

z/OS
3.2

*C/C++
Runtime Library Reference*

Note

Before using this information and the product it supports, read the information in [“Notices” on page 2171](#).

This edition applies to IBM® z/OS® 3.2 (5655-ZOS) and to all subsequent releases and modifications until otherwise indicated in new editions.

| Figures..... | xxxi |
| Tables..... | xxxiii |
| About this document..... | xxxvii |
| Where to find more information..... | xxxix |
| z/OS Basic Skills in IBM Documentation..... | xxxix |
| How to provide feedback to IBM..... | xli |
| Summary of changes..... | xlili |
| Summary of changes for z/OS 3.2..... | xlili |
| Summary of changes for z/OS 3.1..... | xlili |
| Chapter 1. About z/OS C/C++ runtime library..... | 1 |
| AMODE 64 considerations..... | 1 |
| Chapter 2. Header files..... | 3 |
| Feature test macros..... | 3 |
| C/C++ header files..... | 16 |
| aio.h — Asynchronous I/O operations..... | 16 |
| arpa/inet.h — Internet operations..... | 16 |
| arpa/nameser.h — Construct and inspect DNS requests..... | 16 |
| assert.h — Insert diagnostics..... | 16 |
| _Ccsid.h — CCSID to codeset name conversion..... | 17 |
| ceedcct.h — C declarations of Language Environment..... | 17 |
| cics.h — Verify CICS..... | 17 |
| collate.h — Current locale's collating properties..... | 17 |
| cpio.h — CPIO archive values..... | 17 |
| csp.h — Define __csplist macro..... | 17 |
| ctest.h — Debug and diagnostics..... | 17 |
| ctype.h — Character classification..... | 17 |
| decimal.h — Fixed-point decimal operations..... | 18 |
| dirent.h — POSIX directory access..... | 18 |
| dlfcn.h — Define macros for use with dlopen()..... | 18 |
| dll.h — DLL functions..... | 19 |
| dynit.h — Dynamic allocation routines..... | 19 |
| env.h — Set and clear environment variables..... | 19 |
| errno.h — Symbolic constants for errno..... | 19 |
| fcntl.h — POSIX functions for file operations..... | 23 |
| features.h — Feature test macros..... | 23 |
| fenv.h — Floating-point environment..... | 23 |
| float.h — ISO C/C++ constants for floating-point data types..... | 24 |
| fmtmsg.h — Message display structures..... | 27 |
| fnmatch.h — Filename matching types..... | 27 |
| fpxcp.h — Floating-point exception interfaces..... | 27 |
| __ftp.h — FTP resolver functions..... | 27 |
| ftw.h — File tree traversal constants..... | 27 |
| getopt.h — z/OS UNIX function for parsing command line option..... | 27 |

| | |
|---|----|
| __gfunc.h — __gtca and __gtab functions..... | 27 |
| glob.h — Pathname pattern matching types..... | 27 |
| grp.h — Access group databases..... | 27 |
| iconv.h — Code conversion..... | 28 |
| _Ieee754.h — IEEE 754 interfaces..... | 28 |
| ims.h — Invoke IMS facilities..... | 28 |
| inttypes.h — I/O format of integer types..... | 28 |
| iso646.h —Macros for operators..... | 31 |
| langinfo.h —Macros for date and time..... | 32 |
| lc_core.h — Locale-related data structures..... | 34 |
| lc_sys.h — Build references to locale methods in ASCII locales..... | 34 |
| __le_api.h — AMODE 64 C functions in Language Environment..... | 34 |
| leawi.h — Macros for Language Environment Application Writer Interfaces..... | 34 |
| libgen.h — Pattern matching functions..... | 34 |
| limits.h — Standard values for limits on resources..... | 34 |
| localdef.h — Data structures for locale objects..... | 36 |
| locale.h — Locale settings..... | 36 |
| math.h — Floating-point math functions..... | 40 |
| memory.h — Memory operations..... | 45 |
| monetary.h — strfmon() function..... | 45 |
| msgcat.h — Message catalog structures and definitions..... | 45 |
| mtf.h — Multitasking facility functions..... | 45 |
| _Nascii.h — Bimodal application..... | 45 |
| ndbm.h — ndbm database operations..... | 45 |
| netdb.h — Network database operations..... | 45 |
| net/if.h — Network interface structures and definitions..... | 46 |
| net/rtroute.h — Network routing structures and definitions..... | 47 |
| netinet/icmp6.h — ICMPv6 header options..... | 47 |
| netinet/in.h — Internet protocol family..... | 50 |
| netinet/ip6.h — IPv6 header options..... | 51 |
| netinet/tcp.h — Internet Transmission Control Protocol..... | 52 |
| nlist.h — nlist() fucntion..... | 52 |
| nl_types.h — National languages..... | 52 |
| poll.h — poll() function..... | 53 |
| pthread.h — Thread interfaces..... | 53 |
| pwd.h — Access user database through password structure..... | 56 |
| re_comp.h — Regular expression matching functions for re_comp()..... | 56 |
| regex.h — Regular expression functions..... | 57 |
| regexp.h — Regular expression declarations..... | 57 |
| resolv.h — IP Address Resolution..... | 57 |
| rexec.h — rexec() and rexec_af() functions..... | 57 |
| sched.h — Manipulate and examine process execution scheduling..... | 57 |
| search.h — Searching tables..... | 58 |
| setjmp.h — Manipulate program state..... | 58 |
| signal.h — Exception handling..... | 58 |
| spawn.h — spawn() constants and inheritance structure..... | 59 |
| spc.h — System library functions and storage allocation..... | 59 |
| stdalign.h — Alignment..... | 59 |
| stdarg.h — Access arguments in functions with variable-length argument lists..... | 60 |
| stdbool.h — Macros for bool type..... | 60 |
| stddef.h — typedef statements..... | 60 |
| stddef.h — typedef statements..... | 60 |
| stdint.h — Integer types..... | 60 |
| stdio.h — Standard input and output..... | 63 |
| stdio_ext.h — stdio extensions..... | 65 |
| stdlib.h — Standard library functions..... | 65 |
| string.h — String manipulation functions..... | 66 |
| strings.h — String operations..... | 67 |

| | |
|--|----|
| stropts.h — Stream interface..... | 67 |
| syslog.h — System error logging..... | 67 |
| sys/acl.h — Manipulate ACL..... | 67 |
| sys/__cpl.h — __cpl() function and symbolic constants..... | 67 |
| sys/endian.h — Endian-ness of the system..... | 68 |
| sys/epoll.h — I/O event notification facility functions..... | 68 |
| sys/eventfd.h — Standard library function..... | 68 |
| sys/file.h — File manipulation constants..... | 68 |
| sys/__getipc.h — Interprocess communication..... | 68 |
| sys/inotify.h — Monitor and notify file system change functions..... | 68 |
| sys/ioctl.h — System I/O definitions and structures..... | 69 |
| sys/ipc.h — Interprocess communication access structure..... | 69 |
| sys/layout.h — Bidirectional conversion of data between Visual and Implicit formats..... | 69 |
| sys/mman.h — Memory management..... | 69 |
| sys/__msg.h — __console() and __console2() functions..... | 69 |
| sys/mntent.h — w_getmntent() function and related structures and constants..... | 69 |
| sys/modes.h — Macros for stat structure..... | 69 |
| sys/mount.h — File system mount and unmount..... | 69 |
| sys/msg.h — Message queue structures..... | 69 |
| sys/prctl.h — Operations on a process or thread..... | 69 |
| sys/ps.h — w_getpsent() function and w_psproc structure..... | 70 |
| sys/random.h — Random data operations..... | 70 |
| sys/resource.h — XSI resource operations..... | 70 |
| sys/select.h — Select types..... | 70 |
| sys/sem.h — Semaphore facility..... | 70 |
| sys/server.h — WorkLoad Manager services..... | 70 |
| sys/shm.h — Shared memory facility..... | 70 |
| sys/socket.h — Sockets definitions..... | 70 |
| sys/stat.h — z/OS UNIX files and access..... | 70 |
| sys/statfs.h — File system status..... | 71 |
| sys/statvfs.h — File system status..... | 71 |
| sys/time.h — Time types..... | 71 |
| sys/timeb.h — Date and time..... | 71 |
| sys/times.h — Processor times..... | 71 |
| sys/ttydev.h — Terminal I/O functions..... | 71 |
| sys/types.h — typedef symbols and structures..... | 71 |
| sys/uio.h — Vector I/O operations..... | 73 |
| sys/un.h — UNIX-domain sockets..... | 73 |
| sys/__ussos.h — Security facility authorization..... | 73 |
| sys/utsname.h — Operating system name..... | 73 |
| sys/wait.h — Hold processes..... | 73 |
| sys/__wlm.h — WorkLoad Manager functions..... | 73 |
| sys/xattr.h — Extended attributes handling..... | 73 |
| tar.h — tar utility..... | 74 |
| termios.h — POSIX terminal I/O functions..... | 74 |
| tgmath.h — Mathematics and complex data type..... | 74 |
| time.h — Time and date..... | 75 |
| uchar.h — Extended character data types..... | 76 |
| ucontext.h — Context related functions..... | 76 |
| uheap.h — Heap storage..... | 77 |
| ulimit.h — ulimit commands..... | 77 |
| unistd.h — Implementation-specific functions..... | 77 |
| utime.h — File access and time modification..... | 78 |
| utmpx.h — User accounting database..... | 78 |
| varargs.h — Handle variable argument lists..... | 78 |
| variant.h — LC_SYNTAX characters..... | 79 |
| wchar.h — ISO/C Multibyte Support extensions..... | 79 |
| wcstr.h — Multibyte functions..... | 80 |

| | |
|--|----|
| wctype.h — Wide character properties..... | 81 |
| wordexp.h — Word expansion types..... | 81 |
| xti.h — _XOPEN_SOURCE_EXTENDED feature test macro..... | 81 |
| XL C++ header files..... | 83 |
| cassert — Enforce assertions..... | 83 |
| cctype — Classify characters..... | 84 |
| cerrno — Test error codes..... | 84 |
| cfloat — Test floating-point type properties..... | 84 |
| ciso646 — ISO646 variant character sets..... | 84 |
| climits — Test integer type properties..... | 84 |
| clocale — Adapt to different cultural conventions..... | 84 |
| cmath — Common mathematical functions..... | 85 |
| complex.h — Complex math functions..... | 85 |
| csetjmp — Execute non-local goto statements..... | 85 |
| csignal — Exception control..... | 86 |
| cstdarg — Access arguments..... | 86 |
| cstddef — Define data types and macros..... | 86 |
| cstdio — Perform input and output..... | 86 |
| cstdlib — Standard library..... | 86 |
| cstring — Manipulate strings..... | 86 |
| ctime — Convert time and date formats..... | 87 |
| cwchar — Manipulating wide streams and strings..... | 87 |
| cwctype — Wide character classification..... | 87 |
| exception — Exception handling..... | 87 |
| new — Storage allocation and free..... | 88 |
| new.h — Storage allocation and free..... | 89 |
| terminat.h — Exception handling..... | 89 |
| typeinfo — Type identification operator..... | 89 |
| typeinfo.h — Type identification operator..... | 90 |
| unexpected.h — Exception handling..... | 90 |

Chapter 3. Library functions..... 91

| | |
|--|-----|
| Names..... | 91 |
| Unsupported functions and external variables in AMODE 64..... | 91 |
| Standards..... | 92 |
| Using C include files from C++..... | 96 |
| Built-in functions..... | 96 |
| IEEE binary floating-point..... | 97 |
| IEEE decimal floating-point..... | 97 |
| External variables..... | 98 |
| The __restrict__ macro..... | 102 |
| The __NORETURN macro..... | 102 |
| The __noreturn__ macro..... | 103 |
| abort() — Stop a program..... | 103 |
| abs(), absf(), absi() — Calculate integer absolute value..... | 105 |
| accept() — Accept a new connection on a socket..... | 106 |
| accept4() — Accept a new connection on a socket..... | 109 |
| accept_and_recv() — Accept connection and receive first message..... | 111 |
| access() — Determine whether a file can be accessed..... | 115 |
| acl_create_entry() — Add a new extended ACL entry to the ACL..... | 117 |
| acl_delete_entry() — Delete an extended ACL entry from the ACL..... | 118 |
| acl_delete_fd() — Delete an ACL by file descriptor..... | 118 |
| acl_delete_file() — Delete an ACL by file name..... | 119 |
| acl_first_entry() — Return to beginning of ACL working storage..... | 121 |
| acl_free() — Release memory allocated to an ACL data object..... | 121 |
| acl_from_text() — Create an ACL from text..... | 122 |
| acl_get_entry() — Get an ACL entry..... | 124 |

| | |
|---|-----|
| acl_get_fd() — Get ACL by file descriptor..... | 125 |
| acl_get_file() — Get ACL by file name..... | 126 |
| acl_init() — Initialize ACL working storage..... | 128 |
| acl_set_fd() — Set an ACL by file descriptor..... | 129 |
| acl_set_file() — Set an ACL by file name..... | 131 |
| acl_sort() — Sort the extended ACL entries..... | 133 |
| acl_to_text() — Convert an ACL to text..... | 133 |
| acl_update_entry() — Update the extended ACL entry..... | 135 |
| acl_valid() — Validate an ACL..... | 136 |
| acos(), acosf(), acosl() — Calculate arccosine..... | 137 |
| acosd32(), acosd64(), acosd128() - Calculate arccosine..... | 139 |
| acosh(), acoshf(), acoshl() — Calculate hyperbolic arccosine..... | 140 |
| acoshd32(), acoshd64(), acoshd128() - Calculate hyperbolic arccosine..... | 142 |
| advance() — Pattern match given a compiled regular expression..... | 143 |
| __ae_correstbl_query() — Return coded character set ID type (ASCII and EBCDIC)..... | 144 |
| aio_cancel() — Cancel an asynchronous I/O request..... | 146 |
| aio_error() — Retrieve error status for an asynchronous I/O operation..... | 147 |
| aio_read() — Asynchronous read from a socket..... | 148 |
| aio_return() — Retrieve status for an asynchronous I/O operation..... | 151 |
| aio_suspend() — Wait for an asynchronous I/O request..... | 151 |
| aio_write() — Asynchronous write to a socket..... | 153 |
| alarm() — Set an alarm..... | 156 |
| aligned_alloc() — Allocating aligned memory blocks..... | 157 |
| alloca() — Allocate storage from the stack..... | 159 |
| arm_bind_thread() — Bind the current thread to a given transaction..... | 160 |
| arm_blocked() — Indicate the processing of a transaction is blocked..... | 163 |
| arm_correlator_get_length() — Get the actual size of the transaction correlator..... | 165 |
| arm_end_application() — Undefined an ARM application..... | 166 |
| arm_get_correlator_max_length() — Get the max length of the transaction correlator..... | 167 |
| arm_get_timestamp() — Get the current timestamp..... | 168 |
| arm_init_application() — Defines an ARM application..... | 169 |
| arm_init_transaction_type() — Defines and initializes an ARM transaction type..... | 171 |
| arm_start_transaction() — Mark the start of an ARM transaction..... | 173 |
| arm_stop_transaction() — Mark the end of an ARM transaction..... | 174 |
| arm_unbind_thread() — Unbind the current thread to a given transaction..... | 176 |
| arm_unblocked() — Indicate the processing of a transaction is no longer blocked..... | 177 |
| arm_update_transaction() — Update a given transaction..... | 178 |
| asctime(), asctime64() — Convert time to character string..... | 180 |
| asctime_r(), asctime64_r() — Convert date and time to a character string..... | 182 |
| asin(), asinf(), asinl() — Calculate arcsine..... | 183 |
| asind32(), asind64(), asind128() - Calculate arcsine..... | 184 |
| asinh(), asinhf(), asinhl() — Calculate hyperbolic arcsine..... | 186 |
| asinhd32(), asinhd64(), asinhd128() - Calculate hyperbolic arcsine..... | 187 |
| asprintf(), vasprintf() — Print to allocated string..... | 188 |
| assert() — Verify condition..... | 189 |
| atan(), atanf(), atanl(), atan2(), atan2f(), atan2l() — Calculate arctangent..... | 191 |
| atand32(), atand64(), atand128(), atan2d32(), atan2d64(), atan2d128() - Calculate arctangent..... | 192 |
| atanh(), atanhf(), atanh() — Calculate hyperbolic arctangent..... | 194 |
| atanhd32(), atanh64(), atanh128() - Calculate hyperbolic arctangent..... | 195 |
| __atanpid32(), __atanpid64(), __atanpid128() - Calculate arctangent(x)/pi..... | 196 |
| atexit() — Register program termination function..... | 197 |
| __atoe() — ISO8859-1 to EBCDIC string conversion..... | 199 |
| __atoe_l() — ISO8859-1 to EBCDIC conversion operation..... | 200 |
| atof() — Convert character string to double..... | 201 |
| atoi() — Convert character string to integer..... | 202 |
| atol() — Convert character string to long..... | 203 |
| atoll() — Convert character string to signed long long..... | 204 |
| __authenticate() — Authenticate the specified user's credentials..... | 204 |

| | |
|--|-----|
| __a2e_l() — Convert characters from ASCII to EBCDIC..... | 208 |
| __a2e_s() — Convert string from ASCII to EBCDIC..... | 209 |
| a64l() — Convert base 64 string representation to long integer..... | 209 |
| basename() — Return the last component of a path name..... | 210 |
| bcmp() — Compare bytes in memory..... | 211 |
| bcopy() — Copy bytes in memory..... | 212 |
| bind() — Bind a name to a socket..... | 213 |
| bind2addrsel() - Bind with source address selection..... | 217 |
| brk() — Change space allocation..... | 219 |
| bsd_signal() — BSD version of signal()..... | 220 |
| bsearch() — Search arrays..... | 221 |
| btowc() — Convert single-byte character to wide-character..... | 223 |
| bzero() — Zero bytes in memory..... | 224 |
| c16rtomb() — Convert a char16_t character to a multibyte character..... | 224 |
| c32rtomb() — Convert a char32_t character to a multibyte character..... | 226 |
| __cabend() — Terminate the process with an abend..... | 228 |
| cabs(), cabsf(), cabsl() — Calculate the complex absolute value..... | 228 |
| cacos(), cacosf(), cacosl() — Calculate the complex arc cosine..... | 230 |
| cacosh(), cacoshf(), cacoshl() — Calculate the complex arc hyperbolic cosine..... | 231 |
| calloc() — Reserve and initialize storage..... | 232 |
| carg(), cargf(), cargl() — Calculate the argument..... | 234 |
| casin(), casinf(), casinl() — Calculate the complex arc sine..... | 235 |
| casinh(), casinhf(), casinhl() — Calculate the complex arc hyperbolic sine..... | 235 |
| catan(), catanf(), catanl() — Calculate the complex arc tangent..... | 236 |
| catanh(), catanhf(), catanhl() — Calculate the complex arc hyperbolic tangent..... | 237 |
| catclose() — Close a message catalog descriptor..... | 238 |
| catgets() — Read a program message..... | 239 |
| catopen() — Open a message catalog..... | 240 |
| cbrt(), cbrtf(), cbrtl() — Calculate the cube root..... | 241 |
| cbrtd32(), cbrtd64(), cbrtd128() — Calculate the cube root..... | 242 |
| cclass() — Return characters in a character class..... | 243 |
| ccos(), ccosf(), ccosl() — Calculate the complex cosine..... | 245 |
| ccosh(), ccoshf(), ccoshl() — Calculate the complex hyperbolic cosine..... | 246 |
| __CcsidType() — Return coded character set ID type..... | 247 |
| cds() — Compare double and swap..... | 247 |
| cdump() — Request a main storage dump..... | 248 |
| ceil(), ceilf(), ceill() — Round up to integral value..... | 249 |
| ceild32(), ceild64(), ceild128() — Round up to integral value..... | 250 |
| __certificate() — Register, deregister, or authenticate a digital certificate..... | 251 |
| cexp(), cexpf(), cexpl() — Calculate the complex exponential..... | 253 |
| cfgetispeed() — Determine the input baud rate..... | 254 |
| cfgetospeed() — Determine the output baud rate..... | 256 |
| cfsetispeed() — Set the input baud rate in the termios..... | 258 |
| cfsetospeed() — Set the output baud rate in the termios..... | 260 |
| __chattr(), __chattr64() — Change the attributes of a file or directory..... | 261 |
| __chattrat(), __chattrat64() — Change the attributes of a file or directory..... | 265 |
| chaudit() — Change audit flags for a file by path..... | 267 |
| chdir() — Change the working directory..... | 270 |
| __check_resource_auth_np() — Determine access to MVS resources..... | 271 |
| CheckSchEnv() — Check WLM scheduling environment..... | 273 |
| chmod() — Change the mode of a file or directory..... | 274 |
| chown() — Change the owner or group of a file or directory..... | 277 |
| chpriority() — Change the scheduling priority of a process..... | 279 |
| chroot() — Change root directory..... | 281 |
| cimag(), cimagf(), cimagl() — Calculate the complex imaginary part..... | 282 |
| clearenv() — Clear environment variables..... | 283 |
| clearerr() — Reset error and end of file (EOF)..... | 285 |
| clock() — Determine processor time..... | 286 |

| | | |
|--|--|-----|
| clock_gettime() | Retrieve the time of the specified clock..... | 288 |
| clog(), clogf(), clogl() | Calculate the complex natural logarithm..... | 289 |
| clone() | Create a child process..... | 289 |
| close() | Close a file..... | 293 |
| closedir() | Close a directory..... | 296 |
| closelog() | Close the control log..... | 297 |
| clrmemf() | Clear memory files..... | 298 |
| __cnvblk() | Convert block..... | 299 |
| collequiv() | Return a list of equivalent collating elements..... | 300 |
| collorder() | Return list of collating elements..... | 301 |
| collrange() | Calculate the range list of collating elements..... | 303 |
| colltostr() | Return a string for a collating element..... | 304 |
| compile() | Compile regular expression..... | 305 |
| confstr() | Get configurable variables..... | 309 |
| conj(), conjf(), conjl() | Calculate the complex conjugate..... | 311 |
| connect() | Connect a socket..... | 312 |
| ConnectExportImport() | WLM connect for export or import use..... | 316 |
| ConnectServer() | Connect to WLM as a server manager..... | 317 |
| ConnectWorkMgr() | Connect to WLM as a work manager..... | 318 |
| __console() | Console communication services..... | 320 |
| __console2() | Enhanced console communication services..... | 322 |
| ContinueWorkUnit() | Continue WLM work unit..... | 325 |
| __convert_id_np() | Convert between DCE UUID and user ID..... | 326 |
| copysign(), copysignf(), copysignl() | Copy the sign from one floating-point number to another..... | 328 |
| copysignd32(), copysignd64(), copysignd128() | Copy the sign from one floating-point number to another..... | 329 |
| cos(), cosf(), cosl() | Calculate cosine..... | 330 |
| cosd32(), cosd64(), cosd128() | Calculate cosine..... | 332 |
| cosh(), coshf(), coshl() | Calculate hyperbolic cosine..... | 333 |
| coshd32(), coshd64(), coshd128() | Calculate hyperbolic cosine..... | 334 |
| __cospid32(), __cospid64(), __cospid128() | Calculate cosine of pi *x | 335 |
| __cotan(), __cotanf(), __cotanl() | Calculate cotangent..... | 336 |
| __cpl() | CPL interface service..... | 337 |
| cpow(), cpowf(), cpowl() | Calculate the complex power..... | 338 |
| cproj(), cprojf(), cprojl() | Calculate the projection..... | 340 |
| creal(), crealf(), creall() | Calculate the complex real part..... | 341 |
| creat() | Create a new file or rewrite an existing one..... | 342 |
| CreateWorkUnit() | Create WLM work unit..... | 345 |
| crypt() | String encoding function..... | 347 |
| cs() | Compare and swap..... | 348 |
| csid() | Character set ID for multibyte character..... | 348 |
| csin(), csinf(), csinl() | Calculate the complex sine..... | 349 |
| csinh(), csinhf(), csinhl() | Calculate the complex hyperbolic sine..... | 350 |
| __CSNameType() | Return codeset name type..... | 351 |
| csnap() | Request a condensed dump..... | 352 |
| __csplist | Retrieve CSP parameters..... | 353 |
| csqrt(), csqrtf(), csqrtl() | Calculate the complex square root..... | 354 |
| ctan(), ctanf(), ctanl() | Calculate the complex tangent..... | 354 |
| ctanh(), ctanhf(), ctanhl() | Calculate the complex hyperbolic tangent..... | 355 |
| ctdli() | Call to DL/I..... | 356 |
| ctermid() | Generate path name for controlling terminal..... | 358 |
| ctest() | Start debug tool..... | 359 |
| ctime(), ctime64() | Convert time to character string..... | 360 |
| ctime_r(), ctime64_r() | Convert time value to date and time character string..... | 362 |
| ctrace() | Request a traceback..... | 363 |
| cuserid() | Return character login of the user..... | 365 |
| dbm_clearerr() | Clear database error indicator..... | 366 |
| dbm_close() | Close a database..... | 367 |

| | | |
|---|--|-----|
| dbm_delete() | — Delete database record..... | 368 |
| dbm_error() | — Check database error indicator..... | 369 |
| dbm_fetch() | — Get database content..... | 369 |
| dbm_firstkey() | — Get first key in database..... | 370 |
| dbm_nextkey() | — Get next key in database..... | 371 |
| dbm_open() | — Open a database..... | 373 |
| dbm_store() | — Store database record..... | 374 |
| decabs() | — Decimal absolute value..... | 375 |
| decchk() | — Check for valid decimal types..... | 376 |
| decfix() | — Fix up a nonpreferred sign variable..... | 378 |
| DeleteWorkUnit() | — Delete a WLM work unit..... | 379 |
| difftime(), difftime64() | — Compute time difference..... | 380 |
| dirfd() | — Get directory stream file descriptor..... | 381 |
| dirname() | — Report the parent directory of a path name..... | 382 |
| __discarddata() | — Release pages backing virtual storage..... | 383 |
| DisconnectServer() | — Disconnect from WLM server..... | 384 |
| div() | — Calculate quotient and remainder..... | 385 |
| dlclose() | — Close a dlopen() object..... | 386 |
| dLError() | — Get diagnostic information..... | 387 |
| dlopen() | — Gain access to a dynamic link library..... | 388 |
| dlsym() | — Obtain the address of a symbol from a dlopen() object..... | 390 |
| dllfree() | — Free the supplied dynamic link library..... | 392 |
| dllload() | — Load the dynamic link library and connect it to the application..... | 394 |
| dllqueryfn() | — Obtain a pointer to a dynamic link library function..... | 396 |
| dllqueryvar() | — Obtain a pointer to a dynamic link library variable..... | 397 |
| dn_comp() | — Resolver domain name compression..... | 398 |
| dn_expand() | — Resolver domain name expansion..... | 399 |
| dn_find() | — Resolver domain name find..... | 400 |
| dn_skipname() | — Resolver domain name skipping..... | 401 |
| dprintf() | — Print to a file descriptor..... | 402 |
| drand48() | — Pseudo-random number generator..... | 403 |
| dup() | — Duplicate an open file descriptor..... | 404 |
| dup2() | — Duplicate an open file descriptor to another..... | 406 |
| dup3() | — Duplicate an open file descriptor with flag setting..... | 408 |
| dynalloc() | — Allocate a data set..... | 409 |
| dynfree() | — Deallocate a data set..... | 415 |
| dyninit() | — Initialize __dyn_t structure..... | 416 |
| ecvt() | — Convert double to string..... | 417 |
| encrypt() | — Encoding function..... | 418 |
| endgrent() | — Group database entry functions..... | 419 |
| endhostent() | — Close the host information data set..... | 420 |
| endnetent() | — Close network information data sets..... | 421 |
| endprotoent() | — Work with a protocol entry..... | 422 |
| endpwent() | — User database functions..... | 423 |
| endservent() | — Close network services information data sets..... | 424 |
| endutxent() | — Close the utmpx database..... | 425 |
| epoll_create(), epoll_create1() | — Open an epoll file descriptor..... | 426 |
| epoll_ctl() | — Control interface for an epoll file descriptor..... | 427 |
| epoll_wait(), epoll_pwait() | — Wait for an I/O event on an epoll file descriptor..... | 429 |
| erand48() | — Pseudo-random number generator..... | 430 |
| erf(), erfc(), erff(), erfl(), erfcf(), erfcl() | — Calculate error and complementary error functions..... | 432 |
| erfd32(), erfd64(), erfd128(), erfcd32(), erfcd64(), erfcd128() | — Calculate error and complementary error functions..... | 434 |
| __err2ad() | — Return address of reason code of last failure..... | 435 |
| __errno2() | — Return reason code information..... | 436 |
| __etoa() | — EBCDIC to ISO8859-1 string conversion..... | 438 |
| __etoa_l() | — EBCDIC to ISO8859-1 conversion operation..... | 439 |
| eventfd() | — Create a file descriptor for event notification..... | 439 |

| | |
|---|-----|
| exec functions..... | 442 |
| exit() — End program..... | 449 |
| _exit() — End a process and bypass the cleanup..... | 451 |
| _Exit() — Terminate a process..... | 452 |
| exp(), expf(), expl() — Calculate exponential function..... | 453 |
| expd32(), expd64(), expd128() — Calculate exponential function | 454 |
| expm1(), expm1f(), expm1l() — Exponential minus one..... | 455 |
| expm1d32(), expm1d64(), expm1d128() — Exponential minus one..... | 456 |
| ExportWorkUnit() — WLM export service..... | 458 |
| exp2(), exp2f(), exp2l() — Calculate the base-2 exponential..... | 459 |
| exp2d32(), exp2d64(), exp2d128() — Calculate the base-2 exponential..... | 460 |
| extlink_np() — Create an external symbolic link..... | 461 |
| ExtractWorkUnit() — Extract enclave service..... | 463 |
| __e2a_l() — Convert characters from EBCDIC to ASCII..... | 464 |
| __e2a_s() — Convert string from EBCDIC to ASCII..... | 464 |
| fabs(), fabsf(), fabsl() — Calculate floating-point absolute value..... | 465 |
| fabsd32(), fabsd64(), fabsd128() — Calculate floating-point absolute value..... | 466 |
| faccessat() — Determine accessibility of a file relative to directory file descriptor..... | 467 |
| fattach() — Attach a STREAMS-based file descriptor to a file in the file system name space..... | 469 |
| __fbuflen() — Retrieve the buffer size of an open stream..... | 470 |
| __fchattr(), __fchattr64() — Change the attributes of a file or directory by file descriptor..... | 471 |
| fchmod() — Change audit flags for a file by descriptor..... | 473 |
| fchdir() — Change working directory..... | 475 |
| fchmod() — Change the mode of a file or directory by descriptor..... | 476 |
| fchmodat() — Change the mode of a file relative to a directory file descriptor..... | 477 |
| fchown() — Change the owner or group by file descriptor..... | 479 |
| fchownat() — Change owner and group of a file relative to directory file descriptor..... | 481 |
| fclose() — Close file..... | 482 |
| fcntl() — Control open file descriptors..... | 483 |
| fcvt() — Convert double to string..... | 493 |
| fdasynch() — Write changes to direct-access storage..... | 494 |
| fdclosedir() — Closes directory associated with file descriptor..... | 494 |
| fdelrec() — Delete a VSAM record..... | 496 |
| fdetach() — Detach a name from a STREAMS-based file descriptor..... | 497 |
| fdim(), fdimf(), fdiml() — Calculate the positive difference..... | 498 |
| fdimd32(), fdimd64(), fdimd128() — Calculate the positive difference..... | 499 |
| fdopen() — Associate a stream with an open file descriptor..... | 500 |
| fdopendir() — Opens directory associated with file descriptor..... | 502 |
| feclearexcept() — Clear the floating-point exceptions..... | 503 |
| fe_dec_getround() — Get the current rounding mode..... | 504 |
| fe_dec_setround() — Set the current rounding mode..... | 505 |
| fegetenv() — Store the current floating-point environment..... | 507 |
| fegetexceptflag() — Store the states of floating-point status flags..... | 508 |
| fegetround() — Get the current rounding mode..... | 508 |
| feholdexcept() — Save the current floating-point environment..... | 509 |
| feof() — Test end of file (EOF) indicator..... | 510 |
| feraiseexcept() — Raise the supported floating-point exceptions..... | 512 |
| error() — Test for read and write errors..... | 512 |
| fesetenv() — Set the floating-point environment..... | 514 |
| fesetexceptflag() — Set the floating-point status flags..... | 515 |
| fesetround() — Set the current rounding mode..... | 515 |
| fetch() — Get a load module..... | 516 |
| fetchep() — Share writable static..... | 526 |
| fetestexcept() — Test the floating-point status flags..... | 529 |
| feupdateenv() — Save the currently raised floating-point exceptions..... | 529 |
| fflush() — Write buffer to file..... | 530 |
| ffs() — Find first set bit in an integer..... | 532 |
| fgetc() — Read a character..... | 533 |

| | | |
|----------------------------------|--|-----|
| fgetpos() | — Get file position..... | 534 |
| fgets() | — Read a string from a stream..... | 536 |
| fgetwc() | — Get next wide character..... | 538 |
| fgetws() | — Get a wide-character string..... | 539 |
| fileno() | — Get the file descriptor from an open stream..... | 541 |
| finite() | — Determine the infinity classification of a floating-point number..... | 543 |
| __flbf() | — Determine if a stream is line buffered..... | 544 |
| fldata() | — Retrieve file information..... | 546 |
| flocate() | — Locate a VSAM record..... | 549 |
| flock() | — Apply or remove an advisory lock on an open file..... | 552 |
| flockfile() | — stdio locking..... | 553 |
| floor(), floorf(), floorl() | — Round down to integral value..... | 554 |
| floor32(), floor64(), floor128() | — Round down to integral value..... | 555 |
| _flushlbf() | — Flush all open line-buffered files..... | 556 |
| fma(), fmaf(), fmal() | — Multiply then add..... | 559 |
| fmad32(), fmad64(), fmad128() | — Multiply then add..... | 560 |
| fmax(), fmaxf(), fmaxl() | — Calculate the maximum numeric value..... | 561 |
| fmax32(), fmax64(), fmax128() | — Calculate the maximum numeric value..... | 562 |
| fmin(), fminf(), fminl() | — Calculate the minimum numeric value..... | 563 |
| fmin32(), fmin64(), fmin128() | — Calculate the minimum numeric value..... | 564 |
| fmod(), fmodf(), fmodl() | — Calculate floating-point remainder..... | 565 |
| fmod32(), fmod64(), fmod128() | — Calculate floating-point remainder..... | 566 |
| fmtmsg() | — Display a message in the specified format..... | 567 |
| fnmatch() | — Match file name or path name..... | 569 |
| fopen() | — Open a file..... | 571 |
| fork() | — Create a new process..... | 577 |
| fortrc() | — Return FORTRAN return code..... | 581 |
| fp_clr_flag() | — Reset floating-point exception status flag..... | 581 |
| fp_raise_xcp() | — Raise a floating-point exception..... | 582 |
| fp_read_flag() | — Return the current floating-point exception status..... | 584 |
| fp_read_rnd() | — Determine rounding mode..... | 585 |
| fp_swap_rnd() | — Swap rounding mode..... | 586 |
| fpathconf() | — Determine configurable path name variables..... | 587 |
| fpclassify() | — Classifies an argument value..... | 590 |
| __fpending() | — Retrieve number of bytes pending for write..... | 591 |
| fprintf(), printf(), sprintf() | — Format and write data..... | 593 |
| __fpurge() | — Discard pending data in a stream..... | 605 |
| fputc() | — Write a character..... | 606 |
| fputs() | — Write a string..... | 608 |
| fputwc() | — Output a wide-character..... | 609 |
| fputws() | — Output a wide-character string..... | 611 |
| fread() | — Read items..... | 613 |
| __freable() | — Determine if a stream is open for reading..... | 614 |
| __freadahead() | — Retrieve number of bytes remaining in input buffer..... | 616 |
| __freanding() | — Determine if last operation on stream is a read operation..... | 618 |
| free() | — Free a block of storage..... | 620 |
| freeaddrinfo() | — Free addrinfo storage..... | 621 |
| freopen() | — Redirect an open file..... | 622 |
| frexp(), frexpf(), frexpl() | — Extract mantissa and exponent of the floating-point value..... | 624 |
| frexp32(), frexp64(), frexp128() | — Extract mantissa and exponent of the decimal floating-point value..... | 625 |
| fscanf(), scanf(), sscanf() | — Read and format data..... | 626 |
| fseek() | — Change file position..... | 638 |
| fseeko() | — Change file position..... | 641 |
| __fseterr() | — Set stream in error..... | 644 |
| __fsetlocking() | — Set locking type..... | 645 |
| fsetpos() | — Set file position..... | 647 |
| fstat(), fstat64() | — Get status information about a file..... | 649 |

