that are recorded in the backup control data set.

```
LIST DATASETNAME BACKUPCONTROLDATASET
```

This request obtains information about the data set identified by *dsname* from the migration control data set.

```
LIST DATASETNAME(dsname) MIGRATIONCONTROLDATASET
```

This request obtains information about all data sets recorded in both the backup control data set and the migration control data set. In addition, it obtains information about any data sets that have migrated and been recalled.

```
LIST DATASETNAME BOTH INCLUDEPRIMARY
```

This request obtains information about data sets with the qualifier *levelid* recorded in the migration control data set, but only for the data sets on ML1 volumes.

```
LIST LEVEL(levelid) MIGRATIONCONTROLDATASET -  
SELECT(MIGRATIONLEVEL1)
```

This request obtains information about all data sets recorded in the migration control data set as being migrated to SDSP data sets.

```
LIST DATASETNAME MIGRATIONCONTROLDATASET -  
SELECT(SMALLDATASETPACKING)
```

This request obtains a list of all migrated data sets (excluding PDS and PDSE data sets) that were empty at the time of migration.

```
LIST DATASETNAME MIGRATIONCONTROLDATASET -  
SELECT(EMPTY)
```

Related reading

For more information about the LIST command, see [Chapter 53, “LIST command: Listing information from the MCDS, BCDS, and OCDS,” on page 919](#).

Obtaining UNIX file information

You can obtain information about a single UNIX file or about every UNIX file for which DFSMSHsm has any record. You can select subdirectories of UNIX files. Optional parameters allow you to select:

- Information from the backup control data set
- Information about UNIX files with a certain minimum age, maximum age, or between a minimum and a maximum age
- Information about the designated UNIX files on a specific volume

Many permutations exist for requesting information about UNIX files and directories. Some of them are shown here.

Sample requests for information about UNIX files are:

This request obtains information about all UNIX files that are recorded in the backup control data set.

```
LIST FILELEVEL('/ ') RECURSE BACKUPCONTROLDATASET
```

This request obtains information about the UNIX file identified by *pathname* from the backup control data set.

```
LIST FILENAME(pathname) BACKUPCONTROLDATASET
```

This request obtains information about UNIX files sets contained in directory */dir1/dir2* recorded in the backup control data set, but only for the backups on VOLSER MIG102.

```
LIST FILELEVEL('/dir1/dir2/') BACKUPCONTROLDATASET -  
SELECT(VOLUME(MIG102))
```

Related reading

For more information about the LIST command, see [Chapter 53, “LIST command: Listing information from the MCDS, BCDS, and OCDS,”](#) on page 919.

Obtaining copy pool information

You can obtain information about all copy pool fast replication backup versions by using the following command:

```
LIST COPYPPOOL
```

This request provides version information for each copy pool that has at least one attempted backup. The list of source and target volume pairs is not included as part of this list request. The list output consists of the following information:

- Copy pool name
- Version number
- Valid or invalid
- VTOCENQ
- Token
- Backup date and time
- Dump, DASD copy, or both

You can obtain information about a specific copy pool by using the following command:

```
LIST COPYPPOOL(cpname)
```

This request provides detailed version information for each valid or invalid backup version for the specified copy pool. The date and time fields are zero when the PREPARE subparameter is used with the FRBACKUP command. The list output consists of the following information:

- Copy pool name
- Version number
- Valid or invalid
- VTOCENQ
- Token
- Backup date and time (for Prepare versions these fields display a value of zero)
- Source and target volume pairs
- File sequence number
- Dump data set name

- Dump class availability
- Tape device type

You can use keywords FRVOLS, NOVOLS, DUMPVOLS, or ALLVOLS to specify what type of volume information is to be displayed.

- The FASTREPLICATIONVOLS keyword, the default value, indicates that the source/target pairs should be listed.
- The NOVOLS keyword doesn't list any volume pairs data, but lists the dump class information if there is a dump copy version.
- The DUMPVOLS keyword indicates that source and dump volser data for all dump versions should be listed.
- The ALLVOLS keyword indicates all volume pairs should be listed.

The GENERATION(*gennum*) keyword only applies to a situation when the ALLVOLS keyword is specified. The default (GENERATION(*gen0*)) indicates that the most recent DASD and dump versions are to be listed. The *gennum* parameter is required, it means only the indicated generation should be listed. ALLVERS indicates that all DASD and dump versions are to be listed. TOKEN(*token*) refers to a version.

The SELECT keyword provides more flexibility in terms of which records for the copy pools should be listed, FASTREPLICATIONSTATE or DUMPSTATE.

FRSTATE indicates information that is wanted based on the FRBACKUP DASD copy.

- RECOVERABLE indicates that the copy pool volumes can be recovered from the DASD version.
- NONRECOVERABLE indicates that the copy pool volumes cannot be recovered from the DASD version.
- FAILED indicates that the DASD version is NONRECOVERABLE due to a failure during the FRBACKUP or WITHDRAW was done before all volumes in the copy pool were successfully copied
- NONE indicates that a DASD copy does not exist.

DUMPSTATE indicates information that is wanted based on the FRBACKUP DUMP.

- ALLCOMPLETE indicates that all volumes have been successfully dumped to all dump classes specified.
- REQUIREDCOMPLETE indicates that all volumes have been successfully dumped to at least all REQUIRED dump classes.
- PARTIAL indicates that some volumes of a copy pool have been successfully dumped.
- NONE indicates that no dumps are associated with the copy pool.

You can obtain information of volume pairs of all copy pool volumes that are recoverable from the DASD version by using the following command:

```
LIST CP(CPA) ALLVOLS(ALLVERS) SELECT(FRSTATE(REC)) ODS(LIST.CPA)
```

You can obtain information about the volumes contained in a specific copy pool backup storage group by using the following command:

```
LIST COPYPOOLBACKUPSTORAGEGROUP(cpbsgname)
```

This request provides a list of each volume in the copy pool backup storage group that DFSMSHsm has selected as a target volume. Volumes that are defined to the storage group that are not listed have not been selected as target volumes. In addition, the name of the source volume that each target volume is a target for will be listed.

You can obtain information about which copy pool a volume is associated with by using the following command:

```
LIST PRIMARYVOLUME BCDS
```

This request provides information about the copy pools that a primary volume is associated with. Specify either the BCDS or BOTH parameter for this request to process correctly. Use the LIST COPYPOOL(*cpname*) command to determine which target volumes are associated with a particular source volume.

You can obtain information about which copy pools the volume is associated with by using the following command:

```
LIST PVOL BCDS
```

When you use the PVOL parameter, with either the BCDS or BOTH subparameters, DFSMSHsm returns information about which copy pools the volume is associated with. With ALLDUMPS or BCDS subparameters, should also consider copy pool dumps. Copy pool dumps versions should include the name of the source copy pool. If the volume is in a copy pool, associated information needs to be displayed. Target volumes of a copy pool source/target pair do not display information. To determine which target volumes are associated with a particular source volume, you can use the LIST COPYPOOL(*cpname*) command.

You can obtain information about whether the volume resides in a copy pool by using the following command:

```
LIST DVOL
```

You can obtain information about whether the dump class associated with the copy pool is required or optional by using the following command:

```
LIST DUMPCLASS
```

You can obtain information about the host holding a copy pool resource by using the following command:

```
LIST HOST
```

When you use the HOST parameter, DFSMSHsm lists the host holding a copy pool resource. If subparameter RESET is specified, DFSMSHsm resets associated serialization fields.

Obtaining dump class information

You can obtain information about either all dump classes or an individual dump class. The forms of the request for dump class information are:

```
LIST DUMPCLASS
```

```
LIST DUMPCLASS(class)
```

Obtaining dump volume information

You can request information about all dump volumes or specific dump volumes. In addition, you can select the volumes with specific characteristics. The forms of the requests for information about dump volumes are:

```

LIST DUMPVOLUME

LIST DUMPVOLUME -
  SELECT(AVAILABLE)

LIST DUMPVOLUME -
  SELECT(UNAVAILABLE)

LIST DUMPVOLUME -
  SELECT(EXPIRED)

LIST DUMPVOLUME -
  SELECT(UNEXPIRED)

LIST DUMPVOLUME -
  SELECT(NORETENTIONLIMIT)

LIST DUMPVOLUME -
  SELECT(DUMPCCLASS(class))

LIST DUMPVOLUME(volser)

```

The first form of the request obtains information about all the dump volumes in the system. The next six forms of the request obtain information about all dump volumes in the system that meet certain conditions. The eighth form obtains information about all dump volumes in a group of volumes made from the same DASD volume from one dump operation. The variable *volser* can be any of the dump volumes in the group.

You can determine the data sets that were on a particular volume when the volume was dumped. The commands to do this are:

```

LIST ML1(volser) BCDS ALLDUMPS

LIST PRIMARY(volser) BCDS ALLDUMPS

LIST DUMPVOLUME(volser) -
  CONTENTS

```

The first two commands give lists of the volumes to which the source volume has been dumped and the date of the dump. The third command lists the contents of the source volume when it has been dumped. You can specify any one of the dump volumes in the set of dump volumes for *volser* for a particular date.

If a volume is processed by both full-volume dump and incremental backup, DFSMSHsm maintains VTOC copy data sets for both operations. To determine the most up-to-date copy, issue the following command:

```

LIST PRIMARYVOLUME(volser) BCDS

```

If the full-volume dump is more recent than the backup, use the three preceding dump-related commands to obtain the latest VTOC copy. If the backup was more recent than the dump, use the LIST command for BACKUPCONTENTS as indicated in [“Obtaining DFSMSHsm-managed volume information” on page 568](#).

Obtaining DFSMSHsm host serialization information

As DFSMSHsm processes volumes and data sets, it obtains control of certain control data set records. While DFSMSHsm in one z/OS image has control of a control data set record, other hosts in the same or different z/OS image cannot use that control data set record. To determine which control data set records that a particular DFSMSHsm host has control of, issue the following command:

```

LIST HOST(hostid)

```

If one DFSMSHsm host in a multiple DFSMSHsm-host environment fails and you want it to relinquish control of all CDS records, issue the following command:

```

LIST HOST(hostid) RESET

```

LIST HOST and LIST HOST RESET also list the host holding a copy pool resource. When RESET is specified, associated serialization fields are reset.

Obtaining lists of backup and dump parameters and backup volume serial numbers

Note: In the following cases, full backup tapes are not listed after a FIXCDS REFRESH function has been performed.

To obtain a list of all backup and dump parameters and all non-full tape backup volumes and DASD backup volumes, issue the following command:

```
QUERY BACKUP(ALL)
```

To obtain a list of all backup parameters and all non-full daily tape backup volumes and DASD daily backup volumes, issue the following command:

```
QUERY BACKUP(DAILY)
```

To obtain a list of all backup parameters, all non-full daily tape backup volumes, and DASD daily backup volumes assigned to a particular day in the backup cycle, issue the following command:

```
QUERY BACKUP(DAILY(day))
```

To obtain a list of all backup parameters and all non-full spill tape backup volumes and DASD spill backup volumes, issue the following command:

```
QUERY BACKUP(SPILL)
```

To obtain a list of all backup parameters and all non-full tape unassigned backup volumes and DASD unassigned backup volumes, issue the following command:

```
QUERY BACKUP(UNASSIGNED)
```

Running new reports with the DFSMSrmm Report Generator

DFSMSHsm reports can be run with the DFSMSrmm Report Generator. The reports are based on FSR and WWFSR (SMF) data and DFSMSHsm control data set data obtained by DCOLLECT.

For HSM FSR records

```
For HSM FSR Records
  . ARCGAB01 ABARS ABACKUP Statistics
  . ARCGAR01 ABARS ARECOVER Statistics
  . ARCGS00A Statistics for Automatic Space Management
  . ARCGS001 Statistics for DFSMSHsm
  . ARCGS002 Statistics for Backup
  . ARCGS003 Statistics for Migration
  . ARCGS004 Statistics for Recall
  . ARCGS005 Statistics for Recovery
  . ARCGS006 Statistics for Volume Dump
  . ARCGS007 Statistics for Restore from Dump Copy
  . ARCGS008 Statistics for FRBACKUP
  . ARCGS009 Statistics for FRRECOVER
  . ARCGS010 DFSMSHsm Thrashing Report
  . ARCGS011 Statistics for Class Transition
```

Obtaining information about migration and DFSMSHsm-managed volumes

To obtain information about migration and DFSMSHsm-managed volumes, you can select the following types of information:

- All migration volumes
- ML1 volumes
- All ML2 volumes
- ML2 DASD volumes
- ML2 tape volumes
- All migration and DFSMSHsm-managed volumes
- A particular migration or DFSMSHsm-managed volume

You also can select whether the information is to be taken from the backup control data set, the migration control data set, or both, and whether to select only empty volumes.

Again, because of the many possible forms for this request, only a sample is presented.

To request information about all migration volumes from both the migration control data set and the backup control data set, issue the following command:

```
LIST MIGRATIONVOLUME BOTH
```

To request information about all ML1 volumes from the backup control data set, issue the following command:

```
LIST MIGRATIONLEVEL1 BACKUPCONTROLDATASET
```

To request information about empty ML2 volumes from the migration control data set, issue the following command. You can use this command to obtain a list of tapes that can be inserted in the cartridge loader:

```
LIST MIGRATIONLEVEL2(TAPE) -  
MIGRATIONCONTROLDATASET SELECT(EMPTY)
```

To request information about ML2 DASD volumes from both control data sets, issue the following command:

```
LIST MIGRATIONLEVEL2(DASD) BOTH
```

To obtain information about ML2 tape volumes from the migration control data set, issue the following command:

```
LIST MIGRATIONLEVEL2(TAPE) MIGRATIONCONTROLDATASET
```

To obtain information about all DFSMSHsm-managed and migration volumes from both control data sets, issue the following command:

```
LIST VOLUME BOTH
```

To obtain information about a particular volume from the backup control data set, issue the following command:

```
LIST VOLUME(volser) BACKUPCONTROLDATASET
```

Obtaining DFSMSHsm-managed volume information

You can also obtain information about the contents of a particular level 0 volume when the latest or next-to-latest incremental backup was performed. The information can be obtained from the backup control data set, the migration control data set, or both. For information about the incremental backup, you can select information about multiple-volume or VSAM data sets.