| | |
|--|-----|
| fstatat(), fstatat64() — Get file status information relative to a directory file descriptor..... | 651 |
| fstatfs() — Get file system statistics..... | 653 |
| fstatvfs() — Get file system information..... | 654 |
| fsync() — Write changes to direct-access storage..... | 655 |
| ftell() — Get current file position..... | 657 |
| ftello() — Get current file position..... | 659 |
| ftime(), ftime64() — Set the date and time..... | 661 |
| ftok() — Generate an interprocess communication (IPC) key..... | 662 |
| ftruncate() — Truncate a file..... | 663 |
| ftrylockfile() — stdio locking..... | 665 |
| ftw(), ftw64() — Traverse a file tree..... | 666 |
| funlockfile() — stdio unlocking..... | 668 |
| fupdate() — Update a VSAM record..... | 669 |
| futimes() — Change file access and modification times..... | 670 |
| futimesat() — Change timestamps of a file relative to a directory file descriptor..... | 672 |
| fwide() — Set stream orientation | 673 |
| fwprintf(), swprintf(), wprintf() — Format and write wide characters..... | 674 |
| __fwritable() — Determine if a stream is open for writing..... | 676 |
| fwrite() — Write items..... | 678 |
| __fwriting() — Determine if last operation on stream is a write operation..... | 679 |
| fwscanf(), swscanf(), wscanf() — Convert formatted wide-character input..... | 681 |
| gai_strerror() — Address and name information error description..... | 683 |
| gamma() — Calculate gamma function..... | 683 |
| gcvrt() — Convert double to string..... | 684 |
| getaddrinfo() — Get address information..... | 685 |
| getc(), getchar() — Read a character..... | 689 |
| getc_unlocked(), getchar_unlocked(), putc_unlocked(), putchar_unlocked() — Stdio with explicit client locking..... | 691 |
| getclientid() — Get the identifier for the calling application..... | 692 |
| __getclientid() — Get the PID identifier for the calling application..... | 693 |
| getcontext() — Get user context..... | 695 |
| __get_cpuid() — Retrieves the system CPUID..... | 697 |
| getcwd() — Get path name of the working directory..... | 697 |
| getdate(), getdate64() — Convert user format date and time..... | 699 |
| getdtablesize() — Get the file descriptor table size..... | 703 |
| getegid() — Get the effective group ID..... | 703 |
| getentropy() — Fill a buffer with random bytes..... | 704 |
| getenv() — Get value of environment variables..... | 705 |
| __getenv() — Get an environment variable..... | 706 |
| geteuid() — Get the effective user ID..... | 708 |
| getgid() — Get the real group ID..... | 709 |
| getgrent() — Get group database entry..... | 710 |
| getgrgid() — Access the group database by ID..... | 710 |
| getgrgid_r() — Get group database entry for a group ID..... | 711 |
| getgrnam() — Access the group database by name..... | 713 |
| getgrnam_r() — Search group database for a name..... | 714 |
| getgroups() — Get a list of supplementary group IDs..... | 715 |
| getgroupsbyname() — Get supplementary group IDs by user name..... | 717 |
| gethostbyaddr() — Get a host entry by address..... | 718 |
| gethostbyname() — Get a host entry by name..... | 720 |
| gethostent() — Get the next host entry..... | 722 |
| gethostid() — Get the unique identifier of the current host..... | 723 |
| gethostname() — Get the name of the host processor..... | 724 |
| getibmopt() — Get IBM TCP/IP image..... | 725 |
| getibmsockopt() — Get IBM specific options associated with a socket..... | 726 |
| __getipcb(), __getipcb64() — Query interprocess communications..... | 727 |
| getipv4sourcefilter() — Get source filter..... | 729 |
| getitimer() — Get value of an interval timer..... | 730 |

| | | |
|--------------------------------------|---|-----|
| getline() | — Read an entire line from a stream..... | 731 |
| getlogin() | — Get the user login name..... | 732 |
| getlogin_r() | — Get login name..... | 734 |
| __getlogin1() | — Get the user login name..... | 735 |
| getmccoll() | — Get next collating element from string..... | 736 |
| getmsg(), getpmsg() | — Receive next message from a STREAMS file..... | 737 |
| getnameinfo() | — Get name information..... | 739 |
| getnetbyaddr() | — Get a network entry by address..... | 741 |
| getnetbyname() | — Get a network entry by name..... | 743 |
| getnetent() | — Get the next network entry..... | 744 |
| getopt() | — Command option parsing..... | 745 |
| getopt_long() | — Command long option parsing..... | 747 |
| getpagesize() | — Get the current page size..... | 748 |
| getpass() | — Read a string of characters without echo..... | 749 |
| getpeername() | — Get the name of the peer connected to a socket..... | 750 |
| getpgid() | — Get process group ID..... | 751 |
| getpgrp() | — Get the process group ID..... | 752 |
| getpid() | — Get the process ID..... | 754 |
| getpmsg() | — Receive next message from a STREAMS file..... | 755 |
| getppid() | — Get the parent process ID..... | 755 |
| getpriority() | — Get process scheduling priority..... | 756 |
| getprotobyname() | — Get a protocol entry by name..... | 757 |
| getprotobynumber() | — Get a protocol entry by number..... | 759 |
| getprotoent() | — Get the next protocol entry..... | 760 |
| getpwent() | — Get user database entry..... | 761 |
| getpwent_r() | — Get user database entry reentrantly..... | 761 |
| getpwnam() | — Access the user database by user name..... | 761 |
| getpwnam_r() | — Search user database for a name..... | 763 |
| getpwuid() | — Access the user database by user ID..... | 764 |
| getpwuid_r() | — Search user database for a user ID..... | 765 |
| getrandom() | — Obtain a series of random bytes..... | 766 |
| getrlimit() | — Get current or maximum resource consumption..... | 767 |
| getrusage() | — Get information about resource utilization..... | 769 |
| gets() | — Read a string..... | 770 |
| getservbyname() | — Get a server entry by name..... | 772 |
| getservbyport() | — Get a service entry by port..... | 773 |
| getservent() | — Get the next service entry..... | 774 |
| getsid() | — Get process group ID of session leader..... | 776 |
| getsockname() | — Get the name of a socket..... | 777 |
| getsockopt() | — Get the options associated with a socket..... | 778 |
| getsourcefilter() | — Get source filter..... | 785 |
| getstablesz() | — Get the socket table size..... | 787 |
| getsubopt() | — Parse suboption arguments..... | 787 |
| getsyntax() | — Return LC_SYNTAX characters..... | 788 |
| __get_system_settings() | — Retrieves system parameters..... | 789 |
| gettimeofday(), gettimeofday64() | — Get date and time..... | 790 |
| getuid() | — Get the real user ID..... | 792 |
| __getuserid() | — Retrieve the active MVS user ID..... | 793 |
| getutxent(), getutxent64() | — Read next entry in utmpx database..... | 794 |
| getutxid(), getutxid64() | — Search by ID utmpx database..... | 795 |
| getutxline(), getutxline64() | — Search by line utmpx database..... | 797 |
| getw() | — Get a machine word from a stream..... | 798 |
| getwc() | — Get a wide character..... | 799 |
| getwchar() | — Get a wide character..... | 801 |
| getwd() | — Get the current working directory..... | 802 |
| getwmcoll() | — Get next collating element from wide string..... | 803 |
| getxattr(), lgetxattr(), fgetxattr() | — Retrieve an extended attribute value..... | 804 |
| givesocket() | — Make the specified socket available..... | 805 |

| | | |
|-------------------------------------|--|-----|
| glob() | — Generate path names matching a pattern..... | 808 |
| globfree() | — Free storage allocated by glob()..... | 810 |
| gmtime(), gmtime64() | — Convert time to broken-down UTC time..... | 811 |
| gmtime_r(), gmtime64_r() | — Convert a time value to broken-down UTC time..... | 813 |
| grantpt() | — Grant access to the subsidiary pseudoterminal device..... | 814 |
| hcreate() | — Create hash search tables..... | 815 |
| hdestroy() | — Destroy hash search tables..... | 816 |
| __heaprpt() | — Obtain dynamic heap storage report..... | 817 |
| hsearch() | — Search hash tables..... | 818 |
| htonl() | — Translate address host to network long..... | 819 |
| htons() | — Translate an unsigned short integer into network byte order..... | 820 |
| hypot(), hypotf(), hypotl() | — Calculate the square root of the squares of two arguments..... | 821 |
| hypotd32(), hypotd64(), hypotd128() | — Calculate the square root of the squares of two arguments..... | 823 |
| ibmsflush() | — Flush the application-side datagram queue..... | 824 |
| iconv() | — Code conversion..... | 824 |
| iconv_close() | — Deallocate code conversion descriptor..... | 827 |
| iconv_open() | — Allocate code conversion descriptor..... | 828 |
| if_freenameindex() | — Free the memory allocated by if_nameindex()..... | 831 |
| if_indextoname() | — Map a network interface index to its corresponding name..... | 831 |
| if_nameindex() | — Return all network interface names and indexes..... | 832 |
| if_nametoindex() | — Map a network interface name to its corresponding index..... | 833 |
| ilogb(), ilogbf(), ilogbl() | — Integer unbiased exponent..... | 834 |
| ilogbd32(), ilogbd64(), ilogbd128() | — Integer unbiased exponent..... | 835 |
| imaxabs() | — Absolute value for intmax_t..... | 836 |
| imaxdiv() | — Quotient and remainder for intmax_t..... | 837 |
| ImportWorkUnit() | — WLM import service..... | 838 |
| index() | — Search for character..... | 839 |
| inet6_is_srcaddr() | — Socket address verification..... | 840 |
| inet6_opt_append() | — Add an option with length "len" and alignment "align" | 842 |
| inet6_opt_find() | — Search for an option specified by the caller | 843 |
| inet6_opt_finish() | — Return the updated total length of extension header | 844 |
| inet6_opt_get_val() | — Extract data items in the data portion of the option | 845 |
| inet6_opt_init() | — Return the number of bytes for empty extension header..... | 846 |
| inet6_opt_next() | — Parse received option headers returning the next option | 846 |
| inet6_opt_set_val() | — Insert data items into the data portion of the option | 848 |
| inet6_rth_add() | — Add an IPv6 address to end of the routing header | 849 |
| inet6_rth_getaddr() | — Return pointer to the IPv6 address specified | 849 |
| inet6_rth_init() | — Initialize an IPv6 routing header buffer..... | 850 |
| inet6_rth_reverse() | — Reverse the order of the addresses..... | 851 |
| inet6_rth_segments() | — Return number of segments contained in header..... | 852 |
| inet6_rth_space() | — Return number of bytes for a routing header | 853 |
| inet_addr() | — Translate an Internet address into network byte order..... | 854 |
| inet_aton() | — Convert Internet address format from text to binary..... | 855 |
| inet_lnaof() | — Translate a local network address into host byte order..... | 856 |
| inet_makeaddr() | — Create an Internet host address..... | 857 |
| inet_netof() | — Get the network number from the Internet host address..... | 859 |
| inet_network() | — Get the network number from the decimal host address..... | 860 |
| inet_ntoa() | — Get the decimal Internet host address..... | 861 |
| inet_ntop() | — Convert Internet address format from binary to text | 862 |
| inet_pton() | — Convert Internet address format from text to binary..... | 864 |
| initgroups() | — Initialize the supplementary group ID list for the process..... | 865 |
| initstate() | — Initialize generator for random()..... | 866 |
| inotify_add_watch() | — Add a watch to an initialized inotify instance..... | 867 |
| inotify_init(), inotify_init1() | — Initialize an inotify instance..... | 870 |
| inotify_rm_watch() | — Remove an existing watch from an inotify instance..... | 871 |
| insque() | — Insert an element into a doubly-linked list..... | 871 |
| ioctl() | — Control device..... | 872 |
| __ipdbcs() | — Retrieve the list of requested DBCS tables to load..... | 890 |

| | | |
|----------------------------|---|-----|
| __ipDomainName() | Retrieve the resolver supplied domain name..... | 890 |
| __ipdpx() | Retrieve the data set prefix specified..... | 891 |
| __iphost() | Retrieve the resolver supplied hostname..... | 892 |
| __ipmsgc() | Determine the case to use for FTP messages..... | 893 |
| __ipnode() | Retrieve the resolver supplied node name..... | 894 |
| __iptcpn() | Retrieve the resolver supplied jobname or user ID..... | 894 |
| isalnum() | to isxdigit() — Test integer value..... | 895 |
| isalpha() | — Test for an alphabetic character..... | 897 |
| isascii() | — Test for 7-bit US-ASCII character..... | 898 |
| isastream() | — Test a file descriptor..... | 902 |
| isatty() | — Test if descriptor represents a terminal..... | 903 |
| __isBFP() | — Determine application floating-point format..... | 905 |
| isblank() | — Test for blank character classification..... | 905 |
| iscics() | — Verify whether CICS is running..... | 906 |
| iscntrl() | — Test for control classification..... | 907 |
| isdigit() | — Test for decimal-digit classification..... | 907 |
| isfinite() | — Determines if its argument has a finite value..... | 908 |
| isgraph() | — Test for graphic classification..... | 908 |
| isgreater() | — Determines if X is greater than Y..... | 909 |
| isgreaterequal() | — Determines if X is greater than or equal to Y..... | 910 |
| isinf() | — Determines if X is \pm infinity..... | 911 |
| isless() | — Determines if X is less than Y..... | 912 |
| islessequal() | — Determines if X is less than or equal to Y..... | 913 |
| islessgreater() | — Determines if X is less or greater than Y..... | 914 |
| islower() | — Test for lowercase..... | 914 |
| ismccollet() | — Identify a multicharacter collating element..... | 915 |
| isnan() | — Test for NaN..... | 916 |
| isnormal() | — Determines if X is normal..... | 917 |
| __isPosixOn() | — Test for POSIX runtime option..... | 918 |
| isprint() | — Test for printable character classification..... | 918 |
| ispunct() | — Test for punctuation classification..... | 918 |
| isspace() | — Test for space character classification..... | 919 |
| isunordered() | — Determine if either X or Y is unordered..... | 919 |
| isupper() | — Test for uppercase letter classification..... | 920 |
| iswalnum() | to iswxdigit() — Test wide integer value..... | 920 |
| iswblank() | — Test for blank character classification..... | 922 |
| iswcntrl() | — Test for control classification..... | 923 |
| iswctype() | — Test for character property..... | 923 |
| iswdigit() | — Test for hexadecimal-digit classification..... | 924 |
| iswgraph() | — Test for graphic classification..... | 924 |
| iswlower() | — Test for lowercase..... | 924 |
| iswprint() | — Test for printable character classification..... | 924 |
| iswpunct() | — Test for punctuation classification..... | 924 |
| iswspace() | — Test for space character classification..... | 924 |
| iswupper() | — Test for uppercase letter classification..... | 925 |
| iswxdigit() | — Test for hexadecimal-digit classification..... | 925 |
| isxdigit() | — Test for hexadecimal-digit classification..... | 925 |
| itoa() | — Convert int into a string..... | 925 |
| JoinWorkUnit() | — Join a WLM work unit..... | 926 |
| jrand48() | — Pseudo-random number generator..... | 927 |
| j0(), j1(), jn() | — Bessel functions of the first kind..... | 929 |
| kill() | — Send a signal to a process..... | 930 |
| killpg() | — Send a signal to a process group..... | 933 |
| labs() | — Calculate long absolute value..... | 934 |
| __lchattr(), __lchattr64() | — Change the attributes of a file or directory when they point to a symbolic or external link..... | 935 |
| lchown() | — Change owner and group of a file..... | 937 |
| lcong48() | — Pseudo-random number initializer..... | 939 |

| | |
|--|------|
| ldexp(), ldexpf(), ldexpl() — Multiply by a power of two..... | 940 |
| ldexpd32(), ldexpd64(), ldexpd128() — Multiply by a power of ten..... | 941 |
| ldiv() — Compute quotient and remainder of integral division..... | 943 |
| LeaveWorkUnit() — Leave a WLM work unit..... | 944 |
| __le_ceegtjs() — Retrieve the value of an exported JCL symbol..... | 945 |
| __le_ceemict() — Manage the interoperability state of current task..... | 947 |
| __le_ceedsgd() — Usage data collection service..... | 949 |
| __le_cib_get() — Get condition information block..... | 953 |
| __le_condition_token_build() — Build a Language Environment condition token..... | 954 |
| __le_debug_set_resume_mch() — Move the resume cursor to a predefined location represented by a machine state..... | 956 |
| __le_msg_add_insert() — Add insert to a Language Environment message..... | 956 |
| __le_msg_get() — Get a Language Environment message..... | 958 |
| __le_msg_get_and_write() — Get and output a Language Environment message..... | 960 |
| __le_msg_write() — Output a Language Environment message to stderr..... | 961 |
| __le_record_dump() — Record information for the active condition..... | 962 |
| __le_traceback() — Call chain traceback service..... | 963 |
| lfind() — Linear search routine..... | 967 |
| lgamma(), lgammaf(), lgammal() — Log gamma function..... | 968 |
| lgammad32(), lgammad64(), lgammad128() — Log gamma function..... | 970 |
| __librel() — Query release level..... | 971 |
| link() — Create a link to a file..... | 973 |
| linkat() — Create a link to a file relative to directory file descriptor..... | 975 |
| listen() — Prepare the server for incoming client requests..... | 977 |
| listxattr(), llistxattr(), flistxattr() — List extended attribute names..... | 978 |
| llabs() — Calculate absolute value of long long integer..... | 979 |
| lldiv() — Compute quotient and remainder of integral division for long long type..... | 980 |
| llround(), llroundf(), llroundl() — Round to the nearest integer..... | 981 |
| llroundd32(), llroundd64(), llroundd128() — Round to the nearest integer..... | 983 |
| ltoa() — Convert long long into a string..... | 985 |
| localdtconv() — Date and time formatting convention inquiry..... | 986 |
| localeconv() — Query numeric conventions..... | 988 |
| localtime(), localtime64() — Convert time and correct for local time..... | 989 |
| localtime_r(), localtime64_r() — Convert time value to broken-down local time..... | 991 |
| lockf() — Record locking on files..... | 993 |
| log(), logf(), logl() — Calculate natural logarithm..... | 995 |
| logb(), logbf(), logbl() — Unbiased exponent..... | 996 |
| logbd32(), logbd64(), logbd128() — Unbiased exponent..... | 998 |
| logd32(), logd64(), logd128() — Calculate natural logarithm..... | 999 |
| __login(), __login_applid() — Create a new security environment for process..... | 1000 |
| log1p(), log1pf(), log1pl() — Natural log of x+1..... | 1002 |
| log1pd32(), log1pd64(), log1pd128() — Natural log of x+1..... | 1003 |
| log10(), log10f(), log10l() — Calculate base 10 logarithm..... | 1005 |
| log10d32(), log10d64(), log10d128() — Calculate base 10 logarithm..... | 1006 |
| log2(), log2f(), log2l() — Calculate the base-2 logarithm..... | 1007 |
| log2d32(), log2d64(), log2d128() — Calculate the base-2 logarithm..... | 1008 |
| longjmp() — Restore stack environment..... | 1009 |
| _longjmp() — Nonlocal goto..... | 1011 |
| rand48() — Pseudo-random number generator..... | 1013 |
| lrint(), lrintf(), lrintl() and llrint(), llrintf(), llrintl() — Round the argument to the nearest integer..... | 1015 |
| lrintd32(), lrintd64(), lrintd128() and llrintd32(), llrintd64(), llrintd128() — Round the argument to the nearest integer..... | 1017 |
| lround(), lroundf(), lroundl() — Round a decimal floating-point number to its nearest integer..... | 1019 |
| lroundd32(), lroundd64(), lroundd128() — Round a floating-point number to its nearest integer.... | 1020 |
| lsearch() — Linear search and update..... | 1022 |
| lseek() — Change the offset of a file..... | 1023 |
| lstat(), lstat64() — Get status of file or symbolic link..... | 1025 |
| l64a() — Convert long to base 64 string representation..... | 1029 |

| | | |
|----------------------------------|---|------|
| ltoa() | — Convert long into a string..... | 1030 |
| lutimes() | — Change file access and modification times..... | 1031 |
| makecontext() | — Modify user context..... | 1032 |
| malloc() | — Reserve storage block..... | 1035 |
| __malloc24() | — Allocate 24-bit storage..... | 1037 |
| __malloc31() | — Allocate 31-bit storage..... | 1038 |
| __map_init() | — Designate a storage area for mapping blocks..... | 1038 |
| __map_service() | — Set memory mapping service..... | 1040 |
| maxcoll() | — Return maximum collating element..... | 1043 |
| maxdesc() | — Get socket numbers to extend beyond the default range..... | 1043 |
| mblen() | — Calculate length of multibyte character..... | 1044 |
| mbrlen() | — Calculate length of multibyte character..... | 1046 |
| mbrtoc16() | — Convert a multibyte character to a char16_t character..... | 1048 |
| mbrtoc32() | — Convert a multibyte character to a char32_t character..... | 1050 |
| mbrtowc() | — Convert a multibyte character to a wide character..... | 1052 |
| mbsinit() | — Test state object for initial state..... | 1054 |
| mbsrtowcs() | — Convert a multibyte string to a wide-character string..... | 1056 |
| mbstowcs() | — Convert multibyte characters to wide characters..... | 1058 |
| mbtowc() | — Convert multibyte character to wide character..... | 1059 |
| m_create_layout() | — Create and initialize a layout object (bidi data)..... | 1061 |
| m_destroy_layout() | — Destroy a layout object (bidi data)..... | 1062 |
| memccpy() | — Copy bytes in memory..... | 1063 |
| memchr() | — Search buffer..... | 1063 |
| memcmp() | — Compare bytes..... | 1065 |
| memcpy() | — Copy buffer..... | 1066 |
| memmove() | — Move buffer..... | 1067 |
| memset() | — Set buffer to value..... | 1069 |
| m_getvalues_layout() | — Query layout values of a layout object (bidi data)..... | 1070 |
| mkdir() | — Make a directory..... | 1071 |
| mkdirat() | — Make a directory..... | 1074 |
| mkfifo() | — Make a FIFO special file..... | 1075 |
| mkfifoat() | — Make a FIFO special file..... | 1077 |
| mknod() | — Make a directory or file..... | 1078 |
| mknodat() | — Make a directory or file..... | 1081 |
| mkstemp() | — Make a unique filename..... | 1082 |
| mktemp() | — Make a unique file name..... | 1083 |
| mktime(), mktime64() | — Convert local time..... | 1084 |
| __mlockall() | — Lock the address space of a process..... | 1086 |
| mmap() | — Map pages of memory..... | 1087 |
| modf(), modff(), modfl() | — Extract fractional and integral parts of floating-point value..... | 1092 |
| modfd32(), modfd64(), modfd128() | — Extract fractional and integral parts of decimal floating-point value | 1093 |
| __moservices() | — Memory object services..... | 1094 |
| mount() | — Make a file system available..... | 1098 |
| __mount() | — Make a file system available..... | 1102 |
| mprotect() | — Set protection of memory mapping..... | 1106 |
| rand48() | — Pseudo-random number generator..... | 1108 |
| m_setvalues_layout() | — Set layout values of a layout object (bidi data)..... | 1109 |
| msgctl(), msgctl64() | — Message control operations..... | 1110 |
| msgget() | — Get message queue..... | 1112 |
| msgrcv() | — Message receive operation..... | 1115 |
| __msgrcv_timed() | — Message receive operation with timeout..... | 1117 |
| msgsnd() | — Message send operations..... | 1119 |
| msgxrcv(), msgxrcv64() | — Extended message receive operation..... | 1120 |
| msync() | — Synchronize memory with physical storage..... | 1123 |
| m_transform_layout() | — Layout transformation for character strings (bidi data)..... | 1124 |
| munmap() | — Unmap pages of memory..... | 1127 |
| __must_stay_clean() | — Enable or query clean..... | 1128 |

| | |
|--|------|
| m_wtransform_layout() — Layout transformation for wide-character strings (bidi data)..... | 1130 |
| nan(), nanf(), nanl() — Return quiet NaN..... | 1133 |
| nand32(), nand64(), nand128() — Return quiet NaN..... | 1134 |
| nanosleep() — High-resolution sleep..... | 1136 |
| nearbyint(), nearbyintf(), nearbyintl() — Round the argument to the nearest integer..... | 1137 |
| nearbyintd32(), nearbyintd64(), nearbyintd128() — Round the argument to the nearest integer | 1139 |
| nextafter(), nextafterf(), nextafterl() — Next representable double float..... | 1141 |
| nextafterd32(), nextafterd64(), and nextafterd128() — Next representable decimal floating-point value..... | 1142 |
| nexttoward(), nexttowardf(), nexttowardl() — Calculate the next representable value..... | 1144 |
| nexttowardd32(), nexttowardd64(), nexttowardd128() — Calculate the next representable value.. | 1146 |
| nftw(), nftw64() — Traverse a file tree..... | 1147 |
| nice() — Change priority of a process..... | 1150 |
| nlist() — Get entries from a name list..... | 1151 |
| nl_langinfo() — Retrieve locale information..... | 1152 |
| nrnd48() — Pseudo-random number generator..... | 1153 |
| ntohl() — Translate a long integer into host byte order..... | 1154 |
| ntohs() — Translate an unsigned short integer into host byte order..... | 1155 |
| open() — Open a file..... | 1157 |
| openat() — Open a file relative to a directory file descriptor..... | 1162 |
| openat2() — Open a file with more extensions..... | 1164 |
| opendir() — Open a directory..... | 1168 |
| __opendir2() — Open a directory..... | 1170 |
| openlog() — Open the system control log..... | 1172 |
| __open_stat(), __open_stat64() — Open a file and get file status information..... | 1173 |
| __osname() — Get true operating system name..... | 1176 |
| __passwd(), __passwd_applid() — Verify or change user password..... | 1177 |
| pathconf() — Determine configurable path name variables..... | 1179 |
| pause() — Suspend a process pending a signal..... | 1182 |
| pclose() — Close a pipe stream to or from a process..... | 1183 |
| perror() — Print error message..... | 1184 |
| __pid_affinity() — Add or delete process affinity..... | 1186 |
| pipe() — Create an unnamed pipe..... | 1188 |
| pipe2() — Create a pipe..... | 1190 |
| pivot_root() — Change root mount..... | 1191 |
| __poe() — Port of entry information..... | 1192 |
| poll() — Monitor activity on file descriptors and message queues..... | 1196 |
| popen() — Initiate a pipe stream to or from a process..... | 1200 |
| posix_memalign() — Reserve aligned storage block..... | 1201 |
| posix_openpt() — Open a pseudo-terminal device..... | 1203 |
| pow(), powf(), powl() — Raise to power..... | 1204 |
| powd32(), powd64(), powd128() — Raise to power..... | 1205 |
| __pow_i() — Raise to a power (R**I)..... | 1207 |
| __pow_ii() — Raise to a power (I**I)..... | 1208 |
| prctl() — Operate on a process or thread..... | 1209 |
| prlimit() — Get or set the hard and soft resource limits of a specified process..... | 1211 |
| pread() — Read from a file or socket without file pointer change..... | 1213 |
| printf() — Format and write data..... | 1215 |
| pselect() - Monitor activity on files or sockets and message queues..... | 1215 |
| psignal() — Print signal description..... | 1215 |
| pthread_atfork() - Register fork handlers..... | 1216 |
| pthread_attr_destroy() — Destroy the thread attributes object..... | 1219 |
| pthread_attr_getdetachstate() — Get the detach state attribute..... | 1221 |
| pthread_attr_getguardsize() - Get guardsize attribute..... | 1223 |
| pthread_attr_getschedparam() - Get scheduling parameter attributes..... | 1224 |
| pthread_attr_getstack() - Get stack attribute..... | 1226 |
| pthread_attr_getstackaddr() - Get stackaddr attribute..... | 1227 |
| pthread_attr_getstacksize() — Get the thread attribute stacksize object..... | 1229 |

| | | |
|--|--|------|
| pthread_attr_getsynctype_np() | — Get thread sync type..... | 1230 |
| pthread_attr_getweight_np() | — Get weight of thread attribute object..... | 1231 |
| pthread_attr_init() | — Initialize a thread attribute object..... | 1233 |
| pthread_attr_setdetachstate() | — Set the detach state attribute..... | 1234 |
| pthread_attr_setguardsize() | — Set guardsize attribute..... | 1236 |
| pthread_attr_setschedparam() | — Set scheduling parameter attributes..... | 1238 |
| pthread_attr_setstack() | — Set stack attribute..... | 1239 |
| pthread_attr_setstackaddr() | — Set stackaddr attribute..... | 1241 |
| pthread_attr_setstacksize() | — Set the stacksize attribute object..... | 1243 |
| pthread_attr_setsynctype_np() | — Set thread sync type..... | 1245 |
| pthread_attr_setweight_np() | — Set weight of thread attribute object..... | 1246 |
| pthread_cancel() | — Cancel a thread..... | 1247 |
| pthread_cleanup_pop() | — Remove a cleanup handler..... | 1250 |
| pthread_cleanup_push() | — Establish a cleanup handler..... | 1251 |
| pthread_cond_broadcast() | — Broadcast a condition..... | 1253 |
| pthread_cond_destroy() | — Destroy the condition variable object..... | 1254 |
| pthread_cond_init() | — Initialize a condition variable..... | 1255 |
| pthread_cond_signal() | — Signal a condition..... | 1257 |
| pthread_cond_timedwait(), pthread_cond_timedwait64() | — Wait on a condition variable..... | 1259 |
| pthread_cond_wait() | — Wait on a condition variable..... | 1262 |
| pthread_condattr_destroy() | — Destroy condition variable attribute object..... | 1264 |
| pthread_condattr_getkind_np() | — Get kind attribute from a condition variable attribute object..... | 1265 |
| pthread_condattr_getpshared() | — Get the process-shared condition variable attribute..... | 1267 |
| pthread_condattr_init() | — Initialize a condition attribute object..... | 1268 |
| pthread_condattr_setclock() | — Sets the clock selection condition variable attribute..... | 1270 |
| pthread_condattr_setkind_np() | — Set kind attribute from a condition variable attribute object..... | 1270 |
| pthread_condattr_setpshared() | — Set the process-shared condition variable attribute..... | 1272 |
| pthread_create() | — Create a thread..... | 1274 |
| pthread_detach() | — Detach a thread..... | 1276 |
| pthread_equal() | — Compare thread IDs..... | 1277 |
| pthread_exit() | — Exit a thread..... | 1279 |
| pthread_getconcurrency() | — Get the level of concurrency..... | 1280 |
| pthread_getspecific() | — Get the thread-specific value for a key..... | 1281 |
| pthread_getspecific_d8_np() | — Get the thread-specific value for a key..... | 1284 |
| pthread_join() | — Wait for a thread to end..... | 1287 |
| pthread_join_d4_np() | — Wait for a thread to end..... | 1288 |
| pthread_key_create() | — Create thread-specific data key..... | 1290 |
| pthread_key_delete() | — Delete thread-specific data key..... | 1292 |
| pthread_kill() | — Send a signal to a thread..... | 1293 |
| pthread_mutex_destroy() | — Delete a mutex object..... | 1296 |
| pthread_mutex_init() | — Initialize a mutex object..... | 1297 |
| pthread_mutex_lock() | — Wait for a lock on a mutex object..... | 1299 |
| pthread_mutex_trylock() | — Attempt to lock a mutex object..... | 1301 |
| pthread_mutex_unlock() | — Unlock a mutex object..... | 1303 |
| pthread_mutexattr_destroy() | — Destroy a mutex attribute object..... | 1305 |
| pthread_mutexattr_getkind_np() | — Get kind from a mutex attribute object..... | 1306 |
| pthread_mutexattr_getpshared() | — Get the process-shared mutex attribute..... | 1308 |
| pthread_mutexattr_gettype() | — Get type of mutex attribute object..... | 1309 |
| pthread_mutexattr_init() | — Initialize a mutex attribute object..... | 1311 |
| pthread_mutexattr_setkind_np() | — Set kind for a mutex attribute object..... | 1312 |
| pthread_mutexattr_setpshared() | — Set the process-shared mutex attribute..... | 1314 |
| pthread_mutexattr_settype() | — Set type of mutex attribute object..... | 1315 |
| pthread_once() | — Invoke a function once..... | 1317 |
| pthread_rwlock_destroy() | — Destroy a read or write lock object..... | 1319 |
| pthread_rwlock_init() | — Initialize a read or write lock object..... | 1320 |
| pthread_rwlock_rdlock() | — Wait for a lock on a read or write lock object..... | 1321 |
| pthread_rwlock_tryrdlock() | — Attempt to lock a read or write lock object for reading..... | 1322 |
| pthread_rwlock_trywrlock() | — Attempt to lock a read or write lock object for writing..... | 1323 |

| | | |
|---|--|------|
| pthread_rwlock_unlock() | — Unlock a read or write lock object..... | 1324 |
| pthread_rwlock_wrlock() | — Wait for a lock on a read or write lock object for writing..... | 1325 |
| pthread_rwlockattr_destroy() | — Destroy a read or write lock attribute object..... | 1327 |
| pthread_rwlockattr_getpshared() | — Get the processed-shared read or write lock attribute..... | 1328 |
| pthread_rwlockattr_init() | — Initialize a read or write lock attribute object..... | 1329 |
| pthread_rwlockattr_setpshared() | — Set the process-shared read or write lock attribute..... | 1330 |
| pthread_security_np(), pthread_security_applid_np() | — Create or delete thread-level security..... | 1331 |
| pthread_self() | — Get the caller..... | 1334 |
| pthread_setcancelstate() | — Set a thread cancelability state format..... | 1335 |
| pthread_setcanceltype() | — Set a thread cancelability type format..... | 1336 |
| pthread_setconcurrency() | — Set the level of concurrency..... | 1336 |
| pthread_setintr() | — Set a thread cancelability state..... | 1337 |
| pthread_setintrtype() | — Set a thread cancelability type..... | 1339 |
| pthread_set_limit_np() | — Set task and thread limits..... | 1341 |
| pthread_setspecific() | — Set the thread-specific value for a key..... | 1342 |
| pthread_sigmask() | — Examine or change a thread blocked signals format..... | 1345 |
| pthread_tag_np() | — Set and query thread tag data..... | 1346 |
| pthread_testcancel() | — Establish a cancelation point..... | 1347 |
| pthread_testintr() | — Establish a cancelability point..... | 1348 |
| pthread_yield() | — Release the processor to other threads..... | 1350 |
| ptsname() | — Get name of the subsidiary pseudoterminal device..... | 1351 |
| putc(), putchar() | — Write a character..... | 1352 |
| putenv() | — Change or add an environment variable..... | 1354 |
| putmsg(), putpmsg() | — Send a message on a STREAM..... | 1355 |
| puts() | — Write a string..... | 1357 |
| pututxline(), pututxline64() | — Write entry to utmpx database..... | 1359 |
| putw() | — Put a machine word on a stream..... | 1361 |
| putwc() | — Output a wide character..... | 1362 |
| putwchar() | — Output a wide character to standard output..... | 1364 |
| pwrite() | — Write data on a file or socket without file pointer change..... | 1366 |
| qsort() | — Sort array..... | 1367 |
| quantexpd32(), quantexpd64(), quantexpd128() | — Compute the quantum exponent..... | 1369 |
| quantized32(), quantized64(), quantized128() | — Set the exponent of X to the exponent of Y..... | 1370 |
| QueryMetrics() | — Query WLM system information..... | 1372 |
| QuerySchEnv() | — Query WLM scheduling environment..... | 1373 |
| QueryWorkUnitClassification() | — WLM query enclave classification service..... | 1374 |
| raise() | — Raise signal..... | 1375 |
| rand() | — Generate random number..... | 1377 |
| rand_r() | — Pseudo-random number generator..... | 1378 |
| random() | — A better random-number generator..... | 1379 |
| read() | — Read from a file or socket..... | 1380 |
| readdir() | — Read an entry from a directory..... | 1385 |
| __readdir2(), __readdir2_64() | — Read directory entry and get file information..... | 1387 |
| readdir_r() | — Read an entry from a directory..... | 1389 |
| readlink() | — Read the value of a symbolic link..... | 1390 |
| readlinkat() | — Read value of a symbolic link relative to a directory file descriptor..... | 1392 |
| readv() | — Read data on a file or socket and store in a set of buffers..... | 1393 |
| realloc() | — Change reserved storage block size..... | 1395 |
| realpath() | — Resolve path name..... | 1398 |
| re_comp() | — Compile regular expression..... | 1399 |
| recv() | — Receive data on a socket..... | 1401 |
| recvfrom() | — Receive messages on a socket..... | 1404 |
| recvmsg() | — Receive messages on a socket and store in array of message headers..... | 1407 |
| re_exec() | — Match regular expression..... | 1412 |
| regcmp() | — Compile regular expression..... | 1413 |
| regcomp() | — Compile regular expression..... | 1416 |
| regerror() | — Return error message..... | 1418 |
| regex() | — Execute compiled regular expression..... | 1420 |