To obtain information about the contents of a level 0 volume when the latest incremental backup was performed, issue the following command:

```
LIST PRIMARYVOLUME(volser) BCDS BACKUPCONTENTS(0)
```

If a volume is processed by both full-volume dump and incremental backup, DFSMSHsm maintains VTOC copy data sets for both operations. To determine the most up-to-date copy, issue the following command:

```
LIST PRIMARYVOLUME(volser) BCDS
```

If the backup was more recent than the full-volume dump, use the preceding backup-related command to obtain the latest VTOC copy. If the dump was more recent than the backup, issue the following command:

```
LIST DUMPVOLUME(volser) CONTENTS
```

To obtain information about a DFSMSHsm-managed volume that is contained in the migration control data set, issue the following command:

```
LIST PRIMARYVOLUME(volser) MIGRATIONCONTROLDATASET
```

To obtain information about the non-VSAM multiple-volume data sets that were on a level 0 volume at the next-to-latest incremental backup, issue the following command:

```
LIST PRIMARYVOLUME(volser) BCDS BACKUPCONTENTS(1) -  
  SELECT(MULTIPLEVOLUME)
```

To obtain information about the VSAM data sets that were on a level 0 volume at the latest incremental backup, issue the following command:

```
LIST PRIMARYVOLUME(volser) BCDS BACKUPCONTENTS(0) -  
SELECT(VSAM)
```

Obtaining tape volume information

You can obtain information about all tape volumes or specific tape volumes. In addition, you can select the volumes with specific characteristics.

To obtain a list of tape volume information from an OCDS, where you *do not* specify a volume serial number and where you *do not* want a list of data set information for the volume, issue the following command:

```
LIST TAPETABLEOFCONTENTS
```

To obtain a list of tape volume information from an OCDS, where you specify the volume serial number and you *do not* want a list of data set information for the volume, issue the following command:

```
LIST TAPETABLEOFCONTENTS(volser) NODATASETINFORMATION
```

To obtain a list of tape volume information from an OCDS, where you specify the volume serial number and you *do* want a list of data set information for the volume, issue the following command:

```
LIST TAPETABLEOFCONTENTS(volser) DATASETINFORMATION
```

To obtain a list of tape volume information from an OCDS, where you *do not* specify a volume serial number and you want a list of volume entries for all ML1 volumes, issue the following command:

```
LIST TAPETABLEOFCONTENTS SELECT(MIGRATIONLEVEL1)
```

To obtain a list of tape volume information from an OCDS, where you *do not* specify a volume serial number and you want a list of volume entries for all ML2 volumes, issue the following command:

```
LIST TAPETABLEOFCONTENTS SELECT(MIGRATIONLEVEL2)
```

To obtain a list of ML2 partial tape volumes that are currently associated for output by specific migration or recycle tasks, issue the following command:

```
LIST TAPETABLEOFCONTENTS SELECT(ASSOCIATED)
```

To obtain a list of ML2 partial tape volumes that are available for an initial allocation, and are not currently associated for output by any migration or recycle task, issue the following command:

```
LIST TAPETABLEOFCONTENTS SELECT(NOTASSOCIATED)
```

To obtain a list of all ML2 volumes taken away from another function because RECALL needed a data set on the volume, issue the following command:

```
LIST TAPETABLEOFCONTENTS SELECT(RECALLTAKEAWAY)
```

To obtain a list of tape volume information from an OCDS, where you *do not* specify a volume serial number and you want a list of backup volumes, issue the following command:

```
LIST TAPETABLEOFCONTENTS SELECT(BACKUP)
```

To obtain a list of tape volume information from an OCDS, where you *do not* specify a volume serial number and you want a list of both migration and backup volumes, issue the following command:

```
LIST TAPETABLEOFCONTENTS SELECT(BOTH)
```

To obtain a list of tape volume information from an OCDS, where you *do not* specify a volume serial number and you want a list of tape volumes marked full that do not have alternate tape volumes, issue the following command:

```
LIST TAPETABLEOFCONTENTS SELECT(NOALTERNATEVOLUME)
```

To obtain a list of tape volume information from an OCDS, where you *do not* specify a volume serial number and you want a list of tape volumes that have failed recycle, issue the following command:

```
LIST TAPETABLEOFCONTENTS SELECT(FAILEDRECYCLE)
```

To obtain a list of tape volume information from an OCDS, where you *do not* specify a volume serial number and you want a list of tape volumes that have a mismatch between the OCDS TTOC record and the actual tape media, issue the following command:

```
LIST TAPETABLEOFCONTENTS SELECT(FAILEDCREATE)
```

To obtain a list of tape volume information showing volumes that are marked as disaster alternate volumes, issue the following command:

```
LIST TAPETABLEOFCONTENTS SELECT(DISASTERALTERNATEVOLUMES)
```

To obtain a list of tape volume information showing volumes that are capable of being resumed after Audit Mediacontrols was interrupted, issue the following command:

```
LIST TAPETABLEOFCONTENTS SELECT(RESUMEAUDIT)
```

Obtaining user authorization information

To determine the level of DFSMSHsm authorization of a particular user ID, issue the following command:

```
LIST USER(userid)
```

Determining which tape dump volumes are available for output during dump processing

To determine which tape volumes are available for volume dump processing, issue the following command:

```
LIST DUMPVOLUME SELECT(AVAILABLE)
```

This command lists each dump volume that is available for use for dump output.

To find out what tape volumes are available for a particular dump class for volume dump processing, issue the following command:

```
LIST DUMPVOLUME SELECT(AVAILABLE DUMPCCLASS(class))
```

Obtaining information about the DFSMSHsm address space

You can use the DFSMSHsm QUERY command to display the status of DFSMSHsm parameters, statistics, and pending requests. The output of the QUERY command is messages returned to your terminal and written in the DFSMSHsm log.

To obtain a list of parameters that apply to aggregate backup and recovery, issue the following command:

```
QUERY ABARS
```

To obtain a list about what functions are running in DFSMSHsm, issue the following command:

```
QUERY ACTIVE
```

This list includes the following types of information:

- The status of the data set backup function
- The status of variables that affect the placement and selection of requests on the common recall queue
- The processing status of FRBACKUP and FRRECOV COPYPOOL commands

To obtain the Task Control Block addresses of active DFSMSHsm data movement tasks, issue the following command:

```
QUERY ACTIVE(TCBADDRESS)
```

TCBADDRESS is an optional subparameter of ACTIVE requesting only messages directly related to data movement activities be listed, along with extra information allowing cancellation of the active task. For ABARS the Secondary Address Space Index is returned when QUERY ACTIVE(TCBADDRESS) is issued.

To obtain a list of volumes that are defined for aggregate recovery, issue the following command:

```
QUERY ARPPOOL
```

To display the progress of DFSMSHsm automatic functions, issue the following command:

```
QUERY AUTOPROGRESS
```

To obtain a list of backup and dump parameters, including new data set backup parameters, issue the following command:

```
QUERY BACKUP
```

To obtain a list of all backup and dump parameters and all backup volumes, issue the following command:

```
QUERY BACKUP(ALL)
```

To obtain a list of all backup parameters and all daily backup volumes, issue the following command:

```
QUERY BACKUP(DAILY)
```

To obtain a list of all backup parameters and daily backup volumes assigned to a particular day in the backup cycle, issue the following command:

```
QUERY BACKUP(DAILY(day))
```

To obtain a list of all spill parameters and all spill backup volumes, issue the following command:

```
QUERY BACKUP(SPILL)
```

To obtain a list of backup parameters and all unassigned backup volumes, issue the following command:

```
QUERY BACKUP(UNASSIGNED)
```

To obtain a list of parameters from the SETSYS command that are governing the backup of the control data sets, issue the following command:

```
QUERY CDSVERSIONBACKUP
```

To determine how full the DFSMSshm coupling facility structures are, issue the following command:

```
QUERY COMMONQUEUE
```

To determine all outstanding recall requests in the CRQ, issue the following command:

```
QUERY COMMONQUEUE(RECALL)
```

To display space-allocated-and-used statistics for the control data sets, issue the following command:

```
QUERY CONTROLDATASETS
```

To determine if any of the volumes defined to a copy pool are in an active FlashCopy relationship, issue the following command:

```
QUERY COPYPOOL(cpname)
```

For FlashCopy version 2, the source volume may be in more than one relationship. This command can also be used to determine if another backup version can be created when using FlashCopy version 1, or if a recover can be performed. This command works only on FlashCopy relationships.

To display the common service area limits that were specified with the SETSYS command, issue the following command:

```
QUERY CSALIMITS
```

To display a list of requests associated with a specific data set, issue the following command:

```
QUERY DATASETNAME(dsname)
```

Note: This command returns information only for those requests that were initiated by the host on which the QUERY DATASETNAME command is issued.

To display information for active DFSMSshm address spaces in a single z/OS image, issue the following command:

```
QUERY IMAGE
```

To display the key ranges and the associated ML2 volumes, issue the following command:

```
QUERY MIGRATIONLEVEL2
```

Note: This command also displays the volume serial numbers of the tape ML2 volumes that are currently selected as the target volumes for data set and volume migration and secondary space management.

To display a list of the recall pools, issue the following command:

```
QUERY POOL
```

To display a list of requests associated with a specific request number, issue the following command:

```
QUERY REQUEST(reqnum)
```

Note: This command returns information only for those requests that were initiated by the host on which the QUERY REQUEST command is issued.

To display a list of data set levels that are prevented from migrating by the SETMIG command, issue the following command:

```
QUERY RETAIN
```

To display the parameters that you set with the SETSYS command, issue the following command.

```
QUERY SETSYS
```

To display the space statistics on specified primary and ML1 volumes, issue the following command:

```
QUERY SPACE(volser1,volser2,...,volsern)
```

Note: The QUERY SPACE command is not valid for SMS-managed volumes.

To display the parameters you specified in the PROC statement of the DFSMSHsm startup procedure, issue the following command:

```
QUERY STARTUP
```

To display selected DFSMSHsm statistics that have accumulated during the day, issue the following command:

```
QUERY STATISTICS
```

To display the TRAP requests you have established, issue the following command:

```
QUERY TRAPS
```

To display a list of requests associated with a specific user ID, issue the following command:

```
QUERY USER(userid)
```

Note: This command returns information only for those requests that were initiated by the host on which the QUERY USER command is issued.

To display the current volume pools, issue the following command:

```
QUERY VOLUMEPOOL
```

To display requests for DFSMSHsm services that are waiting to be processed, including information on the number of requests waiting in the common recall queue, issue the following command:

```
QUERY WAITING
```

Note: This command returns information only for those requests that were initiated by the host on which the QUERY WAITING command is issued.

Determining which tape volumes are available for output

The QUERY command is also used to determine tape volumes that are to be requested for backup and migration if volumes are available for selection.

Determining which tape backup volumes are available for output

To find out which tape backup volumes are available for volume backup processing, follow this procedure:

1. Issue a QUERY BACKUP command to determine the current day in the backup cycle.
2. Issue a QUERY BACKUP(DAILY(x)) to find out what tapes are assigned to day x in the backup cycle. Replace x with the current day in the backup cycle.
3. Look at the volume serial numbers of the daily backup volumes assigned to the current day in the backup cycle. The first tape daily backup volume shown with an 'A' for available in the ARC0164I message is the first volume that DFSMSHsm considers to allocate when it selects a tape backup volume.
4. To determine which tape backup volumes are empty and available for subsequent volume selection (if you specified SELECTVOLUME(SPECIFIC) on the SETSYS command), issue the following command:

```
LIST BACKUPVOLUME SELECT(EMPTY)
```

You should be aware that additional tapes can be made available by performing the RECYCLE, EXPIREBV, or DELVOL commands, and by creating new backup tapes, which causes existing backup tapes to be invalidated.

Determining which tape migration level 2 volumes are available for output

To find out which tape ML2 volumes are available for migration processing, follow this procedure:

1. Issue a QUERY MIGRATIONLEVEL2 command.
2. Look at the volume serial numbers of the ML2 volumes. The ARC0227I message shows the volser of the tapes currently associated with the respective data set, volume, and secondary space management tasks. These are the tapes DFSMSHsm attempts to allocate when the tasks start. If you want to know what other ML2 tapes exist and might be used in place of these, issue LIST TTOC SELECT(NOTASSOCIATED).
3. Issue one of the following commands to determine which tape ML2 volumes are empty and available for subsequent volume selection (if you specified SELECTVOLUME(SPECIFIC) on the SETSYS command):

```
LIST MIGRATIONLEVEL2(TAPE) SELECT(EMPTY)
```

```
LIST TTOC SELECT(ML2 EMPTY)
```

Obtaining statistical information about DFSMSHsm operations

You can use the REPORT command to obtain statistics about DFSMSHsm's operations. You can report the statistics on either a daily basis for all volumes or a volume basis for specific volumes. You can restrict the scope and format of the statistics reported to the backup, deletion of data sets or UNIX files, migration, recall, recovery, recycle, and spill functions. You can restrict the beginning date of the statistics or the dates between which the statistics are reported. You can also restrict the report to a summary of the statistics.