| | | |
|--|--|------|
| regexec() | — Execute compiled regular expression..... | 1421 |
| regfree() | — Free memory for regular expression..... | 1423 |
| release() | — Delete a load module..... | 1424 |
| remainder(), remainderf(), remainderl() | — Computes the remainder x REM y..... | 1426 |
| remainderd32(), remainderd64(), remainderd128() | — Computes the remainder x REM y..... | 1427 |
| remove() | — Delete file..... | 1429 |
| removexattr(), lremovexattr(), fremovexattr() | — Remove an extended attribute..... | 1430 |
| remque() | — Remove an element from a double linked list..... | 1431 |
| remquo(), remquof(), remquol() | — Computes the remainder..... | 1432 |
| __remquod32(), __remquod64(), __remquod128() | — Computes the remainder..... | 1433 |
| rename() | — Rename file..... | 1434 |
| renameat() | — Change the name or location of a file..... | 1436 |
| renameat2() | — Change the name or location of a file..... | 1438 |
| res_init() | — Domain name resolver initialization..... | 1440 |
| res_mkquery() | — Make resolver query for domain name servers..... | 1442 |
| res_query() | — Resolver query for domain name servers..... | 1443 |
| res_querydomain() | — Build domain name and resolver query | 1445 |
| res_search() | — Resolver query for domain name servers..... | 1446 |
| res_send() | — Send resolver query for domain name servers..... | 1447 |
| __reset_exception_handler() | — Unregister an exception handler routine..... | 1448 |
| rewind() | — Set file position to beginning of file..... | 1449 |
| rewinddir() | — Reposition a directory stream to the beginning..... | 1450 |
| rexec() | — Execute commands one at a time on a remote host..... | 1451 |
| rexec_af() | — Execute commands one at a time on a remote host..... | 1452 |
| rindex() | — Search for character..... | 1453 |
| rint(), rintf(), rintl() | — Round to nearest integral value..... | 1454 |
| rintd32(), rintd64(), rintd128() | — Round to nearest integral value..... | 1455 |
| rmdir() | — Remove a directory..... | 1457 |
| round(), roundf(), roundl() | — Round to the nearest integer..... | 1459 |
| roundd32(), roundd64(), roundd128() | — Round to the nearest integer..... | 1460 |
| rpmatch() | — Test for a yes or no response match..... | 1462 |
| samequantumd32(), samequantumd64(), samequantumd128() | — Determine if exponents X and Y are the same..... | 1463 |
| sbrk() | — Change space allocation..... | 1464 |
| scalb() | — Load exponent..... | 1465 |
| scalbn(), scalbnf(), scalbnl(), scalbln(), scalblnf(), scalblnl() | — Load exponent functions..... | 1466 |
| scalbnd32(), scalbnd64(), scalbnd128() and scalblnd32(), scalblnd64(), scalblnd128() | — Load exponent functions..... | 1468 |
| scanf() | — Read and format data..... | 1469 |
| sched_yield() | — Release the processor to other threads..... | 1469 |
| seed48() | — Pseudo-random number initializer..... | 1470 |
| seekdir() | — Set position of directory stream..... | 1471 |
| select(), pselect() | — Monitor activity on files or sockets and message queues..... | 1472 |
| selectex() | — Monitor activity on files or sockets and message queues..... | 1480 |
| semctl(), semctl64() | — Semaphore control operations..... | 1482 |
| semget() | — Get a set of semaphores..... | 1486 |
| semop() | — Semaphore operations..... | 1488 |
| __semop_timed() | — Semaphore operations with timeout..... | 1491 |
| send() | — Send data on a socket..... | 1493 |
| send_file() | — Send file data over a socket..... | 1496 |
| sendmsg() | — Send messages on a socket..... | 1499 |
| sendto() | — Send data on a socket..... | 1504 |
| __server_classify() | — Set classify area field..... | 1507 |
| __server_classify_create() | — Create a classify area..... | 1510 |
| __server_classify_destroy() | — Delete a classify area..... | 1510 |
| __server_classify_reset() | — Reset a classify area to an initial state..... | 1511 |
| __server_init() | — Initialize server..... | 1512 |
| __server_pwu() | — Process server work unit..... | 1514 |

| | | |
|--------------------------------------|--|------|
| __server_threads_query() | — Query the number of threads..... | 1517 |
| setbuf() | — Control buffering..... | 1518 |
| setcontext() | — Restore user context..... | 1520 |
| setegid() | — Set the effective group ID..... | 1522 |
| setenv() | — Add, delete, and change environment variables..... | 1523 |
| seteuid() | — Set the effective user ID..... | 1526 |
| __set_exception_handler() | — Register an exception handler routine..... | 1528 |
| setgid() | — Set the group ID..... | 1532 |
| setgrent() | — Reset group database to first entry..... | 1533 |
| setgroups() | — Set the supplementary group ID list for the process..... | 1533 |
| sethostent() | — Open the host information data set..... | 1534 |
| sethostname() | — Set the name of the host processor..... | 1535 |
| setibmopt() | — Set IBM TCP/IP image..... | 1536 |
| setibmsockopt() | — Set IBM specific options associated with a socket..... | 1537 |
| setipv4sourcefilter() | — Set source filter..... | 1539 |
| setitimer() | — Set value of an interval timer..... | 1540 |
| setjmp() | — Preserve stack environment..... | 1542 |
| _setjmp() | — Set jump point for a nonlocal goto..... | 1544 |
| setkey() | — Set encoding key..... | 1546 |
| setlocale() | — Set locale..... | 1547 |
| setlogmask() | — Set the mask for the control log..... | 1555 |
| setnetent() | — Open the network information data set..... | 1556 |
| set_new_handler() | — Register a function for new_handler()..... | 1557 |
| setns() | — Allow for a thread to join a descendant namespace..... | 1558 |
| setpeer() | — Preset the socket peer address..... | 1559 |
| setpgid() | — Set process group ID for job control..... | 1560 |
| setpgrp() | — Set process group ID..... | 1562 |
| setpriority() | — Set process scheduling priority..... | 1563 |
| setprotoent() | — Open the protocol information data set..... | 1564 |
| setpwent() | — Reset user database search..... | 1565 |
| setregid() | — Set real and effective group IDs..... | 1565 |
| setreuid() | — Set real and effective user IDs..... | 1566 |
| setrlimit() | — Control maximum resource consumption..... | 1568 |
| setservent() | — Open the network services information data set..... | 1570 |
| setsid() | — Create session, set process group ID..... | 1571 |
| setsockopt() | — Set options associated with a socket..... | 1573 |
| setsourcefilter() | — Set source filter..... | 1581 |
| setstate() | — Change generator for random()..... | 1583 |
| set_terminate() | — Register a function for terminate()..... | 1584 |
| _SET_THLIIPADDR() | — Set the client's IP address..... | 1584 |
| setuid() | — Set the effective user ID..... | 1585 |
| set_unexpected() | — Register a function for unexpected()..... | 1587 |
| setutxent() | — Reset to start of utmpx database..... | 1588 |
| setvbuf() | — Control buffering..... | 1589 |
| setxattr(), lsetxattr(), fsetxattr() | — Set an extended attribute value..... | 1591 |
| shmat() | — Shared memory attach operation..... | 1593 |
| shmctl(), shmctl64() | — Shared memory control operations..... | 1595 |
| shmdt() | — Shared memory detach operation..... | 1596 |
| shmget() | — Get a shared memory segment..... | 1597 |
| shutdown() | — Shut down all or part of a duplex connection..... | 1600 |
| __shutdown_registration() | — Register OMVS shutdown options..... | 1602 |
| sigaction() | — Examine or change a signal action..... | 1605 |
| __sigactionset() | — Examine or change signal actions..... | 1615 |
| sigaddset() | — Add a signal to the signal mask..... | 1621 |
| sigaltstack() | — Set or get signal alternate stack context..... | 1622 |
| sigdelset() | — Delete a signal from the signal mask..... | 1624 |
| sigemptyset() | — Initialize a signal mask to exclude all signals..... | 1626 |
| sigfillset() | — Initialize a signal mask to include all signals..... | 1627 |

| | | |
|---|---|------|
| sighold() | — Add a signal to a thread..... | 1628 |
| sigignore() | — Set disposition to ignore a signal..... | 1629 |
| siginterrupt() | — Allow signals to interrupt functions..... | 1630 |
| sigismember() | — Test if a signal is in a signal mask..... | 1631 |
| siglongjmp() | — Restore the stack environment and signal mask..... | 1633 |
| signal() | — Handle interrupts..... | 1635 |
| signbit() | — Determines whether the sign of its argument is negative..... | 1639 |
| __signgam() | — Return signgam reference..... | 1640 |
| sigpause() | — Unblock a signal and wait for a signal..... | 1640 |
| sigpending() | — Examine pending signals..... | 1641 |
| sigprocmask() | — Examine or change a thread..... | 1643 |
| sigqueue() | — Queue a signal to a process..... | 1646 |
| sigrelse() | — Remove a signal from a thread..... | 1647 |
| sigset() | — Change a signal action or a thread..... | 1648 |
| sigsetjmp() | — Save stack environment and signal mask..... | 1650 |
| sigstack() | — Set or get signal stack context..... | 1652 |
| sigsuspend() | — Change mask and suspend the thread..... | 1654 |
| sigtimedwait() | — Wait for queued signals..... | 1656 |
| sigwait() | — Wait for an asynchronous signal..... | 1658 |
| sigwaitinfo() | — Wait for queued signals..... | 1660 |
| sin(), sinf(), sinl() | — Calculate sine..... | 1662 |
| sind32(), sind64(), sind128() | — Calculate sine..... | 1663 |
| sinh(), sinh(), sinhl() | — Calculate hyperbolic sine..... | 1664 |
| sinhd32(), sinhd64(), sinhd128() | — Calculate hyperbolic sine..... | 1666 |
| __sinpid32(), __sinpid64(), __sinpid128() | — Calculate sine of $\pi * x$ | 1667 |
| sleep() | — Suspend execution of a thread..... | 1668 |
| __smf_record() | — Record an SMF record..... | 1669 |
| __smf_record2() | — Record an SMF record with exit control..... | 1670 |
| snprintf() | — Format and write data..... | 1672 |
| socketatmark() | — Determine whether a socket is at the out-of-band mark | 1673 |
| sock_debug() | — Provide syscall tracing facility..... | 1675 |
| sock_debug_bulk_perf0() | — Produce a report when a socket is configured..... | 1675 |
| sock_do_bulkmode() | — Use bulk mode for messages read by a socket..... | 1676 |
| sock_do_teststor() | — Check for attempt to access storage outside..... | 1676 |
| socket() | — Create a socket..... | 1677 |
| socketpair() | — Create a pair of sockets..... | 1681 |
| spawn(), spawnp() | — Spawn a new process..... | 1682 |
| __spawn2(), __spawnp2() | — Spawn a new process using enhanced inheritance structure..... | 1693 |
| sprintf() | — Format and write data to buffer..... | 1699 |
| sqrt(), sqrtf(), sqrtl() | — Calculate square root..... | 1700 |
| sqrtd32(), sqrtd64(), sqrtd128() | — Calculate square root..... | 1701 |
| srand() | — Set seed for rand() function..... | 1703 |
| srandom() | — Use seed to initialize generator for random()..... | 1704 |
| srand48() | — Pseudo-random number initializer..... | 1705 |
| sscanf() | — Read and format data from buffer..... | 1706 |
| stat(), stat64() | — Get file information..... | 1706 |
| statfs() | — Get file system statistics..... | 1710 |
| statvfs() | — Get file system information..... | 1712 |
| step() | — Pattern match with regular expression..... | 1715 |
| stpcpy() | — Copy string, returning pointer to its end..... | 1716 |
| stpncpy() | — Copy fixed-size string, returning pointer to its end..... | 1717 |
| strcasecmp() | — Case-insensitive string comparison..... | 1718 |
| strcat() | — Concatenate strings..... | 1719 |
| strchr() | — Search for character..... | 1720 |
| strchrnul() | — Find first occurrence of character in string..... | 1721 |
| strcmp() | — Compare strings..... | 1722 |
| strcoll() | — Compare strings..... | 1724 |
| strcpy() | — Copy string..... | 1725 |

| | | |
|-------------------------------------|---|------|
| strcspn() | — Compare strings..... | 1727 |
| strdup() | — Duplicate a string..... | 1728 |
| strerror() | — Get pointer to runtime error message..... | 1729 |
| strerror_r() | — Get copy of runtime error message | 1730 |
| strfmon() | — Convert monetary value to string..... | 1730 |
| strftime() | — Convert to formatted time..... | 1735 |
| strlen() | — Determine string length..... | 1740 |
| strnlen() | — Determine fixed-size string length..... | 1741 |
| strncasecmp() | — Case-insensitive string comparison..... | 1742 |
| strncat() | — Concatenate strings..... | 1743 |
| strncmp() | — Compare strings..... | 1744 |
| strncpy() | — Copy string..... | 1746 |
| strnlen() | — Determine fixed-size string length..... | 1747 |
| strpbrk() | — Find characters in string..... | 1748 |
| strptime() | — Date and time conversion..... | 1749 |
| strrchr() | — Find last occurrence of character in string..... | 1753 |
| strsignal() | — Return string describing signal..... | 1754 |
| strspn() | — Search string..... | 1755 |
| strstr() | — Locate substring..... | 1756 |
| strtcoll() | — Return collating element for string..... | 1757 |
| strtod() | — Convert character string to double..... | 1759 |
| strtod32(), strtod64(), strtod128() | — Convert character string to decimal floating point..... | 1761 |
| strtof() | — Convert character string to float | 1763 |
| strtoimax() | — Convert character string to intmax_t integer type..... | 1764 |
| strtok() | — Tokenize string..... | 1765 |
| strtok_r() | — Split string into tokens..... | 1767 |
| strtol() | — Convert character string to long..... | 1768 |
| strtold() | — Convert character string to long double | 1770 |
| strtoll() | — Convert string to signed long long..... | 1772 |
| strtoul() | — Convert string to unsigned integer..... | 1773 |
| strtoull() | — Convert string to unsigned long long..... | 1775 |
| strtoumax() | — Convert character string to uintmax_t integer type..... | 1777 |
| strxfrm() | — Transform string..... | 1778 |
| __superkill() | — Sends "super" SIGKILL to terminate target process..... | 1780 |
| svc99() | — Access supervisor call..... | 1781 |
| swab() | — Copy and swap bytes..... | 1784 |
| swapcontext() | — Save and restore user context..... | 1784 |
| swprintf() | — Format and write wide characters..... | 1787 |
| swscanf() | — Read a wide-character string..... | 1787 |
| symlink() | — Create a symbolic link to a path name..... | 1787 |
| symlinkat() | — Create a symbolic link to a path name..... | 1790 |
| sync() | — Schedule file system updates..... | 1791 |
| syncfs() | — Schedule specific file system updates..... | 1792 |
| syscall() | — Invokes indirect system calls..... | 1792 |
| sysconf() | — Determine system configuration options..... | 1794 |
| syslog() | — Send a message to the control log..... | 1798 |
| system() | — Execute a command..... | 1800 |
| t_accept() | — Accept a connect request..... | 1804 |
| takesocket() | — Acquire a socket from another program..... | 1806 |
| t_alloc() | — Allocate a library structure..... | 1807 |
| tan(), tanf(), tanl() | — Calculate tangent..... | 1809 |
| tand32(), tand64(), tand128() | — Calculate tangent..... | 1810 |
| tanh(), tanhf(), tanhl() | — Calculate hyperbolic tangent..... | 1812 |
| tand32(), tand64(), tand128() | — Calculate hyperbolic tangent..... | 1813 |
| t_bind() | — Bind an address to a transport endpoint..... | 1814 |
| tcdrain() | — Wait until output has been transmitted..... | 1816 |
| tcflow() | — Suspend or resume data flow on a terminal..... | 1818 |
| tcflush() | — Flush input or output on a terminal..... | 1821 |

| | | |
|-------------------------------------|---|------|
| tcgetattr() | — Get the attributes for a terminal..... | 1823 |
| __tcgetcp() | — Get terminal code page names..... | 1824 |
| tcgetpgrp() | — Get the foreground process group ID..... | 1827 |
| tcgetsid() | — Get process group ID for session leader for controlling terminal..... | 1828 |
| t_close() | — Close a transport endpoint..... | 1829 |
| t_connect() | — Establish a connection with another transport user..... | 1830 |
| tcperror() | — Print the error messages of a socket function..... | 1832 |
| tcsendbreak() | — Send a break condition to a terminal..... | 1833 |
| tcsetattr() | — Set the attributes for a terminal..... | 1835 |
| __tcsetcp() | — Set terminal code page names..... | 1844 |
| tcsetpgrp() | — Set the foreground process group ID..... | 1847 |
| __tcsettables() | — Set terminal code page names and conversion tables..... | 1849 |
| tdelete() | — Binary tree delete..... | 1853 |
| telldir() | — Current location of directory stream..... | 1854 |
| tempnam() | — Generate a temporary file name..... | 1855 |
| terminate() | — Terminate after failures in C++ error handling..... | 1856 |
| t_error() | — Produce error message..... | 1857 |
| tfind() | — Binary tree find node..... | 1858 |
| t_free() | — Free a library structure..... | 1859 |
| tgamma(), tgammaf(), tgammaal() | — Calculate gamma function..... | 1860 |
| tgamma32(), tgamma64(), tgamma128() | — Calculate gamma function | 1861 |
| t_getinfo() | — Get protocol-specific service information..... | 1862 |
| t_getprotaddr() | — Get the protocol addresses..... | 1863 |
| t_getstate() | — Get the current state..... | 1864 |
| time(), time64() | — Determine current UTC time..... | 1865 |
| times() | — Get process and child process times..... | 1867 |
| tinit() | — Attach and initialize MTF subtasks..... | 1869 |
| t_listen() | — Listen for a connect indication..... | 1870 |
| t_look() | — Look at the current event on a transport endpoint..... | 1872 |
| tmpfile() | — Create temporary file..... | 1874 |
| tmpnam() | — Produce temporary file name..... | 1876 |
| toascii() | — Translate integer to a 7-bit ASCII character..... | 1877 |
| __toCcsid() | — Convert codeset name to coded character set ID..... | 1881 |
| __toCSName() | — Convert coded character set ID to codeset name | 1882 |
| tolower(), toupper() | — Convert character case..... | 1883 |
| _tolower() | — Translate uppercase characters to lowercase..... | 1884 |
| t_open() | — Establish a transport endpoint..... | 1884 |
| t_optmgmt() | — Manage options for a transport endpoint..... | 1886 |
| _toupper() | — Translate lowercase characters to uppercase..... | 1891 |
| towlower(), towupper() | — Convert wide character case..... | 1892 |
| towctrans() | — Transliterate wide character transliteration..... | 1893 |
| t_rcv() | — Receive data or expedited data sent over a connection..... | 1893 |
| t_rcvconnect() | — Receive the confirmation from a connect request..... | 1894 |
| t_rcvdis() | — Retrieve information from disconnect..... | 1896 |
| t_rcvrel() | — Acknowledge receipt of an orderly release indication..... | 1897 |
| t_rcvudata() | — Receive a data unit..... | 1898 |
| t_rcvuderr() | — Receive a unit data error indication..... | 1898 |
| trunc(), truncf(), trunci() | — Truncate an integer value..... | 1899 |
| truncd32(), truncd64(), truncd128() | — Truncate an integer value..... | 1900 |
| truncate() | — Truncate a file to a specified length..... | 1901 |
| tsched() | — Schedule MTF subtask..... | 1902 |
| tsearch() | — Binary tree search..... | 1903 |
| t_snd() | — Send data or expedited data over a connection..... | 1904 |
| t_snddis() | — Send user-initiated disconnect request..... | 1906 |
| t_sndrel() | — Initiate an orderly release..... | 1907 |
| t_sndudata() | — Send a data unit..... | 1908 |
| t_strerror() | — Produce an error message string..... | 1909 |
| t_sync() | — Synchronize transport library..... | 1909 |

| | | |
|---|--|------|
| tsyncro() | — Wait for MTF subtask termination..... | 1911 |
| tterm() | — Terminate MTF subtasks..... | 1912 |
| ttyname() | — Get the name of a terminal..... | 1913 |
| ttyname_r() | — Find path name of a terminal..... | 1914 |
| ttyslot() | — Find the slot in the utmpx file of the current user..... | 1915 |
| t_unbind() | — Disable a transport endpoint..... | 1916 |
| twalk() | — Binary tree walk..... | 1917 |
| tzset() | — Set the time zone..... | 1918 |
| ualarm() | — Set the interval timer..... | 1921 |
| __ucreate() | — Create a heap using user-provided storage..... | 1922 |
| __ufree() | — Return storage to a user-created heap..... | 1923 |
| __uheapreport() | — Produce a storage report for a user-created heap..... | 1924 |
| ulimit() | — Get or set process file size limits..... | 1924 |
| ulltoa() | — Convert unsigned long long into a string..... | 1925 |
| ultoa() | — Convert unsigned long into a string..... | 1927 |
| __umalloc() | — Allocate storage from a user-created heap..... | 1928 |
| umask() | — Set and retrieve file creation mask..... | 1929 |
| umount() | — Remove a virtual file system..... | 1931 |
| umount2() | — Unmount file system..... | 1934 |
| uname() | — Display current operating system name..... | 1935 |
| uncaught_exception() | — Determine if an exception is being processed..... | 1937 |
| UnDoExportWorkUnit() | — WLM undo export service..... | 1938 |
| UnDoImportWorkUnit() | — WLM undo import service..... | 1939 |
| unexpected() | — Handle exception not listed in exception specification..... | 1940 |
| ungetc() | — Push character onto input stream..... | 1941 |
| ungetwc() | — Push a wide character onto a stream..... | 1943 |
| unlink() | — Remove a directory entry..... | 1945 |
| unlinkat() | — Remove a directory or directory entry..... | 1946 |
| unlockpt() | — Unlock a pseudoterminal manager and subsidiary pair..... | 1948 |
| unsetenv() | — Delete an environment variable..... | 1949 |
| unshare() | — Isolate a process from one or more of its namespaces..... | 1949 |
| usleep() | — Suspend execution for an interval..... | 1951 |
| utime(), utime64() | — Set file access and modification times..... | 1952 |
| utimensat() | — Change file timestamps with nanosecond precision..... | 1954 |
| utimes(), utimes64() | — Set file access and modification times..... | 1956 |
| __utmpxname() | — Change the utmpx database name..... | 1957 |
| utoa() | — Convert unsigned int into a string..... | 1958 |
| va_arg(), va_copy(), va_end(), va_start() | — Access function arguments..... | 1960 |
| valloc() | — Page-aligned memory allocator..... | 1964 |
| vfork() | — Create a new process..... | 1965 |
| vfprintf() | — Format and print data to stream..... | 1968 |
| vfscanf(), vscanf(), vsscanf() | — Format input of a STDARG argument list..... | 1969 |
| vfwprintf(), vswprintf(), vwprintf() | — Format and write wide characters of a STDARG argument list..... | 1970 |
| vfwscanf(), vwscanf(), vswscanf() | — Wide-character formatted input of a STDARG argument list.... | 1973 |
| vprintf() | — Format and print data to stdout..... | 1974 |
| vsprintf() | — Format and print data to fixed length buffer..... | 1975 |
| vsprintf() | — Format and print data to buffer..... | 1976 |
| vswprintf() | — Format and write wide characters of a stdarg argument list..... | 1977 |
| vwprintf() | — Format and write wide characters of a stdarg argument list | 1977 |

About this document

This document contains reference information that is intended to help you use the header files and functions provided by the z/OS C/C++ runtime to write C or C++ applications.

This document contains reference information about implementing programs that are written in C and C++, which is specific to z/OS C/C++ runtime and z/OS.

This document contains terminology, maintenance, and editorial changes. Technical changes or additions to the text and illustrations are indicated by a vertical line (|) to the left of the change.

You may notice changes in the style and structure of some of the contents in this document; for example, headings that use uppercase for the first letter of initial words only, and procedures that have a different look and format. The changes are ongoing improvements to the consistency and retrievability of information in our documents.

Who should read this document

This document is intended for application programmers interested in writing C and C++ applications using the z/OS C/C++ runtime.

How to read syntax diagrams

This section describes how to read syntax diagrams. It defines syntax diagram symbols, items that may be contained within the diagrams (keywords, variables, delimiters, operators, fragment references, operands) and provides syntax examples that contain these items.

Syntax diagrams pictorially display the order and parts (options and arguments) that comprise a command statement. They are read from left to right and from top to bottom, following the main path of the horizontal line.

For users accessing IBM Documentation using a screen reader, syntax diagrams are provided in dotted decimal format.

The following symbols may be displayed in syntax diagrams:

Symbol

Definition

Indicates the beginning of the syntax diagram.

Indicates that the syntax diagram is continued to the next line.

Indicates that the syntax is continued from the previous line.

Indicates the end of the syntax diagram.

Syntax diagrams contain many different items. Syntax items include:

- Keywords - a command name or any other literal information.
- Variables - variables are italicized, appear in lowercase, and represent the name of values you can supply.
- Delimiters - delimiters indicate the start or end of keywords, variables, or operators. For example, a left parenthesis is a delimiter.
- Operators - operators include add (+), subtract (-), multiply (*), divide (/), equal (=), and other mathematical operations that may need to be performed.

- Fragment references - a part of a syntax diagram, separated from the diagram to show greater detail.
- Separators - a separator separates keywords, variables or operators. For example, a comma (,) is a separator.

Note: If a syntax diagram shows a character that is not alphanumeric (for example, parentheses, periods, commas, equal signs, a blank space), enter the character as part of the syntax.

Keywords, variables, and operators may be displayed as required, optional, or default. Fragments, separators, and delimiters may be displayed as required or optional.

Item type
Definition

Required
 Required items are displayed on the main path of the horizontal line.

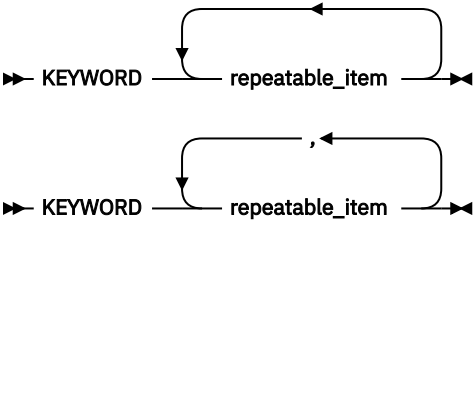

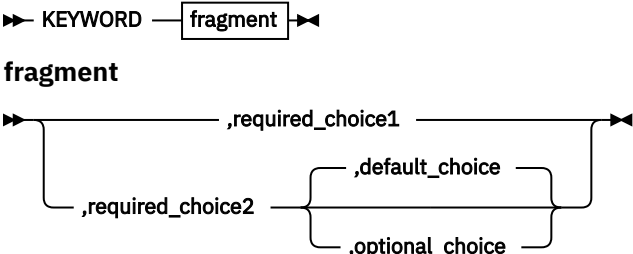

Optional
 Optional items are displayed below the main path of the horizontal line.

Default
 Default items are displayed above the main path of the horizontal line.

The following table provides syntax examples.

| Table 1. Syntax examples | |
|--|----------------|
| Item | Syntax example |
| Required item. Required items appear on the main path of the horizontal line. You must specify these items. | |
| Required choice. A required choice (two or more items) appears in a vertical stack on the main path of the horizontal line. You must choose one of the items in the stack. | |
| Optional item. Optional items appear below the main path of the horizontal line. | |
| Optional choice. An optional choice (two or more items) appears in a vertical stack below the main path of the horizontal line. You may choose one of the items in the stack. | |
| Default. Default items appear above the main path of the horizontal line. The remaining items (required or optional) appear on (required) or below (optional) the main path of the horizontal line. The following example displays a default with optional items. | |

Table 1. Syntax examples (continued)

| Item | Syntax example |
|--|---|
| Variable. Variables appear in lowercase italics. They represent names or values. |  |
| Repeatable item. An arrow returning to the left above the main path of the horizontal line indicates an item that can be repeated. A character within the arrow means you must separate repeated items with that character. An arrow returning to the left above a group of repeatable items indicates that one of the items can be selected, or a single item can be repeated. |  |
| Fragment. The fragment symbol indicates that a labeled group is described below the main syntax diagram. Syntax is occasionally broken into fragments if the inclusion of the fragment would overly complicate the main syntax diagram. |  |

Where to find more information

For an overview of the information associated with z/OS, see [z/OS Information Roadmap](#).

z/OS Basic Skills in IBM Documentation

z/OS Basic Skills in IBM Documentation is a Web-based information resource intended to help users learn the basic concepts of z/OS, the operating system that runs most of the IBM mainframe computers in use today. IBM Documentation is designed to introduce a new generation of Information Technology professionals to basic concepts and help them prepare for a career as a z/OS professional, such as a z/OS system programmer.

Specifically, z/OS Basic Skills is intended to achieve the following objectives:

- Provide basic education and information about z/OS without charge
- Shorten the time it takes for people to become productive on the mainframe
- Make it easier for new people to learn z/OS.

[z/OS Basic Skills in IBM Documentation \(www.ibm.com/docs/en/zos-basic-skills?topic=zosbasics/com.ibm.zos.zbasics/homepage.html\)](http://www.ibm.com/docs/en/zos-basic-skills?topic=zosbasics/com.ibm.zos.zbasics/homepage.html) is available to all users (no login required).

How to provide feedback to IBM

We welcome any feedback that you have, including comments on the clarity, accuracy, or completeness of the information. For more information, see [How to send feedback to IBM](#).

Summary of changes

This information includes terminology, maintenance, and editorial changes. Technical changes or additions to the text and illustrations for the current edition are indicated by a vertical line to the left of the change.

Note: IBM z/OS policy for the integration of service information into the z/OS product documentation library is documented on the z/OS Internet Library under [IBM z/OS Product Documentation Update Policy](http://www.ibm.com/docs/en/zos/latest?topic=zos-product-documentation-update-policy) (www.ibm.com/docs/en/zos/latest?topic=zos-product-documentation-update-policy).

Summary of changes for z/OS 3.2

The following content is new, changed, or no longer included in z/OS 3.2.

New

The following content is new.

September 2025 release

- [“strlen\(\) — Determine fixed-size string length” on page 1741](#)
- [“strcpy\(\) — Copy string, returning pointer to its end” on page 1716](#)
- [“strncpy\(\) — Copy fixed-size string, returning pointer to its end” on page 1717](#)
- [“strlen\(\) — Determine fixed-size string length” on page 1741](#)
- [“strsignal\(\) — Return string describing signal” on page 1754](#)
- [“wcsnlen\(\) — Determine fixed-size wide-character string length” on page 2006](#)
- [“wcpncpy\(\) — Copy wide-character string, returning pointer to its end” on page 1986](#)
- [“wcpncpy\(\) — Copy fixed-size wide-character string, returning pointer to its end” on page 1987](#)

Changed

The following content is changed.

September 2025 release

- Release updates are made to [“__librel\(\) — Query release level” on page 971](#) and [“__osname\(\) — Get true operating system name” on page 1176](#). [“uname\(\) — Display current operating system name” on page 1935](#) is also updated.
- [“strftime\(\) — Convert to formatted time” on page 1735](#).
- [“fopen\(\) — Open a file” on page 571](#)

Deleted

The following content is deleted.

September 2025 release

- None.

Summary of changes for z/OS 3.1

The following content is new, changed, or no longer included in z/OS 3.1.

New

The following content is new.

June 2024 refresh

New library functions:

- The [fdclosedir\(\)](#) function closes the directory that is associated with a file descriptor.
- The [fdopendir\(\)](#) function opens the directory that is associated with a file descriptor.
- The [getpwent_r\(\)](#) function gets user database entry reentrantly.
- The [syscall\(\)](#) function invokes indirect system calls.

February 2024 refresh

The [__authenticate\(\)](#) function authenticates the specified user's credentials.

September 2023 release

New header files:

- The [getopt.h](#) header file contains definitions for command-line option parsing functions.
- The [sys/epoll.h](#) header file contains definitions for I/O event notification facility functions.
- The [sys/eventfd.h](#) header file contains the definition for the [eventfd\(\)](#) functions.
- The [sys/inotify.h](#) header file contains definitions for monitoring file system event functions.
- The [sys/mount.h](#) header file contains definitions for mount and unmount file system operations functions.
- The [sys/prctl.h](#) header file contains definitions for operations on a process or thread.
- The [sys/random.h](#) header file contains definitions for random data operations, including declarations, constants, and structures.
- The [sys/xattr.h](#) header file contains definitions for extended attribute handling functions.

New library functions:

- The [accept4\(\)](#) function is used by a server to accept a connection request from a client.
- The [asprintf\(\)](#) and [vasprintf\(\)](#) functions are analogs of [sprintf\(\)](#) and [vsprintf\(\)](#), except that they allocate a string large enough to hold the output including the terminating NULL byte, and return a pointer to it via the first argument.
- The [__chatrat\(\)](#) and [__chatrat64\(\)](#) functions modify the attributes that are associated with a file.
- The [clone\(\)](#) function creates a child process.
- The [dprintf\(\)](#) function prints to a file descriptor.
- The [dup3\(\)](#) function duplicates an open file descriptor with flag setting.
- The [epoll_create\(\)](#) and [epoll_create1\(\)](#) functions open an [epoll](#) file descriptor.
- The [epoll_ctl\(\)](#) function controls the interface for an [epoll](#) file descriptor.
- The [epoll_wait\(\)](#) and [epoll_pwait\(\)](#) functions wait for an I/O event on an [epoll](#) file descriptor.
- The [eventfd\(\)](#) function creates a file descriptor for event notification.
- The [faccessat\(\)](#) function determines the accessibility of a file relative to directory file descriptor.
- The [fchmodat\(\)](#) function changes the mode of a file relative to a directory file descriptor.
- The [fchownat\(\)](#) function changes the owner and group of a file relative to the directory file descriptor.
- The [flock\(\)](#) function applies or removes an advisory lock on an open file.
- The [fstatat\(\)](#) and [fstatat64\(\)](#) functions get file status information relative to a directory file descriptor.
- The [futimesat\(\)](#) function changes the timestamps of a file relative to a directory file descriptor.
- The [getentropy\(\)](#) function fills a buffer with random bytes.

- The [`getopt_long\(\)`](#) function is a command-line parser that accepts long options, which begin with two dashes.
- The [`getrandom\(\)`](#) function obtains a series of random bytes.
- The [`getxattr\(\)`](#), [`lgetxattr\(\)`](#), and [`fgetxattr\(\)`](#) functions retrieve an extended attribute value.
- The [`inotify_add_watch\(\)`](#) function adds a watch to an initialized `inotify` instance.
- The [`inotify_init\(\)`](#) and [`inotify_init1\(\)`](#) functions initialize an `inotify` instance.
- The [`inotify_rm_watch\(\)`](#) function removes an existing watch from an `inotify` instance.
- The [`linkat\(\)`](#) function creates a link to a file relative to the directory file descriptor.
- The [`listxattr\(\)`](#), [`llistxattr\(\)`](#), and [`flistxattr\(\)`](#) functions list extended attribute names.
- The [`mkdirat\(\)`](#) function makes a directory.
- The [`mkfifoat\(\)`](#) function makes a FIFO special file.
- The [`mknodat\(\)`](#) function makes a directory or file.
- The [`nanosleep\(\)`](#) function specifies high-resolution sleep.
- The [`openat\(\)`](#) function opens a file relative to a directory file descriptor.
- The [`openat2\(\)`](#) function opens a file with more extensions.
- The [`pipe2\(\)`](#) function creates a pipe.
- The [`pivot_root\(\)`](#) function changes the root mount.
- The [`posix_memalign\(\)`](#) function reserves a block of storage and returns a pointer to the reserved storage in `memptr`.
- The [`prctl\(\)`](#) function operates on a process or thread.
- The [`prlimit\(\)`](#) function gets or sets the hard and soft resource limits of a specified process.
- The [`psignal\(\)`](#) function prints a signal description.
- The [`readlinkat\(\)`](#) function reads the value of a symbolic link that is relative to a directory file descriptor.
- The [`removexattr\(\)`](#), [`lremovexattr\(\)`](#), and [`fremovexattr\(\)`](#) functions remove an extended attribute.
- The [`renameat\(\)`](#) function changes the name or location of a file.
- The [`renameat2\(\)`](#) function changes the name or location of a file.
- The [`sethostname\(\)`](#) function sets the name of the host processor.
- The [`setns\(\)`](#) function allows for a thread to join a descendant namespace.
- The [`setxattr\(\)`](#), [`lsetxattr\(\)`](#), and [`fsetxattr\(\)`](#) functions set an extended attribute value.
- The [`symlinkat\(\)`](#) function creates a symbolic link to a path name.
- The [`syncfs\(\)`](#) function schedules specific file system updates.
- The [`umount2\(\)`](#) function unmounts a file system.
- The [`unlinkat\(\)`](#) function removes a directory or directory entry.
- The [`unshare\(\)`](#) function isolates a process from one or more of its namespaces.
- The [`utimensat\(\)`](#) function changes file timestamps with nanosecond precision.
- The [`wait4\(\)`](#) function waits for a child process to change state.

Changed

The following content is changed.

April 2025 refresh

- [`syscall\(\)`](#) — Invokes indirect system calls” on page 1792 is updated.

March 2025 refresh

Information about AT-TLS considerations is added to the EWOULDBLOCK return code for [read\(\)](#), [readv\(\)](#), [recv\(\)](#), [recvfrom\(\)](#), and [recvmsg\(\)](#).