To report daily statistics about data sets and UNIX files that are backed up and to send the report to a DASD data set, issue the following command:

```
REPORT DAILY FUNCTION(BACKUP) OUTDATASET(dsname)
```

To obtain daily statistics about all functions, issue the following command:

```
REPORT DAILY FUNCTION
```

The report is sent to the SYSOUT class specified with the SETSYS command.

To obtain volume statistics for all volumes and to send the report to SYSOUT class A, issue the following command. This report also includes the total number of times that a fast replication backup was

successfully created for a volume and the number of failed attempts for the volume. Recover statistics that are associated with the fast replication operation are also reported.

```
REPORT VOLUME FUNCTION SYSOUT(A)
```

To obtain volume statistics for one volume about migration between two dates and delete the statistics records after the report is printed, issue the following command:

```
REPORT VOLUME(volser FUNCTION(MIGRATION) -  
FROMDATE(date) TODATE(date) DELETE
```

To obtain statistics for UNIX files, the VOLSER, %UNIX%, can be specified on the VOLUME parameter. Because UNIX files are not allocated on a DASD volume, DFSMSHsm uses %UNIX% as the volume indicator when backing up a UNIX file. Only one %UNIX% may be specified on the command.

You can issue the following command:

```
REPORT VOLUME(%UNIX% FUNCTION(BACKUP))
```

After you have formatted a report, you can free the space allocated for the statistics that made up the report. To clean up unneeded report statistics, do one of the following:

- Issue the DELETE parameter of the REPORT command. DFSMSHsm deletes the statistics records (used as input for the report) after the REPORT command finishes its processing. For example, if you allocate one additional cylinder for the accumulation of statistics and control records for one week, issue the DELETE parameter of the REPORT command once a week.
- Specify how often DFSMSHsm deletes MCDS data set records and statistics records with the MIGRATIONCLEANUPDAYS(*recalldays statdays*) parameter of the SETSYS command. The cleanup of these records occurs as a part of secondary space management.

Related reading

- For an alternate method of gathering information about DFSMSHsm activities from SMF records, see [“Running new reports with report generator” on page 575](#) and [z/OS DFSMSrmm Reporting](#).
- For complete syntax of the report command, see Chapter 63, [“REPORT Command: Requesting reports based on DFSMSHsm statistics records,” on page 1043](#).

Running new reports with report generator

DFSMSHsm reports can be run with the DFSMSrmm Report Generator. The reports are based on FSR and WWFSR (SMF) data and DFSMSHsm control data set data that is obtained by DCOLLECT.

For HSM FSR Records

- ARCGAB01 ABARS ABACKUP Statistics
- ARCGAR01 ABARS ARECOVER Statistics
- ARCGS00A Statistics for Automatic Space Management
- ARCGS001 Statistics for DFSMSHsm
- ARCGS002 Statistics for Backup
- ARCGS003 Statistics for Migration
- ARCGS004 Statistics for Recall
- ARCGS005 Statistics for Recovery
- ARCGS006 Statistics for Volume Dump
- ARCGS007 Statistics for Restore from Dump Copy
- ARCGS008 Statistics for FRBACKUP

- ARCGS009 Statistics for FRRECOVER
- ARCGS010 DFSMSHsm Thrashing Report
- ARCGS011 Statistics for Class Transition

For DCOLLECT Records

- ARCGDB01 DCOLLECT BACKUP DATA
- ARCGDD01 DCOLLECT DASD CAPACITY PLANNING
- ARCGDM01 DCOLLECT MIGRATION DATA
- ARCGDT01 DCOLLECT TAPE CAPACITY PLANNING

The reporting records are:

ARCFSR2 (SYS1.MACLIB)

Reformatted from ARCFSR for reporting records with DFSMSrmm Report Generator. Maps FSR DS records for DFSMSHsm in SMF form. Skeleton is ARCGFSRC.

ARCWFSR2 (SYS1.MACLIB)

Reformatted from ARCWWFSR for reporting records with DFSMSrmm Report Generator. Maps WWFSR for DFSMSHsm in SMF form. Skeleton is ARCGWFSC.

ARCGFSRC/ARCGWFSC

Supplied skeletons used by the generator to convert FSR and WWFSR records to FSR2 and WWFSR2 records respectively. Shipped in SYS1.DGTSLIB.

Note: Report generator cannot process the ARCFSR and ARCWWFSR records. ARCFSR and ARCWWFSR records are converted to ARCFSR2 and ARCWWFSR2, respectively, using ARCGFSRC and ARCGWFSC while running DFSMSrmm report generator.

ARCUTILP (SYS1.MACLIB)

It is much easier to create and manage reports, within the DFSMSrmm Report Generator, when the TYPE keyword is used to specify a single record type such as TYPE=M. Otherwise, all records are mapped. ARCUTILP provides keywords to map each structure. TYPE=ALL|M|B|C|T is as follows:

- ALL = For all structures
- M = Migrate
- B = Backup
- C = DASD Capacity Planning
- T = Tape Capacity Planning

No conversion is needed for ARCUTILP records as each type is uniquely written.

Prior to creating DFSMSHsm reports by using the DFSMSrmm Report Generator, DFSMSHsm FSR and WWFSR records need to be collected. They are written to SMF data sets by DFSMSHsm. Following is a JCL sample that collects this data from SMF. In this case SYS1.MANX and SYS1.MANY are the output ds from SMF, but this can vary depending upon setup.

The DFSMSrmm Report Generator includes sample report types for DFSMSHsm FSR and DCOLLECT reporting. When DFSMSrmm Report Generator searches for sample report definitions in the installation (SAMPLIB) library it looks for DFSMSHsm sample members with the prefixes ARCG and EDGG.

This sample JCL describes collecting SMF records containing FSR and WWFSR Records for use in running DFSMSrmm Report Generator.

For more information about EFASMFDP and IFASMFDL see [*z/OS MVS System Management Facilities \(SMF\)*](#).

SMF dump sample JCL:

```

//SMFDUMP JOB ,
//* USE D SMF TO SEE DS STATUS
//* USE D SMF,0 TO SEE SMF SETTINGS
//* USE SWITCH SMF TO SWAP THE ACTIVE AND INACTIVE DS
//* NOTE OPTIONS = DUMP | CLEAR | ALL
//* ONLY INACTIVE DS CAN BE CLEARED
//* DEFAULT ALL = DUMP AND CLEAR
//DUMPSMF EXEC PGM=IFASMFDP,REGION=512K
//INDD0 DD DSN=SYS1.MANX,DISP=SHR
//INDD1 DD DSN=SYS1.MANY,DISP=SHR
//DUMPOUT DD DSN=DFHSM.EXTRACT,UNIT=SYSALLDA,
// DISP=(NEW,CATLG),SPACE=(CYL,(50,5),RLSE)
//SYSPRINT DD SYSOUT=*
//SYSIN DD *
INDD(INDD0,OPTIONS(DUMP))
INDD(INDD1,OPTIONS(DUMP))
OUTDD(DUMPOUT,TYPE(xxx))
/*

```

Where xxx is the DFSMSHsm SMF type you used. Refer to the startup procedure for DFSMSHsm or issue QUERY SETSYS.

For more information about IFASMF DL and IFASMF DP see Dumping SMF log streams - IFASMF DL and Dumping SMF log streams - IFASMF DP in Using the SMF Dump Programs in [z/OS MVS System Management Facilities \(SMF\)](#).

This is sample JCL for collecting DCOLLECT records for possible use when running DFSMSrmm Report Generator.

The DCOLLECT job step can be generated within the DFSMSHsm Report Generator by selecting **Create report data...Y (Y/N)** in the JCL generation panel (EDGPG022).

DCOLLECT sample JCL:

```

//DCOLLECT JOB ,
//STEP1 EXEC PGM=IDCAMS
//OUTDS DD DSN=DFHSM.DCOLLECT.DATA,DISP=(NEW,CATLG),
// UNIT=SYSALLDA,
// DCB=(LRECL=644,BLKSIZE=0,RECFM=VB),SPACE=(CYL,(50,2)),
// AVGREC=K
//SYSPRINT DD SYSOUT=A
//MCDS DD DSN=DFHSM.MCDS,DISP=SHR
//BCDS DD DSN=DFHSM.BCDS,DISP=SHR
//SYSIN DD *
DCOLLECT -
OUTFILE(OUTDS) -
MIGRATEDATA -
BACKUPDATA -
CAPD
/*

```

To start the DFSMSrmm report generator use option, G - Report Generation, on the ISMF Storage Administrator Primary Panel.

Set up need only be done once for a given user.

Select 0-Options. This only needs to be done once.

Panel Help

DFSMSrmm Report Generator

Option ==>

```

0  OPTIONS          - Specify dialog options and defaults
1  REPORT           - Work with reports
2  REPORT TYPE      - Work with report types
3  REPORTING TOOL    - Work with reporting tools
X  EXIT             - Exit DFSMSrmm dialog
Enter selected option or END command. For more info., enter HELP or PF1.

```

The options menu has three selections:

- USER - Sets up basics and must be done by all users at least one time.

- SORT - Specifies sort information for DFSMSrmm report users.
- REPORT - Specifies Report options.

See Figure 8. Selecting the Options Option on the DFSMSrmm Dialog Options Menu Panel in Chapter 2, Using the DFSMSrmm Report Generator in [z/OS DFSMSrmm Reporting](#) for specifying libraries for the report generator.

At a minimum the JCL job card should be added. This will be used by all jobs submitted by Report Generator. If the job card is not supplied, the JCL generation uses the ISPF job card if it exists. If not, it generates a default job card.

```

X  EXIT            - Exit DFSMSrmm dialog
Enter selected option or END command. For more info., enter HELP or PF1.
```

Notice the number of columns between each heading is set on the Reporting Tool Panel.

Report Types are provided by DFSMSShsm as the outline for creating reports.

Table 52. Report Types Supplied by DFSMSHsm

Name	Description
ARCGWFSR	DFSMSHsm ABARS Report
ARCGDBCK	DFSMSHsm DCOLLECT BACKUP
ARCGDDSD	DFSMSHsm DCOLLECT DASD CAP
ARCGDMIG	DFSMSHsm DCOLLECT MIGRATION
ARCGDTAP	DFSMSHsm DCOLLECT TAPE CAP
ARCGFSR2	DFSMSHsm FSR-SMF Records

Report Type has predefined types but the user may modify and add their own, however, it is not necessary since sample reports are also provided.

Panel Help

DFSMSImm Report Generator

Option ==>

```

0  OPTIONS          - Specify dialog options and defaults
1  REPORT           - Work with reports
2  REPORT TYPE      - Work with report types

After selecting generate report the following panel variables should be entered:

input data set

The set of records for the report that must be made up of ARCF SR2, ARCWF SR2, or ARCUTILP (DCOLLECT). These records are previously converted except ARCUTILP records which do not need to be converted.

date format

YYYYDDD is specific to DFSMSHsm FSR records.

create report data

When Y tells Report Generator that Skeleton_Variable_2 has source data ARCF SR or ARCWWFSR that must be converted to ARCF SR2 or ARCWF SR2. If this is the case, the Skeleton_Variable_1 must provide the FSR record type as defined in DFSMSHsm's command SETSYS SMF(xx). This step will also create the temporary data set named in **input data set**. This may be changed to a non-temporary data set by modifying the generated JCL. Using a non-temporary data set allows preservation of the input data set for other reports.

Panel Help

DFSMSrmm Report Generation - ARCGS001

Command ==>

Enter or change the skeleton variables for the generated JCL:

Input data set 'DFHSM.EXTRACT.REFORMAT'

Date format YYYYDDD

(American, European, Iso, Julian, or free form)

Required if you use variable dates (&TODAY;) in your selection criteria.

Create report data . . N (Y/N)

Choose Y if you want an extract step included into your generated JCL.

Additional skeleton variables, if an extract step is included:

Skeleton Variable_1 . . X'FF'

Skeleton Variable_2 . . DFHSM.EXTRACT

Skeleton Variable_3 . .

The skeleton selection depends on the reporting macro . . . : **ARCF SR2**
and macro keyword . . :

Enter END command to start the report generation or CANCEL

The J line command tell Report Generator to display the JCL for editing and submission.

The report may be run by issuing SUB after the line command J displays the JCL in edit or from the Report Generator JCL library as defined in the set up panels. The report may be viewed in the output of the JCL or in an output data set if one was defined.

A thrashing report (ARCGS010) is created from the DFSMSrmm Report Definition (ARCGS004) panel to demonstrate the simplicity of creating new reports from the supplied reports.

Add new selection criteria by entering the S line command by FSR2AGE.

Panel Help

	14		FSR2RC	RC (hex)	8	4	B
*			FSR2TYPE	FUNCTION TYPE - Use browse (M) macro	36	1	B

In this example we are adding thrashing criteria, which in this case is two days between migrate and recall. The report job will then include any records indicating that recall occurred within two days of migration. Each installation should define the number of days between migration and recall which constitute thrashing.

DFSMSrmm Report Criteria - ARCGS004 Row 1 to 4 of 4
Command ===> Scroll ===> CSR

Report title : Statistics for Recall

Use END to save changes or CANCEL

The following line commands are valid: B,D,N,P,R,T, and I (for details)

Comparison operators: EQ =, NE <>, GT >, GE >=, LT <, LE <=, IN, BW, SE, SN

Conjunction: AND, OR, AND(,)AND

S	Field name	Op	Compare value(s)	Conj	Len	Typ
	FSR2DATR	BW	&TODAY; - 7 Days,&TODAY;	AND(8	C
	FSR2TYPE	EQ	X'04'	OR	1	B
	FSR2TYPE	EQ	X'05')AND	1	B
	FSR2AGE	LE	X'0002'		2	B

Note:

1. Date criteria needs adjustment

Sample reports all have a relative date specified for reporting. This date needs to be changed prior to generating reports.

2. Reports are provided as the foundation for creating user defined reports.

Sample report definitions and report types are provided as the foundation for creating your own installation and user-defined reports.

3. DCOLLECT reports require IDCAMS DCOLLECT be run first to generate source data

The DCOLLECT job step is generated as part of the J option to generate JCL - if the user specifies

Create report data . . Y.

Reporting on DFSMSHsm FSR and WWFSR records requires that you use the ARCFSR2 and ARCWFSR2 macros in the report generator with converted SMF data before use or select **Create report data . . Y** and use the generator to create the JCL to convert the records inline.

For more details about the DFSMSrmm Report Generator see Chapter 2, Using the DFSMSrmm Report Generator in *z/OS DFSMSrmm Reporting*.

Using the problem determination aid to trace DFSMSHsm processing

To help you gather information about DFSMSHsm processing, DFSMSHsm provides the problem determination aid (PDA). This aid can be used for both primary and secondary address spaces. It gathers diagnostic information at specific internal module points, records the data in a wraparound table in storage, and writes the data to data sets on DASD. You use the diagnostic information to provide data to your service representative should a problem develop with DFSMSHsm. The purpose of the PDA is to gather sufficient information during DFSMSHsm execution to enable subsequent analysis to pinpoint module flow and resource usage related to any given problem.

Note: If the DFSMSHsm PDOX data set is on a non-SMS volume that will be backed up, use the `ALTERDS datasetname VERSIONS(0)` command to prevent DFSMSHsm from backing it up.

If the PDOX data set is on an SMS volume that will be backed up, assign it to an SMS management class that does not allow backup copies.

Specifying to DFSMSHsm to use the PDA

In order for the PDA to trace DFSMSHsm processing, it must not be disabled in the ARCCMDxx member referred to in the startup member. If you disable it at that time, no space is set aside for the circular file in storage, and the DASD data sets are not opened. The PDA is controlled by the following command:

```
SETSYS PDA
```

The default (if you do not specify the SETSYS command with the PDA parameter in the ARCCMDxx member) is PDA(ON).

If you do not want to use the PDA, add the following command to the ARCCMDxx member:

```
SETSYS PDA(NONE)
```

If you specify PDA(NONE), no space is set aside for the circular file in storage, and the DASD data sets are not opened.

After the PDA is started, you can turn it off and on during DFSMSHsm operation. To turn the PDA off, issue the following command:

```
SETSYS PDA(OFF)
```

The PDA stops recording the diagnostic data, but the circular file space remains in storage, and the DASD data sets remain open.

To resume use of the PDA, issue the following command:

```
SETSYS PDA(ON)
```

Using the TRAP command to obtain information about conditions in the system when an error occurs

The TRAP command allows you to determine conditions in the system if an error occurs. You can test for all error codes in all modules, for a specific error code in all modules, for all error codes in a specific module, or for a specific error code in a specific module. When an error occurs, you can have DFSMSHsm abnormally end, log the error, or take a SNAP dump. You can control whether the abnormal end or SNAP dump occurs always, never, or once.

Note: TRAP is not supported in the secondary address space.

To trap all error codes in all modules and cause an abnormal end for every error, issue the following command:

```
TRAP ALL ABEND(ALWAYS)
```

To trap all error codes in all modules and cause an abnormal end once, issue the following command:

```
TRAP ALL ABEND(ONCE)
```

To trap a specific error code in a specific module and log the error, issue the following command:

```
TRAP module errorcode LOG
```

When the error indicated by *errorcode* occurs in the module indicated by *module*, an entry is written in the DFSMSHsm log.

To cause a SNAP dump every time a specific error code occurs in a specific module, issue the following command:

```
TRAP module errorcode SNAP(ALWAYS)
```

Related reading

For more information about the TRAP command, see [z/OS DFSMSHsm Diagnosis](#).

Using DEBUG to determine the results of DFSMSHsm processing without moving data sets

When you first set up DFSMSHsm or when you make major changes to the data set selection parameters you have established for it, you may want to know which data sets are selected during volume space management, backup and backup expiration before you allow it to move any data sets. To allow this freedom to test, DFSMSHsm provides a DEBUG mode of operation. To run in DEBUG mode, put the following command in the ARCCMDxx member for the DFSMSHsm host on which you want to perform the testing:

```
SETSYS DEBUG
```

The DEBUG parameter of the SETSYS command permits DFSMSHsm to exercise all of its volume backup, dump, and migration functions; but instead of moving or deleting data sets, it merely writes messages to the activity logs to indicate what data set movement or deletion would have occurred. For example, if you are already using DFSMSHsm and want to test the effects of the EXPIREBV command, you could issue the SETSYS DEBUG command followed by the EXPIREBV command. DFSMSHsm would then write messages to the activity logs, indicating which of your backup versions would have been deleted by the EXPIREBV command.

Issuing the ABACKUP and ARECOVER commands while SETSYS DEBUG is in effect causes the commands to be processed as if the VERIFY parameter were in effect.

If DFSMSHsm is stopped when it is running in DEBUG mode, any command requests that have not been processed are lost and are not processed when DFSMSHsm is restarted. See [“Stopping DFSMSHsm” on page 595](#) for a discussion of restarting processing when DFSMSHsm is restarted.

The FREQUENCY parameter of the DEFINE DUMPCCLASS command is calculated from the last date that the level 0 volume was dumped while DFSMSHsm was not in DEBUG mode. This date is not updated when DFSMSHsm is running in DEBUG mode because it would prevent volume dumps from processing on schedule when NODEBUG is specified. In DEBUG mode, if the date last dumped is zeros, the FREQUENCY value is not calculated, the level 0 volume is eligible to be dumped, and the date last dumped is not

updated. To cancel the effect of the DEBUG parameter of the SETSYS command, you can issue the following command:

```
SETSYS NODEBUG
```

However, if the DEBUG parameter is specified in the ARCCMDxx member, you may find it more convenient just to remove the SETSYS DEBUG command from the ARCCMDxx member.

Chapter 15. DFSMSHsm tape libraries

A system-managed tape library is a named collection of storage groups, and tape subsystems and their associated tape cartridges.

Automated tape library

An automated tape library (ATL) allows you to use system-managed storage for mountable tape cartridges. Mount requests for these cartridges are handled by a robotic tape cartridge handler. An ATL provides management facilities for tape volumes, but does not manage the data sets contained on those tape volumes.

Related reading

For more information about the automated tape library, see [*z/OS DFSMSHsm Implementation and Customization Guide*](#).

Manual tape library

A manual tape library (MTL) also allows you to use system-managed storage for mountable tape cartridges. Like an ATL, it provides management facilities for tape volumes, but does not manage the data sets contained on those tape volumes. Unlike an ATL, mount requests are directed to a human operator.

Related reading

For more information about a manual tape library, see [*z/OS DFSMSHsm Implementation and Customization Guide*](#).

Chapter 16. Using DFSMSHsm with DFSMSrmm

The z/OS component, DFSMSrmm provides enhanced management for tape volumes that DFSMSHsm uses for each of its tape functions. Precisely how the two products work together depends on how you use each of them in your installation.

DFSMSHsm can tell DFSMSrmm when it no longer requires a tape volume or when a tape volume changes status. When DFSMSHsm is using DFSMSrmm, it cannot mistakenly overwrite one of its own tape volumes if an operator mounts a tape volume in response to a request for a non-specific tape volume.

DFSMSrmm supports any of the naming conventions DFSMSHsm uses for its tape data sets, and all DFSMSHsm options—with the exception of password security on tape volumes—are supported.

DFSMSrmm lets you use a system scratch tape pool or a DFSMSHsm-managed tape pool. DFSMSrmm manages the movement of disaster recovery and vital record data for both pool types. It also provides a way to retain DFSMSHsm tapes until the contents are invalid.

Recommendation: Use the system scratch tape pool.

You must let DFSMSHsm decide whether a tape volume contains valid data and whether it should return to the scratch pool or DFSMSHsm-managed tape pool.

You can manage the retention of valid tape volumes in two ways:

- Use DFSMSrmm vital record specifications to retain tape volumes until DFSMSHsm finishes with them.
- Set up DFSMSHsm to use expiration date protected tape volumes. Use the date 99365 to prevent DFSMSrmm from considering the volumes for release at any time.

You should use vital record specifications because you can avoid expiration dates, operator message handling, and the need to reinitialize tape volumes before you can reuse them. However, if you are using a DFSMSHsm-managed tape pool, you can use expiration date protection without this overhead; DFSMSHsm can override expiration protection for its own tape volumes.

DFSMSHsm uses the DFSMSrmm EDGTVEXT interface to maintain the correct volume status. DFSMSrmm provides a programming interface so you can use the DFSMSHsm exit.

Related reading

For more information about the DFSMSrmm EDGTVEXT interface, see [*z/OS DFSMSrmm Implementation and Customization Guide*](#).

Retaining DFSMSHsm tape volumes by expiration date

If you use the system scratch tape pool for DFSMSHsm tape volumes, you need a way to manage tape volumes protected with expiration dates. In this situation, DFSMSrmm lets you automate the responses to expiration date protection messages for system scratch pool tape volumes.

Related reading

For more information about using the system scratch tape pool for DFSMSHsm tape volumes, see [*z/OS DFSMSrmm Implementation and Customization Guide*](#).

Retaining DFSMSHsm tape volumes by DFSMSrmm vital record processing

DFSMSrmm vital record processing uses either data set names or volume serial numbers to determine how long to keep tapes. This retention period overrides any expiration date or retention period previously

specified for the volume. In addition, you can use vital record specifications to identify volumes that should be moved out of the library for safe keeping.

Related reading

For more information about DFSMSrmm vital record processing, see [z/OS DFSMSrmm Implementation and Customization Guide](#).

Tape security when using DFSMSHsm and DFSMSrmm

The way in which you use the DFSMSHsm option DFSMSHsm TAPESECURITY may conflict with the way DFSMSrmm protects volumes.

Related reading

For more information about protecting volumes, see [z/OS DFSMSrmm Implementation and Customization Guide](#).

Recommendations for using DFSMSHsm with DFSMSrmm

You should perform the following steps when running DFSMSHsm with DFSMSrmm:

- Run DFSMSHsm with a system scratch pool that DFSMSrmm manages.
- Protect HSM tape data either using RACF TAPEVOL profiles and SETSYS TAPESECURITY(RACF), or using RACF DATASET profiles by using the RACF TAPEDSN option or the DEVSUPxx keyword TAPEAUTHDSN=YES.
- Use retention period and AUTOREUSE for automatic dumps.
- Set the following DFSMSHsm parameters. For the system options, specify:

```
SETSYS SELECTVOLUME(SCRATCH) -  
TAPERELETION(SCRATCH) -  
TAPESECURITY(RACF) -  
PARTIALTAPE(REUSE)
```

For automatic dump definitions, specify:

```
DEFINE DUMPCLASS(class -  
AUTOREUSE -  
RETENTIONPERIOD(days))
```

Chapter 17. Operating procedures for DFSMSHsm

The computing system operator is expected to perform certain operations for DFSMSHsm. This topic describes those operations. You might want to copy this topic to provide your system operators with directions for performing the operations.

The following operations are described here:

- Partitioning DFSMSHsm functions
- Starting DFSMSHsm
- Stopping DFSMSHsm
- Preventing DFSMSHsm functions from running
- Allowing previously prevented DFSMSHsm functions to run
- Canceling DFSMSHsm queued requests
- Altering the Priority of DFSMSHsm Queued Requests
- Printing DFSMSHsm log information
- Restarting DFSMSHsm after an abnormal end
- Running automatic functions concurrently
- Updating the DFSMSHsm control data sets

Partitioning DFSMSHsm functions

This topic describes the capabilities and functions of DFSMSHsm and the uses for DFSMSHsm control data sets. When you map these functions against the storage management needs of your installation, you might want to allocate certain subsets of functions to specific DFSMSHsm hosts. In this context, a host is a DFSMSHsm address space that performs automatic functions, such as migration. Secondary address spaces that perform aggregate backups and recovery (ABARS) belong to the main host and are not themselves considered hosts.

One z/OS image can have more than one DFSMSHsm host. In a sysplex, multiple z/OS images can each have one or more hosts, all sharing the same set of control data sets (an HSMplex).

There are two possible modes of host activity that you can specify at startup time for any host: HOSTMODE=MAIN (the default) and HOSTMODE=AUX.

HOSTMODE=MAIN

This (main) DFSMSHsm host

- Processes implicit requests, such as recalls, or deletes migrated data sets, from user address spaces
- Processes explicit commands from TSO, such as HSEND CMD and HBACKDS, as well as requests from batch jobs, such as ARCINBAK
- Manages ABARS secondary address spaces
- Allows MODIFY commands from a console or from an HSM Monitor/Tuner (HMT)
- Can run automatic backup, dump, and space management

HOSTMODE=AUX

This (auxiliary) DFSMSHsm host

- Allows MODIFY commands from a console or from an HSM Monitor/Tuner (HMT)
- Can run automatic backup, dump, or space management

In addition, another keyword PRIMARY identifies the primary host in an HSMplex.

Rule: Within one z/OS image, all started hosts must be running DFSMSHsm V2R10, or a later release.

Note:

1. Up to 39 DFSMSHsm hosts can be started concurrently in an HSMplex.
2. Within one z/OS image, any started host running on V2R10 or subsequent releases can share data with any host running on prior releases in the same HSMplex, but from a different z/OS image.
3. An HSMplex can consist of both single and multiple DFSMSHsm-host environments.

There are several advantages to starting more than one DFSMSHsm host in an z/OS image:

- Multiple DFSMSHsm address spaces mean less work per address space and less contention between functions, because each SYSZTIOT resource serializes only functions in its address space.
- Multiple DFSMSHsm address spaces mean that each address space that is doing some part of DFSMSHsm's work can have an appropriate MVS dispatching priority for that type of work.
- Multiple DFSMSHsm address spaces provide a larger number of tasks that perform any given DFSMSHsm function; for example, migration.
- DFSMSHsm functions that operate in more than one address space allow more MIPs that are allocated to DFSMSHsm functions.

Within a single z/OS image, you can have one of the following combinations, all sharing the same set of control data sets:

- One main host
- One main host and one or more auxiliary hosts

Note: Because you can start up or shut down hosts in any order, another permitted (but normally temporary) combination is one or more auxiliary hosts without a main host.

Related reading

For more information about the HOSTMODE and PRIMARY keywords, see the topic about DFSMSHsm multiple host environments in the *z/OS DFSMSHsm Implementation and Customization Guide*.

Starting DFSMSHsm

Before you can start DFSMSHsm, you must have a DFSMSHsm start procedure.

DFSMSHSM is used as the start procedure name. You can replace DFSMSHSM with any identification you designate for your computing system.

You can start DFSMSHsm in either of two ways:

- The first time you start DFSMSHsm after it is installed, you can load your system control program at initial program load. In response to the request:

IEA101A SPECIFY SYSTEM PARAMETERS

you reply with:

R 0,CLPA,CMD=nn

where CMD=nn identifies the startup member in the PARMLIB data set for COMMNDnn, which contains a START DFSMSHsm command. You add the START command for DFSMSHsm to your parameter library member, COMMNDnn, in the following manner:

COM='S DFSMSHSM,parameters'

- You can issue the START DFSMSHsm command from the system console after the system control program is loaded at initial program load. You do not have to load the system control program at initial program load to restart DFSMSHsm. The command to start DFSMSHsm is:

S DFSMSHSM,parameters

DFSMSHsm only runs as a started task; you cannot start DFSMSHsm as a batch job. If you plan to run more than one DFSMSHsm host in an z/OS image, you must issue the START command once for each host. At that time, you must specify a unique host identifier in the startup procedure, on the START command itself, or in an ARCSTRxx PARMLIB member that is referred to by the startup procedure or by the command.

Rule: To enable a multiple address space environment for DFSMSHsm, you must specify a new keyword HOSTMODE in the DFSMSHsm start procedure.

If you start more than one DFSMSHsm host in an image, the following conditions must exist:

- All the hosts must share the same set of control data sets; that is, they must be in the same HSMplex.
- All the hosts, therefore, share the same journal.
- Each host has its own log, activity logs, and PDA data sets.

To assist in problem analysis, you may want to incorporate the host-identifier characters into the names of the procedures that are used to start those hosts.

When DFSMSHsm gains control after a START command has been issued, a message (ARC0001I) is issued to notify the operator that DFSMSHsm is starting up. After the control data sets are opened and all major subtasks are attached, another message (ARC0008I) is issued to notify the operator that initialization is successful and that DFSMSHsm is ready to accept commands.

Messages appear at the system console for each DFSMSHsm command processed from the parameter library member if the monitoring of startup messages is in effect when the command is processed. These messages are only informational but could be useful if any problems occur. You start monitoring startup messages by specifying one of the following:

- COM='S DFSMSHSM,STARTUP=YES'
- SETSYS MONITOR(STARTUP)

You stop monitoring startup messages by specifying one of the following:

- COM='S DFSMSHSM,STARTUP=NO'
- SETSYS MONITOR(NOSTARTUP)

You can include the SETSYS command in the parameter library member as many times as you want. This allows you to control which commands issue messages to the system console when DFSMSHsm is starting.

You can install DFSMSHsm on multiple z/OS images of a sysplex or in multiple hosts in one z/OS image (or both). However, be sure that the HOST parameter of the startup procedure or the HOST parameter that is specified with the START command is unique for each instance of DFSMSHsm that shares the same set of control data sets.

Note: You cannot start the DFSMSHsm ABARS secondary address space from the operator's console by using an MVS START command. If you attempt this, DFSMSHsm fails the command.

Related reading

For more information about creating a start procedure, see [z/OS DFSMSHsm Implementation and Customization Guide](#).

Stopping DFSMSHsm

To stop DFSMSHsm, issue the following MODIFY command:

F DFSMSHSM,STOP

F DFSMSHSM,STOP without additional keywords causes no promotion of a secondary host.

Note: DFSMSHSM is the started procedure name. You can replace it with any identification you designate for your computing system.

You can also issue the MVS STOP DFSMSHSM command. When DFSMSHsm is stopped, the normal job-log information is spooled to the printer along with the DFSMSHsm log and activity logs that DFSMSHsm maintains. Either one of the STOP commands causes an orderly shutdown of the DFSMSHsm address space and an orderly closing of the DFSMSHsm control data sets.

F DFSMSHSM,STOP PROMOTE makes the host eligible to have its unique functions taken over by a promotable host. You can issue a STOP PROMOTE command on a primary host, or a host that runs secondary space management, in sysplex environment with secondary host promotion enabled. This causes an orderly shutdown, and allows another host to take over the unique functions of the stopped primary host, or the secondary space management functions of the stopped host running secondary space management.

F DFSMSHSM,STOP DUMP issues a dump and makes the host eligible to have its unique functions taken over by a promotable host.

In a sysplex, a manual shutdown of the primary or secondary space management host, without using the PROMOTE or DUMP parameters, does not automatically cause promotion of another host, because it is assumed that there is a reason for the shutdown, such as for routine maintenance or because all systems in the sysplex are being shut down.

An orderly shutdown means that each attached subtask ends and all DFSMSHsm secondary address spaces must complete processing. Because many DFSMSHsm commands and automatic functions are potentially long-running, DFSMSHsm periodically checks whether shutdown has been requested, to prevent a delay in the shutdown process. If DEFERMOUNT is used, or the correct tape was not mounted during end volume processing, and the timer was set by the MOUNTWAITTIME parameter of the SETSYS command, the timer expires and checks for shutdown. Volume functions check for shutdown before processing the next data set. After all subtasks have been detached and all secondary address spaces have completed processing, DFSMSHsm issues a message (ARC0002I) to notify the operator that shutdown is complete and returns control to the system.

When DFSMSHsm is shut down and restarted but MVS has not been reloaded at initial program load, user and HSEND CMD commands that did not complete are restarted as part of the DFSMSHsm initialization process. Commands entered from the system console that have not been processed are lost, and any request that exceeds the extended common service area (ECSA) limit per address space is also lost.

Related reading

For more information about the secondary host promotion function, see [*z/OS DFSMSHsm Implementation and Customization Guide*](#).

Shutdown processing on the common recall queue

When a host shuts down in a common recall queue (CRQ) environment, WAIT recall requests on the CRQ fail with RC=65, but new NOWAIT requests replace the failed requests. The new requests have the same priority as the original and can be processed by any eligible host that is connected to the CRQ. NOWAIT requests remain available in the CRQ.

Preventing DFSMSHsm functions from running

You can prevent all or part of DFSMSHsm's functions from running without stopping DFSMSHsm. You can also interrupt all or part of the functions after they have begun running. For those functions that process on a volume basis (backup, dump, migration, and recover), you can choose whether to interrupt the function at the end of the data set currently being processed or at the end of the volume currently being processed. You use the HOLD command to prevent or interrupt DFSMSHsm processing.

To prevent or interrupt all DFSMSHsm processing, issue the following command:

```
HOLD ALL
```

Note: HOLD ALL does not control the hold level of the common recall queue (CRQ) placement and selection functions. To place a hold on the CRQ, specify HOLD COMMONQUEUE, with its optional subparameters.

To queue all aggregate backup processing and prevent any new commands from being processed, issue the following command:

```
HOLD ABACKUP
```

To queue all aggregate recovery processing and prevent any new commands from being processed, issue the following command:

```
HOLD ARECOVER
```

To interrupt AUDIT command processing after it finishes the current data set, issue the following command:

```
HOLD AUDIT
```

To interrupt or prevent all backup processing, issue the following command:

```
HOLD BACKUP
```

Backup is held by this command at the end of the data set currently being processed. To hold automatic backup processing but allow command backup processing, issue the following command:

```
HOLD BACKUP(AUTO)
```

Automatic backup is stopped by this command at the end of the data set currently being processed, but command backup processing continues and is allowed to start new data sets or volumes.

To interrupt or prevent backup processing at the end of the volume currently being processed, issue the following command:

```
HOLD BACKUP ENDOFVOLUME
```

To specify that a host should neither place requests on nor select requests from the common recall queue, issue the following command. After you issue HOLD COMMONQUEUE, any requests already in the CRQ remain available for processing by hosts that are connected to the CRQ. If no CRQ hosts are available, and the request is a WAIT, it fails. The originating host processes all recall requests that are received after you issue HOLD COMMONQUEUE.

```
HOLD COMMONQUEUE or HOLD COMMONQUEUE(RECALL)
```

To specify that the host should not place any additional requests onto the CRQ, issue the following command. After you issue this command, the host places all new recall requests in the local queue and continues to select requests to process from the CRQ. The host selects the highest priority request available in the local and common recall queues. When the highest priority request in the local queue and the highest priority request in the CRQ match, the host selects the request from the local queue. If you specify this command on all hosts, then all hosts place new recall requests in the local queue, but continue to select requests to process from the CRQ.

`HOLD COMMONQUEUE(RECALL(PLACEMENT))`

To specify that a host should continue to place but not select recall requests in the CRQ, issue the following command. After you issue this command, if a host places a request in the local queue because the CRQ is unavailable, the host processes that request. If you specify this command on all hosts, all WAIT requests in the CRQ fail because no host is available to process them.

`HOLD COMMONQUEUE(RECALL(SELECTION))`

To prevent or interrupt dump processing, issue the following command. Dump processing stops at the end of the volume currently being processed.

`HOLD DUMP`

To prevent or interrupt automatic dump processing, issue the following command. Automatic dump processing stops at the end of the volume currently being processed. Processing initiated by DUMP commands is allowed to start.

`HOLD DUMP(AUTO)`

To specify no data movement, issue the following command.

Note: The SETSYS EMERGENCY command does not affect the placement of recall requests onto the common recall queue by the host with the command in effect, as other active hosts can process those requests.

`SETSYS EMERGENCY`

To interrupt dump processing at the end of the current unit of work being processed (typically a number of tracks or a cylinder), issue the following command:

`HOLD DUMP ENDOFDATASET`

To interrupt expiration of backup data sets by the EXPIREBV command, issue the following command. Expiration of backup versions ends when the data set that is being processed expires.

`HOLD EXPIREBV`

To prevent fast replication from processing any new FRBACKUP commands, issue the following command. No new fast replication backup commands are selected for processing.

`HOLD FRBACKUP`

To prevent fast replication from processing any new FRRECOV commands, issue the following command. No new fast replication recover commands are selected for processing.

`HOLD FRRECOV`

To interrupt or prevent processing by the LIST command, issue the following command. LIST command processing stops immediately. This command can be useful if a list command is returning a large amount of data to your terminal and you want to interrupt the process. In such a case, the operator may be required to issue the HOLD command.

`HOLD LIST`

You can prevent DFSMSHsm from making entries in the DFSMSHsm log. Even though the log entries are prevented, DFSMSHsm continues to make entries in the activity logs. To prevent entries into the DFSMSHsm log, issue the following command:

```
HOLD LOG
```

To interrupt or prevent all migration processing, issue the following command. All migration stops at the end of the data set currently being processed.

```
HOLD MIGRATION
```

To interrupt or prevent only automatic volume space management and automatic secondary space management, issue the following command. Automatic volume space management and automatic secondary space management stops at the end of the data set currently being processed, but migration caused by commands is allowed to start.

```
HOLD MIGRATION(AUTO)
```

To interrupt migration at the end of the volume currently being processed, issue the following command:

```
HOLD MIGRATION ENDOFVOLUME
```

To prevent all recall processing, including no more processing from an already mounted migration tape, issue the following command.

Note: In a common recall queue (CRQ) environment, with the HOLD RECALL command in effect, the host is not eligible to select requests from the CRQ.

```
HOLD RECALL
```

To prevent all recall processing from tape volumes (except those from already mounted migration tapes) but allow recall processing from DASD volumes, issue the following command.

Note: In a CRQ environment, with the HOLD RECALL(TAPE) command in effect, the host is not eligible to select requests requiring tape from the CRQ.

```
HOLD RECALL(TAPE)
```

To prevent recall processing from tape volumes when the RECALL command is issued by a TSO user but to allow all other recall processing, issue the following command.

Note: In a CRQ environment, with the HOLD RECALL (TAPE(TSO)) command in effect, the host is not eligible to select requests requiring tape and TSO from the CRQ.

```
HOLD RECALL(TAPE(TSO))
```

To prevent all recover processing, including no more processing from an already mounted backup tape, issue the following command:

```
HOLD RECOVER
```

To prevent recover processing for data sets on tape backup (except those from already mounted backup tapes) and dump volumes but to allow recover processing for data sets on DASD backup volumes, issue the following command:

```
HOLD RECOVER(TAPEDATASET)
```

To interrupt or prevent recycle processing, issue the following command. Recycle processing stops at the end of the data set being processed.