March 2024 refresh

The [gethostid\(\)](#), [gethostname\(\)](#), [getsockopt\(\)](#), [sethostname\(\)](#), and [setsockopt\(\)](#) functions are changed for network support for IBM z/OS Container Platform.

February 2024 refresh

The [unistd.h](#) header file declares the [__authenticate\(\)](#) function.

September 2023 release

- The [mount\(\)](#) and [umount\(\)](#) functions supports different parameters and functions when both [_OPEN_SYS](#) and [_XPLATFORM_SOURCE](#) are defined.
- Two new file flags [O_CLOEXEC](#) and [O_DIRECT](#) are added for the [fcntl\(\)](#) function.
- The *type* parameter of [socket\(\)](#) specifies the type and flags of the created socket.
- The [stdio.h](#) header file declares more functions: [asprintf\(\)](#), [dprintf\(\)](#), [renameat\(\)](#), [renameat2\(\)](#), [vasprintf\(\)](#).
- The [sys/stat.h](#) header file declares more functions: [__chattrat\(\)](#), [__chattrat64\(\)](#), [fstatat\(\)](#), [fstatat64\(\)](#), [mkdirat\(\)](#), [mkfifoat\(\)](#), [mknodat\(\)](#).
- The [time.h](#) header file declares one more function: [nanosleep\(\)](#).
- Chapter 4, “Using high performance libraries,” on page 2085 is moved from z/OS XL C/C++ Programming Guide to this book.

Deleted

The following content is deleted.

September 2023 release

- The "XL C/C++ Macros" chapter is deleted.

Chapter 1. About z/OS C/C++ runtime library

z/OS C/C++ runtime library contains header files, macros, and functions to write C or C++ applications. Some of the header files and functions are required by various language standards, such as C and C++, some are for compiler or system-specific needs, and some are for additional functions.

AMODE 64 considerations

AMODE 64 restrictions are indicated as a dependency or as a restriction note. For example:

Restriction: This header file is not supported in AMODE 64.

Following are restrictions for AMODE 64:

- Hiperspace is not supported.
- The SPC facility is not supported.
- The following header files are not supported:
 - csp.h
 - ims.h
 - leawi.h
 - mtf.h
 - re_comp.h
 - regexp.h
 - spc.h
- The following feature test macros are obsolete:
 - _LARGE_FILES
 - _LARGE_MEMSee the feature test macro description for more details.
- The following feature test macros are not supported:
 - __LIBASCII
 - _OE_SOCKETS
- The following functions are not supported:
 - advance()
 - brk()
 - compile()
 - __console()
 - __csplist
 - ctdli()
 - fortrc()
 - __openMvsRel()
 - __pcblist
 - re_comp()
 - re_exec()
 - regcmp()
 - regex()

- sbrk()
- sock_debug_bulk_perf0()
- sock_do_bulkmode()
- step()
- tsched()
- tsetsubt()
- tsyncro()
- tterm()
- valloc()
- The following external variables are not supported:
 - __loc1
 - loc1
 - loc2
 - locs

Chapter 2. Header files

This part describes each header file, explains its contents, and lists the functions that use the file. The function descriptions are described in [Chapter 3, “Library functions,”](#) on page 91.

The header files provided with the z/OS C/C++ runtime library contain macro and constant definitions, type definitions, and function declarations. The header files fall into two categories:

- “C/C++ header files” on page 16: can be used with any of the IBM z/OS C/C++ compilers.
- “XL C++ header files” on page 83: can be used with the z/OS XL C++ compiler only.

Some functions require definitions and declarations from header files to work correctly. The inclusion of header files is optional, as long as the necessary statements from the header files are coded directly into the source.. You can use the `#include` directive to select header files to include with your application, for example, `#include <stdio.h>`.

The following header files are not supported in AMODE 64:

- `csp.h`
- `ims.h`
- `leawi.h`
- `mtf.h`
- `re_comp.h`
- `regexp.h`
- `spc.h`

Related information

For information about the `#include` directive, see [z/OS XL C/C++ Language Reference](#) and [z/OS XL C/C++ User's Guide](#).

Feature test macros

Many of the symbols that are defined in headers are "protected" by a feature test macro. These "protected" symbols are invisible to the application unless the user defines the feature test macro with `#define`, using either of the following methods:

- In the source code before including any header files.
- On the compilation command.

The compiler does not define or undefine these macros.

The following feature test macros are obsolete in AMODE 64:

- `_LARGE_FILES`
- `_LARGE_MEM`

See the feature test macro description for more details.

The following feature test macros are not supported in AMODE 64:

- `__LIBASCII`
- `_OE_SOCKETS`

Table 2 on page 4 summarizes the relationships between the feature test macros and the standards. 'Yes' indicates that a feature test macro makes visible the symbols that are related to a standard.

Feature test macros that do not apply to POSIX standards are not listed in this table.

Table 2. Feature test macros and standards

| Feature Test Macro | POSIX.1 | POSIX.1a | POSIX.2 | POSIX.4a | XPG4.2 | XPG4.2 Ext | SUSv3 | SUSv4 |
|--------------------------|---------|----------|---------|----------|--------|------------|-------|-------|
| _ALL_SOURCE | Yes | Yes | Yes | Yes | Yes | Yes | | |
| _ALL_SOURCE_NO_THREADS | Yes | Yes | Yes | | Yes | Yes | | |
| _OE_SOCKETS | Yes | Yes | | | | | | |
| _OPEN_DEFAULT | Yes | Yes | Yes | | | | | |
| _OPEN_SOURCE 1 | Yes | Yes | Yes | Yes | | | | |
| _OPEN_SOURCE 2 | Yes | Yes | Yes | Yes | Yes | Yes | | |
| _OPEN_SOURCE 3 | Yes | Yes | Yes | Yes | Yes | Yes | | |
| _OPEN_SYS | Yes | Yes | Yes | Yes | | | | |
| _OPEN_SYS_IPC_EXTENSIONS | Yes | Yes | | | Yes | | | |
| _OPEN_SYS_PTY_EXTENSIONS | Yes | Yes | | | Yes | Yes | | |
| _OPEN_SYS SOCK_EXT | Yes | Yes | | Yes | Yes | | | |
| _OPEN_THREADS | Yes | Yes | | Yes | | | | |
| _POSIX1_SOURCE 1 | Yes | | | | | | | |
| _POSIX1_SOURCE 2 | Yes | Yes | | | | | | |
| _POSIX_C_SOURCE 1 | Yes | | | | | | | |
| _POSIX_C_SOURCE 2 | Yes | | Yes | | | | | |
| _POSIX_C_SOURCE 200112L | Yes | Yes | Yes | | | | Yes | |
| _POSIX_C_SOURCE 200809L | Yes | Yes | Yes | | | | Yes | Yes |
| _POSIX_SOURCE | Yes | | | | | | | |
| _XOPEN_SOURCE | Yes | | Yes | | Yes | | | |
| _XOPEN_SOURCE_EXTENDED 1 | Yes | | Yes | | Yes | Yes | | |
| _XOPEN_SOURCE 500 | Yes | | Yes | | Yes | Yes | | |
| _XOPEN_SOURCE 600 | Yes | Yes | Yes | | Yes | Yes | Yes | |

The following feature test macros are supported:

_ALL_SOURCE

This feature test macro exposes the following namespaces: POSIX.1, POSIX.1a, POSIX.2, POSIX.4a draft 6, XPG4, and XPG4.2, as well as additions to z/OS UNIX drawn from Single UNIX Specification, Version 2.

In addition, defining _ALL_SOURCE makes visible a number of symbols, which are not permitted under ISO C/C++, POSIX, or XPG4, but which are provided as an aid to porting C-language applications to z/OS UNIX System Services. Extensions made visible with the following feature test macros are implicit in _ALL_SOURCE:

- _OPEN_SYS_DIR_EXT
- _OPEN_SYS_EXT
- _OPEN_SYS_IPC_EXTENSIONS
- _OPEN_SYS_MAP_EXTENTION
- _OPEN_SYS_PTY_EXTENSIONS
- _OPEN_SYS SOCK_EXT
- _OPEN_SYS SOCK_EXT2
- _OPEN_SYS SOCK_IPV6

If `_OPEN_THREADS` is not explicitly defined in the application, `_ALL_SOURCE` defines `_OPEN_THREADS` 1 except when any of the following are present:

- `_ALL_SOURCE_NO_THREADS`
- `_UNIX03_THREADS`
- `_XOPEN_SOURCE 600`

`_ALL_SOURCE` does not expose functionality that is first introduced in Single UNIX Specification, Version 3 under macro definitions `_XOPEN_SOURCE 600` or `_POSIX_C_SOURCE 200112L`, although it does tolerate interfaces made visible by defining `_OPEN_THREADS` to 2 or 3.

To stabilize the namespace, no future extensions, whether POSIX, XOPEN, or MVS, will expand the definition of `_ALL_SOURCE`. Any future enhancement requires new, explicit feature test macros to add symbols to this namespace.

`_ALL_SOURCE_NO_THREADS`

This feature test macro provides the same function as `_ALL_SOURCE`, except it does not expose threading services (`_OPEN_THREADS`).

`_IEEEV1_COMPATIBILITY`

In 1999, the C/C++ Runtime Library provided IEEE754 floating-point arithmetic support in support of the IBM Java group. The Java™ language had a bit-wise requirement for its math library, meaning that all platforms needed to produce the same results as Sun Microsystems' `fdlibm` (Freely Distributed LIBM) library. Therefore, Sun Microsystems' `fdlibm` code was ported to the C/C++ Runtime Library to provide IEEE754 floating-point arithmetic support. Subsequent to the C/C++ Runtime Library's 1999 release of IEEE754 floating-point math support, IBM's Java group provided their own support of IEEE754 floating point arithmetic and no longer use the C/C++ Runtime Library for this support.

Beginning in z/OS V1R9, a subset of the original `fdlibm` functions are being replaced by new versions that are designed to provide improved performance and accuracy. The new versions of these functions are replaced at the existing entry points. However, as a migration aid, IBM has provided new entry points for the original `fdlibm` versions. Applications that take no action automatically use the updated functions. There are two methods for accessing the original functions.

This feature test macro provides an environment for the following C/C++ functions:

- Do not include `<math.h>`.
- Include `<math.h>` and define the `_FP_MODE_VARIABLE` feature test macro.

Either of the two types of functions causes the application to be running in what is called "variable" mode regarding floating-point math functions that are called within the compile unit. See z/OS XL C/C++ Programming Guide for more details on the environment variable.

The second method is through a feature test macro that can be used by applications that do include `<math.h>` and do not define the `_FP_MODE_VARIABLE` feature test macro.

If the application conforms to the rules of the second method, then the feature test macro can be used to access the original `fdlibm` versions of the following functions:

```
acos(), acos(), asin(), asinh(), atan(), atanh(), atan2(),
cbrt(), cos(), cosh(), erf(), erfc(), exp(), expm1(), gamma(),
hypot(), lgamma(), log(), log1p(), log10(), pow(), rint(), sin(),
sinh(), tan(), tanh()
```

A recompile and relink of the application is required to access the original `fdlibm` versions.

`_ISOC99_SOURCE`

This feature test macro makes available all interfaces that are associated with ISO/IEC 9899:1999 except for interfaces requiring a compiler that is designed to support C99. This feature test macro also exposes the namespace that is normally exposed by the `_MSE_PROTOS` feature test macro, unless

`_NOISOC99_SOURCE` is defined. The `_ISOC99_SOURCE` feature test macro is not required when a compiler that is designed to support C99 is used.

Note: If both `_NOISOC99_SOURCE` and `_ISOC99_SOURCE` are defined before inclusion of the first header, new C99 interfaces are not exposed.

`_LARGE_FILES`

The `_LARGE_FILES` feature test macro enables certain functions to operate on MVS data sets and z/OS UNIX files that are larger than 2 GB and VSAM extended addressability data sets larger than 4 GB. When this feature test macro is selected, it must be used when the [long long data type support](#) is enabled.

The following functions are enabled to operate on z/OS UNIX files of all sizes by expanding appropriate offset and file size values to a 64-bit value:

```
creat(), fcntl(), fgetpos(), fopen(), freopen(), fseek(), fseeko(),
fsetpos(), fstat(), fstatat(), ftell(), ftello(), ftruncate(), getrlimit(),
lockf(), lseek(), lstat(), mmap(), open(), read(), setrlimit(),
stat(), truncate(), write()
```

The `_LARGE_FILES` feature test macro also enables the `fseeko()` and `ftello()` functions to operate on MVS data sets larger than 2 GB and VSAM data sets larger than 4 GB by expanding the parameter and return type width to 64 bits. The `fgetpos()`, `fopen()`, `freopen()`, and `fsetpos()` functions implicitly support operations on these sized data sets and therefore do not require the `_LARGE_FILES` feature test macro to be defined.

Note: Using `AMODE 64` obsoletes this feature test macro. Large files are automatically supported in the LP64 programming model, therefore automatically included for `AMODE 64 C/C++` applications. The c99 compiler defines the `long long` data type as a standard type by default.

Restriction: This feature test macro is incompatible with the `__LIBASCII` feature test macro.

`_LARGE_MEM`

This feature test macro is provided for `AMODE 31` applications that need access to `AMODE 64` values. Use of large memory support requires the [long long data type support](#).

Note: This feature test macro is obsolete in `AMODE 64`. Therefore, large memory support is automatic in the LP64 programming model, all behaviors regarding large memory are automatically included for `AMODE 64 C/C++` applications.

`_LARGE_TIME_API`

This feature test macro exposes new typedefs, structures, and functions so that an application can work with constructed calendar times up to and including the artificial limit of 23:59:59 on December 31, 9999 Coordinated Universal Time.

`__LIBASCII`

This feature test macro provides an ASCII-like environment for the following C/C++ functions:

```
access(), asctime(), atof(), atoi(), atol(), chdir(), chmod(),
chown(), creat(), ctime(), dlopen(), dlload(), dlqueryfn(), dynalloc()
ecvt(), execv(), execve(), execvp(), fcvt(), fdopen(), fopen(),
freopen(), ftok(), gcvt(), getcwd(), getenv(), getgnam(),
gethostbyaddr(), gethostbyname(), gethostname(), getlogin(),
getopt(), getpass(), getpwnam(), getpwuid(), getservbyname(),
getwd(), inetaddr(), inet_ntoa(), isalnum(), isalpha(), iscntrl(),
isdigit(), isgraph(), islower(), isprint(), ispunct(), isspace(),
isupper(), isxdigit(), link(), localeconv(), mbstowcs(), mbtowc(),
mkdir(), mknod(), mktemp(), nl_langinfo(), open(), opendir(),
perror(), popen(), ptsname(), putenv(), readdir(), regcomp(),
remove(), rename(), rexec(), rmdir(), scanf(), setenv(), setkey(),
setlocale(), setvbuf(), sprintf(), sscanf(), stat(), statvfs(),
strcasecmp(), strerror(), strncasecmp(), strtod(), strtol(),
```

```
strtoul(), system(), tempnam(), tmpnam(), toascii(), tolower(),
toupper(), uname(), unlink(), utime(), utimes()
```

For each application program that uses one or more of these functions, where the input/output is ASCII, add the following feature test macro:

- `#define __LIBASCII`
- Recompile that uses the `CONV(ISO8859-1)` option to cause the compiler to generate all strings that are defined in the source program in ASCII rather than EBCDIC format.

Note:

- This feature test macro is not supported in AMODE 64.
- Enhanced ASCII and `__LIBASCII` are independent and must not be used together. Using Enhanced ASCII and `__LIBASCII` together is not supported.
- The `libascii` functions are as thread-safe as the runtime library except for the `getopt()` function. The `libascii` `getopt()` function is not thread-safe. The second argument is changed for a short time from EBCDIC to ASCII and then back to EBCDIC. This feature test macro is incompatible with the `_LARGE_FILES` feature test macro.

`_LONGMAP`

Programs that are compiled with [long external names](#) and which use POSIX functions must define `_LONGMAP` when using the Prelinker outside of a z/OS UNIX shell environment.

`_MSE_PROTOS`

The `_MSE_PROTOS` feature test macro does the following:

1. Selects behavior for a multibyte extension support (MSE) function declared in `wchar.h` as specified by ISO/IEC 9899:1990/Amendment 1:1994 instead of behavior for the function as defined by CAE Specification, System Interfaces and Headers, Issue 4, July 1992 (XPG4).
2. Exposes declaration of an MSE function declared in `wchar.h`, which is specified by ISO/IEC 9899:1990/Amendment 1:1994 but not by XPG4.

Note: Defining `_ISOC99_SOURCE` or using a compiler that is designed to support C99 also exposes this namespace if `_NOISOC99_SOURCE` is not also defined.

`_NOISOC99_SOURCE`

This feature test macro prevents exposure of new interfaces that are part of the C99 standard. This feature test macro must be defined before inclusion of the first header in order to prevent new C99 interfaces from being exposed.

Note: If both `_NOISOC99_SOURCE` and `_ISOC99_SOURCE` are defined before inclusion of the first header, new C99 interfaces will not be exposed.

`_OE_SOCKETS`

This feature test macro defines a BSD-like socket interface for the function prototypes and structures involved. This can be used with `_XOPEN_SOURCE_EXTENDED 1` and the XPG4.2 socket interfaces are replaced with the BSD-like interfaces.

Restriction: This feature test macro is not supported in AMODE 64.

`_OPEN_DEFAULT`

When defined to 0, and if no other feature test macro is defined, then all symbols will be visible. If in addition to `_OPEN_DEFAULT` only POSIX and/or XPG4 feature test macros are defined, then only the

symbols so requested will be visible. Otherwise, additional symbols (for example, those visible when runtime library extensions are included), might be exposed.

When defined to 1, this provides the base level of z/OS UNIX functionality, which is POSIX.1, POSIX.1a and POSIX.2.

_OPEN_MSGQ_EXT

This feature test macro defines an interface, which enables use of `select()`, `selectex()` and `poll()` to monitor message and file descriptors.

_OPEN_SOURCE

When defined to 1, this defines all of the functionality that was available on MVS 5.1. This macro is equivalent to specifying `_OPEN_SYS`.

When defined to 2, this defines all of the functionality that is available on MVS 5.2.2, including XPG4, XPG4.2, and all of the z/OS UNIX extensions.

When defined to 3, this macro is equivalent to specifying `_ALL_SOURCE`.

If `_OPEN_THREADS` is not explicitly defined in the application, `_OPEN_SOURCE` will define `_OPEN_THREADS` 1 except when any of the following are present:

- `_ALL_SOURCE_NO_THREADS`
- `_UNIX03_THREADS`
- `_XOPEN_SOURCE` 600

_OPEN_SYS

When defined to 1, this indicates that symbols required by POSIX.1, POSIX.1a, POSIX.2 are made visible. Any symbols that are defined by the `_OPEN_THREADS` macro are allowed.

If `_OPEN_THREADS` is not explicitly defined in the application, `_OPEN_SYS` will define `_OPEN_THREADS` 1 except when any of the following are present:

- `_ALL_SOURCE_NO_THREADS`
- `_UNIX03_THREADS`
- `_XOPEN_SOURCE` 600

Additional symbols can be made visible if any of the exposed standards explicitly allows the symbol to appear in the header in question or if the symbol is defined as a z/OS UNIX System Services extension.

_OPEN_SYS_DIR_EXT

This feature test macro defines the interface and function prototypes for `__opendir2()` and `__readdir2()`.

_OPEN_SYS_FILE_EXT

When defined to any value with `#define`, `_OPEN_SYS_FILE_EXT` indicates that symbols required for file conversion, file tagging, and file attributes manipulation functions are made visible.

_OPEN_SYS_IF_EXT

When defined to 1, this feature test macro exposes BSD-like socket definitions that are found in `<net/if.h>` and `<sys/ioctl.h>` that are needed to manipulate network interfaces. This feature test macro is made available beginning with z/OS V1R9.

_OPEN_SYS_IPC_EXTENSIONS

This feature test macro defines z/OS UNIX extensions to the X/Open InterProcess Communications functions. When `_OPEN_SYS_IPC_EXTENSIONS` is defined, the POSIX.1, POSIX.1a, and the XPG4 symbols are visible. This macro should be used in `_XOPEN_SOURCE`.

`_OPEN_SYS_Mutex_EXT`

This feature test macro allows pthread condition variables and mutexes with shared memory. When this feature is defined, `pthread_mutex_t` and `pthread_cond_t` grow significantly in size.

When either `_XOPEN_SOURCE 600` or `_UNIX03_THREADS` are defined, the namespace includes all elements made visible by the `_OPEN_SYS_Mutex_EXT` macro. In this case, `_OPEN_SYS_Mutex_EXT` is redundant and does not need to be defined by the application.

`_OPEN_SYS_PTY_EXTENSIONS`

This feature test macro defines z/OS UNIX extensions to the X/Open Pseudo TTY functions. When `_OPEN_SYS_PTY_EXTENSIONS` is defined, the POSIX.1, POSIX.1a, XPG4, and XPG4.2 symbols are visible. This macro should be used in `_XOPEN_SOURCE_EXTENDED 1`.

`_OPEN_SYS_SOCK_EXT`

This feature test macro defines the interface for function prototypes and structures for the extended sockets and bulk mode support.

`_OPEN_SYS_SOCK_EXT2`

This feature test macro defines the function prototype and interfaces for `accept_and_recv()`.

`_OPEN_SYS_SOCK_EXT3`

This feature test macro defines the function prototypes and interfaces for multicast source filtering.

`_OPEN_SYS_SOCK_EXT4`

This feature test macro defines interfaces in `netinet/in.h` used for sending UDP reply packets on the same inbound interface as the request arrived.

`_OPEN_SYS_SOCK_IPV6`

When defined, indicates that symbols related to Internet Protocol Version 6 (IPv6) are made visible.

Defining `_XOPEN_SOURCE` to 600 will expose the IPv6 symbols that are required in Single Unix Specification, Version 3. However, these symbols only comprise a subset of the complete namespace that is associated with `_OPEN_SYS_SOCK_IPV6`. Although an application is allowed to define both macros, such an application may not be strictly conforming to Single UNIX Specification, Version 3.

`_OPEN_THREADS`

When defined to 1, this indicates that symbols required by POSIX.1, POSIX.1a, and POSIX.4a (draft 6) are made visible.

When defined to 2, additional pthread functions that are introduced in z/OS V1R07 from Single UNIX Specification, Version 3 are made visible, along with those made visible when this is defined to 1. The following symbols are added to the namespace when `_OPEN_THREADS` is defined to 2:

| Interfaces | Constants |
|---------------------------------------|-------------------------------------|
| <code>pthread_getconcurrency()</code> | <code>PTHREAD_CANCEL_ENABLE</code> |
| <code>pthread_setconcurrency()</code> | <code>PTHREAD_CANCEL_DISABLE</code> |

| Interfaces | Constants |
|--------------------------|-----------------------------|
| pthread_setcancelstate() | PTHREAD_CANCEL_DEFERRED |
| pthread_setcanceltype() | PTHREAD_CANCEL_ASYNCHRONOUS |
| pthread_sigmask() | |
| pthread_testcancel() | |
| pthread_key_delete() | |

When defined to 3, all pthread functions that are required for the Threads option of Single UNIX Specification, Version 3 are exposed, although behavior and function signatures are still based on the POSIX.4a draft 6 specification. In addition to the symbols exposed by `_OPEN_THREADS 2`, `_OPEN_THREADS 3` adds the following symbols to the namespace:

| Interfaces | Constants |
|------------------------------|--------------------------|
| pthread_atfork() | PTHREAD_CANCEL_CANCELED |
| pthread_attr_getguardsize() | PTHREAD_COND_INITIALIZER |
| pthread_attr_getschedparam() | PTHREAD_CREATE_DETACHED |
| pthread_attr_getstack() | PTHREAD_CREATE_JOINABLE |
| pthread_attr_getstackaddr() | PTHREAD_EXPLICIT_SCHED |
| pthread_attr_setguardsize() | |
| pthread_attr_setschedparam() | |
| pthread_attr_setstack() | |
| pthread_attr_setstackaddr() | |

Thread interfaces listed above and first exposed by `_OPEN_THREADS 2` or `3` are fully compliant with Single UNIX Specification, Version 3. However, the other threading interfaces in the library will not exhibit the new behavior or use function signatures that are changed in the new standard. Applications that define `_UNIX03_THREADS` or `_XOPEN_SOURCE 600` will obtain threads support that complies fully with Single UNIX Specification, Version 3.

If `_OPEN_THREADS` is defined with `_XOPEN_SOURCE 600`, `_OPEN_THREADS` takes precedence and overrides the default threads behavior of `_XOPEN_SOURCE 600`. However, `_OPEN_THREADS` and `_UNIX03_THREADS` are mutually exclusive.

Note: Feature test macros `_OPEN_SYS`, `_OPEN_SOURCE`, and `_ALL_SOURCE` incorporate `_OPEN_THREADS 1` by default, if `_OPEN_THREADS` has not been explicitly defined in the application, except when any of the following are present:

- `_ALL_SOURCE_NO_THREADS`
- `_UNIX03_THREADS`
- `_XOPEN_SOURCE 600`

`_POSIX1_SOURCE`

- When defined to 1, it has the same meaning as `_POSIX_SOURCE`.
- When defined to 2, both the POSIX.1a symbols and the POSIX.1 symbols are made visible. Additional symbols can be made visible if `POSIX.1a` explicitly allows the symbol to appear in the header in question.

`_POSIX_C_SOURCE`

- When defined to 1, it indicates that symbols required by POSIX . 1 are made visible. Additional symbols can be made visible if POSIX . 1 explicitly allows the symbol to appear in the header in question.
- When defined to 2, both the POSIX . 1 and POSIX . 2 symbols are made visible.
- When defined to 200112L, the Single UNIX Specification, Version 3 symbols are made visible, including POSIX.1 and POSIX.2. Since Version 3 is aligned with the ISO C standard (ISO/IEC 9899:1999), this definition of the feature test macro also exposes the C99 namespace.
- The `_POSIX_C_SOURCE` 200112L definition is available beginning with z/OS V1R9. Targeting earlier releases result in an error during compile time.
- Additional symbols can be made visible if POSIX . 2 explicitly allows the symbol to appear in the header in question.

`_POSIX_SOURCE`

When defined to any value with `#define`, it indicates that symbols required by POSIX . 1 are made visible. Additional symbols can be made visible if POSIX . 1 explicitly allows the symbol to appear in the header in question.

`_SHARE_EXT_VARS`

This feature test macro provides access to POSIX and XPG4 external variables of an application from a dynamically loaded module such as a DLL. For those external variables that have a function to access a thread-specific value, it provides access to the thread-specific value of the external variable without having to explicitly invoke the function.

Individual variables can be externalized by using the feature test macros that are prefixed with `_SHR_` and the feature test macros that are shown as follows. The entire set can be accessed by defining `_SHARE_EXT_VARS`.

Note: When an application is compiled with the XPLINK or LP64 option:

- The POSIX and XPG4 external variables are resolved through the C runtime library sidedeck in the SCEELIB data set and will be accessible from all dynamically loaded modules. See [z/OS XL C/C++ Programming Guide](#) for more details.
- The `_SHARE_EXT_VARS` feature test macro, and the following feature test macros with the `_SHR_` prefix, are only necessary for accessing the thread-specific values without having to explicitly invoke the function.

`_SHR_DAYLIGHT`

To share access to the daylight external variable from a dynamically loaded module such as a DLL, define the `_SHR_DAYLIGHT` feature test macro and include `time.h` in your program source.

`_SHR_ENVIRON`

If you have declared `char **environ` in your program and want to access the environment variable array from a dynamically loaded module such as a DLL, define the `_SHR_ENVIRON` feature test macro and include `stdlib.h` in the program source.

`_SHR_H_ERRNO`

To share access to the `h_errno` external variable from a dynamically loaded module such as a DLL, define the `_SHR_H_ERRNO` feature test macro and include `netdb.h` in your program source.

`_SHR__LOC1`

To share access to the `__loc1` external variable from a dynamically loaded module such as a DLL, define `_SHR__LOC1` feature test macro and include `libgen.h` in your program source.

`_SHR_LOC1`

To share access to the `loc1` external variable from a dynamically loaded module such as a DLL, define `_SHR_LOC1` feature test macro and include `regexp.h` in your program source.

`_SHR_LOC2`

To share access to the `loc2` external variable from a dynamically loaded module such as a DLL, define `_SHR_LOC2` feature test macro and include `regexp.h` in your program source.

`_SHR_LOCS`

To share access to the `locs` external variable from a dynamically loaded module such as a DLL, define `_SHR_LOCS` feature test macro and include `regexp.h` in your program source.

`_SHR_OPTARG`

To share access to the `optarg` external variable from a dynamically loaded module such as a DLL, define the `_SHR_OPTARG` feature test macro and include `unistd.h` or `stdio.h` in your program source.

`_SHR_OPTERR`

To share access to the `opterr` external variable from a dynamically loaded module such as a DLL, define the `_SHR_OPTERR` feature test macro and include `unistd.h` or `stdio.h` in your program source.

`_SHR_OPTIND`

To share access to the `optind` external variable from a dynamically loaded module such as a DLL, define `_SHR_OPTIND` feature test macro and include `unistd.h` or `stdio.h` in your program source.

`_SHR_OPTOPT`

To share access to the `optopt` external variable from a dynamically loaded module such as a DLL, define the `_SHR_OPTOPT` feature test macro and include `unistd.h` or `stdio.h` in your program source.

`_SHR_SIGNGAM`

To share access to the `siggam` external variable from a dynamically loaded module such as a DLL, define the `_SHR_SIGNGAM` feature test macro and include `math.h` in your program source.

`_SHR_T_ERRNO`

To share access to the `t_errno` external variable from a dynamically loaded module such as a DLL, define the `_SHR_T_ERRNO` feature test macro and include `xti.h` in your program source.

`_SHR_TIMEZONE`

To share access to the time zone external variable from a dynamically loaded module such as a DLL, define the `_SHR_TIMEZONE` feature test macro and include `time.h` in your program source. To avoid namespace pollution when `_SHR_TIMEZONE` is defined, the time zone variable must be referred to as `_timezone`.

_SHR_TZNAME

To share access to the *tzname* external variable from dynamically loaded module such as a DLL, define the `_SHR_TZNAME` feature test macro and include `time.h` in your program source.

__STDC_CONSTANT_MACROS

This feature test macro is required by C++ applications wanting to expose macros for integer constants as documented in `<stdint.h>`.

__STDC_FORMAT_MACROS

This feature test macro is required by C++ applications wanting to expose macros for format specifiers as documented in `<inttypes.h>`.

__STDC_WANT_DEC_FP__

This macro is added to the C99 DFP specification for C and C++. The user defines this macro when DFP support is wanted. It causes all DFP-oriented definitions in `<math.h>` and other headers to be exposed if `__IBM_DFP` is defined.

__STDC_LIMIT_MACROS

This feature test macro is required by C++ applications wanting to expose limits of specified-width integer types and limits of other integer types as documented in `<stdint.h>`.

__STRICT_ANSI_C__

This feature test macro exposes the macro `setjmp`.

__STRICT_POSIX__

This feature test macro exposes the macro `sigsetjmp`.

_TR1_C99

This feature test macro exposes the C++ TR1 C99 namespace as described in Chapter 8 of *ISO/IEC DTR 19768: Draft Technical Report on C++ Library Extensions*.

When both the `_TR1_C99` and `_AIX_COMPATIBILITY` Feature Test Macros are defined, the `_AIX_COMPATIBILITY` takes precedence. This affects the `copysign()`, `scalbn()`, and the floating point classification functions.

When both the `_TR1_C99` and `_FP_MODE_VARIABLE` feature test macros are defined, float overloads are not supported for the following functions:

`atan2()`, `copysign()`, `fdim()`, `fma()`, `fmax()`, `fmin()`, `fmod()`, `frexp()`, `hypot()`, `ldexp()`, `modf()`, `nextafter()`, `nexttoward()`, `pow()`, `remainder()`, `remquo()`, `scalbln()`, and `scalbn()`

Also, when both the `_TR1_C99` and `_FP_MODE_VARIABLE` feature test macros are set, the long double overloads are not supported for `frexp()` and `ldexp()`.

This feature test macro requires the use of the z/OS V1.10 z/OS XL C++ compiler or later.

_UNIX03_SOURCE

This feature test macro exposes new Single UNIX Specification, Version 3 interfaces. It does not change the behavior of existing APIs, nor expose interfaces that are controlled by feature test macros such as `_XOPEN_SOURCE_EXTENDED`. Functions and behavior that is exposed by `_UNIX03_SOURCE` are a subset and not the complete implementation of the Single UNIX Specification, Version 3. To

expose the full Single UNIX Specification, Version 3 implementation available in the C/C++ Runtime, see `_XOPEN_SOURCE` or `_POSIX_C_SOURCE`.

| Release | Interfaces Exposed with <code>_UNIX03_SOURCE</code> |
|-----------|---|
| z/OS V1R6 | <code>dlclose()</code> , <code>dlderror()</code> , <code>dlopen()</code> , <code>dlsym()</code> |
| z/OS V1R7 | <code>sched_yield()</code> , <code>strerror_r()</code> , <code>unsetenv()</code> |
| z/OS V1R8 | <code>flockfile()</code> , <code>ftrylockfile()</code> , <code>funlockfile()</code> , <code>getc_unlocked()</code> , <code>getchar_unlocked()</code> , <code>putc_unlocked()</code> , <code>putchar_unlocked()</code> |
| z/OS V1R9 | <code>posix_openpt()</code> , <code>pselect()</code> , <code>socketatmark()</code> |
| z/OS 3.1 | <code>posix_memalign()</code> |

Note: This feature test macro does not expose any new pthread interfaces. See `_OPEN_THREADS` and `_UNIX03_THREADS` to expose pthread interfaces.

`_UNIX03_THREADS`

This feature test exposes all pthread functions, function signatures, and behaviors required for the Threads option of Single UNIX Specification, Version 3. The macro is available for compilers targeting z/OS V1R9 or later.

Defining `_UNIX03_THREADS` exposes the content that is covered by feature test macro `_OPEN_SYS_MUTEX_EXT` so that the latter is redundant and need not be defined with `_UNIX03_THREADS`.

It is not necessary to define this feature test macro, if `_XOPEN_SOURCE` is defined to 600. Unless `_OPEN_THREADS` is defined, `_XOPEN_SOURCE` 600 will make available the same interfaces and behaviors as `_UNIX03_THREADS`.

`_UNIX03_THREADS` and `_OPEN_THREADS` are mutually exclusive.

`_UNIX03_WITHDRAWN`

Defining this feature test macro exposes any language elements, previously in the Legacy Feature Group or marked obsolescent, that have been removed from Single Unix Specification, Version 3. These elements would not otherwise be visible in the namespace that is exposed by compiling with `_XOPEN_SOURCE` 600 or `_POSIX_C_SOURCE` 200112L.

The following withdrawn symbols are exposed when `_UNIX03_WITHDRAWN` is defined:

| Functions | Constants |
|------------------------------|------------------------------------|
| <code>brk()</code> | <code>CLOCK_TICKS</code> |
| <code>chroot()</code> | <code>IUCLC</code> |
| <code>cuserid()</code> | <code>L_cuserid</code> |
| <code>gamma()</code> | <code>NOSTR</code> |
| <code>getdtablesize()</code> | <code>OLCUC</code> |
| <code>getpagesize()</code> | <code>PASS_MAX</code> |
| <code>getpass()</code> | <code>_SC_2_C_VERSION</code> |
| <code>getw()</code> | <code>_SC_PASS_MAX</code> |
| <code>putw()</code> | <code>_SC_XOPEN_XCU_VERSION</code> |
| <code>regcmp()</code> | <code>TMP_MAX</code> |
| <code>regex()</code> | <code>XCASE</code> |

| Functions | Constants |
|------------|--------------------------|
| sbrk() | YESSTR |
| sigstack() | |
| ttyslot() | |
| valloc() | External Variable |
| wait3() | __loc1 |

_VARARG_EXT_

This feature test macro allows users of the `va_arg`, `va_end`, and `va_start` macros to define the `va_list` type differently.

_XOPEN_SOURCE

This feature test macro defines the functionality that is defined in the XPG4 standard dated July 1992.

When defined to 500, this feature test macro makes available certain key functions that are associated with Single UNIX Specification, Version 2.

When defined to 600, this feature test macro exposes the complete implementation of the Single UNIX Specification, Version 3, including the namespace defined by `_POSIX_C_SOURCE` 200112L as well as namespaces associated with the X/Open System Interface (XSI) extension and these options and option groups:

- File synchronization
- Memory mapped files
- Memory protection
- Realtime signals extension
- Thread stack address attribute
- Thread stack size attribute
- Thread process-shared synchronization
- Thread-safe functions
- Threads
- Encryption option group
- Legacy option group
- XSI streams option group

The use of `_XOPEN_SOURCE` 600 exposes namespaces that are covered by several other feature test macros, and as such, makes those macros redundant. The following need not be defined when `_XOPEN_SOURCE` 600 is defined:

| | |
|-------------------------------------|----------------------------------|
| <code>_ISOC99_SOURCE</code> | <code>_POSIX_C_SOURCE</code> |
| <code>_UNIX03_THREADS</code> | <code>_OPEN_SYS_MUTEX_EXT</code> |
| <code>_UNIX03_SOURCE</code> | <code>_POSIX_SOURCE</code> |
| <code>_XOPEN_SOURCE_EXTENDED</code> | |

If `_OPEN_THREADS` is defined with `_XOPEN_SOURCE` 600, `_OPEN_THREADS` takes precedence and overrides Single UNIX Specification, Version 3 threads behavior. Whenever `_OPEN_THREADS` is in effect, the `_OPEN_SYS_MUTEX_EXT` extensions are also dropped, unless the application explicitly defines this macro.