```
HOLD RECYCLE
```

To interrupt or prevent REPORT command processing, issue the following command:

```
HOLD REPORT
```

Allowing previously prevented DFSMSHsm functions to run

You can use the RELEASE command to allow DFSMSHsm to run functions that you previously prevented from running, and to allow activity logs to be closed and produced as output.

To allow all held DFSMSHsm functions except logging to run, issue the following command. This command does not restart writing in the DFSMSHsm log and does not cause the activity logs to be closed and processed.

Note: RELEASE ALL does not control the releasing of holds on the common recall queue. You must instead specify RELEASE COMMONQUEUE, with its optional subparameters.

```
RELEASE ALL
```

To allow the ABACKUP command to be processed, issue the following command. Any queued ABACKUP commands are allowed to process.

```
RELEASE ABACKUP
```

To allow the ARECOVER command to be processed, issue the following command. Any queued ARECOVER commands are allowed to process.

```
RELEASE ARECOVER
```

To allow the AUDIT command to be processed, issue the following command. Any queued AUDIT commands are allowed to process. Any AUDIT command that was interrupted by a HOLD command does not restart.

```
RELEASE AUDIT
```

To release all held backup functions, issue the following command. All backup processing is allowed to start. If the time is still within the backup start window, automatic backup starts processing any functions that have not already been processed. Any volumes that were not already fully processed are candidates for processing if less than 24 hours has passed since automatic backup was last started from the beginning and if the time is still within the backup window.

```
RELEASE BACKUP
```

To allow automatic backup processing that was prevented by a HOLD BACKUP(AUTO) command, issue the following command. This command does not release automatic backup processing if automatic backup is prevented by a HOLD BACKUP command that prevents any backup processing. If the time is still within the backup start window, automatic backup starts processing any functions that had not been processed when backup was held or interrupted. Any volumes that were not already fully processed are candidates for processing if less than 24 hours has passed since automatic backup was last started from the beginning, and if the time is still within the backup window.

Note: If automatic backup is not scheduled to run on a particular day, you can use the BACKUP parameter of the RELEASE command to move backup versions (and backup migrated data sets). Automatic backup is not scheduled to run if you have specified SETSYS AUTOBACKUPSTART(0) or if you have specified N for this day in the backup cycle.

```
RELEASE BACKUP(AUTO)
```

To allow processing of data set or UNIX file backups to both tape and ML1 DASD that were prevented by a HOLD BACKUP(DSCOMMAND) command, issue the following command.

Note: Use of the BACKUP(DSCOMMAND) parameter allows data set or UNIX file backup by command processing. This command will not affect automatic backup processing.

```
RELEASE BACKUP(DSCOMMAND)
```

To allow processing of data set or UNIX file backups that are directed to ML1 DASD that were prevented by a HOLD BACKUP(DSCOMMAND(DASD)) command, issue the following command:

```
RELEASE BACKUP(DSCOMMAND(DASD))
```

To allow processing of data set or UNIX file backups that were directed to tape that were prevented by a HOLD BACKUP(DSCOMMAND(TAPE)) command, issue the following command:

```
RELEASE BACKUP(DSCOMMAND(TAPE))
```

To allow processing of data set or UNIX file backups that were directed to DASD that were prevented by a HOLD BACKUP(AUTO DSCOMMAND(DASD)) command, issue the following command:

```
RELEASE BACKUP(AUTO DSCOMMAND(DASD))
```

To allow processing of data set backups that were directed to tape if they were prevented by a HOLD BACKUP(AUTO DSCOMMAND(TAPE)) command, issue the following command.

Note: If you release a particular category, you will release the hold on that category's subcategory, as well. However, you cannot release a subcategory if the initial HOLD function occurred at a higher level. In contrast, you can release the higher level and then hold the complementary subcategory.

```
RELEASE BACKUP(AUTO DSCOMMAND(TAPE))
```

To release a common recall queue hold at the COMMONQUEUE level, holds at the RECALL level, and holds at the PLACEMENT and SELECTION level, issue the following command.

Note: When RELEASE COMMONQUEUE is issued, all unselected requests on the local queue move to the CRQ.

```
RELEASE COMMONQUEUE
```

If there is not a CRQ hold at the COMMONQUEUE level, to release a hold at the COMMONQUEUE(RECALL) level and a hold at the PLACEMENT and SELECTION level, issue the following command.

Note: When RELEASE COMMONQUEUE(RECALL) is issued, all unselected requests on the local queue move to the CRQ.

```
RELEASE COMMONQUEUE(RECALL)
```

To release a CRQ hold at the PLACEMENT level only if a hold is not at a higher level also, issue the following command.

Note: When RELEASE COMMONQUEUE(RECALL(PLACEMENT)) is issued, all unselected requests on the local queue move to the CRQ.

```
RELEASE COMMONQUEUE (RECALL (PLACEMENT))
```

To release a CRQ hold at the SELECTION level only if a hold is not at a higher level also, issue the following command:

```
RELEASE COMMONQUEUE (RECALL (SELECTION))
```

To allow dump processing to run, issue the following command. Any queued dump commands are allowed to process. If the time is still within the dump window, automatic dump starts processing any functions that had not been completed when the dump function was held.

```
RELEASE DUMP
```

To allow automatic dump processing to run if automatic dump was held by a HOLD DUMP(AUTO) command, issue the following command. If the time is still within the dump start window, automatic dump starts processing any functions that had not been completed when the dump function was held.

```
RELEASE DUMP (AUTO)
```

To allow expiration of backup versions if EXPIREBV was held by a HOLD EXPIREBV command, issue the following command. New EXPIREBV commands are processed. Any EXPIREBV processing that was interrupted by the HOLD EXPIREBV command is not restarted.

```
RELEASE EXPIREBV
```

To release the fast replication process by the FRBACKUP command, issue the following command.

```
RELEASE FRBACKUP
```

To release the fast replication process by the FRRECOV command, issue the following command.

```
RELEASE FRRECOV
```

To close the activity log data sets and process them, issue the following command. This command causes one of two actions.

- If the activity logs are directed to a SYSOUT data set, the activity logs are closed and printed.
- If the activity logs are directed to DASD data sets, the current DASD data sets are closed and new activity log data sets are allocated.

```
RELEASE HARDCOPY
```

To allow LIST command processing, issue the following command. Any queued LIST commands are allowed to process. Any list operation that was in process when list was held is not restarted.

```
RELEASE LIST
```

To allow entries to the DFSMSHsm log after the entries have been prevented, issue the following command:

```
RELEASE LOG
```

To allow all migration processing, issue the following command. Any queued MIGRATION commands are allowed to begin processing. If the time is still within the automatic primary space management or automatic secondary space management processing windows, any automatic primary space management or automatic secondary space management functions that were not completed when migration was held begin processing.

```
RELEASE MIGRATION
```

To allow automatic primary space management or automatic secondary space management processing if they were prevented by a HOLD MIGRATION(AUTO) command, issue the following command. If the time is still within the automatic primary space management or automatic secondary space management processing windows, any automatic primary space management or automatic secondary space management functions that were not completed when automatic primary space management or automatic secondary space management was held are started.

```
RELEASE MIGRATION(AUTO)
```

When DFSMSHsm is migrating data sets to both DASD and tape devices, an error condition can end migration to either of the device types without ending migration to the other. After the error is corrected, you can restart migration to the device that had the error by issuing one of the following commands:

```
RELEASE MIGRATION(AUTO)
RELEASE MIGRATION
```

To allow all recall processing, issue the following command. Any queued RECALL commands are allowed to process. In a common recall queue (CRQ) environment, RELEASE RECALL makes the host eligible to select requests from the CRQ.

```
RELEASE RECALL
```

To allow recall from tape data sets if recall was held by a HOLD RECALL(TAPE) command, issue the following command:

```
RELEASE RECALL(TAPE)
```

To allow recall from tape data sets that were requested by TSO users (if the recall was held by a HOLD RECALL(TAPE(TSO)) command, issue the following command:

```
RELEASE RECALL(TAPE(TSO))
```

To release the hold on recalls from DASD volumes, issue the following command:

```
RELEASE RECALL(DASD)
```

Note that there is no accompanying HOLD RECALL(DASD) command; instead, the RELEASE RECALL(DASD) command essentially converts a HOLD RECALL state to a HOLD RECALL(TAPE) state.

To allow all recover processing, issue the following command. Any queued RECOVER commands are allowed to process.

```
RELEASE RECOVER
```

To allow data sets or UNIX files to be recovered from tape volumes if recover processing was held by a HOLD RECOVER(TAPEDATASET) command, issue the following command:

```
RELEASE RECOVER(TAPEDATASET)
```

To allow recycle processing, issue the following command. Any queued recycle requests begin processing. Any volumes that were being recycled when recycle was held are not restarted.

```
RELEASE RECYCLE
```

To allow REPORT commands to be processed, issue the following command. Any queued report requests begin processing. Any report that was in process when reporting was held is not restarted.

Note: If DFSMSHsm functions are being held because of a journal-inhibited condition and that condition cannot be resolved at that time, the following DFSMSHsm commands can be issued to bypass journaling.

- SETSYS NOJOURNAL
- RELEASE XXX (for whatever function you want to release)
- SETSYS JOURNAL (after a successful CONTROLDATASET BACKUP and the journal reset is completed)

```
RELEASE REPORT
```

Attention: If journaling is bypassed, you cannot perform a CONTROLDATASET RECOVERY for that period of time the journal was inhibited. The journal updates are lost for that period of time.

Canceling DFSMSHsm requests

DFSMSHsm lets you cancel queued requests for:

- An individual command
- A user ID
- A data set name
- A UNIX file

Rule: If you are using the common recall queue, you must submit the cancel request on the same host that originated the recall request that you want to cancel.

Use the CANCEL command to identify the commands for cancellation. The only commands that can be canceled are those commands that have not started. Identification of the commands to cancel can be specified by the DFSMSHsm request number, user ID, or data set name or UNIX file. Use the QUERY command to find the request numbers, user IDs, data set names, or UNIX files. Use the QUERY ACTIVE command to determine which DFSMSHsm requests are currently being processed. Use the QUERY ACTIVE(TCBADDRESS) to obtain the Task Control Block addresses of active DFSMSHsm data movement tasks.

Exceptions:

1. Depending on whether you choose to back up data sets that are in use (see “Specifying how DFSMSHsm should respond to a data set in use” on page 191), DFSMSHsm during a BACKVOL can schedule multiple requests to retry backing up (BACKDS) data sets found to be open for update when backup was initially attempted. All requests scheduled during one BACKVOL are assigned the same request number originally assigned to the BACKVOL request itself. Canceling the request number cancels all requests. To cancel only one request, use the DATASETNAME parameter.
2. Data set recoveries scheduled during a volume recovery (or during APPLYINCREMENTAL processing following a volume restore) are assigned the *same* request number originally assigned to the volume recovery or volume restore request. Canceling that request number cancels *all* those requests. To cancel only one request, use the DATASETNAME parameter.

A CANCEL command with the USERID, DATASETNAME, or FILENAME parameters cancels all existing nonexecuting requests having the specified user ID or data set name or UNIX file name.

The following command cancels a single request:

```
CANCEL REQUEST(num)
```

If you issue the CANCEL REQUEST(*num*) command for an active FRRECOV DSNAME request that is processing more than one single data set, then all queued data set requests for that command fail and no additional requests are generated. All data set recovery MWEs generated by a single FRRECOV DSNAME command have the same request number. Hence, the CANCEL REQUEST(*num*) command cancels all queued data set recovery MWEs that originate from the same FRRECOV command.

If you issue the CANCEL REQUEST(*num*) command with a request number of the Fast Replication dumps, all dumps in progress are canceled, any queued DUMP MWEs fail, and no additional requests are generated. When a Fast Replication DUMP command is processed, individual volume DUMP MWEs with the same request number are generated for all volumes in each storage group defined to the copy pool.

The following command cancels the requests of a particular user:

```
CANCEL USERID(userid)
```

The following command cancels the requests for a particular data set:

```
CANCEL DATASETNAME(dsn)
```

Note:

- Depending on whether you choose to back up data sets that are in use (see [“Specifying how DFSMSHsm should respond to a data set in use” on page 191](#)), DFSMSHsm during autobackup can schedule multiple requests to retry backing up (BACKDS) data sets found to be open for update when backup was initially attempted. Each request scheduled during autobackup has a request number of zero, which you cannot specify with the REQUEST parameter. You should use the DATASETNAME parameter to cancel one of these requests.
- You can cancel individual data set MWEs generated from the same FRRECOV command by using the CANCEL DATASETNAME(*dsn*) command. You cannot use the CANCEL DATASETNAME command to cancel the main FRRECOV DSNAME MWE.

The following command cancels the requests for a particular UNIX file:

```
CANCEL FILENAME('pathname')
```

Note: The path name must be enclosed in single quotes and be an absolute path starting with a forward slash (/) character.

The following command cancels a particular ABARS secondary address space:

```
CANCEL SASINDEX(sasindex)
```

sasindex is an integer value between 1 and 64 received from the QUERY ACTIVE(TCBADDRESS) command. The CANCEL command may be controlled by RACF FACILITY class.

The following command cancels a particular active task:

```
CANCEL TCBADDRESS(X'tcbaddress')
```

tcbaddress is an 8-digit value received from the QUERY ACTIVE(TCBADDRESS) command. Volume level activity generally goes to the next data set after a data set task is canceled, so to also end the volume task you should issue the appropriate HOLD command before canceling the data movement task.

'TCB' is the first *tcbaddress* to cancel. If the function does not end, then a 'TCB2' address is given, and the *tcbaddress* in 'TCB2' can then be used. If the function still does not end and a 'TCB3' address is given, then the *tcbaddress* in 'TCB3' can be used. If the TCB value is '****?***', then no TCB was found.

When canceling a hung journal back task, allow any active CDS backup tasks to run to completion. If a CDS backup task is also hung, cancel it before canceling the hung journal backup task. The CANCEL command may be controlled by RACF FACILITY class.

The CANCEL and QUERY commands cannot be canceled.

Note: A backup or recover request for a directory or wildcard can result in many files being processed. Each of these requests has the same request number, so if you wish to cancel a long running directory request, specifying REQNUM will cancel all the files that haven't been started yet.

Altering the priority of DFSMSHsm queued requests

You can use the DFSMSHsm ALTERPRI command to alter the priority of queued requests. You can alter the priority of the following request types: ABACKUP, ARECOVER, BACKDS, BACKVOL, DELETE, FRBACKUP, FREEVOL, FRRECOV, MIGRATE, RECALL, and RECOVER. You cannot alter the priority of BACKVOL CDS commands and requests selected for processing. When you need to alter the priority of queued requests, you can use the ALTERPRI command. The ALTERPRI command affects queued requests only; it does not affect new requests.

The HIGH parameter of the ALTERPRI command, which is the default, alters the specified request so that it has the highest priority on its respective queue. Conversely, the LOW parameter alters the request so that it has the lowest priority on its respective queue. The mutually exclusive REQUEST, USER, DATASETNAME, or FILENAME parameters indicate which requests DFSMSHsm should re-prioritize. (Use the QUERY REQUEST command to determine the request number to issue on the ALTERPRI command.) DFSMSHsm re-prioritizes all queued requests that match the REQUEST, USERID, DATASETNAME, or FILENAME criteria specified on the ALTERPRI command.

The BACKVOL STORAGEGROUP, BACKVOL VOLUMES, FRBACKUP DUMP, FRBACKUP DUMPONLY, and FRRECOV DSNAME commands, and requests for single volume recovery from incremental backups, each generate multiple requests, all with the same request number. An ALTERPRI REQUEST command issued to re-prioritize one of these requests alters the priority of all requests generated for the command that are queued at the time of ALTERPRI processing.

Note: To re-prioritize a recall request on the common recall queue, issue the ALTERPRI command on the same host from where the recall request originates.

Note: The priority of one or more CDQ or CVQ queued requests can be changed for requests that originate in the host that issued the ALTERPRI command, and match the REQUEST or USERID filter criteria.

The DATASETNAME keyword is not supported when you issue an ALTERPRI command against a FRRECOV DSNAME request. When an ALTERPRI DSNAME command is issued, and a FRRECOV DSNAME request for the same data set exists on the queue during ALTERPRI processing, the FRRECOV DSNAME request is skipped. To alter the priority of a FRRECOV DSNAME request, use the REQUEST keyword.

The following command alters all requests for a particular data set so that they have the highest priority on their respective queues:

```
ALTERPRI DATASETNAME(dsname)
```

The following command alters all requests for a particular UNIX file so that they have the highest priority on their respective queues:

```
ALTERPRI FILENAME('pathname')
```

The following command alters all requests with a particular request number so that they have the highest priority on their respective queue:

```
ALTERPRI REQUEST(reqnum) HIGH
```

The following command alters all requests issued by a particular user so that they have the lowest priority on their respective queues:

ALTERPRI USERID(userid) LOW

Printing DFSMSHsm log information

The information in the DFSMSHsm log can be used to determine the status of the data sets and volumes in DFSMSHsm. Figure 85 on page 607 shows the DFSMSHsm log printing environment.

Figure 85. DFSMSHsm Log and Edit Log Overview

The DFSMSHsm log is actually two data sets, called LOGX and LOGY. LOGX is used to write the log information into, while LOGY is being processed for the information it contains. When LOGX becomes full, the data set receives a D37-04 ABEND indicating that it ran out of space. DFSMSHsm automatically switches the LOGX and LOGY data sets: LOGX becomes LOGY, and LOGY becomes LOGX. This switch allows access to the data recently recorded in the log.

The following messages are displayed on the operator's console:

```
IEC031I D37-04, IFG0554T, DFHSM, DFHSM, ARCLOGX,
        HSMLIB, DFHSM, HSMLGX
ARC0020I *****
ARC0024I DFSMSHsm LOGGING INHIBITED DUE TO EOV ERROR
ARC0024I (CONT.) ON LOG
ARC0020I *****
ARC0020I *****
ARC0027I DFSMSHsm LOG SWITCHED
ARC0020I *****
```

You can also force the logs to be switched by entering the SWAPLOG command. The following message are displayed:

```
ARC0020I *****
ARC0027I  DFSMSHsm LOG SWITCHED
ARC0020I *****
```

In either case, it is now possible to use the ARCPRLOG program and the ARCPEDIT programs to process LOGY. You use the ARCPRLOG program to do an initial formatting of the information in the log and to print the log.

If the LOGY data set or the edit-log data set is RACF-protected, you must take special steps before calling the HSMLOG procedure. The HSMLOG procedure processes the ARCPRLOG program to read, format, and print information in the LOGY data set and to insert selected log records into the edit-log data set. The HSMLOG procedure normally resides in SYS1.SAMPLIB in member ARCSTRST, and the ARCPRLOG program normally resides in the LINKLIB data set. After processing the ARCPRLOG program, the HSMLOG procedure empties the LOGY data set. If the HSMLOG procedure is called as a started task, the RACF started-procedures table (ICHRIN03) must be updated to include the procedure name (HSMLOG) and the RACF user ID to be associated with the procedure when it is started. If the HSMLOG procedure is called as part of a job, you must code `USER=userid` on the JCL JOB statement. In either case, the *userid* specified in the RACF started-procedures table or the *userid* specified on the JOB statement must have sufficient RACF access authority to read and update the LOGY data set.

If the edit-log data set is RACF-protected, you must take special steps before calling the HSMEDIT procedure. The HSMEDIT procedure processes the ARCPEDIT program to format and print the information in the edit-log data set. The HSMEDIT procedure normally resides in SYS1.SAMPLIB in member ARCSTRST, and the ARCPEDIT program normally resides in the LINKLIB data set. If the HSMEDIT procedure is called as a started task, the RACF started-procedures table must be updated to include the procedure name (HSMEDIT) and the RACF user ID to be associated with the procedure when it is started. If the HSMEDIT procedure is called as part of a job, you must code `USER=userid` on the OS/VS2 JCL JOB statement. In either case, the *userid* specified in the RACF started-procedures table or the *userid* specified on the JOB statement must have sufficient RACF access authority to read the edit-log data set.

The ARCPRLOG program selects the management work elements (MWEs) from all DFSMSHsm commands and the statistics records for each completed DFSMSHsm function for output to the ARCPEDIT program. You use the ARCPEDIT program to analyze, edit, and print the selected log records produced by the ARCPRLOG program.

The following example of JCL uses the ARCPRLOG and ARCPEDIT programs with the PROCLIB data set. Job HSMLOG initially analyzes, edits, and prints the information from the log and the LOGY data set.

```
//HSMLOG      JOB
//PRINTLOG    EXEC PGM=ARCPRLOG
//ARCPRINT    DD  SYSOUT=A
//ARCLOG      DD  DSN=DFHSM.HSMLOGY1,DISP=OLD
//ARCEdit     DD  DSN=DFHSM.EDITLOG,DISP=OLD
//*
//EMPTYLOG    EXEC PGM=IEBGENER
//SYSPRINT    DD  SYSOUT=A
//SYSIN       DD  DUMMY
//SYSUT2      DD  DSN=DFHSM.HSMLOGY1,DISP=OLD
//SYSUT1      DD  DUMMY,DCB=(DFHSM.HSMLOGY1)
//*
```

Note:

1. If the HSMLOGY1 data set is empty, do not use the ARCPRLOG program. If you do, unpredictable results can occur.
2. DSN=DFHSM.EDITLOG is only an example data set, created by the starter set. Specify your PS data set name, as appropriate.
3. Note that the log data set used as input to the ARCPRLOG program should not be compressed. This is because the log data set is created with RECFM=F but is opened by ARCPRLOG for update with RECFM=U. This is not allowed for compressed data sets. The input ARCLOG must be either the

HSMLOGY data set or an exact copy of HSMLOGY, with the same attributes: RECFM=F, LRECL=2048, BLKSIZE=2048.

4. The ARCPEDIT program must only be used for the selected records produced by the ARCPRLOG program.
5. Note that FSR records containing more than 144 tape volume entries are truncated when written to the LOGX/LOGY data sets. The formatted dump of each FSR in the ARCPRLOG output will include only the portion of the FSR that was written to the log. When the output volumes included in an FSR for RECYCLE have been truncated, the ARCPRLOG and ARCPEDIT output will display "TOVOL=*****".

Job EDITLOG formats and prints selected log records produced by the HSMLOG job.

```
//EDITLOG JOB
//EDITLOG PROC UID=DFHSM
//EDITLOG EXEC PGM=ARCPEDIT
//ARCPRINT DD SYSOUT=A
//ARCLOG DD DSN=&UID..EDITLOG,DISP=SHR
//
//*
```

Figure 86 on page 612, Figure 87 on page 613, and Figure 88 on page 614 show examples of the printed log output. The following is an alphabetical list of the information contained in the printed log output:

Field Name	Meaning
ABCC	System abnormal end completion code
ALLOC	Time of day allocated
APPLYINC	Indicates APPLYINCREMENTAL or not
ASCB	Pointer to the address space control block of the requester
AVGTIME	Average time for migration, per data set
BLKR	Number of 16K blocks read from a tape backup volume
BLKW	Number of 16K blocks written to a tape backup volume
BUFL	Length of buffer for the "control data set read" management work element
BUFU	Amount of buffer for the "control data set read" management work element
BYTR	Number of bytes read
BYTW	Number of bytes written
CCNT	Number of management work elements processed in the current request
CMDL	Length of the command
CMDO	Offset for TSO scan and parse
CMDT	Command text
COPY DSN	Data set name for the backup version
CPUSEC	Total job step time in milliseconds for the day
DARC	Dynamic allocation error return code
DATE	Date of the log record
DCOP FAIL	Number of requested dump copies that failed
DCOP REQ	Number of dump copies requested
DEVT	Device type as in the UCB
DFLGS	Dump restore flags
DLM	Date last migrated
DLU	Date last used

Field Name	Meaning
DSN	Data set name
DSORG	Data set organization
DUMP COPY REQUESTS	Number of dump copies requested
DUMPCLAS(ES)	DUMPCLASes listed or none
DUMPVOL	Dump volume serial
END	Time of day ended
FAILURES	Number of dump copy failures
FFLGS	Subsequent migration flags
FLGS	Flag bytes
FLG2	More DFSMSHsm flags
FLG3	More DFSMSHsm flags
FRVOL	Volume from which the backup version was copied
FRVSN	Volume from which the data set migrated
FUNC	Function description
GEN	Backup version generation number requested
GROUP	Group name for RACF
GROUP	Group name for RACF
HOST	Host identifier of an DFSMSHsm address space
ID	Log record code identification
JOBNM	Job name of the requesting job
KEY	DFSMSHsm record key
LEN	Length of the management work element
MCNT	Number of management work elements in the request
MIG	Migration
MSGID	Message identification
MWE FUNC	Function code of the management work element
NABEND	Number of DFSMSHsm subtask ABENDs for the day
NAME	Contents of the management work element
NDCOPFAIL	Number of dump copies that failed
NDCOPSSYS	Number of dump copies requested by the system
NDCOPSUSE	Number of dump copies requested by the user
NDSMIGFAIL	Number of failing migrate requests
NDSMIGL1	Number of migrates to ML1
NDSMIGL2	Number of migrates to ML2
NDSPW	New data set password for the recovered data set
NDSRECAFAIL	Recall failures
NDSRECAL1	Recalls from L1
NDSRECAL2	Recalls from L2
NDSRESTFAIL	Number of data set restores that failed
NDSRESTSREQ	Number of data set restores requested

Field Name	Meaning
NDUMPFAIL	Number of volume dumps that failed
NDUMPSSYS	Number of volume dumps requested by the system
NDUMPSUSE	Number of volume dumps requested by the user
NEWDSN	New data set name for the recovered data set
NGBRECA	Gigabytes read during recall
NGBYTMIG	Gigabytes read during migration
NI	Number of inserts in the message
NIPL	Number of DFSMSHsm startups for day
NKBRECA	Kilobytes read during recall
NKBYTMIG	Kilobytes read during migration
NMBRECA	Megabytes read during recall
NMBYTMIG	Megabytes read during migration
NMWE	Number of DFSMSHsm MWEs received
NSHUT	Number of DFSMSHsm shutdowns for day
NTBRECA	Terabytes read during recall
NTBYTMIG	Terabytes read during migration
NVOLRESTFAIL	Number of volume restores that failed
NVOLRESTSREQ	Number of volume restores requested
PW	Data set password
RACFLG	RACF flags
RC	Return code from the request
REAS	Reason code for the errors
RECFM	Record format
RETPD(S)	Retention period list
RQN	Request number
SEQN	Sequence number of this management work element in a multiple request
START	Time of day started
TO	Message directed to
TOD	Time of day
TOVOL	Volume to which the backup version was copied
TOVSN	Volume to which the data set migrated
TRKR	Number of tracks read
TRKW	Number of tracks written
TSCR	Create time stamp (always blank)
TSLU	Last update time stamp (always blank)
TYPE	DFSMSHsm record type
UID	User identification
VER	Backup version number requested
VSN	Volume serial number

Note: The TRKR and TRKW fields are approximate values for the number of tracks read and written and can vary, based on the blocking factors used.

Figure 88. Example of a Summary List from the ARCPEDIT Program

Restarting DFSMSHsm after an abnormal end

DFSMSHsm automatically recovers after most abnormal terminations. However, if DFSMSHsm could not recover from the abnormal end and the RESTART keyword was used in the PROC statement of the startup procedure, DFSMSHsm will restart itself. The RESTART keyword allows you to specify a startup procedure—which can be the same or different from the original startup procedure—and to pass additional parameters to DFSMSHsm. RESTART is only valid in an ESA environment.

Should an abnormal end occur that interrupts MVS processing, DFSMSHsm can process any waiting requests as long as the extended common service area (ECSA) is not disturbed. When DFSMSHsm is restarted, it will process any requests that are waiting in the ECSA.

Recovery from an abnormal end could possibly extend long enough to cause checking for the need to restart to occur outside the automatic processing window for migration, backup, or dump. Should such an incident occur and should you want the automatic function to restart, issue one of the following commands (as appropriate for the function that you want to start):

```
SETSYS PRIMARYSPMGMTSTART (starttime,endingtime)
SETSYS SECONDARYSPMGMTSTART (starttime,endingtime)
SETSYS AUTOBACKUPSTART (starttime,lateststarttime,quiescetime)
SETSYS AUTODUMPSTART (starttime,lateststarttime,quiescetime)
```

Leave *starttime* as it is for normal operations. Change *endingtime*, *lateststarttime* and *quiescetime* to be later than the time that DFSMSHsm is restarted. *starttime* specifies the planned start time. *Endingtime* or *quiescetime* determine when DFSMSHsm stops processing new volumes for the automatic function being processed. Because you do not change the *starttime* specification, DFSMSHsm recognizes that you are not defining a new start window for the function. After the function has completed, you can issue a new SETSYS command to reset *endingtime*, *lateststarttime*, and *quiescetime* to their former values.

If a DFSMSHsm host fails in a sysplex environment where secondary host promotion is enabled, the unique functions of a primary host, or the secondary space management processing of any host are eligible to be taken over by a promoted host, when certain conditions are met.

If you are using the common recall queue (CRQ) when a host fails, all of the host's recall requests on the CRQ remain intact. They are eligible for processing by other active hosts, and the coupling facility notifies the remaining connected hosts of the failure. Also, requests that were in-process remain on the CRQ and are available for restart by other hosts.

Related reading

For more information about secondary host promotion, see [z/OS DFSMSHsm Implementation and Customization Guide](#).

Running automatic functions concurrently

Although the example system that has been used to explain the automatic functions of DFSMSHsm used different times for automatic backup, dump, and migration, any or all of the functions can run concurrently, either in the same host or in different hosts.

When running the automatic functions concurrently, you must remember that the first thing that automatic backup does on the primary host is to optionally back up the control data sets. While the control data sets are being backed up, automatic dump, automatic volume space management and automatic secondary space management are delayed. Also, if automatic dump, automatic volume space management or automatic secondary space management are running when automatic backup begins to back up the control data sets, backup of the control data sets is delayed until migration and dump tasks complete the volumes they are processing and automatic secondary space management completes one of its level functions. If automatic backup starts first, none of the other processes can start until the control data sets are backed up.

Note: Functions such as recycle, tape copy, and audit perform similarly to automatic functions in regards to contention with CDS backup.

Example: In the example system, assume that DFSMSHsm host 1 performs level functions and backup; DFSMSHsm host 2 performs migration; and DFSMSHsm host 3 performs dump. The commands provided are only those that would be particularly different from the examples that have been shown before.

First, the time when each of the DFSMSHsm hosts begins processing must be defined. Issue the following commands:

For DFSMSHsm host 1:

```
SETSYS AUTOBACKUPSTART(0001,0100,0200)
SETSYS SECONDARYSPMGMTSTART(0800,1600)
```

For DFSMSHsm host 2:

```
SETSYS PRIMARYSPMGMTSTART(0030,0500)
```

For DFSMSHsm host 3:

```
SETSYS AUTODUMPSTART(0030,0300,0500)
```

Automatic backup is started early in z/OS image 1 to allow it to back up the control data sets. After the control data sets are backed up, the other automatic functions are started.

For concurrent processing as it has been previously defined, the z/OS images that are to process each function must be defined to the storage groups. The MIGRATE SYSTEM/SYS GROUP NAME, BACKUP SYSTEM/SYS GROUP NAME, and DUMP SYSTEM/SYS GROUP NAME attributes are used in the storage groups to provide the definitions for SMS-managed volumes.

For example, the attributes in all storage groups would be set as follows:

```
BACKUP SYSTEM/SYS GROUP NAME ===> PRC1
```

```
MIGRATE SYSTEM/SYS GROUP NAME ===> PRC2
```

```
DUMP SYSTEM/SYS GROUP NAME ===> PRC3
```

Note: System group names can also be used for BACKUP SYSTEM/SYS GROUP NAME, MIGRATE SYSTEM/SYS GROUP NAME, and DUMP SYSTEM/SYS GROUP NAME.

Use the ADDVOL command to provide z/OS image definitions for non-SMS-managed volumes. For example, the following ADDVOL commands can be used to control the common volumes (GP0001, GP0002, GP0003).

For DFSMSHsm host 1:

```
ADDVOL GP0001 PRIMARY(NOAUTOMIGRATION, AUTOBACKUP, -  
NOAUTODUMP)  
ADDVOL GP0002 PRIMARY(NOAUTOMIGRATION, AUTOBACKUP, -  
NOAUTODUMP)  
ADDVOL GP0003 PRIMARY(NOAUTOMIGRATION, AUTOBACKUP, -  
NOAUTODUMP)
```

For DFSMSHsm host 2:

```
ADDVOL GP0001 PRIMARY(AUTOMIGRATION, NOAUTOBACKUP, -  
NOAUTODUMP)  
ADDVOL GP0002 PRIMARY(AUTOMIGRATION, NOAUTOBACKUP, -  
NOAUTODUMP)  
ADDVOL GP0003 PRIMARY(AUTOMIGRATION, NOAUTOBACKUP, -  
NOAUTODUMP)
```

For DFSMSHsm host 3:

```
ADDVOL GP0001 PRIMARY(NOAUTOMIGRATION, NOAUTOBACKUP, -  
AUTODUMP)  
ADDVOL GP0002 PRIMARY(NOAUTOMIGRATION, NOAUTOBACKUP, -  
AUTODUMP)  
ADDVOL GP0003 PRIMARY(NOAUTOMIGRATION, NOAUTOBACKUP, -  
AUTODUMP)
```

Updating the DFSMSHsm control data sets

You can use the UPDTCDS command to update specific fields within the control data sets. Specifically, you can update the expiration date of copy pool dump copies. DFSMSHsm updates all of the corresponding control data set records with the value specified on the UPDTCDS command.

To display the current versions, dump classes and expiration dates for existing dump copies associated with a copy pool, use the LIST COPYPOOL(*cpname*) command. You can then use this information to issue the UPDTCDS command to update an expiration date for a dump copy.

The following command updates the expiration date for copy pool COPYPOOL1, version 124, class ONSITE to 2050/12/31.

```
UPDTCDS COPYPOOL(COPYPOOL1) VERSION(124) DUMPEXPIRATION(DUMPCCLASS(ONSITE) NEWDATE(2050/12/31))
```

Chapter 18. RACF considerations

Throughout this document, the use of the Resource Access Control Facility (RACF) is recommended because DFSMSHsm requests RACF authorization before it allows access to data sets or UNIX files by non-DFSMSHsm-authorized users. RACF can also prevent access to DFSMSHsm-owned data sets except by users with specific RACF authorization.

In addition, by utilizing FACILITY class profiles, RACF can control command-level access for end-users and storage administrators.

You can use SECLABEL CLASS to control data set access. During initialization, DFSMSHsm checks to see if SECLABEL CLASS is active. If SECLABEL CLASS or RACF is activated or deactivated after DFSMSHsm startup, you must stop and restart DFSMSHsm to reset the SECLABEL indicator.

All RACF requests from DFSMSHsm are made through the system authorization facility (SAF). SAF conditionally directs control to RACF (if present) or to a user-supplied processing routine. RACF is determined to be installed by inspection of control block fields. If a RACF-equivalent product sets these fields the same as RACF, DFSMSHsm operates as if RACF were installed. Data management checks the user's authority during data set open when the user attempts to access the data.

RACF basics

To understand the relationship between RACF and DFSMSHsm, you must understand the RACF concepts of RACF profiles, RACF indication, always-call support, and protect-all environment.

RACF data set profiles

RACF controls data set access by identifying and verifying authorized users and by preventing unauthorized users from accessing data. RACF uses the information in a data set profile to determine whether a user is authorized to access the data set.

RACF has two types of RACF data set profiles: *generic* and *discrete*. The generic data set profile describes one or more data sets that have a similar name structure. For example, all data sets with the high-level name qualifier 'JJJ' can be described in a single generic data set profile. The discrete data set profile describes a specific data set on a particular volume.

Generic profile

RACF TSO commands create and maintain generic data set profiles. Generic profiles are never dynamically created, copied, renamed, or deleted by the operating system or DFSMSHsm. You must activate generic profile support with a RACF SETROPTS command before RACF can use generic profiles for authorization checking.

Generic profiles are designed to work with data sets that conform to a particular naming convention. A single access list then describes the access authorities to all those data sets.

Examples: The following are three generic profiles:

GRP12.LIB.*	Access list A
GRP12.*.CNTL	Access list B

GRP12.*

Access list C

When RACF searches a profile for data set GRP12.SRC.CNTL, it finds that the first profile does not match. The second profile does match; RACF verifies the user's authority with access list B. Note that the third profile also matches, but because it is less specific than the second, RACF does not use it.

In a generic profile definition, an * (asterisk) means any characters that are acceptable to the syntax of a data set name.

Generic profiles contain the following elements:

- Allow for security management by exception. In most cases, data sets that share the same naming conventions have the same security requirements. One profile can apply to many data sets with the same security requirements.
- Are more static than discrete profiles. They are not deleted when a data set is deleted.
- Make data set protection insensitive to DASD migration.
- Enhance performance as compared to discrete profiles. The most recently used generic profiles are kept in storage and are more often reused. Fewer updates to the RACF data set are needed.

Discrete data set profiles

Discrete data set profiles provide a one-to-one relationship between a specific data set on a specific volume and its security authorization requirements. To maintain the one-to-one relationship, discrete profiles are:

- Optionally created when a DASD data set is allocated
- Renamed when the data set is renamed
- Deleted when the data set is scratched

RACF indication implies that a data set is protected by a discrete RACF data set profile.

Related reading

For more information about defining RACF discrete and generic data set profiles, see [z/OS Security Server RACF Security Administrator's Guide](#) and [z/OS Security Server RACF Command Language Reference](#).

RACF indication

A RACF-indicated data set is one whose RACF indicator is on. For a non-VSAM data set, the RACF indicator is a bit in the volume table of contents (VTOC) of the DASD volume on which the data set resides. For a VSAM data set, the RACF indicator is a bit in the catalog record. The indicator remains with the data set even if the data set is moved to another system. If the data set profile is not moved also or is somehow lost, a RACF security administrator must take some action before anyone can access the data set.

You can use the SETSYS RACFIND command to cause DFSMSHsm to set the RACF indicator in the VTOC entry for migrated data sets, or for backup versions if the original data sets are RACF-indicated when they are migrated or backed up. Use the RACFIND parameter to RACF protect DFSMSHsm-owned data sets when you use RACF discrete data set profiles.

Always-call support

A RACF always-call environment exists when all data accesses on behalf of non-DFSMSHsm-authorized users result in the invocation of RACF for authorization checking, regardless of the setting of the RACF indicator in the VTOC entry or catalog record. Always-call is a system-wide convention for protection that is available to data sets that are allocated on DASD. With always-call support, resource managers in the operating system call RACF, regardless of the setting of the RACF indicator in the data set's DSCB. Some of the resource managers of the operating system are:

- OPEN/CLOSE/EOF
- DADSM ALLOCATE/EXTEND/RENAME/SCRATCH
- IEHMOVE

For details on the security facilities in your system, see your Security Administrator.

Without an always-call environment, generic profiles do not necessarily provide protection for the data sets they cover, because an unauthorized user might be able to access the data sets if the RACF indicator is not on. In this environment, use only discrete profiles. When the RACFIND parameter of the SETSYS command is in effect, DFSMSHsm turns on the VTOC entry RACF indicator to prohibit access to the backup versions and migration copies of RACF-indicated data sets.

RACF indicator with always-call

RACF's response to resource management authorization requests depends on the RACF indicator setting.

If the authorized requester (the caller) informs RACF that it believes the data set is protected by a discrete profile (by using the RACFIND=YES parameter), RACF first looks for a discrete profile. If none is found, RACF checks for a matching generic profile. If no generic profile is found, RACF rejects the request.

If the authorized requester (the caller) informs RACF that it believes the data set is not protected by a discrete profile (by using the RACFIND=NO parameter), RACF checks only for a generic profile.

A fundamental difference exists between RACF-indicated and non-RACF-indicated data sets. If no profile is found, RACF denies requests for RACF-indicated data sets but allows access for non-RACF-indicated data sets.

RACF protect-all environment

You have the option to fail access to data sets that are covered by neither a discrete nor a generic RACF profile. This environment is specified with the RACF SETROPTS command and the PROTECTALL keyword. If this option is in effect, RACF returns a "not-authorized" return code when normal access checking or data set creation authorization checking is done. For the DFSMSHsm user, it means that failure caused by a lack of profile does not appear to be different from failure caused by a lack of authorization.