The `_XOPEN_SOURCE 600` definition is available beginning with z/OS V1R9. Targeting earlier releases result in an error during compile time.

Full support of Single UNIX Specification, Version 3 requires use of a C99 compliant compiler. Most of the namespace is available to older compilers, but some elements of Version 3 (such as `<complex.h>` or `<tgmath.h>`) will not be visible.

`_XOPEN_SOURCE_EXTENDED`

When defined to 1, this defines the functions that are defined in the XPG4 standard plus the set of “Common APIs for UNIX-based Operating Systems”, April 1994, draft.

`_XPLATFORM_SOURCE`

This feature test macro exposes new typedef types, structures, and functions to provide cross-platform portability.

C/C++ header files

The C/C++ header files can be used with any of the IBM z/OS C/C++ compilers. They are shipped in the CEE.SCEEH* data sets and in the `/usr/include` directory in z/OS UNIX.

For the information about `builtins.h`, refer to the C++98 language standard (ISO/IEC 14882:1998).

`aio.h` — Asynchronous I/O operations

The `aio.h` header file contains definitions for asynchronous I/O operations. It declares these functions:

| | | |
|----------------------------|--------------------------|---------------------------|
| <code>aio_read()</code> | <code>aio_write()</code> | <code>aio_cancel()</code> |
| <code>aio_suspend()</code> | <code>aio_error()</code> | <code>aio_return()</code> |

Note: There are several sockets oriented extensions to asynchronous I/O available with the BPX1AIO callable service, such as asynchronous `accept()`, asynchronous `accept_and_recv()`, asynchronous forms of all five pairs of read and write type operations, and receiving I/O completion notifications via an ECB, exit program, or through a message queue. The `<aio.h>` header contains all the structure fields, constants, and prototypes necessary to use BPX1AIO from a C program. These extensions are exposed when the `_AIO_OS390` feature test macro is defined. The BPX1AIO stub resides in `SYS1.CSSLIB` and must be bound with your program. For a more detailed description of asynchronous I/O services, see BPX1AIO in *z/OS UNIX System Services Programming: Assembler Callable Services Reference*.

`arpa/inet.h` — Internet operations

The `arpa/inet.h` header file contains definitions for internet operations.

`arpa/nameser.h` — Construct and inspect DNS requests

The `arpa/nameser.h` header file contains the definitions used to support the construction of queries and the inspection of answers received from a Domain Name Server available in a network. It also contains the macros `GETSHORT()`, `PUTSHORT()`, `GETLONG()`, and `PUTLONG()` that are used to construct or inspect DNS requests.

`assert.h` — Insert diagnostics

The `assert.h` header file defines the `assert()` macro that allows you to insert diagnostics into your code. You must include `assert.h` when you use `assert()`.

_Ccsid.h — CCSID to codeset name conversion

The `_Ccsid.h` header file declares functions, symbols and data types used in CCSID to codeset name conversion.

ceedcct.h — C declarations of Language Environment

The `ceedcct.h` header file contains C declarations of the Language Environment® condition tokens.

cics.h — Verify CICS

The `cics.h` header file declares the `iscics()` function, which verifies whether CICS® is running.

collate.h — Current locale's collating properties

The `collate.h` header includes declarations of functions that allow retrieval of information regarding the current locale's collating properties. It declares these functions:

| | | | | |
|--------------------------|---------------------------|---------------------------|--------------------------|--------------------------|
| <code>cclass()</code> | <code>collequiv()</code> | <code>collorder()</code> | <code>collrange()</code> | <code>colltostr()</code> |
| <code>getmccoll()</code> | <code>getwmccoll()</code> | <code>ismccollet()</code> | <code>maxcoll()</code> | <code>strtcoll()</code> |

For more information about the effect of locale, see `setlocale()`, `locale.h`, or look up the individual functions in this topic. For still more information, see "Internationalization: Locales and Character Sets" in *z/OS XL C/C++ Programming Guide*.

cpio.h — CPIO archive values

The `cpio.h` header file contains CPIO archive values.

csp.h — Define __csplist macro

Restriction: This header file is not supported in AMODE 64.

The `csp.h` header file declares the `__csplist` macro, which obtains the CSP parameter list.

These macros are *not* supported under z/OS UNIX and they are not supported for C++ applications.

ctest.h — Debug and diagnostics

The `ctest.h` header file contains declarations for the functions that involve debugging and diagnostics. The diagnostic functions are:

| | | | |
|----------------------|----------------------|----------------------|-----------------------|
| <code>cdump()</code> | <code>csnap()</code> | <code>ctest()</code> | <code>ctrace()</code> |
|----------------------|----------------------|----------------------|-----------------------|

ctype.h — Character classification

The `ctype.h` header file declares functions used in character classification. The functions declared are:

| | | | | |
|----------------------------|-------------------------|-------------------------|-------------------------|------------------------|
| <code>isalnum()</code> | <code>isalpha()</code> | <code>isblank()</code> | <code>iscntrl()</code> | <code>isdigit()</code> |
| <code>isgraph()</code> | <code>islower()</code> | <code>isprint()</code> | <code>ispunct()</code> | <code>isspace()</code> |
| <code>isupper()</code> | <code>isxdigit()</code> | <code>tolower()</code> | <code>toupper()</code> | |
| <code>_XOPEN_SOURCE</code> | | | | |
| <code>isascii()</code> | <code>toascii()</code> | <code>_tolower()</code> | <code>_toupper()</code> | |

For more information about the effect of locale, see `setlocale()`, `locale.h`, or look up the individual functions in this topic. For still more information, see "Internationalization: Locales and Character Sets" in *z/OS XL C/C++ Programming Guide*.

decimal.h — Fixed-point decimal operations

The `decimal.h` header file is not supported under z/OS C++ applications.

The `decimal.h` header file contains declarations for those built-in functions that perform fixed-point decimal operations. The functions declared are:

`decabs()` `decchk()` `decfix()`

The header file also contains definitions of constants that specify the ranges of the `decimal` data types.

dirent.h — POSIX directory access

The `dirent.h` header file contains constants, prototypes, and typedef definitions for POSIX directory access functions. It declares the following functions.

`_OPEN_SYS_DIR_EXT`

`__opendir2()` `__readdir2()` `__readdir2_64()`

`_POSIX_SOURCE`

`closedir()` `opendir()` `readdir()` `rewinddir()`

`_XOPEN_SOURCE`

`seekdir()` `telldir()`

`_XOPEN_SOURCE 500`

`readdir_r()`

`_POSIX_C_SOURCE 200809L`

`dirfd()` `fdopendir()`

`_XPLATFORM_SOURCE`

`fdclosedir()`

This header file can be used by C++ POSIX(OFF) functions.

dlfcn.h — Define macros for use with dlopen()

The `dlfcn.h` header file declares the following macros for use in the construction of a `dlopen()` mode argument::

RTLD_LAZY

Relocations are performed at an implementation-defined time.

RTLD_NOW

Relocations are performed when the object is loaded.

RTLD_GLOBAL

All symbols are available for relocation processing of other modules.

RTLD_LOCAL

All symbols are not made available for relocation processing by other modules.

`dlclose()` `dLError()` `dlsym()` `dlopen()`

dll.h — DLL functions

The `dll.h` header file declares the following functions:

`dllload()` `dllqueryvar()` `dllqueryfn()` `dllfree()`

Use this header file when using these functions to import functions and variables from a DLL.

dynit.h — Dynamic allocation routines

The `dynit.h` header file contains information for dynamic allocation routines. Specifically, it contains declarations of the `dynalloc()` and `dynfree()` functions, the definition of the `dyninit()` macro, declarations of related structures, and definitions of related constants.

env.h — Set and clear environment variables

The `env.h` header file is used to declare the `setenv()` and `clearenv()` functions, which are used in POSIX programs to set and clear environment variables. The `env.h` header file requires the `_POSIX1_SOURCE 2` feature test macro.

errno.h — Symbolic constants for errno

The `errno.h` header file defines the symbolic constants that are returned in the external variable `errno`.

Table 3. Definitions in `errno.h`

| | |
|----------------------|-----------------------------------|
| EACCES | Permission denied |
| EADDRINUSE | Address in use |
| EADDRNOTAVAIL | Address not available |
| EADV | Advertise error |
| EAFNOSUPPORT | Address family not supported |
| EAGAIN | Resource temporarily unavailable |
| EALREADY | Connection already in progress |
| EBADF | Bad file descriptor |
| EBADMSG | Bad message |
| EBUSY | Resource busy |
| ECANCELED | Operation canceled |
| ECHILD | No child processes |
| ECICS | Function not supported under CICS |
| ECOMM | Communication error on send |
| ECONNABORTED | Connection aborted |
| ECONNREFUSED | Connection refused |
| ECONNRESET | Connection reset |
| EDEADLK | Resource deadlock avoided |
| EDESTADDRREQ | Destination address required |
| EDOM | Domain error |

Table 3. Definitions in *errno.h* (continued)

| | |
|---------------------------|--|
| EDOTDOT | Cross mount point (not an error) |
| EDQUOT | Reserved |
| EEXIST | File exists |
| EFAULT | Bad address |
| EFBIG | File too large |
| EHOSTDOWN | Host is down |
| EHOSTUNREACH | Destination host can not be reached |
| EIBMBADCALL | A bad socket-call constant in IUCV header |
| EIBMBADPARM | Other IUCV header error |
| EIBMCANCELLED | Request canceled |
| EIBMCONFLICT | Conflicting call outstanding on socket |
| EIBMIUCVERR | Request failed due to IUCV error |
| EIBMSOCKINUSE | Assigned socket number already in use |
| EIBMSOCKOUTOFRANGE | Assigned socket number out of range |
| EIDRM | Identifier removed |
| EILSEQ | Illegal byte sequence |
| EINPROGRESS | Connection in progress |
| EINTR | Interrupted function call |
| EINTRNODATA | Function call interrupted before any data received |
| EINVAL | Invalid argument |
| EIO | Input/output error |
| EISCONN | Socket is already connected |
| EISDIR | Is a directory |
| ELEMSGERR | Message file was not found in z/OS UNIX |
| ELEMULTITHREAD | Function not allowed in a multithreaded environment |
| ELEMULTITHREADFORK | Function not allowed in child of fork() in multithreaded environment |
| ELENOFORK | Language Environment member language cannot tolerate a fork() |
| ELOOP | A loop exists in symbolic links encountered during resolution of the path argument |
| EMFILE | Too many open files |
| EMLINK | Too many links |
| EMSGSIZE | Message too long |
| EMULTIHOP | Multihop is not allowed |
| EMVSBADCHAR | Bad character in environment variable name |
| EMVSCATLG | Catalog obtain error |
| EMVSCPLERROR | A CPL service failed |

Table 3. Definitions in *errno.h* (continued)

| | |
|-----------------------|--|
| EMVSCVAF | Catalog Volume Access Facility error |
| EMVSDYNALC | Dynamic allocation error |
| EMVSERR | An MVS internal error |
| EMVSEXPIRE | Password has expired |
| EMVSINITIAL | Process initialization err |
| EMVSNORTL | Access to the z/OS UNIX version of the C RTL is denied |
| EMVSNOTXP | z/OS UNIX are not active |
| EMVSPARM | Bad parameters were passed to the service |
| EMVSPASSWORD | Password is invalid |
| EMVSPATHOPTS | Access mode argument conflicts with PATHOPTS parameter |
| EMVSPFSFILE | PDSE/X encountered a permanent file error |
| EMVSPFSPERM | PDSE/X encountered a system error |
| EMVSSAF2ERR | SAF/RACF [®] error |
| EMVSSAFEXTRERR | SAF/RACF extract error |
| EMVSTODNOTSET | System TOD clock not set |
| ENAMETOOLONG | File name too long |
| ENETDOWN | The local interface to use or reach the destination |
| ENETRESET | Network dropped connection on reset |
| ENETUNREACH | Network unreachable |
| ENFILE | Too many open files in system |
| ENOBUFS | No buffer space available |
| ENODATA | No message available |
| ENODEV | No such device |
| ENOENT | No such file or directory |
| ENOEXEC | Exec format error |
| ENOLINK | The link has been severed |
| ENOLCK | No locks available |
| ENOMEM | Not enough space |
| ENOMSG | No message of desired type |
| ENONET | Machine is not on the network |
| ENOPROTOOPT | Protocol not available |
| ENOREUSE | The socket cannot be reused |
| ENOSPC | No space left on device |
| ENOSR | No stream resource |
| ENOSYS | Function not implemented |
| ENOSTR | Not a stream |

Table 3. Definitions in *errno.h* (continued)

| | |
|---------------------------|--|
| ENOTBLK | Block device required |
| ENOTCONN | The socket is not connected. |
| ENOTDIR | Not a directory |
| ENOTEMPTY | Directory not empty |
| ENOTSOCK | Descriptor does not refer to a socket |
| ENOTSUP | Not supported. |
| ENOTTY | Inappropriate I/O control operation |
| ENXIO | No such device or address |
| EOFFLOADboxDOWN | Offload box down |
| EOFFLOADboxERROR | Offload box error |
| EOFFLOADboxRESTART | Offload box restarted |
| EOPNOTSUPP | Operation not supported on socket |
| EOVERFLOW | Value too large to be stored in data type |
| EPERM | Operation not permitted |
| EPFNOSUPPORT | Protocol family not supported |
| EPIPE | Broken pipe |
| EPROCLIM | Too many processes |
| EPROTO | Protocol error |
| EPROTONOSUPPORT | Protocol not supported |
| EPROTOTYPE | The socket type is not supported by the protocol |
| ERANGE | Range error or pole error |
| EREMCHG | Remote address changed |
| EREMOTE | Too many levels of remote in path |
| EROFS | Read-only file system |
| ERREMOTE | Object is remote |
| ESHUTDOWN | Cannot send after socket shutdown |
| ESOCKTNOSUPPORT | Socket type not supported |
| ESPIPE | Invalid seek |
| ESRCH | No such process |
| ESRMNT | srmount error |
| ESTALE | The file handle is stale |
| ETIME | Stream ioctl() timeout |
| ETIMEDOUT | Socket not connected |
| ETOOMANYREFS | Too many references: cannot splice |
| ETXTBSY | Text file busy |
| EUSERS | Too many users |
| EWouldBLOCK | Problem on nonblocking socket |

Table 3. Definitions in `errno.h` (continued)

| | |
|--------------|---|
| EXDEV | A link to a file on another file system was attempted |
| E2BIG | Argument list too long |

The `errno.h` header file also defines `errno`, which is a modifiable lvalue having type `int`. If you intend to test the value of `errno` after library function calls, first set it to 0, because the library functions do not reset the value to 0.

`strerror()` or `perror()` functions can be used to print the description of the message associated with a particular `errno`.

To test for the explicit error, use the macro names defined in `errno.h`, rather than specific values of these macros. Doing so will ensure future compatibility and portability.

`errno.h` also declares the `__errno2()` prototype.

fcntl.h – POSIX functions for file operations

The `fcntl.h` header file declares the following POSIX functions for creating, opening, rewriting, and manipulating files.

| | | |
|--------------------------------------|------------------------|--------------------------|
| <code>_POSIX_C_SOURCE</code> 200809L | | |
| <code>faccessat()</code> | <code>openat()</code> | <code>utimensat()</code> |
| <code>_POSIX_SOURCE</code> | | |
| <code>creat()</code> | <code>fcntl()</code> | <code>open()</code> |
| <code>_XPLATFORM_SOURCE</code> | | |
| <code>futimesat()</code> | <code>openat2()</code> | |

The header also contains these constants:

| | |
|--------------------------------|-----------------------|
| <code>_XPLATFORM_SOURCE</code> | |
| <code>O_CLOEXEC</code> | <code>O_DIRECT</code> |

features.h – Feature test macros

The `features.h` header file contains definitions for feature test macros. For information on feature test macros, see [“Feature test macros” on page 3](#).

fenv.h – Floating-point environment

The `fenv.h` header contains the following data types, macros and functions. This header is supported under IEEE Binary Floating-Point only and is required to define the feature test macro `_ISOC99_SOURCE` or requires the compiler that is designed to support C99 to expose the functionality. The decimal floating-point macros, prefixed by `FE_DEC_` and `_FE_DEC_`, are used by the `fe_dec_getround` and `fe_dec_setround` functions to get and set the rounding mode of decimal floating-point operations. Decimal floating-point functionality additionally requires the `__STDC_WANT_DEC_FP__` feature test macro to be defined.

Data types

fenv_t
represents the entire floating-point environment.

fexcept_t
represents the floating-point status flags collectively.

Macros

FE_DIVBYZERO

defines the divide by zero exception

_FE_DEC_AWAYFROMZERO

rounds away from zero

FE_DEC_DOWNWARD

rounds towards minus infinity

_FE_DEC_PREPAREFORSHORTER

rounds to prepare for shorter precision

FE_DEC_TONEAREST

rounds to nearest

FE_DEC_TONEARESTFROMZERO

rounds to nearest, ties away from zero

_FE_DEC_TONEARESTTOWARDZERO

rounds to nearest, ties toward zero

FE_DEC_TOWARDZERO

rounds toward zero

FE_DEC_UPWARD

rounds toward plus infinity

FE_INEXACT

defines the inexact exception

FE_INVALID

defines the invalid exception

FE_OVERFLOW

defines the overflow exception

FE_UNDERFLOW

defines the underflow exception

FE_ALL_EXCEPT

defines the bitwise OR of all the exception macros.

FE_DOWNWARD

rounds towards minus infinity

FE_TONEAREST

rounds to nearest

FE_TOWARDZERO

rounds toward zero

FE_UPWARD

rounds towards plus infinity

FE_DFL_ENV

defines the floating-point environment as it was available at program start up

Functions

| | | | | |
|------------------------|--------------------------|--------------------------|--------------------------|-----------------------|
| feclearexcept() | fegetenv() | fegetexceptflag() | fegetround() | feholdexcept() |
| feraiseexcept() | fesetenv() | fesetexceptflag() | fesetround() | fetestexcept() |
| feupdateenv() | fe_dec_getround() | | fe_dec_setround() | |

float.h — ISO C/C++ constants for floating-point data types

The `float.h` header file contains definitions of constants listed in ISO C/C++ 5.2.4.2.2, that describe the characteristics of the internal representations of the three floating-point data types, `float`, `double`, and `long double`. The definitions are:

Constant

Description

FLT_ROUNDS

The rounding mode for floating-point addition.

FLT_RADIX

The radix for IBM z/OS C applications.

The FLT_RADIX value depends on the representation that is used for the floating-point types:

- When [IEEE floating point representation](#) is used, the FLT_RADIX value is 16.
- When [Hexadecimal floating point representation](#) is used, the FLT_RADIX value is 2

FLT_MANT_DIG**DBL_MANT_DIG****LDBL_MANT_DIG**

The number of hexadecimal digits stored to represent the significand of a fraction.

FLT_DIG**DBL_DIG****LDBL_DIG**

The number of decimal digits, q , such that any floating-point number with q decimal digits can be rounded into a floating-point number with p radix FLT_RADIX digits and back again, without any change to the q decimal digits.

FLT_MIN_EXP**DBL_MIN_EXP****LDBL_MIN_EXP**

The minimum negative integer such that FLT_RADIX raised to that power minus 1 is a normalized floating-point number.

FLT_MIN_10_EXP DBL_MIN_10_EXP**LDBL_MIN_10_EXP**

The minimum negative integer such that 10 raised to that power is in the range of normalized floating-point numbers.

FLT_MAX_EXP**DBL_MAX_EXP****LDBL_MAX_EXP**

The maximum integer such that FLT_RADIX raised to that power minus 1 is a representable finite floating-point number.

FLT_MAX_10_EXP**DBL_MAX_10_EXP****LDBL_MAX_10_EXP**

The maximum integer such that 10 raised to that power is in the range of representable finite floating-point numbers.

FLT_MAX**DBL_MAX****LDBL_MAX**

The maximum representable finite floating-point number.

FLT_EPSILON**DBL_EPSILON****LDBL_EPSILON**

The difference between 1.0 and the least value greater than 1.0 that is representable in the given floating-point type.

FLT_MIN**DBL_MIN****LDBL_MIN**

The minimum normalized positive floating-point number.

DECIMAL_DIG

The minimum number of decimal digits needed to represent all the significant digits for type long double.

FLT_EVAL_METHOD

Describes the evaluation mode for floating point operations. This value is 1, which evaluates all operations and constants of types float and double to type double and that of long double to type long double.

DEC_EVAL_METHOD

The decimal floating-point evaluation format.

FLT_MAXDIG10

DBL_MAXDIG10

LDBL_MAXDIG10

The number of base 10 digits required to ensure that values which differ by only one smallest unit in the last place (ulp) are always differentiated.

FLT_SUBNORM

DBL_SUBNORM

LDBL_SUBNORM

Characterize the presence or absence of subnormal numbers:

- -1: indeterminable
- 0: absent (type does not support subnormal numbers)
- 1: present (type does support subnormal numbers)

FLT_DECIMAL_DIG

DBL_DECIMAL_DIG

LDBL_DECIMAL_DIG

The number of decimal digits, n, such that any floating-point number with p radix b digits can be rounded to a floating-point number with n decimal digits and back again without change to the value.

FLT_TRUE_MIN

DBL_TRUE_MIN

LDBL_TRUE_MIN

The minimum positive floating-point number.

The float.h header file also contains constants that describe the characteristics of the internal representations of the three decimal floating-point data types, _Decimal32, _Decimal64, and _Decimal128. The prefixes DEC32_, DEC64_, and DEC128_ are used to denote the types _Decimal32, _Decimal64, and _Decimal128, respectively.

Constant

Description

DEC32_MANT_DIG

DEC64_MANT_DIG

DEC128_MANT_DIG

The number of digits in the coefficient.

DEC32_MIN_EXP

DEC64_MIN_EXP

DEC128_MIN_EXP

The minimum exponent.

DEC32_MAX_EXP

DEC64_MAX_EXP

DEC128_MAX_EXP

The maximum exponent.

DEC32_MAX

DEC64_MAX

DEC128_MAX

The maximum representable finite decimal floating number.

DEC32_EPSILON
DEC64_EPSILON
DEC128_EPSILON

The difference between 1 and the least value greater than 1 that is representable in the given floating point type.

DEC32_MIN
DEC64_MIN
DEC128_MIN

The minimum normalized positive decimal floating number.

DEC32_SUBNORMAL_MIN
DEC64_SUBNORMAL_MIN
DEC128_SUBNORMAL_MIN

The minimum subnormal (denormalized) positive Decimal Floating Point number.

DEC_EVAL_METHOD

The decimal floating-point evaluation format.

fmtmsg.h — Message display structures

The `fmtmsg.h` header file contains message display structures.

fnmatch.h — Filename matching types

The `fnmatch.h` header file contains filename matching types.

fpxcp.h — Floating-point exception interfaces

The `fpxcp.h` header file declares floating-point exception interfaces.

__ftp.h — FTP resolver functions

The `__ftp.h` header file contains definitions for FTP resolver functions.

ftw.h — File tree traversal constants

The `ftw.h` header file contains file tree traversal constants.

getopt.h — z/OS UNIX function for parsing command line option

The `getopt.h` header file contains definitions for command line option parsing functions.

__gfunc.h — __gtca and __gtab functions

The `__gfunc.h` header file defines the `__gtca` and `__gtab` functions.

glob.h — Pathname pattern matching types

The `glob.h` header file contains pathname pattern matching types.

grp.h — Access group databases

The `grp.h` header file declares functions used to access group databases.

`_POSIX_SOURCE`

`getgrgid()`

`__getgrgid1()`

`getgrnam()`

`__getgrnam1()`

`_OPEN_SYS`

Header files

| | | |
|--------------------------|--------------|------------|
| initgroups() | setgroups() | |
| _XOPEN_SOURCE_EXTENDED 1 | | |
| setgrent() | endgrent() | getgrent() |
| _XOPEN_SOURCE 500 | | |
| getgrgid_r() | getgrnam_r() | |

iconv.h — Code conversion

The `iconv.h` header file declares the `iconv_open()`, `iconv()`, and `iconv_close()` functions that deal with code conversion.

_Ieee754.h — IEEE 754 interfaces

The `_Ieee754.h` header file declares IEEE 754 interfaces.

ims.h — Invoke IMS facilities

Restriction: This header file is not supported in AMODE 64.

The `ims.h` header file declares the `ctdli()` function that invokes IMS facilities. The function is *not* supported from a z/OS UNIX program running POSIX(ON).

inttypes.h — I/O format of integer types

The following macros are defined in `inttypes.h`. Each expands to a character string literal containing a conversion specifier which can be modified by a length modifier that can be used in the *format* argument of a formatted input/output function when converting the corresponding integer type. These macros have the general form of PRI (character string literals for the `fprintf()` and `fwprintf()` family of functions) or SCN (character string literals for the `fscanf()` and `fwscanf()` family of functions), followed by the conversion specifier, followed by a name corresponding to a similar type name in `<inttypes.h>`. In these names, the suffix number represents the width of the type. For example, `PRIdFAST32` can be used in a format string to print the value of an integer of type `int_fast32_t`.

This header defines the type `imaxdiv_t`.

Note: Requires `long long` to be available.

`imaxdiv_t` is a structure type that is the type of the value returned by the `imaxdiv()` function. It is functionally equivalent to `lldiv_t`.

Compile requirement:

In the following list all macros with the suffix MAX or 64 require `long long` to be available.

| | | | |
|------------|-------------|-------------|-------------|
| PRId8 | PRId16 | PRId32 | PRId64 |
| PRIdLEAST8 | PRIdLEAST16 | PRIdLEAST32 | PRIdLEAST64 |
| PRIdFAST8 | PRIdFAST16 | PRIdFAST32 | PRIdFAST64 |
| PRIdMAX | | | |
| PRIdPTR | | | |
| PRId8 | PRId16 | PRId32 | PRId64 |
| PRIdLEAST8 | PRIdLEAST16 | PRIdLEAST32 | PRIdLEAST64 |
| PRIdFAST8 | PRIdFAST16 | PRIdFAST32 | PRIdFAST64 |
| PRIdMAX | | | |

PRIiPTR

Example

```
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>
int main(void)
{
    int8_t i = 40;
    printf("Demonstrating the use of the following macros:\n");
    printf("Using PRId8, the printed value of 40 "
        "is %" PRId8"\n", i);
    printf("Using PRIiFAST8, the printed value of 40 "
        "is %" PRIiFAST8"\n", i);
    printf("Using PRioLEAST8, the printed value of 40 "
        "is %" PRioLEAST8 "\n", i);
    return 0;
}
```

Output:

```
Demonstrating the use of the following macros:
Using PRId8, the printed value of 40 is 40
Using PRIiFAST8, the printed value of 40 is 40
Using PRioLEAST8, the printed value of 40 is 50
```

Compile requirement:

In the following list all macros with the suffix MAX or 64 require `long long` to be available.

Macros for `fprintf` family for unsigned integers:

| | | | |
|------------|-------------|-------------|-------------|
| PRIo8 | PRIo16 | PRIo32 | PRIo64 |
| PRioLEAST8 | PRioLEAST16 | PRioLEAST32 | PRioLEAST64 |
| PRioFAST8 | PRioFAST16 | PRioFAST32 | PRioFAST64 |
| PRioMAX | | | |
| PRioPTR | | | |
| PRIu8 | PRIu16 | PRIu32 | PRIu64 |
| PRIuLEAST8 | PRIuLEAST16 | PRIuLEAST32 | PRIuLEAST64 |
| PRIuFAST8 | PRIuFAST16 | PRIuFAST32 | PRIuFAST64 |
| PRIuMAX | | | |
| PRIuPTR | | | |
| PRIx8 | PRIx16 | PRIx32 | PRIx64 |
| PRIxLEAST8 | PRIxLEAST16 | PRIxLEAST32 | PRIxLEAST64 |
| PRIxFAST8 | PRIxFAST16 | PRIxFAST32 | PRIxFAST64 |
| PRIxMAX | | | |
| PRIxPTR | | | |
| PRIX8 | PRIX16 | PRIX32 | PRIX64 |
| PRIXLEAST8 | PRIXLEAST16 | PRIXLEAST32 | PRIXLEAST64 |
| PRIXFAST8 | PRIXFAST16 | PRIXFAST32 | PRIXFAST64 |
| PRIXMAX | | | |
| PRIXPTR | | | |

Example

```
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>

int main(void)
{
    uint32_t i = 24000;
    printf("Demonstrating the use of the following macros:\n");
    printf("Using PRIuPTR, the address of the variable "
           "is %" PRIuPTR "\n", i);
    printf("Using PRIXFAST32, the printed value of 24000 "
           "is %" PRIXFAST32 "\n", i);
    printf("Using PRILEAST32, the printed value of 24000 "
           "is %" PRILEAST32 "\n", i);
    return 0;
}
```

Output:

```
Demonstrating the use of the following macros:
Using PRIuPTR, the address of the variable is 538874544
Using PRIXFAST32, the printed value of 24000 is 5DC0
Using PRILEAST32, the printed value of 24000 is 5dc0
```

Compile requirement:

In the following list all macros with the suffix MAX or 64 require long long to be available.

Macros for fscanff family for signed integers:

| | | | |
|------------|-------------|-------------|-------------|
| SCNd8 | SCNd16 | SCNd32 | SCNd64 |
| SCNdLEAST8 | SCNdLEAST16 | SCNdLEAST32 | SCNdLEAST64 |
| SCNdFAST8 | SCNdFAST16 | SCNdFAST32 | SCNdFAST64 |
| SCNdMAX | | | |
| SCNdPTR | | | |
| SCNi8 | SCNi16 | SCNi32 | SCNi64 |
| SCNiLEAST8 | SCNiLEAST16 | SCNiLEAST32 | SCNiLEAST64 |
| SCNiFAST8 | SCNiFAST16 | SCNiFAST32 | SCNiFAST64 |
| SCNiMAX | | | |
| SCNiPTR | | | |

Example

```
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>

int main(void)
{
    int32_t i;
    printf("Enter decimal value ");
    scanf("%i" SCNdFAST32, &i);
    printf("Print result: %" PRIuFAST32 "\n", i);
    return 0;
}
```

Output:

```
Enter decimal value 23
Print result: 23
```

Compile requirement:

In the following list all macros with the suffix MAX or 64 require `long long` to be available.

Macros for `fscanf` family for signed integers:

| | | | |
|------------|-------------|-------------|-------------|
| SCNo8 | SCNo16 | SCNo32 | SCNo64 |
| SCNoLEAST8 | SCNoLEAST16 | SCNoLEAST32 | SCNoLEAST64 |
| SCNoFAST8 | SCNoFAST16 | SCNoFAST32 | SCNoFAST64 |
| SCNoMAX | | | |
| SCNoPTR | | | |
| SCNu8 | SCNu16 | SCNu32 | SCNu64 |
| SCNuLEAST8 | SCNuLEAST16 | SCNuLEAST32 | SCNuLEAST64 |
| SCNuFAST8 | SCNuFAST16 | SCNuFAST32 | SCNuFAST64 |
| SCNuMAX | | | |
| SCNuPTR | | | |
| SCNx8 | SCNx16 | SCNx32 | SCNx64 |
| SCNxLEAST8 | SCNxLEAST16 | SCNxLEAST32 | SCNxLEAST64 |
| SCNxFAST8 | SCNxFAST16 | SCNxFAST32 | SCNxFAST64 |
| SCNxMAX | | | |
| SCNxPTR | | | |

Example

```
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>

int main(void)
{
    intmax_t i;
    printf("Enter hex value ");
    scanf("%" SCNxMAX, &i);
    printf("Print result: %020" PRIxMAX "\n", i);
    return 0;
}
```

Output :

```
Enter hex value 0x32
Print result: 0000000000000000000032
```

iso646.h —Macros for operators

The header file `iso646.h` allows the user to use the following macros in place of the associated operator.

Macros

Operators

and

`&&`

and_eq

`&=`

bitand

`&`

bitor

`|`

```
compl
~
not
!
not_eq
!=
or
||
or_eq
|=
xor
^
xor_eq
^=
```

langinfo.h —Macros for date and time

The langinfo.h header file contains the declaration for the nl_langinfo() function. The header file also defines the macros that, in turn, define constants used to identify the information queried by nl_langinfo() in the current locale. The following macros are defined:

Table 4. Item Values defined in langinfo.h

| Item Name | Description |
|------------|--|
| ABDAY_1 | Abbreviated first day of the week |
| ABDAY_2 | Abbreviated second day of the week |
| ABDAY_3 | Abbreviated third day of the week |
| ABDAY_4 | Abbreviated fourth day of the week |
| ABDAY_5 | Abbreviated fifth day of the week |
| ABDAY_6 | Abbreviated sixth day of the week |
| ABDAY_7 | Abbreviated seventh day of the week |
| ABMON_1 | Abbreviated first month |
| ABMON_2 | Abbreviated second month |
| ABMON_3 | Abbreviated third month |
| ABMON_4 | Abbreviated fourth month |
| ABMON_5 | Abbreviated fifth month |
| ABMON_6 | Abbreviated sixth month |
| ABMON_7 | Abbreviated seventh month |
| ABMON_8 | Abbreviated eighth month |
| ABMON_9 | Abbreviated ninth month |
| ABMON_10 | Abbreviated tenth month |
| ABMON_11 | Abbreviated eleventh month |
| ABMON_12 | Abbreviated twelfth month |
| ALT_DIGITS | String of semicolon separated alternative symbols for digits |
| AM_STR | String for morning |

Table 4. Item Values defined in *langinfo.h* (continued)

| Item Name | Description |
|-------------|--|
| CODESET | Current encoded character set of the process |
| CRNCYSTR | Local currency symbol, preceded by '-' if the symbol should appear before the value, '+' if the symbol should appear after the value, or '.' if the symbol should replace the radix character. |
| D_FMT | String for formatting date |
| D_T_FMT | String for formatting date and time |
| DAY_1 | Name of the first day of the week |
| DAY_2 | Name of the second day of the week |
| DAY_3 | Name of the third day of the week |
| DAY_4 | Name of the fourth day of the week |
| DAY_5 | Name of the fifth day of the week |
| DAY_6 | Name of the sixth day of the week |
| DAY_7 | Name of the seventh day of the week |
| ERA | String of semicolon separated era segments |
| ERA_D_FMT | String for era date format |
| ERA_D_T_FMT | String for era date and time format |
| ERA_T_FMT | String for era time format |
| MON_1 | Name of the first month |
| MON_2 | Name of the second month |
| MON_3 | Name of the third month |
| MON_4 | Name of the fourth month |
| MON_5 | Name of the fifth month |
| MON_6 | Name of the sixth month |
| MON_7 | Name of the seventh month |
| MON_8 | Name of the eighth month |
| MON_9 | Name of the ninth month |
| MON_10 | Name of the tenth month |
| MON_11 | Name of the eleventh month |
| MON_12 | Name of the twelfth month |
| NOEXPR | Negative response expression |
| NOSTR | Negative response string |
| PM_STR | String for afternoon |
| RADIXCHAR | Radix character |
| T_FMT | String for formatting time |
| T_FMT_AMPM | String for formatting time in 12-hour clock format |
| THOUSEP | Separator for thousands |
| YESEXPR | Affirmative response expression |

Table 4. Item Values defined in *langinfo.h* (continued)

| Item Name | Description |
|-----------|-----------------------------|
| YESSTR | affirmative response string |

Note:

The YESSTR and NOSTR constants are kept for historical reasons. They were part of the Legacy Feature in Single UNIX Specification, Version 2. They have been withdrawn and are not supported as part of Single UNIX Specification, Version 3.

If it is necessary to continue using these constants in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

For more information about the effect of locale, see `setlocale()`, `locale.h`, or look up the individual functions in this topic. For still more information, see "Internationalization: Locales and Character Sets" in *z/OS XL C/C++ Programming Guide*.

lc_core.h — Locale-related data structures

The `lc_core.h` header file contains locale-related data structures.

lc_sys.h — Build references to locale methods in ASCII locales

The `lc_sys.h` header file contains definitions used by the `localedef` utility for building references to locale methods in ASCII locales.

__le_api.h — AMODE 64 C functions in Language Environment

The `__le_api.h` header file declares the following AMODE 64 C functions in Language Environment:

| | | |
|--|---|------------------------------------|
| <code>__le_ceegtjs()</code> | <code>__le_ceemict()</code> | <code>__le_ceedsgd()</code> |
| <code>__le_cib_get()</code> | <code>__le_condition_token_build()</code> | <code>__le_msg_add_insert()</code> |
| <code>__le_msg_get()</code> | <code>__le_msg_get_and_write()</code> | <code>__le_msg_write()</code> |
| <code>__le_set_debug_resume_mch()</code> | | |

Restrictions:

- This header is supported in AMODE 64 only. For AMODE 31, the `leawi.h` header file should be used.

leawi.h — Macros for Language Environment Application Writer Interfaces

Restriction: This header file is not supported in AMODE 64. For AMODE 64, the `__le_api.h` header file should be used.

The `leawi.h` header file contains internal macros. The header file is required for applications that use Language Environment Application Writer Interfaces (LE AWI).

libgen.h — Pattern matching functions

The `libgen.h` header file contains definitions for pattern matching functions.

limits.h — Standard values for limits on resources

The `limits.h` header file contains symbolic names that represent standard values for limits on resources, such as the maximum value for an object of type `char`.

Table 5. Definitions of resource limits (*limits.h*)

| | |
|----------------------------|--------------------------------------|
| ATEXIT_MAX | 2048 |
| BC_DIM_MAX | 32768 |
| BC_SCALE_MAX | 32767 |
| BC_STRING_MAX | 2048 |
| CHAR_BIT | 8 |
| CHAR_MAX | 127 (<code>_CHAR_SIGNED</code>) |
| CHAR_MAX | 255 |
| CHAR_MIN | (-128) (<code>_CHAR_SIGNED</code>) |
| CHAR_MIN | 0 |
| COLL_WEIGHTS_MAX | 2 |
| __DIR_NAME_MAX | 256 |
| EXPR_NEST_MAX | 32 |
| INT_MAX | 2147483647 |
| INT_MIN | (-2147483647 - 1) |
| LINE_MAX | 2048 |
| LLONG_MAX | (9223372036854775807LL) |
| LLONG_MIN | (-LLONG_MAX-1) |
| LONG_MAX | 2147483647 |
| LONGLONG_MAX | (9223372036854775807LL) |

| ULONG_MAX | 4294967295U |
| ULONGLONG_MAX | (18446744073709551615ULL) |
| ULLONG_MAX | (18446744073709551615ULL) |
| USHRT_MAX | 65535 |
| When compiled with SUSV3 thread support (_UNIX03_THREADS or _XOPEN_SOURCE 600), limits.h adds the following constants: | |
| PTHREAD_STACK_MIN | 4096 (1048576 in 64-bit) |
| _POSIX_THREAD_DESTRUCTOR_ITERATIONS | 4 |
| _POSIX_THREAD_KEYS_MAX | 128 |
| _POSIX_THREAD_THREADS_MAX | 64 |

localdef.h — Data structures for locale objects

The `localdef.h` header file defines data structures for locale objects which are loaded by `setlocale()`. The data structures in `localdef.h` are not a supported programming interface.

locale.h — Locale settings

The `locale.h` header file contains declarations for the `localdtconv()` and `localeconv()` library functions, which retrieve values from the current locale, and for the `setlocale()` function, used to query or change locale settings for internationalized applications.

The `locale.h` file declares the `lconv` structure. [Table 6 on page 37](#) below shows the elements of the `lconv` structure and the defaults for the C locale.

Table 6. Elements of `lconv` Structure

| Element | Purpose of Element | Default |
|--------------------------------------|---|------------------------|
| <code>char *decimal_point</code> | Decimal-point character used to format non-monetary quantities. | "." |
| <code>char *thousands_sep</code> | Character used to separate groups of digits to the left of the decimal-point character in formatted non-monetary quantities. | "" |
| <code>char *grouping</code> | String indicating the size of each group of digits in formatted non-monetary quantities. The value of each character in the string determines the number of digits in a group. A value of <code>CHAR_MAX</code> indicates that there are no further groupings. 0 indicates that the previous element is to be used for the remainder of the digits. | "" |
| <code>char *int_curr_symbol</code> | International currency symbol for the current locale. The first three characters contain the alphabetic international currency symbol. The fourth character (usually a space) is the character used to separate the international currency symbol from the monetary quantity. | "" |
| <code>char *currency_symbol</code> | Local currency symbol of the current locale. | "" |
| <code>char *mon_decimal_point</code> | Decimal-point character used to format monetary quantities. | "." |
| <code>char *mon_thousands_sep</code> | Separator for digits in formatted monetary quantities. | "" |
| <code>char *mon_grouping</code> | String indicating the size of each group of digits in formatted monetary quantities. The value of each character in the string determines the number of digits in a group. A value of <code>CHAR_MAX</code> indicates that there are no further groupings. 0 indicates that the previous element is to be used for the remainder of the digits. | "" |
| <code>char *positive_sign</code> | String indicating the positive sign used in monetary quantities. | "" |
| <code>char *negative_sign</code> | String indicating the negative sign used in monetary quantities. | "" |
| <code>char int_frac_digits</code> | The number of displayed digits to the right of the decimal place for internationally formatted monetary quantities. | <code>UCHAR_MAX</code> |
| <code>char frac_digits</code> | Number of digits to the right of the decimal place in monetary quantities. | <code>UCHAR_MAX</code> |
| <code>char p_cs_precedes</code> | Value indicating the placement of the currency symbol in a nonnegative, formatted monetary quantity. For a list of valid values, see Table 7 on page 39 . | <code>UCHAR_MAX</code> |

Table 6. Elements of Iconv Structure (continued)

| Element | Purpose of Element | Default |
|-------------------------|---|-----------|
| char p_sep_by_space | Value indicating the use of white space in a nonnegative, formatted monetary quantity. For a list of valid values, see Table 7 on page 39 . | UCHAR_MAX |
| char n_cs_precedes | Value indicating the placement of the currency symbol in a negative, formatted monetary quantity. For a list of valid values, see Table 7 on page 39 . | UCHAR_MAX |
| char n_sep_by_space | Value indicating the use of white space in a negative, formatted monetary quantity. For a list of valid values, see Table 7 on page 39 . | UCHAR_MAX |
| char p_sign_posn | Value indicating the position of the <code>positive_sign</code> for a nonnegative formatted monetary quantity. For a list of valid values, see Table 7 on page 39 . | UCHAR_MAX |
| char n_sign_posn | Value indicating the position of the <code>negative_sign</code> for a negative formatted monetary quantity. For a list of valid values, see Table 7 on page 39 . | UCHAR_MAX |
| char *left_parenthesis | Negative-valued monetary symbol. Note: This element is an IBM-specific extension. | "" |
| char *right_parenthesis | Negative-valued monetary symbol. Note: This element is an IBM-specific extension. | "" |
| char *debit_sign | Debit_sign character string. Note: This element is an IBM-specific extension. | "" |
| char *credit_sign | Credit_sign character string. Note: This element is an IBM-specific extension. | "" |
| char int_p_cs_precedes | For international formatting, value indicating the placement of the currency symbol in a nonnegative, monetary quantity. For a list of valid values, see Table 7 on page 39 . | UCHAR_MAX |
| char int_n_cs_precedes | For international formatting, value indicating the placement of the currency symbol in a negative, monetary quantity. For a list of valid values, see Table 7 on page 39 . | UCHAR_MAX |
| char int_p_sep_by_space | For international formatting, value indicating the use of white space in a nonnegative, monetary quantity. For a list of valid values, see Table 7 on page 39 . | UCHAR_MAX |
| char int_n_sep_by_space | For international formatting, value indicating the use of white space in a negative, monetary quantity. For a list of valid values, see Table 7 on page 39 . | UCHAR_MAX |

Table 6. Elements of `lconv` Structure (continued)

| Element | Purpose of Element | Default |
|-----------------------------------|--|------------------------|
| <code>char int_p_sign_posn</code> | For international formatting, value indicating the position of the positive sign for a nonnegative monetary quantity. For a list of valid values, see Table 7 on page 39 . | <code>UCHAR_MAX</code> |
| <code>char int_n_sign_posn</code> | For international formatting, value indicating the position of the negative sign for a negative monetary quantity. For a list of valid values, see Table 7 on page 39 . | <code>UCHAR_MAX</code> |

For a list of valid values, see [Table 7 on page 39](#).

Table 7. Monetary Formatting Values

| Element | Values |
|---------------------------|---|
| <code>cs_precedes</code> | 0 The <code>currency_symbol</code> succeeds the value for the formatted monetary quantity; |
| | 1 The <code>currency_symbol</code> precedes the value for the formatted monetary quantity |
| <code>sep_by_space</code> | 0 No space separates the <code>currency_symbol</code> from the formatted monetary quantity; |
| | 1 If <code>currency_symbol</code> and sign string are adjacent, a space separates them from the value. Otherwise, the currency symbol and value are separated by a space. |
| | 2 If <code>currency_symbol</code> and sign string are adjacent, a space separates them from each other. Otherwise, the sign string and value are separated by a space. |
| <code>sign_posn</code> | 0 Parentheses surround the quantity and <code>currency_symbol</code> ; |
| | 1 The sign string precedes the quantity and <code>currency_symbol</code> ; |
| | 2 The sign string succeeds the quantity and <code>currency_symbol</code> ; |
| | 3 The sign string immediately precedes <code>currency_symbol</code> ; |
| | 4 The sign string immediately succeeds <code>currency_symbol</code> ; |
| | 5 Substitute <code>debit_sign</code> or <code>credit_sign</code> for <code>negative_sign</code> or <code>positive_sign</code> , respectively. |

Note: This value is an IBM-specific extension.

The `locale.h` file declares the `dtconv` structure:

```
struct dtconv {
    char *abbrev_month_names[12]; /* Abbreviated month names */
    char *month_names[12];       /* full month names */
    char *abbrev_day_names[7];   /* Abbreviated day names */
    char *day_names[7];         /* full day names */
    char *date_time_format;      /* date and time format */
    char *date_format;           /* date format */
    char *time_format;           /* time format */
    char *am_string;             /* AM string */
    char *pm_string;             /* PM string */
    char *time_format_ampm;      /* long date format */
    char *iso_std8601_2000;      /* ISO 8601:2000 std date format*/
};
```

Note: This structure is an IBM-specific extension.

The `locale.h` file also contains macro definitions for use with the `setlocale()` function:

| | | | |
|-------------|------------|----------|-------------|
| LC_ALL | LC_COLLATE | LC_CTYPE | LC_MONETARY |
| LC_NUMERIC | LC_TIME | LC_TOD | NULL |
| LC_MESSAGES | LC_SYNTAX | | |

The aspects of a program related to national language or to cultural characteristics (such as time zone, currency symbols, and sorting order of characters) can be customized at run time using different locales, to suit users' requirements at those locales. See the internationalization topic in [z/OS XL C/C++ Programming Guide](#).

math.h — Floating-point math functions

The `math.h` header file contains function declarations for all the floating-point math functions:

No feature test macro required.

Notes:

1. `nan()`, `nanf()`, and `nanl()` functions are supported under IEEE only.
2. For the C99 math functions, it is required to define the feature test macro `_ISO_C99_SOURCE` or requires a compiler that is designed to support C99 to expose the functionality.

| tan() | tanf() | tanh() | tanhf() | tanhl() |
| tanl() | tgamma() | tgammaf() | tgammal() | |

Special Behavior for C++: For C++ applications, each of the base functions in the following list is also overloaded for float, double, and long double. For example:

- float sqrt(float)
- double sqrt(double)
- long double sqrt(long double)

_XOPEN_SOURCE

For C++ applications, the following functions are overloaded for `_Decimal32`, `_Decimal64`, and `_Decimal128`:

| | | | | |
|-------------|-------------|--------------|----------|------------|
| abs() | acos() | acosh() | asin() | asinh() |
| atan() | atan2() | atanh() | cbrt() | ceil() |
| copysign() | cos() | cosh() | erf() | erfc() |
| exp() | expm1() | exp2() | fabs() | fdim() |
| floor() | fma() | fmax() | fmin() | fmod() |
| frexp() | hypot() | ilogb() | ldexp() | lgamma() |
| llrint() | llround() | log() | log1p() | log2() |
| log10() | logb() | lrint() | lround() | modf() |
| nearbyint() | nextafter() | nexttoward() | pow() | quantexp() |
| remainder() | rint() | round() | scalbn() | scalbln() |
| sin() | sinh() | sqrt() | tan() | tanh() |
| tgamma() | trunc() | | | |

For example:

- `_Decimal32 ceil(_Decimal32)`
- `_Decimal64 ceil(_Decimal64)`

- `_Decimal128 ceil(_Decimal128)`

`_TR1_C99`: The following functions provide additional overloads.

| | | | | |
|---------------------------|------------------------|--------------------------|--------------------------|--------------------------|
| <code>acos()</code> | <code>acosh()</code> | <code>asin()</code> | <code>asinh()</code> | <code>atan()</code> |
| <code>atanh()</code> | <code>atan2()</code> | <code>cbrt()</code> | <code>ceil()</code> | <code>copysign()</code> |
| <code>cos()</code> | <code>cosh()</code> | <code>erf()</code> | <code>erfc()</code> | <code>exp()</code> |
| <code>exp2()</code> | <code>expm1()</code> | <code>fabs()</code> | <code>fdim()</code> | <code>floor()</code> |
| <code>fma()</code> | <code>fmax()</code> | <code>fmin()</code> | <code>fmod()</code> | <code>frexp()</code> |
| <code>hypot()</code> | <code>ilogb()</code> | <code>ldexp()</code> | <code>lgamma()</code> | <code>llrint()</code> |
| <code>llround()</code> | <code>log()</code> | <code>log10()</code> | <code>log1p()</code> | <code>log2()</code> |
| <code>logb()</code> | <code>lrint()</code> | <code>lround()</code> | <code>nearbyint()</code> | <code>nextafter()</code> |
| <code>nexttoward()</code> | <code>pow()</code> | <code>remainder()</code> | <code>remquo()</code> | <code>rint()</code> |
| <code>round()</code> | <code>scalbln()</code> | <code>scalbn()</code> | <code>sin()</code> | <code>sinh()</code> |
| <code>sqrt()</code> | <code>tan()</code> | <code>tanh()</code> | <code>tgamma()</code> | <code>trunc()</code> |

- If any argument corresponding to a double parameter has type long double, all arguments corresponding to double parameters are effectively cast to long double. The return type will be the same return type as if the 'C' long double version of the function was called.
- Otherwise, if any argument corresponding to a double parameter has type double or an integer type, all arguments corresponding to double parameters are effectively cast to double. The return type will be the same return type as if the 'C' double version of the function was called.
- Otherwise, all arguments corresponding to double parameters are effectively cast to float. The return type will be the same return type as if the 'C' float version of the function was called.

Object-like macros: Additional object-like macros provided by the `math.h` header are described.

Note: The floating point macros and the macros `INFINITY` and `NAN` are supported under IEEE only.

DEC_INFINITY

A constant expression of type `_Decimal32` representing infinity.

DEC_NAN

A quiet decimal floating NaN for the type `_Decimal32`.

HUGE_VAL_D32

A constant expression of type `_Decimal32` representing +infinity.

HUGE_VAL_D64

A constant expression of type `_Decimal64` representing +infinity.

HUGE_VAL_D128

A constant expression of type `_Decimal128` representing +infinity.

HUGE_VALF

A very large positive number that expands to a float expression

HUGE_VALL

A very large positive number that expands to a long double expression.

INFINITY

A constant expression of type float representing positive infinity.

NAN

A constant expression of type float representing a quiet NaN.

FP_INFINITE

The value of the macro `fpclassify` for an argument that is plus or minus infinity. This expands to an integer constant expression.

FP_NAN

The value of the macro `fpclassify` for an argument that is not-a-number (NaN). This expands to an integer constant expression.

FP_NORMAL

The value of the macro `fpclassify` for an argument that is finite and normalized. This expands to an integer constant expression.

FP_SUBNORMAL

The value of the macro `fpclassify` for an argument that is finite and denormalized. This expands to an integer constant expression.

FP_ZERO

The value of the macro `fpclassify` for an argument that is positive or negative. This expands to an integer constant expression.

FP_FAST_FMA

Indicates that the `fma` function generally executes about as fast as, or faster than, a multiply and an add of double operands.

FP_FAST_FMAF

This is the float version of `FP_FAST_FMA`.

FP_FAST_FMAL

This is the long double version of `FP_FAST_FMA`.

Note: Decimal floating-point does not support `FP_FAST_FMA32`, `FP_FAST_FMA64`, and `FP_FAST_FMA128`.

FP_ILOGBO

The value returned by `ilogb()` if its argument is zero.

FP_ILOGBNAN

The value returned by `ilogb()` if its argument is a NaN.

MATH_ERRNO

This is defined as value 1 (one) and is used for testing the value of the macro `math_errhandling` to determine whether a math function reports an error by storing a nonzero value in `errno`.

MATH_ERREXCEPT

This is defined as value 2 and is used for testing the value of the macro `math_errhandling` to determine whether a math function reports an error by raising an invalid floating point exception.

math_errhandling

This macro expands to an expression that has type `int` and the value `MATH_ERRNO`, `MATH_ERREXCEPT`, or the bitwise OR of both. This implementation defines this macro as `MATH_ERRNO`.

Function-like macros or C++ function templates: Additional function-like macros or C++ function templates provided by the `<math.h>` header are listed.

| | | | | |
|----------------------------|----------------------------|------------------------------|--------------------------|-------------------------------|
| <code>fpclassify()</code> | <code>isfinite()</code> | <code>ininf()</code> | <code>isgreater()</code> | <code>isgreaterequal()</code> |
| <code>isless()</code> | <code>islessequal()</code> | <code>islessgreater()</code> | <code>isnan()</code> | <code>isnormal()</code> |
| <code>isunordered()</code> | <code>signbit()</code> | | | |

The header file includes declarations for the built-in functions `abs()` and `fabs()`. For information about built-in functions, see [“Built-in functions”](#) on page 96.

The `math.h` header file declares the macro `HUGE_VAL`, which expands to a positive double constant expression, not necessarily representable as a `float`. Similarly, the macros `HUGE_VALF` and `HUGE_VALL` are respectively `float` and `long double` analogs of `HUGE_VAL`.

For all mathematical functions, a *domain error* occurs when an input argument is outside the range of values allowed for that function. If a domain error occurs, `errno` is set to the value of `EDOM`.

A range error occurs if the result of the function cannot be represented in a float, double, long double, `_Decimal32`, `_Decimal64`, or `_Decimal128` value. If the magnitude of the result is too large (overflow), the function returns the positive or negative value of the macro `HUGE_VAL`, `HUGE_VALF`, `HUGE_VALL`, `HUGE_VAL_D32`, `HUGE_VAL_D64`, or `HUGE_VAL_D128`, as applicable, and sets `errno` to `ERANGE`. If the result is too small (underflow), the function returns 0.

A pole error occurs if the function has an exact infinite result as the finite input arguments are approached in the limit (for example, `log(0.0)`). If a pole error occurs, the function sets `errno` to `ERANGE`.

`float_t` and `double_t` are floating-point types whose type depends on the value of `FLT_EVAL_METHOD`. `FLT_EVAL_METHOD` is 1 which implies both `float_t` and `double_t` are double.

Note: Decimal floating-point does not support `FP_FAST_FMAD32`, `FP_FAST_FMAD64`, and `FP_FAST_FMAD128`.

memory.h — Memory operations

The `memory.h` header file contains declarations for memory operations.

monetary.h — strfmon() function

The `monetary.h` header file contains the declaration for the `strfmon()` function.

For more information about the effect of locale, see `setlocale()`, `locale.h`, or look up the individual functions in this topic. For still more information, see "Internationalization: Locales and Character Sets" in *z/OS XL C/C++ Programming Guide*.

msgcat.h — Message catalog structures and definitions

The `msgcat.h` header file contains message catalog structures and definitions. The data structures in `msgcat.h` are not a supported programming interface.

mtf.h — Multitasking facility functions

Restriction: This header file is not supported in AMODE 64.

The `mtf.h` header file contains declarations for the multitasking facility (MTF) functions:

`tinit()` `tsched()` `tsyncro()` `tterm()`

`tsched()` is a built-in function.

This header file also contains definitions of macros for certain return values from the above functions.

This header file is supported only under z/OS C applications. The functions are *not* supported under z/OS UNIX.

_Nascii.h — Bimodal application

The `_Nascii.h` header file contains the externals for the correspondence table and functions that support bimodal application development.

ndbm.h — ndbm database operations

The `ndbm.h` header file contains definitions for ndbm database operations.

netdb.h — Network database operations

The `netdb.h` header file contains definitions for network database operations.

net/if.h — Network interface structures and definitions

The `net/if.h` header file contains network interface structures and definitions.

_OE_SOCKETS

_OPEN_SYS_IF_EXT 1

The following structures are declared:

- `ifaddr`
- `ifconf`
- `ifnet`
- `ifreq`

The following macros are declared:

- `IF_ADJ`
- `IF_DEQUEUE`
- `IF_DEQUEUEIF`
- `IF_DROP`
- `IF_ENQUEUE`
- `IF_PREPEND`
- `IF_QFULL`
- `IFF_ALLMULTI`
- `IFF_BRIDGE`
- `IFF_BROADCAST`
- `IFF_CANTCHANGE`
- `IFF_CHECKSUM`
- `IFF_DEBUG`
- `IFF_LOOPBACK`
- `IFF_MULTICAST`
- `IFF_NOARP`
- `IFF_NOTRAILERS`
- `IFF_POINTOMULTIPT`
- `IFF_POINTOPOINT`
- `IFF_PROMISC`
- `IFF_RUNNING`
- `IFF_SNAP`
- `IFF_UP`
- `IFF_VIRTUAL`
- `IFNET_SLOWHZ`
- `IFQ_MAXLEN`

_OPEN_SYS SOCK_IPV6

_POSIX_C_SOURCE 200112L

The following structure is declared:

- `if_nameindex`

The following macro is declared:

- `IF_NAMESIZE`

The following functions are declared:

- `if_freenameindex`
- `if_indextoname`
- `if_nameindex`
- `if_nametoindex`

net/rtroute.h — Network routing structures and definitions

The `net/rtroute.h` header file contains network routing structures and definitions.

netinet/icmp6.h — ICMPv6 header options

The `netinet/icmp6.h` header file defines structures and constants for ICMPv6 header options.

The following structures are exposed with this header file:

- `icmp6_hdr`
- `nd_router_solicit`
- `nd_router_advert`
- `nd_neighbor_solicit`
- `nd_neighbor_advert`
- `nd_redirect`
- `nd_opt_hdr`
- `nd_opt_prefix_info`
- `nd_opt_rd_hdr`
- `nd_opt_mtu`
- `mld_hdr`
- `icmp6_router_renum`
- `rr_pco_match`
- `rr_pco_use`
- `rr_result`

The following definitions are associated with the `icmp6_hdr` structure:

- `icmp6_data32`
- `icmp6_data16`
- `icmp6_data8`
- `icmp6_pptr`
- `icmp6_mtu`
- `icmp6_id`
- `icmp6_seq`
- `icmp6_maxdelay`

The following definitions are associated with ICMPv6 Type and Code values:

- `ICMP6_DST_UNREACH`
- `ICMP6_PACKET_TOO_BIG`
- `ICMP6_TIME_EXCEEDED`
- `ICMP6_PARAM_PROB`
- `ICMP6_INFOMSG_MASK`
- `ICMP6_ECHO_REQUEST`

Header files

- ICMP6_ECHO_REPLY
- ICMP6_DST_UNREACH_NOROUTE
- ICMP6_DST_UNREACH_ADMIN
- ICMP6_DST_UNREACH_BEYONDScope
- ICMP6_DST_UNREACH_ADDR
- ICMP6_DST_UNREACH_NOPORT
- ICMP6_TIME_EXCEED_TRANSIT
- ICMP6_TIME_EXCEED_REASSEMBLY
- ICMP6_PARAMPROB_HEADER
- ICMP6_PARAMPROB_NEXTHDR
- ICMP6_PARAMPROB_OPTION

The following definitions are associated with the `nd_router_solicit` structure:

- ND_ROUTER_SOLICIT
- `nd_rs_type`
- `nd_rs_code`
- `nd_rs_cksum`
- `nd_rs_reserved`

The following definitions are associated with the `nd_router_advert` structure:

- ND_ROUTER_ADVERT
- `nd_ra_type`
- `nd_ra_code`
- `nd_ra_cksum`
- `nd_ra_curhoplimit`
- `nd_ra_flags_reserved`
- ND_RA_FLAG_MANAGED
- ND_RA_FLAG_OTHER
- `nd_ra_router_lifetime`

The following definitions are associated with the `nd_neighbor_solicit` structure:

- ND_NEIGHBOR_SOLICIT
- `nd_ns_type`
- `nd_ns_code`
- `nd_ns_cksum`
- `nd_ns_reserved`

The following definitions are associated with the `nd_neighbor_advert` structure:

- ND_NEIGHBOR_ADVERT
- `nd_na_type`
- `nd_na_code`
- `nd_na_cksum`
- `nd_na_flags_reserved`
- ND_NA_FLAG_ROUTER
- ND_NA_FLAG_SOLICITED
- ND_NA_FLAG_OVERRIDE

The following definitions are associated with the `nd_redirect` structure:

- `ND_REDIRECT`
- `nd_rd_type`
- `nd_rd_code`
- `nd_rd_cksum`
- `nd_rd_reserved`

The following definitions are associated with the `nd_opt_hdr` structure:

- `ND_OPT_SOURCE_LINKADDR`
- `ND_OPT_TARGET_LINKADDR`
- `ND_OPT_PREFIX_INFORMATION`
- `ND_OPT_REDIRECTED_HEADER`
- `ND_OPT_MTU`

The following definitions are associated with the `nd_opt_prefix_info` structure:

- `ND_OPT_PI_FLAG_ONLINK`
- `ND_OPT_PI_FLAG_AUTO`

The following definitions are associated with the `mld_hdr` structure:

- `MLD_LISTENER_QUERY`
- `MLD_LISTENER_REPORT`
- `MLD_LISTENER_REDUCTION`
- `mld_type`
- `mld_code`
- `mld_cksum`
- `mld_maxdelay`
- `mld_reserved`

The following definitions are associated with the `icmp6_router_renum` structure:

- `ICMP6_ROUTER_RENUMBERING`
- `rr_type`
- `rr_code`
- `rr_cksum`
- `rr_seqnum`
- `ICMP6_RR_FLAGS_TEST`
- `ICMP6_RR_FLAGS_REQRESULT`
- `ICMP6_RR_FLAGS_FORCEAPPLY`
- `ICMP6_RR_FLAGS_SPECSITE`
- `ICMP6_RR_FLAGS_PREVDONE`

The following definitions are associated with the `rr_pco_match` structure:

- `RPM_PCO_ADD`
- `RPM_PCO_CHANGE`
- `RPM_PCO_SETGLOBAL`

The following definitions are associated with the `rr_pco_use` structure:

- `ICMP6_RR_PCOUSE_RAFLAGS_ONLINK`
- `ICMP6_RR_PCOUSE_RAFLAGS_AUTO`

Header files

- ICMP6_RR_PCOUSE_FLAGS_DECRVLTIME
- ICMP6_RR_PCOUSE_FLAGS_DECRPLTIME
- nd_ns_reserved

The following definitions are associated with the `rr_result` structure:

- ICMP6_RR_RESULT_FLAGS_OOB
- ICMP6_RR_RESULT_FLAGS_FORBIDDEN

netinet/in.h — Internet protocol family

The `netinet/in.h` header file contains definitions for the internet protocol family.

The following structure definition is supported for IPv6:

- `struct ip6_mtuinfo{}`;

The following functions are supported for IPv6:

- `bind2addrsel()`
- `inet6_is_srcaddr()`
- `inet6_rth_space()`
- `inet6_rth_init()`
- `inet6_rth_add()`
- `inet6_rth_reverse()`
- `inet6_rth_segments()`
- `inet6_rth_getaddr()`
- `inet6_opt_init()`
- `inet6_opt_append()`
- `inet6_opt_finish()`
- `inet6_opt_set_val()`
- `inet6_opt_next()`
- `inet6_opt_find()`
- `inet6_opt_get_val()`

The following macros are supported for IPv6:

```
IN6_IS_ADDR_LINKLOCAL
IN6_IS_ADDR_LOOPBACK
IN6_IS_ADDR_MC_GLOBAL
IN6_IS_ADDR_MC_LINKLOCAL
IN6_IS_ADDR_MC_NODELOCAL
IN6_IS_ADDR_MC_ORGLOCAL
IN6_IS_ADDR_MC_SITELOCAL
IN6_IS_ADDR_MULTICAST
IN6_IS_ADDR_SITELOCAL
IN6_IS_ADDR_UNSPECIFIED
IN6_IS_ADDR_V4COMPAT
IN6_IS_ADDR_V4MAPPED
```

Structures:

```
struct ip_mreq{
    struct in_addr imr_multiaddr;
    struct in_addr imr_interface;
};
```

Socket options:

- MCAST_INCLUDE
- MCAST_EXCLUDE
- IP_BLOCK_SOURCE
- IP_UNBLOCK_SOURCE
- IP_ADD_SOURCE_MEMBERSHIP
- IP_DROP_SOURCE_MEMBERSHIP
- IPV6_ADDR_PREFERENCES
- MCAST_JOIN_GROUP
- MCAST_LEAVE_GROUP
- MCAST_BLOCK_SOURCE
- MCAST_UNBLOCK_SOURCE
- MCAST_JOIN_SOURCE_GROUP
- MCAST_LEAVE_SOURCE_GROUP

Structure: Multicast filter support is accessed by defining feature test macro `_OPEN_SYS_SOCKET_EXT3`. The feature test also exposes symbols in `sys/socket.h`.

```
struct ip_mreq{}
struct ip_mreq_source {};
struct group_req {};
struct group_source_req {};
setipv4sourcefilter()
getipv4sourcefilter()
setsourcefilter()
getsourcefilter()
```

netinet/ip6.h — IPv6 header options

The `netinet/ip6.h` header file defines structures and constants for IPv6 header options.

The following structures are exposed with this header file:

- `ip6_hdr`
- `ip6_hbh`
- `ip6_dest`
- `ip6_rthdr`
- `ip6_rthdr0`
- `ip6_frag`
- `ip6_opt`
- `ip6_opt_jumbo`
- `ip6_opt_nsap`
- `ip6_opt_tunnel`
- `ip6_opt_router`

The following definitions are associated with the `ip6_hdr` structure:

- `ip6_vcf`
- `ip6_flow`
- `ip6_plen`
- `ip6_nxt`
- `ip6_hlim`

Header files

- `ip6_hops`
- `ip6_src`
- `ip6_dst`

The following definitions are associated with the extension header structure:

- `IP6F_OFF_MASK`
- `IP6F_RESERVED_MASK`
- `IP6F_MORE_FRAG`

The following definitions are associated with the option header structure:

- `IP6OPT_TYPE`
- `IP6OPT_TYPE_SKIP`
- `IP6OPT_TYPE_DISCARD`
- `IP6OPT_TYPE_FORCEICMP`
- `IP6OPT_TYPE_ICMP`
- `IP6OPT_MUTABLE`
- `IP6OPT_PAD1`
- `IP6OPT_PADN`
- `IP6OPT_JUMBO`
- `IP6OPT_NSAP_ADDR`
- `IP6OPT_TUNNEL_LIMIT`
- `IP6OPT_ROUTER_ALERT`
- `IP6OPT_JUMBO_LEN`
- `IP6_ALERT_MLD`
- `IP6_ALERT_RSVP`
- `IP6_ALERT_AN`

netinet/tcp.h — Internet Transmission Control Protocol

The `netinet/tcp.h` header contains definitions for the Internet Transmission Control Protocol (TCP).

nlist.h — nlist() function

The `nlist.h` header file declares the `nlist()` function.

nl_types.h — National languages

The `nl_types.h` header file defines the following types:

| | |
|----------------------|---|
| <code>nl_item</code> | int used as manifest constant by <code>nl_langinfo()</code> |
| <code>nl_catd</code> | pointer to a catalog descriptor structure |

The header also contains these constants:

| | |
|----------------------|----------------------------|
| <code>NL_SETD</code> | <code>NL_CAT_LOCALE</code> |
|----------------------|----------------------------|

The following functions are prototyped:

| | | |
|-------------------------|------------------------|------------------------|
| <code>catclose()</code> | <code>catgets()</code> | <code>catopen()</code> |
|-------------------------|------------------------|------------------------|

No feature test macro is required for `nl_item`.

To expose the other definitions in this header, compile with the `_XOPEN_SOURCE` feature test macro defined.

For more information about the effect of locale, see `setlocale()`, `locale.h`, or look up the individual functions in this topic. For more information, see "Internationalization: Locales and Character Sets" in *z/OS XL C/C++ Programming Guide*.

poll.h — poll() function

The `poll.h` header file contains definitions for the `poll()` function.

pthread.h — Thread interfaces

The `pthread.h` header file contains function declarations and mappings for threading interfaces and defines a number of constants used by those functions. The header includes the `sched.h` header. When `_UNIX03_THREADS` is defined, `pthread.h` also includes the `time.h` header. For `_OPEN_THREADS` applications, `pthread.h` defines the `timespec` and `timespec64` structures.

There is a lot of overlap in the namespaces identified by the `_OPEN_THREADS` and `_UNIX03_THREADS` feature test macros. There are, however, behavioral differences between functions of the same name exposed by `_OPEN_THREADS` (POSIX.4a Draft 6) and by `_UNIX03_THREADS` (Single UNIX Specification, Version 3). See the individual function descriptions for specific details.

`_OPEN_THREADS 1`

| <code>PTHREAD_SCOPE_GLOBAL</code> | <code>PTHREAD_SCOPE_LOCAL</code> |
| <code>SCHED_FIFO</code> | <code>SCHED_OTHER</code> |
| <code>SCHED_RR</code> | <code>PRIO_PROTECT</code> |

Furthermore, `pthread.h` defines these macros:

| | |
|--------------------------------------|--|
| <code>PTHREAD_MUTEX_DEFAULT</code> | <code>PTHREAD_MUTEX_ERRORCHECK</code> |
| <code>PTHREAD_MUTEX_NORMAL</code> | <code>PTHREAD_MUTEX_INITIALIZER</code> |
| <code>PTHREAD_MUTEX_RECURSIVE</code> | <code>PTHREAD_RWLOCK_INITIALIZER</code> |
| <code>__THDQ_LENGTH</code> | |
| <code>_OPEN_THREADS 2</code> | |
| <code>PTHREAD_CANCEL_ENABLE</code> | <code>PTHREAD_CANCEL_DISABLE</code> |
| <code>PTHREAD_CANCEL_DEFERRED</code> | <code>PTHREAD_CANCEL_ASYNCHRONOUS</code> |

pwd.h — Access user database through password structure

The `pwd.h` header file declares functions that access the user database through a password structure. The header file also defines the `passwd` structure.

```
_POSIX_SOURCE

getpwnam()                getpwuid()

_XOPEN_SOURCE_EXTENDED 1

endpwent()                getpwent()                setpwent()

_XPLATFORM_SOURCE 1

getpwent_r()
```

re_comp.h — Regular expression matching functions for re_comp()

The `re_comp.h` header file contains regular expression matching functions for `re_comp()`.

Note:

This header is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use `regcomp()`, `regexexec()`, `regerror()` and `regfree()` functions and the header, which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001 Regular Expressions.

Applications conforming to Single UNIX Specification, Version 3 must not include the `<re_comp.h>` header file.

regex.h — Regular expression functions

The `regex.h` header file contains definitions for the following regular expression functions.

`regcomp()` `regerror()` `regexexec()` `regfree()`

The `regex.h` header file declares the `regex_t` type, which can store a compiled regular expression.

The `regex.h` header file declares the following macros:

- Values of the *cflags* parameter of the `regcomp()` function: `REG_EXTENDED`, `REG_ICASE`, `REG_NEWLINE`, `REG_NOSUB`
- Values of the *eflags* parameter of the `regexexec()` function: `REG_NOTBOL`, `REG_NOTEOL`
- Values of the *errcode* parameter of the `regerror()` function: `REG_*`.

regexp.h — Regular expression declarations

The `regexp.h` header file contains regular expression declarations.

Note:

This header is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use `regcomp()`, `regexexec()`, `regerror()` and `regfree()` functions and the header, which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001 Regular Expressions.

Applications conforming to Single UNIX Specification, Version 3 must not include the `<regexp.h>` header file.

resolv.h — IP Address Resolution

The `resolv.h` header file contains the `__res_state` structure and the definitions to support the IP Address Resolution functions commonly called the Resolver. It contains the prototypes for the following functions — `dn_comp()`, `dn_expand()`, `dn_find()`, `dn_skipname()`, `res_init()`, `res_mkquery()`, `res_query()`, `res_querydomain()`, `res_search()`, and `res_send()` — which are used to communicate with a Domain Name Server (DNS).

rexec.h — rexec() and rexec_af() functions

The `rexec.h` header file declares the `rexec()` and `rexec_af()` functions.

sched.h — Manipulate and examine process execution scheduling

The `sched.h` header file declares functions to manipulate and examine process execution scheduling.

`_UNIX03_SOURCE`

`sched_yield()`

`_XPLATFORM_SOURCE`

`clone()`

`setns()`

`unshare()`

When compiled with SUSV3 thread support (`_UNIX03_THREADS` or `_XOPEN_SOURCE 600`), `sched.h` defines the following symbols:

`SCHED_FIFO`

`SCHED_OTHER`

`SCHED_RR`

and the `sched_param` structure.

search.h — Searching tables

The `search.h` header file contains definitions for searching tables.

setjmp.h — Manipulate program state

The `setjmp.h` header file contains function declarations for `longjmp()` and `setjmp()`, which use the system stack to affect the program state. It also defines one buffer type `jmp_buf`, which the `setjmp()` and `longjmp()` functions use to save and restore the program state.

_POSIX_SOURCE: `setjmp.h` declares the functions `siglongjmp()` and `sigsetjmp()` and defines a buffer type `sigjmp_buf` that is used by `siglongjmp()` and `sigsetjmp()`.

Notes: If strict standard conformance is needed:

- `__STRICT_ANSI_C__` declares the macro `setjmp`.
- `__STRICT_POSIX__` declares the macro `sigsetjmp`.

_XOPEN_SOURCE_EXTENDED 1: `setjmp.h` declares the functions `_longjmp()` and `_setjmp()`.

signal.h — Exception handling

The `signal.h` header file defines the following values.

- Functions:

| | |
|----------------------|-----------------------|
| <code>raise()</code> | <code>signal()</code> |
|----------------------|-----------------------|

- Macros:

| | | | |
|----------------------|----------------------|----------------------|--------------------------|
| <code>SIG_DFL</code> | <code>SIG_ERR</code> | <code>SIG_IGN</code> | <code>SIG_PROMOTE</code> |
|----------------------|----------------------|----------------------|--------------------------|

- Signals:

| | | | | |
|-----------------------|----------------------|----------------------|----------------------|----------------------|
| <code>SIGABND</code> | <code>SIGABRT</code> | <code>SIGFPE</code> | <code>SIGILL</code> | <code>SIGINT</code> |
| <code>SIGIOERR</code> | <code>SIGSEGV</code> | <code>SIGTERM</code> | <code>SIGUSR1</code> | <code>SIGUSR2</code> |

- The type `sig_atomic_t`, which is the largest integer type the processor can load or store automatically in the presence of asynchronous interrupts.

The following functions are supported only in a POSIX program. You must specify the `POSIX(ON)` runtime option for these functions.

| | | | | |
|----------------------------|---------------------------|-------------------------------|---------------------------|----------------------------|
| <code>kill()</code> | <code>sigaction()</code> | <code>__sigactionset()</code> | <code>sigaddset()</code> | <code>sigdelset()</code> |
| <code>sigemptyset()</code> | <code>sigfillset()</code> | <code>sigismember()</code> | <code>siglongjmp()</code> | <code>sigpending()</code> |
| <code>sigprocmask()</code> | <code>sigsuspend()</code> | <code>sigtimedwait()</code> | <code>sigwait()</code> | <code>sigwaitinfo()</code> |

The following values are available in z/OS UNIX only:

- Signals:

| | | | | |
|----------------------|------------------------|------------------------|-----------------------|------------------------|
| <code>SIGALRM</code> | <code>SIGCHLD</code> | <code>SIGCLD</code> | <code>SIGCONT</code> | <code>SIGDSIOER</code> |
| <code>SIGHUP</code> | <code>SIGIO</code> | <code>SIGKILL</code> | <code>SIGPIPE</code> | <code>SIGQUIT</code> |
| <code>SIGSTOP</code> | <code>SIGTHCONT</code> | <code>SIGTHSTOP</code> | <code>SIGTRACE</code> | <code>SIGTRAP</code> |
| <code>SIGTSTP</code> | <code>SIGTTIN</code> | <code>SIGTTOU</code> | | |

- The structures `sigaction`, `__sigactionset_t`, `__sigactionset_s`, `sigset_t`, and `pid_t`.
- *options* arguments for `sigprocmask()`: `SIG_BLOCK`, `SIG_UNBLOCK`, and `SIG_SETMASK`.
- Flags for the `sa_flags` field, available in z/OS UNIX only: `SA_NOCLDSTOP` and `_SA_OLD_STYLE`.

`_POSIX_C_SOURCE 200809L`

- Functions :

psignal()

_XOPEN_SOURCE_EXTENDED 1:

- Signals:

| | | | | |
|---------|---------|-----------|----------|--------|
| SIGBUS | SIGPOLL | SIGPROF | SIGSYS | SIGURG |
| SIGXCPU | SIGXFSZ | SIGVTALRM | SIGWINCH | |

- Functions:

| | | | | |
|----------------|------------|---------------|-----------|-------------|
| bsd_signal() | killpg() | sigaltstack() | sighold() | sigignore() |
| siginterrupt() | sigpause() | sigrelse() | sigset() | sigstack() |

Note: `bsd_signal()` has been marked obsolescent in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The `sigaction()` function is preferred for portability.

_OPEN_THREADS 2:

- Functions:

pthread_sigmask()

_UNIX03_THREADS:

- pthread_kill()

spawn.h — spawn() constants and inheritance structure

The `spawn.h` header file contains `spawn()` constants and inheritance structure.

spc.h — System library functions and storage allocation

Restriction: This header file is not supported in AMODE 64.

This header file is supported only for z/OS C applications.

The `spc.h` header file contains declarations for the functions available in the system programming environment, as described in “using the System Programming C Facility” in [z/OS XL C/C++ Programming Guide](#). The functions are:

| | | | | |
|-----------|-----------|------------|------------|-----------|
| edcxregs | edcxusr | edcxusr2 | __xhotc() | __xhotl() |
| __xhott() | __xhotu() | __xregs() | __xsacc() | __xsrvc() |
| __xusr() | __xusr2() | __24malc() | __4kmalc() | |

The `spc.h` header file also declares these functions, used for the allocation of storage and writing of strings, (which are described in [Chapter 3, “Library functions,”](#) on page 91):

| | | | | |
|----------|--------|----------|-----------|-----------|
| calloc() | free() | malloc() | realloc() | sprintf() |
|----------|--------|----------|-----------|-----------|

stdalign.h — Alignment

The `stdalign.h` header file defines macros that are associated with alignment, which is introduced in the C11 (ISO/IEC 9899:2011) standard:

| | | | |
|---------|---------|----------------------|----------------------|
| alignas | alignof | __alignas_is_defined | __alignof_is_defined |
|---------|---------|----------------------|----------------------|

stdarg.h — Access arguments in functions with variable-length argument lists

The `stdarg.h` header file defines macros used to access arguments in functions with variable-length argument lists:

`va_arg()` `va_copy()` `va_start()` `va_end()`

The `stdarg.h` header file also defines the structure `va_list`.

stdbool.h — Macros for bool type

The `<stdbool.h>` header defines the following macros:

bool

expands to `_Bool`

__bool_true_false_are_defined

expands to `1`

false

expands to `0`

true

expands to `1`

Restriction: This header is not supported for C++ applications.

stddef.h — typedef statements

The `stddef.h` header file contains definitions of the commonly used pointers, variables, and types, from the typedef statements, as listed below:

ptrdiff_t

The signed long type of the result of subtracting two pointers.

size_t

typedef for the type of the value returned by `sizeof`.

wchar_t

typedef for a wide-character constant.

max_align_t

An object type whose alignment is as great as is supported in all contexts.

`stddef.h` defines the macros `NULL` and `offsetof`. `NULL` is a pointer that never points to a data object. The `offsetof` macro expands to the number of bytes between a structure member and the start of the structure. The `offsetof` macro has the form `offsetof(structure_type, member)`

stddef.h — typedef statements

The `stddef.h` header file contains the same information as found in `<stddef.h>`.

stdint.h — Integer types

The `stdint.h` header defines integer types, limits of specified width integer types, limits of other integer types and macros for integer constant expressions.

Note: For the exact width integer types, minimum width integer types and limits of specified width integer types we support *bit sizes* *N* with the values 8, 16, 32, and 64.

The following exact width integer types are defined.

- `intN_t`

- `uintN_t`

The following minimum-width integer types are defined.

- `int_leastN_t`
- `uint_leastN_t`

The following fastest minimum-width integer types are defined. These types are the fastest to operate with among all integer types that have at least the specified width.

- `int_fastN_t`
- `uint_fastN_t`

The following greatest-width integer types are defined. These types hold the value of any signed/unsigned integer type.

Note: Requires long long to be available.

- `intmax_t`
- `uintmax_t`

The following integer types capable of holding object pointers are defined.

- `intptr_t`
- `uintptr_t`

Object-like macros for limits of integer types: Additional object-like macros provided by the `stdint.h` header are described.

Note: For the exact width integer limits, minimum width integer limits and limits of specified width integer types we support *bit sizes* N with the values 8, 16, 32, and 64.

Macros for limits of exact width integer types:

- `INTN_MAX`
- `INTN_MIN`
- `UINTN_MAX`

Macros for limits of minimum width integer types:

- `INT_LEASTN_MAX`
- `INT_LEASTN_MIN`
- `UINT_LEASTN_MAX`

Macros for limits of fastest minimum width integer types:

- `INT_FASTN_MAX`
- `INT_FASTN_MIN`
- `UINT_FASTN_MAX`

Macros for limits of greatest width integer types:

Note: Requires long long to be available.

- `INTMAX_MAX`
- `INTMAX_MIN`
- `UINTMAX_MAX`

Macros for limits of pointer integer types:

- `INTPTR_MAX`
- `INTPTR_MIN`
- `UINTPTR_MAX`

Header files

Macros for limits of ptrdiff_t:

- PTRDIFF_MAX
- PTRDIFF_MIN

Macros for limits of sig_atomic_t:

- SIG_ATOMIC_MAX
- SIG_ATOMIC_MIN

Macro for limit of size_t:

- SIZE_MAX

Macros for limits of wchar_t:

- WCHAR_MAX
- WCHAR_MIN

Macros for limits of wint_t:

- WINT_MAX
- WINT_MIN

Function-like macros for integer constants: Additional function-like macros provided by the stdint.h header are described.

Note: For the following macro for minimum width integer constants, we support *bit sizes* *N* with the values 8, 16, 32, and 64.

Macros for minimum width integer constants:

- INTN_C(value)
- UINTN_C(value)

Example:

```
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>

int main(void)
{
    uint32_t a = UINT32_C(1234);
    printf("%u\n", a );
}

Output
1234
```

Example of how the compiler expands the macro:

```
|    uint32_t a = UINT32_C(1234);
+    uint32_t a = 1234U;
```

Macros for greatest width integer constants:

Note: Requires long long to be available.

- INTMAX_C(value)
- UINTMAX_C(value)

Example:

```
/* long long required */
#define _ISOC99_SOURCE
#include <inttypes.h>
```

```
#include <stdio.h>

int main(void)
{
    intmax_t a = INTMAX_C(45268724);
    printf("%jd\n", a );
}

Output

45268724
```

Example of how the compiler expands the macro with the LP64 compiler option:

```
| intmax_t a = INTMAX_C(45268724);
+ intmax_t a = 45268724L;
```

Otherwise the compiler expands to:

```
| intmax_t a = INTMAX_C(45268724);
+ intmax_t a = 45268724LL;
```

stdio.h — Standard input and output

The `stdio.h` header file declares functions that deal with standard input and output. One of these functions, `fdopen()`, is supported only in a POSIX program.

The `stdio.h` header file also declares these functions:

| | | | | |
|--------------------------|--------------------------|-------------------------|------------------------|-------------------------|
| <code>asprintf()</code> | <code>clearerr()</code> | <code>clrmemf()</code> | <code>dprintf()</code> | <code>fclose()</code> |
| <code>fdelrec()</code> | <code>feof()</code> | <code>ferror()</code> | <code>fflush()</code> | <code>fgetc()</code> |
| <code>fgetpos()</code> | <code>fgets()</code> | <code>fldata()</code> | <code>flocate()</code> | <code>fopen()</code> |
| <code>fprintf()</code> | <code>fputc()</code> | <code>fputs()</code> | <code>fread()</code> | <code>freopen()</code> |
| <code>fscanf()</code> | <code>fseek()</code> | <code>fseeko()</code> | <code>fsetpos()</code> | <code>ftell()</code> |
| <code>ftello()</code> | <code>fupdate()</code> | <code>fwrite()</code> | <code>getc()</code> | <code>getchar()</code> |
| <code>getline()</code> | <code>gets()</code> | <code>perror()</code> | <code>printf()</code> | <code>putchar()</code> |
| <code>putc()</code> | <code>puts()</code> | <code>remove()</code> | <code>rename()</code> | <code>renameat()</code> |
| <code>renameat2()</code> | <code>rewind()</code> | <code>scanf()</code> | <code>setbuf()</code> | <code>setvbuf()</code> |
| <code>sprintf()</code> | <code>sscanf()</code> | <code>svc99()</code> | <code>tmpfile()</code> | <code>tmpnam()</code> |
| <code>ungetc()</code> | <code>vasprintf()</code> | <code>vfprintf()</code> | <code>vprintf()</code> | <code>vsprintf()</code> |

Defined types in stdio.h

The `FILE` type is defined in `stdio.h`. Stream functions use a pointer to the `FILE` type to get access to a given stream. The system uses the information in the `FILE` structure to maintain the stream. The C standard streams `stdin`, `stdout`, and `stderr` are also defined in `stdio.h`.

The type `fpos_t` is defined in `stdio.h` for use with `fgetpos()` and `fsetpos()`.

The types `__S99parms`, `__S99rbx_t`, and `__S99empaarms_t` are defined in `stdio.h` for use with the `svc99()` function.

The type `fldata_t` is defined in `stdio.h` for use with the `fldata()` function.

The types `__amrc_type` and `__amrc2_type` are defined in `stdio.h` for use in determining error information when I/O functions fail.

Macros defined in stdio.h

You can use these macros as constants in your programs, but you should not alter their values.

BUFSIZ

Specifies the buffer size to be used by the `setbuf()` library function when you are allocating buffers for stream I/O. This value is the expected size of the user's buffer supplied to `setbuf()`. If a larger buffer is required, for example, if *blocksize* is larger than BUFSIZ, or if special buffer attributes are required, IBM z/OS C/C++ applications will not use the user's buffer.

EOF

The value returned by an I/O function when the End Of File (EOF) (or in some cases, an error) is found.

FOPEN_MAX

The maximum number of files that can be open simultaneously.

FILENAME_MAX

The maximum number of characters in a filename. Can be used in the size specification of an array (for example, to hold the filename returned by `fldata()`).

L_tmpnam

The size of the longest temporary name that can be generated by the `tmpnam()` function.

L_ctermid

Maximum size of a character array for `ctermid()` output. This macro is supported only in a POSIX program.

NULL

A pointer which never points to a data object.

TMP_MAX

The minimum number of unique file names that can be generated by the `tmpnam()` function.

The macros `SEEK_CUR`, `SEEK_END`, and `SEEK_SET` expand to integral constant expressions and can be used as the third argument to `fseek()`.

The macros `_IOFBF`, `_IOLBF`, and `_IONBF` expand to integral constant expressions with distinct values suitable for use as the third argument to the `setvbuf()` function.

The following macros expand to integer constant expressions suitable for interpreting values returned by `fldata()`, in the `fldata_t` structure.

| | | | |
|---------------------------|-----------------------|--------------------------|-------------------------|
| <code>__APPEND</code> | <code>__BINARY</code> | <code>__BLOCKED</code> | <code>__DISK</code> |
| <code>__DUMMY</code> | <code>__ESDS</code> | <code>__ESDS_PATH</code> | <code>__HFS</code> |
| <code>__HIPERSPACE</code> | <code>__KSDS</code> | <code>__KSDS_PATH</code> | <code>__MEMORY</code> |
| <code>__MSGFILE</code> | <code>__NORLS</code> | <code>__NOTVSAM</code> | <code>__OTHER</code> |
| <code>__PRINTER</code> | <code>__READ</code> | <code>__RECORD</code> | <code>__RLS</code> |
| <code>__RSDS</code> | <code>__TAPE</code> | <code>__TDQ</code> | <code>__TERMINAL</code> |
| <code>__TEXT</code> | <code>__UPDATE</code> | <code>__WRITE</code> | |

The following macros expand to integral constant expressions suitable for use as the fourth argument to the `flocate()` function.

| | | | |
|-------------------------|---------------------------|---------------------------|-----------------------|
| <code>__KEY_EQ</code> | <code>__KEY_EQ_BWD</code> | <code>__KEY_FIRST</code> | <code>__KEY_GE</code> |
| <code>__KEY_LAST</code> | <code>__RBA_EQ</code> | <code>__RBA_EQ_BWD</code> | |

The following macros expand to integral constant expressions suitable for use as the argument to the function `clrmemf()`.

__CURRENT __CURRENT_LOWER __LOWER

The following macros expand to integral constant expressions suitable for use to determine the last operation reported in the `__amrc_type` structure. All these macros are described in [z/OS XL C/C++ Programming Guide](#).

| | | |
|-------------------|-----------------------|----------------------|
| __BSAM_BDL | __BSAM_CLOSE | __BSAM_CLOSE_T |
| __BSAM_NOTE | __BSAM_OPEN | __BSAM_POINT |
| __BSAM_READ | __BSAM_STOW | __BSAM_WRITE |

stdio_ext.h — stdio extensions

The `stdio_ext.h` header file contains prototypes and related definitions for the set of stdio extensions that allows access to the internal portions of the `FILE` structure.

stdlib.h — Standard library functions

The `stdlib.h` header file contains declarations for the following functions:

| | | | | |
|-----------------------------------|-------------------------------------|--------------------------------------|---------------------------------------|-----------------------------------|
| <code>abort()</code> | <code>abs()</code> ^[1,3] | <code>aligned_alloc()</code> | <code>alloca()</code> ^[1] | <code>atexit()</code> |
| <code>atof()</code> | <code>atoi()</code> | <code>atol()</code> | <code>bsearch()</code> | <code>calloc()</code> |
| <code>cds()</code> ^[1] | <code>clearenv()</code> | <code>cs()</code> ^[1] | <code>csid()</code> | <code>div()</code> ^[3] |
| <code>exit()</code> | <code>fetch()</code> ^[2] | <code>fetchp()</code> ^[2] | <code>free()</code> | <code>getenv()</code> |
| <code>labs()</code> | <code>ldiv()</code> | <code>llabs()</code> | <code>lldiv()</code> | <code>__librel()</code> |
| <code>malloc()</code> | <code>mblen()</code> | <code>mbstowcs()</code> | <code>mbtowc()</code> | <code>__moservices()</code> |
| <code>qsort()</code> | <code>rand()</code> | <code>realloc()</code> | <code>release()</code> ^[2] | <code>rpmatch()</code> |

Header files

| | | | | |
|--------------------|------------------|---------------------------|---------------------------|----------------------------|
| setenv() | srand() | strtod() | strtol() | strtoll() |
| strtoul() | strtoull() | system() | unatexit() | wcsid() |
| wcstombs() | wctomb() | strtod32() ^[4] | strtod64() ^[4] | strtod128() ^[4] |
| _UNIX03_SOURCE | | | | |
| unsetenv() | posix_memalign() | | | |

[1] Built-in function.

[2] Not supported under C++ applications.

[3] Special Behavior for C++: For C++ applications, the functions `abs()` and `div()` are also overloaded for the type `long`.

[4] The `__STDC_WANT_DEC_FP__` feature test macro is required to expose decimal floating-point functionality.

Two type definitions are added to `stdlib.h` for the Compare and Swap functions `cs()` and `cds()`. The structures defined are `__cs_t` and `__cds_t`.

The type `size_t` is declared in the header file. It is used for the type of the value returned by `sizeof`. The type `wchar_t` is declared and used for a wide character constant. For more information on the types `size_t` and `wchar_t`, see [“stddef.h — typedef statements”](#) on page 60.

The `stdlib.h` declares `div_t` and `ldiv_t`, which define the structure types that are returned by `div()` and `ldiv()`.

The `stdlib.h` file also contains definitions for the following macros:

NULL

The NULL pointer constant (also defined in `stddef.h`).

EXIT_SUCCESS

Used by the `atexit()` function.

EXIT_FAILURE

Used by the `atexit()` function.

RAND_MAX

Expands to an integer representing the largest number that the `RAND` function can return.

MB_CUR_MAX

Expands to an integer representing the maximum number of bytes in a multibyte character. This value is dependent on the current locale.

If `MB_CUR_MAX` is set to 1, multibyte functions will behave as if all multibyte characters are one byte long; wide-character functions are *not* supported and full DBCS support is *not* provided. If `MB_CUR_MAX` is 4, all DBCS support provided by the library is enabled.

string.h — String manipulation functions

The `string.h` header file declares the string manipulation functions and their built-in versions:

No feature test macro required.

| | | | | |
|--------------|-------------|--------------|--------------|--------------|
| memchr()[1] | memcmp()[1] | memcpy()[1] | memmove() | memset()[1] |
| strcat()[1] | strchr()[1] | strcmp()[1] | strcoll() | strcpy()[1] |
| strcspn() | strerror() | strlen()[1] | strncat()[1] | strncmp()[1] |
| strncpy()[1] | strpbrk() | strrchr()[1] | strspn() | strstr() |
| strtok() | strxfrm() | | | |

`_POSIX_C_SOURCE 200809L`

`stpcpy()` `stpncpy()` `strlen()` `strsignal()`

`_UNIX03_SOURCE`

`strerror_r`

[1] Built-in function.

`_XOPEN_SOURCE`

`memccpy()`

`_XOPEN_SOURCE_EXTENDED 1`

`strdup()`

`_XPLATFORM_SOURCE 1`

`strchrnul()`

The `string.h` header file also defines the macro `NULL` and the type `size_t`. For more information see [“stddef.h — typedef statements”](#) on page 60.

strings.h — String operations

The `strings.h` header file contains definitions for string operations.

stropts.h — Stream interface

The `stropts.h` header file declares the following functions:

| | | | |
|------------------------|--------------------------|-----------------------|------------------------|
| <code>fattach()</code> | <code>fdetach()</code> | <code>getmsg()</code> | <code>getpmsg()</code> |
| <code>ioctl()</code> | <code>isastream()</code> | <code>putmsg()</code> | <code>putpmsg()</code> |

syslog.h — System error logging

The `syslog.h` header file contains definitions for system error logging.

sys/acl.h — Manipulate ACL

The `sys/acl.h` header enables users to manipulate ACLs. It also declares the following functions:

| | | | |
|---------------------------------|---------------------------------|------------------------------|---------------------------------|
| <code>acl_create_entry()</code> | <code>acl_delete_entry()</code> | <code>acl_delete_fd()</code> | <code>acl_delete_file()</code> |
| <code>acl_first_entry()</code> | <code>acl_free()</code> | <code>acl_from_text()</code> | <code>acl_get_entry()</code> |
| <code>acl_get_fd()</code> | <code>acl_get_file()</code> | <code>acl_init()</code> | <code>acl_set_fd()</code> |
| <code>acl_set_file()</code> | <code>acl_sort()</code> | <code>acl_to_text()</code> | <code>acl_update_entry()</code> |
| <code>acl_valid()</code> | | | |

sys/__cpl.h — __cpl() function and symbolic constants

The `sys/__cpl.h` header contains definition for the `__cpl()` function. It also defines the following constants:

Table 8. Symbolic Constants defined in `sys/___cpl.h`

| Symbolic Constant | Description |
|-------------------|--|
| CPL_QUERY | Request data from available Coupling Facilities |
| CPL_CFSIZER | Request a structure size. |
| CPL_CFSIZER_W_LVL | Request a structure size with the level of the CF. |
| CPL_CFSIZER_VPL | Request a structure size and CFLevel with variable-length parameter list. |
| CPL_IXLCSP | Request a structure size and CFLevel with IXLCSP parameter list. |
| CPL_IXLMG | Request data from available coupling facilities with IXLMG parameter list. |
| CPL_IXCQUERY | Request data from the CFRM policy with IXCQUERY parameter list. |
| CPL_CFSIZER_VPL | Request a structure size and Cf Level with variable-length parameter list. |
| CPL_IXLCSP | Request a structure size and CFLevel with IXLCSP parameter list. |
| CPL_IXLMG | Request data from available coupling facilities with IXLMG parameter list. |
| CPL_IXCQUERY | Request data from the CFRM policy with IXCQUERY parameter list. |

sys/endian.h — Endian-ness of the system

The `sys/endian.h` header file defines the byte order, according to byte significance from low address to high.

sys/epoll.h — I/O event notification facility functions

The `sys/epoll.h` header file contains definitions for I/O event notification facility functions.

sys/eventfd.h — Standard library function

The `sys/epoll.h` header file contains definition for the `eventfd()` function.

sys/file.h — File manipulation constants

The `sys/file.h` header file defines file manipulation constants and the following function.

`_XPLATFORM_SOURCE`

`flock()`

sys/___getipc.h — Interprocess communication

The `sys/___getipc.h` header file contains definitions to get interprocess communication information.

sys/inotify.h — Monitor and notify file system change functions

The `sys/inotify.h` header file contains definitions for monitoring file system event functions.

sys/ioctl.h — System I/O definitions and structures

The `sys/ioctl.h` header file contains system I/O definitions and structures.

sys/ipc.h — Interprocess communication access structure

The `sys/ipc.h` header file contains definitions for the interprocess communication access structure.

sys/layout.h — Bidirectional conversion of data between Visual and Implicit formats

The `sys/layout.h` header file contains declarations for supporting bidirectional (Bidi) conversion of data between Visual (MVS) and Implicit (z/OS UNIX) formats. Initial support is for Arabic and Hebrew data.

sys/mman.h — Memory management

The `sys/mman.h` header file contains memory management declarations.

sys/__messag.h — __console() and __console2() functions

The `sys/__messag.h` header file contains definitions for the `__console()` and `__console2()` functions.

sys/mntent.h — w_getmntent() function and related structures and constants

This header file is protected by the `_OPEN_SYS` feature test macro.

The `sys/mntent.h` header file declares the `w_getmntent()` function and it defines the `mnte3`, `mnte2`, and `w_mntent` structures, along with some related constants.

sys/modes.h — Macros for stat structure

The `sys/modes.h` header file contains several macro definitions:

- Defined constant masks and bits for values of type `mode_t`, such as the `st_mode` field of the `stat` struct
- A defined constant mask for the `st_genvalue` field of the `stat` struct
- Function-like macros for testing values of the `st_mode` field of the `stat` struct.

Under IBM z/OS C support, these definitions are included in `sys/stat.h` to make `sys/stat.h` conform with POSIX.

sys/mount.h — File system mount and unmount

The `sys/inotify.h` header file contains definitions for mount and unmount file system operations functions.

sys/msg.h — Message queue structures

The `sys/msg.h` header file contains definitions for message queue structures.

sys/prctl.h — Operations on a process or thread

The `sys/prctl.h` header file contains definitions for operations on a process or thread.

sys/ps.h — w_getpsent() function and w_psproc structure

The `sys/ps.h` header file declares the `w_getpsent()` function that provides process data and defines the structure `w_psproc` along with some related constants.

It requires the `_OPEN_SOURCE 1` feature test macro.

sys/random.h — Random data operations

The `sys/random.h` header file contains definitions for random data operations, including declarations, constants, and structures that are used by the following function.

`_XPLATFORM_SOURCE`

`getrandom()`

sys/resource.h — XSI resource operations

The `sys/resource.h` header file contains definitions for XSI resource operations, including declarations, constants, and structures used by the following functions:

- `getpriority()`
- `getrlimit()`
- `getrusage()`
- `prlimit()`
- `setpriority()`
- `setrlimit()`

sys/select.h — Select types

The `sys/select.h` header file contains definitions for select types.

sys/sem.h — Semaphore facility

The `sys/sem.h` header file contains definitions for the semaphore facility.

sys/server.h — WorkLoad Manager services

The `sys/server.h` header file contains definitions for using WorkLoad Manager services.

sys/shm.h — Shared memory facility

The `sys/shm.h` header file contains definitions for the shared memory facility.

sys/socket.h — Sockets definitions

The `sys/socket.h` header file contains sockets definitions.

The structure `sockaddr_storage` is exposed by defining the feature test macro `_OPEN_SYS_SOCKET_IPV6` or `_OPEN_SYS_SOCKET_EXT3`.

Flag `O_CLOEXEC` and `O_DIRECT` are exposed by defining the feature test macro `_XPLATFORM_SOURCE`.

sys/stat.h — z/OS UNIX files and access

The `sys/stat.h` header file declares the following functions related to z/OS UNIX files and their access:

| | | | | |
|---------------------------|-----------------------------|------------------------|------------------------|------------------------|
| <code>__chattrat()</code> | <code>__chattrat64()</code> | <code>chaudit()</code> | <code>chmod()</code> | <code>creat()</code> |
| <code>fchaudit()</code> | <code>fchmod()</code> | <code>fstat()</code> | <code>fstat64()</code> | <code>fstatat()</code> |

| | | | | |
|-------------|---------------|-----------------|-----------|-----------|
| fstatat64() | lstat() | lstat64() | mkdir() | mkdirat() |
| mkfifo() | mkdirat() | mknod() | mknodat() | __mount() |
| mount() | __open_stat() | __open_stat64() | stat() | stat64() |
| umask() | umount() | | | |

sys/statfs.h – File system status

The `sys/statfs.h` header file contains functions that provide file system status.

sys/statvfs.h – File system status

The `sys/statvfs.h` header file contains definitions for file system status.

sys/time.h – Time types

The `sys/time.h` header file contains definitions for time types. It declares the following functions.

| | |
|--------------------------------|------------------------|
| <code>_XPLATFORM_SOURCE</code> | |
| <code>futimes()</code> | <code>lutimes()</code> |

sys/timex.h – Date and time

The `sys/timex.h` header file declares the `ftime()` and `ftime64()` functions that set the date and time. This header file requires the `_XOPEN_SOURCE_EXTENDED` feature test macro.

sys/times.h – Processor times

The `sys/times.h` header file declares the `times()` function that gets processor times for use by processes. It requires the `_POSIX_SOURCE` feature test macro.

sys/ttydev.h – Terminal I/O functions

The `sys/ttydev.h` header file defines constants used by the terminal I/O functions.

sys/types.h – typedef symbols and structures

The `sys/types.h` header file defines a collection of *typedef* symbols and structures.

Table 9. *sys/types.h: _OE_SOCKETS or _ALL_SOURCE*

| | |
|----------------|----------------|
| u_char | unsigned char |
| u_int | unsigned int |
| ushort | unsigned short |
| u_short | unsigned short |
| u_long | unsigned long |

Table 10. *sys/types.h: _OE_SOCKETS or _XOPEN_SOURCE_EXTENDED 1*

| | |
|------------------|-------------------------------|
| in_addr_t | Internet address |
| ip_addr_t | Internet address |
| caddr_t | Used for message data pointer |

Table 11. *sys/types.h: _OPEN_THREADS*

| | |
|----------------------------|---------------------------------------|
| pthread_t | Identify a thread |
| pthread_attr_t | Identify a thread attribute object |
| pthread_mutex_t | Mutexes |
| pthread_mutexattr_t | Identify a mutex attribute object |
| pthread_cond_t | Condition variables |
| pthread_condattr_t | Identify a condition attribute object |
| pthread_key_t | Thread-specific data keys |
| pthread_once_t | Dynamic package initialization |

Table 12. *sys/types.h: _POSIX_SOURCE*

| | |
|--------------------------|-----------------------------------|
| dev_t | Device numbers |
| gid_t | Group IDs |
| ino_t | File serial numbers |
| mode_t | Some file attributes |
| nlink_t | Link counts |
| off_t | File sizes, long |
| pid_t | Process IDs and process group ids |
| size_t | unsigned long |
| ssize_t | Signed long |
| uid_t | user IDs |
| time_t | Time values |
| clock_t | Time values, int |
| clockid_t | Clock ID type, int |
| sigset_t | Signal set |
| cc_t | cc_t |
| tty control chars | |
| speed_t | tty baud rate |
| tcflag_t | tty modes |
| mtm_t | Mount requests |
| rdev_t | Device numbers |

| suseconds_t | Time values in range [-1,1,000,000] |

Table 15. *sys/types.h: _XOPEN_SOURCE_EXTENDED 1*

| | |
|--------------------|--|
| id_t | General identifier, can contain a pid_t or a gid_t |
| useconds_t | Microseconds |
| sa_family_t | Address family |
| in_port_t | AF_INET port |

sys/uio.h — Vector I/O operations

The `sys/uio.h` header file contains definitions for vector I/O operations.

sys/un.h — UNIX-domain sockets

The `sys/un.h` header file contains definitions for UNIX-domain sockets.

sys/__ussos.h — Security facility authorization

The `sys/__ussos.h` header file contains the `_SET_THLIIPADDR()` macro, which sets a client's IP address for security facility authorization (SAF).

sys/utsname.h — Operating system name

The `sys/utsname.h` header file declares the `utsname` structure and the `uname()` function, which returns the name of the current operating system. It requires the `_POSIX_SOURCE` feature test macro.

sys/wait.h — Hold processes

The `sys/wait.h` header file declares the following functions, used for holding processes.

`_POSIX_SOURCE:`

`wait()` `waitpid()`

`_XOPEN_SOURCE_EXTENDED 1:`

`waitid()` `wait3()`

Note: `wait3()` has been withdrawn in Single UNIX Specification, Version 3.

`_XPLATFORM_SOURCE`

`wait4()`

sys/__wlm.h — WorkLoad Manager functions

The `sys/__wlm.h` header file contains definitions for WorkLoad Manager functions.

sys/xattr.h — Extended attributes handling

The `sys/xattr.h` header file contains definitions for extended attributes handling functions.

tar.h — tar utility

The `tar.h` header file contains definitions for the tar utility.

termios.h — POSIX terminal I/O functions

The `termios.h` header file contains constants, prototypes, and typedef definitions of POSIX terminal I/O functions. It includes the `__termcp` structure, and declares the following functions:

| | | | | |
|----------------------------|----------------------------|----------------------------|------------------------------|-------------------------|
| <code>cfgetispeed()</code> | <code>cfgetospeed()</code> | <code>cfsetispeed()</code> | <code>cfsetospeed()</code> | <code>tcdrain()</code> |
| <code>tcflow()</code> | <code>tcflush()</code> | <code>tcgetattr()</code> | <code>__tcgetcp()</code> | <code>tcgetsid()</code> |
| <code>tcsendbreak()</code> | <code>tcsetattr()</code> | <code>__tcsetcp()</code> | <code>__tcsettables()</code> | |

These functions are supported only in a POSIX program.

The `termios.h` header file also contains constants, prototypes and typedef definitions for the `w_ioctrl()` function.

tgmath.h — Mathematics and complex data type

The header `tgmath.h` includes the headers `math.h` and `complex.h` and defines a number of type-generic macros. This requires the compiler that is designed to support C99.

Use of the macro invokes a function whose corresponding real type and type domain are determined by the arguments for the generic parameters. If there is more than one real floating type argument, usual arithmetic conversions are applied to the real floating type arguments so that they have compatible types. Then,

- If any argument has type `_Decimal128`, the type determined is `_Decimal128`.
- Otherwise, if any argument has type `_Decimal64`, the type determined is `_Decimal64`.
- Otherwise, if any argument has type `_Decimal32`, the type determined is `_Decimal32`.
- Otherwise, if any argument has type `long double`, the type determined is `long double`.
- Otherwise, if any argument has type `double` or is of integer type, the type determined is `double`.
- Otherwise, if none of the above the type determined is `float`.

All the functions in `math.h` and `complex.h` have their corresponding type generic macros in this header where if for a function in `math.h`, there is a corresponding `c` prefixed function in `complex.h`, then the corresponding type generic macro has the same name as the one in `math.h`. The macros are:

| | | | | | |
|-------------------|----------------------------|------------------------|-------------------------|---------------------|------------------------|
| acos | <code>acosh</code> | <code>asin</code> | <code>asinh</code> | <code>atan</code> | <code>atan2</code> |
| atanh | <code>carg</code> | <code>cbrt</code> | <code>ceil</code> | <code>cimag</code> | <code>conj</code> |
| copysign | <code>cos</code> | <code>cosh</code> | <code>cproj</code> | <code>creal</code> | <code>erf</code> |
| erfc | <code>exp</code> | <code>exp2</code> | <code>expm1</code> | <code>fabs</code> | <code>fdim</code> |
| floor | <code>fma</code> | <code>fmax</code> | <code>fmin</code> | <code>fmod</code> | <code>frexp</code> |
| hypot | <code>ilogb</code> | <code>ldexp</code> | <code>lgamma</code> | <code>llrint</code> | <code>llround</code> |
| log | <code>log10</code> | <code>log1p</code> | <code>log2</code> | <code>logb</code> | <code>lrint</code> |
| lround | <code>nearbyint</code> | <code>nextafter</code> | <code>nexttoward</code> | <code>pow</code> | <code>remainder</code> |
| remquo | <code>rint</code> | <code>round</code> | <code>scalbln</code> | <code>scalbn</code> | <code>sin</code> |
| sinh | <code>sqrt</code> | <code>tan</code> | <code>tanh</code> | <code>tgamma</code> | <code>trunc</code> |
| quantize() | <code>samequantum()</code> | | | | |

[1] The following type-generic macros are not supported for decimal-floating point types: `carg()`, `cimag()`, `conj()`, `cproj()`, `creal()`.

Restrictions:

- This header does not support the `_FP_MODE_VARIABLE` feature test macro.
- This header is not supported for C++ applications.

For example:

The macro `exp(int n)` invokes the function `exp(int n)`

The macro `acosh(float f)` invokes the function `acoshf(float f)`

The macro `log(float complex fc)` invokes the complex function `clogf(float complex fc)`

The macro `pow(double complex dc, float f)` invokes `cpow(double complex dc, float f)`

)

time.h — Time and date

The `time.h` header file declares the time and date functions:

| | | | | |
|-------------------------|--------------------------|-----------------------------------|--------------------------|-------------------------|
| <code>asctime()</code> | <code>clock()</code> | <code>clock_gettime()</code> | <code>ctime()</code> | <code>difftime()</code> |
| <code>gmtime()</code> | <code>localtime()</code> | <code>mktime()</code> | <code>nanosleep()</code> | <code>strftime()</code> |
| <code>strptime()</code> | <code>time()</code> | <code>tzset()</code> ¹ | | |

Note:

1. This function is supported only in a POSIX program.

The `time.h` header file also provides:

- A structure `timespec` that contains the following members:

| | | |
|---------------------|-----------------------|-------------|
| <code>time_t</code> | <code>tv_sec;</code> | seconds |
| <code>long</code> | <code>tv_nsec;</code> | nanoseconds |

- A structure `timespec64` that contains the following members:

| | | |
|-----------------------|-----------------------|-------------|
| <code>time64_t</code> | <code>tv_sec;</code> | seconds |
| <code>long</code> | <code>tv_nsec;</code> | nanoseconds |

Note: In addition to the requirements for accessing structure `timespec`, feature test macro `_LARGE_TIME_API` is needed to expose `timespec64`.

- A structure `tm` that contains the components of a calendar time. See Table 16 on page 76 for a list of the members of the `tm` structure. This structure is used by the functions `asctime()`, `gmtime()`, `localtime()`, `mktime()`, `strftime()`, and `strptime()`.
- A macro `CLOCKS_PER_SEC` equal to the number per second of the value returned by the `clock()` function.
- Types `clock_t`, `clockid_t`, `time_t`, and `size_t`.
- The NULL pointer constant. For more information on NULL and the type `size_t`, see “[stddef.h — typedef statements](#)” on page 60.
- The macro `CLK_TCK`, which is the number of clock ticks per second, is kept for historical reasons. It was used in connection with the return value of the `clock()` function. `CLK_TCK` has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use `sysconf(_SC_CLK_TCK)` instead of the `CLK_TCK` macro.

However, if it is necessary to continue using this symbol in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols that are removed in Single UNIX Specification, Version 3.

| Table 16. Fields of tm Structure | |
|----------------------------------|--|
| Field | Description |
| tm_sec | Seconds (0-60) |
| tm_min | Minutes (0-59) |
| tm_hour | Hours (0-23) |
| tm_mday | Day of month (1-31) |
| tm_mon | Month (0-11; January = 0) |
| tm_year | Year (current year minus 1900) |
| tm_wday | Day of week (0-6; Sunday = 0) |
| tm_yday | Day of year (0-365; January 1 = 0) |
| tm_isdst | Zero if Daylight Saving Time is not in effect; positive if Daylight Saving Time is in effect; negative if the information is not available. |
| tm_gmtoff ¹ | Time zone that is used to compute this broken-down time value, including any adjustment for daylight saving. It represents the number of seconds that must be added to Coordinated Universal Time to get local time. |
| tm_zone ¹ | Name for the time zone that is used to compute this broken-down time value. |

Note:

1. Only when `_XPLATFORM_SOURCE` is defined, this field is included in the `tm` structure. The value of this field is available only after the `localtime_r()` function is called with `_XPLATFORM_SOURCE` defined. In other cases, using this field might result in unknown behavior.

The time functions are affected by the current locale selected. The `LC_CTYPE` category affects the behavior of the `strftime()`, `strptime()`, and `wcsftime()` functions. The `LC_TOD` category affects the behavior of the `gmtime()`, `mktime()`, and `localtime()` functions.

uchar.h — Extended character data types

This header defines typedefs and macros associated with extended character data types.

The following typedefs are defined:

char16_t char32_t mbstate_t size_t

The following object-like macros are defined:

__STDC_UTF_16__ __STDC_UTF_32__

The `uchar.h` header file also declares functions that deal with conversions between multibyte characters and `char16_t`/`char32_t`. The following functions are declared:

mbrtoc16() mbrtoc32() c16rtomb() c32rtomb()

ucontext.h — Context related functions

The `ucontext.h` header file contains the prototypes and definitions needed by the following functions:

getcontext() setcontext() makecontext() swapcontext()

uheap.h — Heap storage

The `uheap.h` header file contains the prototypes and definitions needed by the following functions:

| | | | |
|--------------------------|--------------------------|------------------------|------------------------------|
| <code>__ucreate()</code> | <code>__umalloc()</code> | <code>__ufree()</code> | <code>__uheapreport()</code> |
|--------------------------|--------------------------|------------------------|------------------------------|

ulimit.h — ulimit commands

The `ulimit.h` header file contains definitions for **ulimit** commands.

unistd.h — Implementation-specific functions

The `unistd.h` header file declares a number of implementation-specific functions:

| | | | |
|--------------------------------|-------------------------|-------------------------------|--|
| <code>__atoe()</code> | <code>__atoe_l()</code> | <code>__authenticate()</code> | <code>__check_resource_auth_n p()</code> |
| <code>__convert_id_np()</code> | <code>__etoea()</code> | <code>__etoea_l()</code> | <code>__isPosixOn()</code> |
| <code>__smf_record()</code> | <code>__wsinit()</code> | | |

XPLINK

| | | | |
|------------------------|------------------------|------------------------|------------------------|
| <code>__a2e_l()</code> | <code>__a2e_s()</code> | <code>__e2a_l()</code> | <code>__e2a_s()</code> |
|------------------------|------------------------|------------------------|------------------------|

There are also a large number of POSIX and UNIX functions declared, shown below with the minimum feature test macro needed to expose them:

| | | | |
|------------------------------|----------------------------|--------------------------|-------------------------------|
| <code>access()</code> | <code>alarm()</code> | <code>chdir()</code> | <code>chown()</code> |
| <code>close()</code> | <code>ctermid()</code> | <code>dup()</code> | <code>dup2()</code> |
| <code>execl()</code> | <code>execle()</code> | <code>execlp()</code> | <code>execv()</code> |
| <code>execve()</code> | <code>execvp()</code> | <code>_exit()</code> | <code>fork()</code> |
| <code>fpathconf()</code> | <code>getcwd()</code> | <code>getegid()</code> | <code>geteuid()</code> |
| <code>getgid()</code> | <code>getgroups()</code> | <code>getlogin()</code> | <code>getpgrp()</code> |
| <code>getpid()</code> | <code>getppid()</code> | <code>getuid()</code> | <code>isatty()</code> |
| <code>link()</code> | <code>lseek()</code> | <code>pathconf()</code> | <code>pause()</code> |
| <code>pipe()</code> | <code>read()</code> | <code>rmdir()</code> | <code>setgid()</code> |
| <code>setpgid()</code> | <code>setsid()</code> | <code>setuid()</code> | <code>sleep()</code> |
| <code>sysconf()</code> | <code>tcgetpgrp()</code> | <code>tcsetpgrp()</code> | <code>ttyname()</code> |
| <code>unlink()</code> | <code>write()</code> | | |
| <code>__certificate()</code> | <code>__getlogin1()</code> | <code>__login()</code> | <code>__pid_affinity()</code> |

POSIX1_SOURCE = 2

| | | | |
|------------------------|-------------------------|--------------------------|-------------------------|
| <code>fchown()</code> | <code>fsync()</code> | <code>ftruncate()</code> | <code>readlink()</code> |
| <code>setegid()</code> | <code>setgeuid()</code> | <code>symlink()</code> | |

POSIX_C_SOURCE = 2

| | | | |
|---------------------|---------------------|---------------------|---------------------|
| <code>optarg</code> | <code>opterr</code> | <code>optind</code> | <code>optopt</code> |
|---------------------|---------------------|---------------------|---------------------|

External Variables

`_POSIX_C_SOURCE` 200809L

Header files

faccessat() fchownat() linkat() readlinkat() symlinkat() unlinkat()

_XOPEN_SOURCE

chroot() confstr() crypt() cuserid()
encrypt() getopt() getpass() nice()
swab()

_XOPEN_SOURCE = 500

brk() fchdir() fdatsync() getdtablesize()
gethostid() gethostname() getlogin_r() getpagesize()
getpgid() getsid() getwd() lchown()
lockf() pread() pwrite() sbrk()
setpgrp() setregid() setreuid() sync()
truncate() ttyname_r() ualarm() usleep()
vfork()

_XPLATFORM_SOURCE

dup3() getentropy() pipe2() pivot_root()
syncfs() syscall()

The `unistd.h` header file also defines many symbols to represent configuration variables and implementation features provided. Some of these are used at compile time, while others are used to interrogate the system at run time, using `sysconf()`, `confstr()`, `pathconf()`, or `fpathconf()`.

utime.h — File access and time modification

The `utime.h` header file declares the `utimbuf` and `utimbuf64` structures and the `utime()` and `utime64()` functions, which are used to set file access and modification times.

The `utime()` and `utime64()` function are supported only in a POSIX program.

Note: Feature test macro `_LARGE_TIME_API` is needed to expose the `utimbuf64` structure.

utmpx.h — User accounting database

The `utmpx.h` header file contains user accounting database definitions.

varargs.h — Handle variable argument lists

The `varargs.h` header file contains definitions for handling variable argument lists.

Note:

This header is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use the `<stdarg.h>` header to support variable argument list functionality compatible with IEEE Std 1003.1-2001.

Applications conforming to Single UNIX Specification, Version 3 must not include the header file.

variant.h — LC_SYNTAX characters

The `variant.h` header file declares the `getsyntax()` function, which returns LC_SYNTAX characters. It also contains the declaration of the `variant` structure:

```
struct variant {
    char    *codeset;           /* code set of the current locale */
    char    backslash;         /* encoding of \ */
    char    right_bracket;     /* encoding of ] */
    char    left_bracket;      /* encoding of [ */
    char    right_brace;       /* encoding of } */
    char    left_brace;        /* encoding of { */
    char    circumflex;        /* encoding of ^ */
    char    tilde;             /* encoding of ~ */
    char    exclamation_mark;  /* encoding of ! */
    char    number_sign;       /* encoding of # */
    char    vertical_line;     /* encoding of | */
    char    dollar_sign;       /* encoding of $ */
    char    commercial_at;     /* encoding of @ */
    char    grave_accent;      /* encoding of ` */
};

struct variant *getsyntax(void);
```

For more information about the effect of locale, see `setlocale()`, `locale.h`, or look up the individual functions in this topic. For still more information, see "Internationalization: Locales and Character Sets" in *z/OS XL C/C++ Programming Guide*.

wchar.h — ISO/C Multibyte Support extensions

The `wchar.h` header file contains the declaration for the supported subset of the ISO/C Multibyte Support extensions introduced in ISO/IEC 9899:1990/Amendment 1:1993(E) extensions. You don't need to include `stdio.h` and `stdarg.h` to use the header file. The following functions are declared in `wchar.h`. `wmemchr()`, `wmemcpy()`, `wmemcmp()`, and `wmemset()` are also available as their built-in versions.

| | | | | |
|--|---|-------------------------|--------------------------|--|
| <code>btowc()</code> | <code>fgetwc()</code> | <code>fgetws()</code> | <code>fputwc()</code> | <code>fputws()</code> |
| <code>fwide()</code> | <code>fwprintf()</code> | <code>fwscanf()</code> | <code>getwc()</code> | <code>getwchar()</code> |
| <code>mbrlen()</code> | <code>mbrtowc()</code> | <code>mbsinit()</code> | <code>mbsrtowcs()</code> | <code>putwc()</code> |
| <code>putwchar()</code> | <code>swprintf()</code> | <code>swscanf()</code> | <code>ungetwc()</code> | <code>vfwprintf()</code> |
| <code>vfwscanf()</code> | <code>vswprintf()</code> | <code>vswscanf()</code> | <code>vwprintf()</code> | <code>vwscanf()</code> |
| <code>wcrtomb()</code> | <code>wcscat()</code> | <code>wcschr()</code> | <code>wcscmp()</code> | <code>wscoll()</code> |
| <code>wcscpy()</code> | <code>wcscspn()</code> | <code>wcsftime()</code> | <code>wcslen()</code> | <code>wcsncat()</code> |
| <code>wcsncmp()</code> | <code>wcsncpy()</code> | <code>wcspbrk()</code> | <code>wcsrchr()</code> | <code>wcsrtombs()</code> |
| <code>wcsspn()</code> | <code>wcsstr()</code> | <code>wcstod()</code> | <code>wcstok()</code> | <code>wcstol()</code> |
| <code>wcstoll()</code> | <code>wcstoul()</code> | <code>wcstoull()</code> | <code>wcswidth()</code> | <code>wcsxfrm()</code> |
| <code>wctob()</code> | <code>wcwidth()</code> | <code>wmemchr()</code> | <code>wmemcpy()</code> | <code>wmemcmp()</code> |
| <code>wmemmove()</code> | <code>wmemset()</code> | <code>wprintf()</code> | <code>wscanf()</code> | <code>wcstod32()</code> ^[1] |
| <code>wcstod64()</code> ^[1] | <code>wcstod128()</code> ^[1] | | | |

1. The `__STDC_WANT_DEC_FP__` feature test macro is required to expose decimal floating-point functionality.

`_POSIX_C_SOURCE 200809L`

`wcpncpy()` `wcpcnpy()` `wcsnlen()`

The header file `wchar.h` contains definitions of the following types:

mbstate_t

Conversion-state information needed when converting between sequences of multibyte characters and wide characters.

size_t

typedef for the type of the value returned by *sizeof*.

wchar_t

typedef for a wide-character constant.

wint_t

An integral type unchanged by integral promotions that can hold any value corresponding to members of the extended character set, as well as WEOF (see below).

FILE

The FILE structure type is defined in both `stdio.h` and `wchar.h`. Stream functions use a pointer to the FILE type to get access to a given stream. The system uses the information in the FILE structure to maintain the stream. The C standard streams `stdin`, `stdout`, and `stderr` are also defined in `stdio.h`.

va_list

This type is defined in both `stdarg.h` and `wchar.h`.

The header file `wchar.h` also contains definitions of the following constants:

NULL

A pointer that never points to a data object.

WEOF

Expands to a constant expression of type `wint_t`, whose value does not correspond to any member of the extended character set. It indicates End Of File (EOF).

WCHAR_MIN

Defines the lower limit of the `wchar_t` type.

WCHAR_MAX

Defines the upper limit of the `wchar_t` type.

You can perform wide-character input/output on the streams described in the ISO/IEC 9899:1990 standard, sub-clause 7.9.2. This standard expands the definition of a stream to include an *orientation* for both text and binary streams. For more information about DBCS orientation, see the section on Double-Byte Characters Sets in [z/OS XL C/C++ Programming Guide](#).

The wide-character string functions are also declared in `wcstr.h` for compatibility with previous releases of C/370, although `wcstr.h` may be withdrawn in the future.

For more information about the effect of locale, see `setlocale()`, `locale.h`, or look up the individual functions in this topic. For still more information, see the "Internationalization: Locales and Character Sets" in [z/OS XL C/C++ Programming Guide](#).

wcstr.h — Multibyte functions

The `wcstr.h` header file declares the following multibyte functions:

| | | | | |
|------------------------|------------------------|------------------------|------------------------|------------------------|
| <code>wcscat()</code> | <code>wcschr()</code> | <code>wcscmp()</code> | <code>wscpy()</code> | <code>wcscspn()</code> |
| <code>wcslen()</code> | <code>wcsncat()</code> | <code>wcsncmp()</code> | <code>wcsncpy()</code> | <code>wcspbrk()</code> |
| <code>wcsrchr()</code> | <code>wcsspn()</code> | <code>wcswcs()</code> | | |

`wcstr.h` also defines the types `size_t`, `NULL`, `wchar_t`, and `wint_t`.

The wide-character string functions are also declared in `wchar.h` for compatibility with previous releases of C/370. `wcstr.h` may be withdrawn in future releases of the IBM z/OS C/C++ product.

`wcstr.h` is a non-standard header that is provided for compatibility with previous releases of C/370. Functions in `wcstr.h` are exposed by enabling the [runtime library extensions](#). The `wcstr.h` header might be withdrawn in future releases of the IBM z/OS C/C++ product. The wide character functions in `wcstr.h` are also declared in the `wchar.h` header, which is the standard interface.

wctype.h — Wide character properties

The `wctype.h` header declares functions that deal with wide character properties. The following are declared as functions and are also defined as macros:

| | | | | |
|-------------------------|-------------------------|--------------------------|-------------------------|-------------------------|
| <code>iswalnum()</code> | <code>iswalpha()</code> | <code>iswblank()</code> | <code>iswcntrl()</code> | <code>iswctype()</code> |
| <code>iswdigit()</code> | <code>iswgraph()</code> | <code>iswlower()</code> | <code>iswprint()</code> | <code>iswpunct()</code> |
| <code>iswspace()</code> | <code>iswupper()</code> | <code>iswxdigit()</code> | <code>towlower()</code> | <code>towupper()</code> |
| <code>wctype()</code> | | | | |

The following are declared as prototypes only:

| | | |
|--------------------------|------------------------|-----------------------|
| <code>towctrans()</code> | <code>wctrans()</code> | <code>wctype()</code> |
|--------------------------|------------------------|-----------------------|

The `wctype.h` header defines the types `wctrans_t`, `wctype_t` and `wint_t`. The `wctype.h` defines the macro `WEOF`, which expands to a constant expression of type `wint_t`, whose value does not correspond to any member of the extended character set. The macro `WEOF` indicates End Of File (EOF).

wordexp.h — Word expansion types

The `wordexp.h` header file contains definitions for word expansion types.

xti.h — _XOPEN_SOURCE_EXTENDED feature test macro

The `xti.h` header file declares the following symbolic constants under the `_XOPEN_SOURCE_EXTENDED` feature test macro:

Table 17. Symbolic Constants defined in xti.h

| Symbolic Constant | Description |
|-------------------|-------------------------------|
| TBADADDR | Incorrect addr format |
| TBADOPT | Incorrect option format |
| TACCES | Incorrect permissions |
| TBADF | Illegal transport fd |
| TNOADDR | Could not allocate addr |
| TOUTSTATE | Out of state |
| TBADSEQ | Bad call sequence number |
| TSYSERR | System error |
| TLOOK | Event requires attention |
| TBADDATA | Illegal amount of data |
| TBUFOVFLW | Buffer not large enough |
| TFLOW | Flow control |
| TNODATA | No data |
| TNODIS | Discon_ind not found on queue |
| TNOUDERR | unitdata error not found |

Table 17. Symbolic Constants defined in xti.h (continued)

| Symbolic Constant | Description |
|-------------------|------------------------------------|
| TBADFLAG | Bad flags |
| TNOREL | No ord rel found on queue |
| TNOTSUPPORT | Primitive not supported |
| TSTATECHNG | State currently changing |
| TNOSTRUCTYPE | unknown struct-type requested |
| TBADNAME | Invalid transport name |
| TBADQLEN | Qlen is zero |
| TADDRBUSY | Address in use |
| TINDOUT | Outstanding connect indications |
| TPROVMISMATCH | Transport provider mismatch |
| TRESQLEN | Resfd specified to accept w/qlen>0 |
| TRESADDR | Resfd not bound to same addr as fd |
| TQFULL | Incoming connection queue full |
| TPROTO | XTI protocol error |
| T_LISTEN | Connection indication received |
| T_CONNECT | Connect confirmation received |
| T_DATA | Normal data received |
| T_EXDATA | Expedited data received |
| T_DISCONNECT | Disconnect received |
| T_UDERR | Datagram error indication |
| T_ORDREL | Orderly release indication |
| T_GODATA | Sending normal data is possible |
| T_GOEXDATA | Sending expedited data is possible |
| T_EVENTS | Event mask |
| T_MORE | More data |
| T_EXPEDITED | Expedited data |
| T_NEGOTIATE | Set opts |
| T_CHECK | Check opts |
| T_DEFAULT | Get default opts |
| T_SUCCESS | Successful |
| T_FAILURE | Failure |
| T_CURRENT | Current opts |
| T_PARTSUCCESS | Partial success |
| T_READONLY | Read-only |
| T_NOTSUPPORT | Not supported |
| T_BIND | S |

XL C++ header files

The XL C++ header files can be used with the z/OS XL C++ compiler only.

For the information about the following XL C/C++ header files, refer to the C++98 language standard (ISO/IEC 14882:1998).

- algorithm
- bitset
- complex
- deque
- fstream
- functional
- iomanip
- ios
- iosfwd
- istream
- iterator
- limits
- list
- locale
- map
- memory
- numeric
- ostream

cassert — Enforce assertions

The `cassert` header file contains definitions for C++ for enforcing assertions when functions execute. Include the standard header into a C++ program to effectively include the standard header `<assert.h>` within the `std` namespace.

```
namespace std {  
  #include <assert.h>  
};
```

cctype — Classify characters

The `cctype` header file contains definitions for C++ for classifying characters. Include the standard header into a C++ program to effectively include the standard header `<cctype.h>` within the `std` namespace.

```
namespace std {  
#include <cctype.h>  
};
```

cerrno — Test error codes

The `cerrno` header file contains definitions for C++ for testing error codes reported by library functions. Include the standard header into a C++ program to effectively include the standard header `<errno.h>` within the `std` namespace.

```
namespace std {  
#include <errno.h>  
};
```

cfloat — Test floating-point type properties

The `cfloat` header file contains definitions for C++ for testing floating-point type properties. Include the standard header into a C++ program to effectively include the standard header `<float.h>` within the `std` namespace.

```
namespace std {  
#include <float.h>  
};
```

ciso646 — ISO646 variant character sets

The `ciso646` header file contains definitions for C++ for programming in ISO646 variant character sets. Include the standard header into a C++ program to effectively include the standard header `<iso646.h>` within the `std` namespace.

```
namespace std {  
#include <iso646.h>  
};
```

climits — Test integer type properties

The `climits` header file contains definitions for C++ for testing integer type properties. Include the standard header into a C++ program to effectively include the standard header `<limits.h>` within the `std` namespace.

```
namespace std {  
#include <limits.h>  
};
```

locale — Adapt to different cultural conventions

The `locale` header file contains definitions for C++ for adapting to different cultural conventions. Include the standard header into a C++ program to effectively include the standard header `<locale.h>` within the `std` namespace.

```
namespace std {  
#include <locale.h>  
};
```

cmath — Common mathematical functions

The `cmath` header file contains definitions for C++ for computing common mathematical functions. Include the standard header into a C++ program to effectively include the standard header `<math.h>` within the `std` namespace.

```
namespace std {
#include <math.h>
};
```

complex.h — Complex math functions

The `complex.h` header file contains function declarations for all the complex math functions listed below.

| | | | | |
|------------------------|------------------------|------------------------|-----------------------|-----------------------|
| <code>cabs()</code> | <code>cabsf()</code> | <code>cabsl()</code> | <code>cacos()</code> | <code>cacosf()</code> |
| <code>cacosh()</code> | <code>cacoshf()</code> | <code>cacoshl()</code> | <code>cacosl()</code> | <code>carg()</code> |
| <code>cargf()</code> | <code>cargl()</code> | <code>casin()</code> | <code>casinf()</code> | <code>casinh()</code> |
| <code>casinhf()</code> | <code>casinhl()</code> | <code>casinl()</code> | <code>catan()</code> | <code>catanf()</code> |
| <code>catanh()</code> | <code>catanhf()</code> | <code>catanhl()</code> | <code>catanl()</code> | <code>ccos()</code> |
| <code>ccosf()</code> | <code>ccosh()</code> | <code>ccoshf()</code> | <code>ccoshl()</code> | <code>ccosl()</code> |
| <code>cexp()</code> | <code>cexpf()</code> | <code>cexpl()</code> | <code>cimag()</code> | <code>cimagf()</code> |
| <code>cimagl()</code> | <code>clog()</code> | <code>clogf()</code> | <code>clogl()</code> | <code>conj()</code> |
| <code>conjf()</code> | <code>conjl()</code> | <code>cpow()</code> | <code>cpowf()</code> | <code>cpowl()</code> |
| <code>cproj()</code> | <code>cprojf()</code> | <code>cprojl()</code> | <code>creal()</code> | <code>crealf()</code> |
| <code>creall()</code> | <code>csin()</code> | <code>csinf()</code> | <code>csinh()</code> | <code>csinhf()</code> |
| <code>csinhl()</code> | <code>csinl()</code> | <code>csqrt()</code> | <code>csqrtf()</code> | <code>csqrtl()</code> |
| <code>ctan()</code> | <code>ctanf()</code> | <code>ctanh()</code> | <code>ctanhf()</code> | <code>ctanhl()</code> |
| <code>ctanl()</code> | | | | |

The `complex.h` header file defines the following macros:

complex

expands to `_Complex`, where `_Complex` is a type specifier.

_Complex_I

expands to `const float _Complex` with the value of the imaginary unit

I

expands to `_Complex_I`

Compile requirement: Use of this header requires a compiler that is designed to support C99.

csetjmp — Execute non-local goto statements

The `csetjmp` header file contains definitions for C++ for executing non-local `goto` statements. Include the standard header into a C++ program to effectively include the standard header `<setjmp.h>` within the `std` namespace.

```
namespace std {
#include <setjmp.h>
};
```

csignal — Exception control

The `csignal` header file contains definitions for C++ for controlling various exceptional conditions. Include the standard header into a C++ program to effectively include the standard header `<signal.h>` within the `std` namespace.

```
namespace std {  
#include <signal.h>  
};
```

cstdarg — Access arguments

The `cstdarg` header file contains definitions for C++ for accessing a varying number of arguments. Include the standard header into a C++ program to effectively include the standard header `<stdarg.h>` within the `std` namespace.

```
namespace std {  
#include <stdarg.h>  
};
```

cstddef — Define data types and macros

The `cstddef` header file contains definitions for C++ for defining several useful types and macros. Include the standard header into a C++ program to effectively include the standard header `<stddef.h>` within the `std` namespace.

```
namespace std {  
#include <stddef.h>  
};
```

cstdio — Perform input and output

The `cstdio` header file contains definitions for C++ for performing input and output. Include the standard header into a C++ program to effectively include the standard header `<stdio.h>` within the `std` namespace.

```
namespace std {  
#include <stdio.h>  
};
```

cstdlib — Standard library

The `cstdlib` header file contains definitions for C++ for performing a variety of operations. Include the standard header into a C++ program to effectively include the standard header `<stdlib.h>` within the `std` namespace.

```
namespace std {  
#include <stdlib.h>  
};
```

cstring — Manipulate strings

The `cstring` header file contains definitions for C++ for manipulating several kinds of strings. Include the standard header into a C++ program to effectively include the standard header `<string.h>` within the `std` namespace.

```
namespace std {  
#include <string.h>  
};
```

ctime — Convert time and date formats

The `ctime` header file contains definitions for C++ for converting between various time and date formats. Include the standard header into a C++ program to effectively include the standard header `<time.h>` within the `std` namespace.

```
namespace std {
#include <time.h>
};
```

cwchar — Manipulating wide streams and strings

The `cwchar` header file contains definitions for C++ for manipulating wide streams and several kinds of strings. Include the standard header into a C++ program to effectively include the standard header `<wchar.h>` within the `std` namespace.

```
namespace std {
#include <wchar.h>
};
```

cwctype — Wide character classification

The `cwctype` header file contains definitions for C++ for classifying wide characters. Include the standard header into a C++ program to effectively include the standard header `<cwctype.h>` within the `std` namespace.

```
namespace std {
#include <cwctype.h>
};
```

exception — Exception handling

The `exception` header file defines several types and functions related to the handling of exceptions.

```
namespace std {
class exception;
class bad_exception;
typedef void (*terminate_handler)();
typedef void (*unexpected_handler)();
terminate_handler
    set_terminate(terminate_handler ph) throw();
unexpected_handler
    set_unexpected(unexpected_handler ph) throw();
void terminate();
void unexpected();
bool uncaught_exception();
};
```

bad_exception

```
class bad_exception : public exception {
};
```

The class describes an exception that can be thrown from an `unexpected` handler. The value returned by `what()` is an implementation-defined C string. None of the member functions throw any exceptions.

exception

```
class exception {
public:
    exception() throw();
    exception(const exception& rhs) throw();
    exception& operator=(const exception& rhs) throw();
    virtual ~exception() throw();
    virtual const char* what() const throw();
};
```

The class serves as the base class for all exceptions thrown by certain expressions and by the Standard C++ library. The C string value returned by `what()` is left unspecified by the default constructor, but may be defined by the constructors for certain derived classes as an implementation-defined C string. None of the member functions throw any exceptions.

`terminate_handler`

```
typedef void (*terminate_handler)();
```

The type describes a pointer to a function suitable for use as a terminate handler.

`unexpected_handler`

```
typedef void (*unexpected_handler)();
```

The type describes a pointer to a function suitable for use as an unexpected handler.

new — Storage allocation and free

The `<new>` header file defines several types and functions that control allocation and freeing of storage under program control.

Some of the functions declared in this header are replaceable. The implementation supplies a default version. A program can, however, define a function with the same signature to replace the default version at link time. The replacement version must satisfy the requirements of the function.

```
namespace std {
    typedef void (*new_handler)();
    class bad_alloc;
    class nothrow_t;
    extern const nothrow_t nothrow;
    // FUNCTIONS
    new_handler set_new_handler(new_handler ph) throw();
};
// OPERATORS
void operator delete(void *p) throw();
void operator delete(void *, void *) throw();
void operator delete(void *p, const std::nothrow_t&) throw();
void operator delete[](void *p) throw();
void operator delete[](void *, void *) throw();
void operator delete[](void *p, const std::nothrow_t&) throw();
void *operator new(std::size_t n) throw(std::bad_alloc);
void *operator new(std::size_t n, const std::nothrow_t&) throw();
void *operator new(std::size_t n, void *p) throw();
void *operator new[](std::size_t n) throw(std::bad_alloc);
void *operator new[](std::size_t n, const std::nothrow_t&) throw();
void *operator new[](std::size_t n, void *p) throw();
```

The `<new>` header file supercedes the `new.h` header, which remains for compatibility as a wrapper to `<new>`.

`bad_alloc`

```
class bad_alloc : public exception {
};
```

The class describes an exception thrown to indicate that an allocation request did not succeed. The value returned by `what()` is an implementation-defined C string. None of the member functions throw any exceptions.

`new_handler`

```
typedef void (*new_handler)();
```

The type points to a function suitable for use as a new handler.

`nothrow`

```
extern const nothrow_t nothrow;
```

The object is used as a function argument to match the parameter type `nothrow_t`.

`nothrow_t`

```
class nothrow_t {};
```

The class is used as a function parameter to operator `new` to indicate that the function should return a null pointer to report an allocation failure, rather than throw an exception.

new.h — Storage allocation and free

The ISO/ANSI C++ Standard (ISO/IEC 14882:1998(E)) supersedes this header with the new header `<new>`. However, `new.h` remains for compatibility as a wrapper for a [target operating system release](#) of z/OS V1R2 and later.

For compilations with a [target operating system release](#) before z/OS V1R2, the `new.h` header file declares the `set_new_handler()` function, which is used for z/OS C++ exception handling (`try`, `throw`, and `catch`). This header file also declares array and non-array version of the allocation operator `new` and the deallocation operator `delete`.

terminat.h — Exception handling

The ISO/ANSI C++ Standard (ISO/IEC 14882:1998(E)) supersedes this header with the new header `<exception>`. However, `terminat.h` remains for compatibility as a wrapper for a [target operating system release](#) of z/OS V1R2 and later.

For compilations with a [target operating system release](#) before z/OS V1R2, the `terminat.h` header file, which is used for C++ exception handling, declares the `terminate()` and `set_terminate()` functions.

typeinfo — Type identification operator

The `typeinfo` header file defines several types associated with the type identification operator `typeid`, which yields information about both static and dynamic types.

```
namespace std {
    class type_info;
    class bad_cast;
    class bad_typeid;
};
```

`type_info`

The class describes type information generated within the program by the implementation. Objects of this class effectively store a pointer to a name for the type, and an encoded value suitable for comparing two types for equality or collating order. The names, encoded values, and collating order for types are all unspecified and may differ between program executions.

An expression of the form `typeid x` is the only way to construct a (temporary) `type_info` object. The class has only a private copy constructor. Since the assignment operator is also private, you cannot copy or assign objects of class `type_info` either.

```
class type_info {
public:
    virtual ~type_info();
    bool operator==(const type_info& rhs) const;
    bool operator!=(const type_info& rhs) const;
    bool before(const type_info& rhs) const;
    const char *name() const;
private:
    type_info(const type_info& rhs);
    type_info& operator=(const type_info& rhs);
};

type_info::operator!=
```

```
bool operator!=(const type_info& rhs) const;
The function returns !(*this == rhs).

type_info::operator==
bool operator==(const type_info& rhs) const;
The function returns a nonzero value if *this and rhs represent the
same type.

type_info::before
bool before(const type_info& rhs) const;
The function returns a nonzero value if *this precedes rhs in the
collating order for types.

type_info::name
const char *name() const;
The function returns a C string which specifies the name of the type.
```

bad_cast

```
class bad_cast : public exception {
};
```

The class describes an exception thrown to indicate that a dynamic cast expression, of the form:

```
dynamic_cast<type>(expression)
```

generated a null pointer to initialize a reference. The value returned by `what()` is an implementation-defined C string. None of the member functions throw any exceptions.

bad_typeid

```
class bad_typeid : public exception {
};
```

The class describes an exception thrown to indicate that a typeid operator encountered a null pointer. The value returned by `what()` is an implementation-defined C string. None of the member functions throw any exceptions.

typeinfo.h — Type identification operator

The ISO/ANSI C++ Standard (ISO/IEC 14882:1998(E)) supersedes this header with the new header `<typeinfo>`. While this header represents function that did not previously exist on the z/OS and OS/390® operating systems, it is being provided now for compatibility as a wrapper to `<typeinfo>`.

The `typeinfo.h` header file contains definitions for types associated with the type identification operator `typeid`, which yields information about both static and dynamic types.

unexpected.h — Exception handling

The ISO/ANSI C++ Standard (ISO/IEC 14882:1998(E)) supersedes this header with the new header `<exception>`. However, `unexpected.h` remains for compatibility as a wrapper for a [target operating system release of z/OS V1R2 and later](#).

For compilations with a [target operating system release before z/OS V1R2](#), the `unexpected.h` header file, which is used for C++ exception handling, declares the `unexpected()` and `set_unexpected()` functions.

Chapter 3. Library functions

This topic describes the z/OS C/C++ runtime library functions, including the built-in library functions used by the IBM z/OS C/C++ compilers.

Names

Identifiers (function names, macros, types) defined by the various standards in the headers are reserved. Also reserved are:

- Identifiers that begin with an underscore and either an uppercase letter or another underscore.
- Identifiers that end with “_t”.

Do not use these reserved identifiers for any purpose other than those defined in the documentation.

All identifiers other than the ISO C identifiers comprise the *user's name space*. You are free to use any of these names. However, a number of names in the z/OS C/C++ runtime library encroach on the user's name space. This is a result of our desire to provide names that are meaningful and easy to remember, or to support industry-defined names, for example: `fetchep()` or `pthread_cancel()`. The header files cause these names to be renamed into reserved names and these in turn are mapped onto the external entry point names that usually are operating-system specific.

If you want to use names in the z/OS C/C++ runtime library that are in the user's name space as defined, just include the appropriate header. If you cannot include the appropriate header because it would bring in other names that collide with your own private names, but you still want to use some of the functions defined there, you can refer to these functions by their reserved internal names. These reserved names are unique, not longer than 8 characters, and usually start with a double underscore.

When long external names are not supported, the compiler automatically maps all underscores and lowercase letters in external identifiers in source code to ‘@’ characters and uppercase characters in the object deck. Thus, to refer to the `fetchep()` function without including the `stdlib.h` header, you can use its reserved internal name `__fetchep()`, which is then automatically mapped to the external entry point `@@FTCHEP`. For C++ functions, you must ensure C linkage by declaring the functions as `extern “C”`.

Functions that are mapped this way have the external entry point listed in the function description in this part under the heading, “External Entry Point”.

Related information

- See [#pragma csect and #pragma map](#) in *z/OS XL C/C++ Language Reference* for more information about external names.
- See [Prelinking and linking z/OS XL C/C++ programs](#) in *z/OS XL C/C++ User's Guide*.
- See [Naming conventions](#) in *z/OS XL C/C++ Programming Guide* for details about external names.

Unsupported functions and external variables in AMODE 64

All examples have been tested to work in 31-bit mode. Some examples might not work in 64-bit mode (AMODE 64). As examples are updated for AMODE 64, a statement of AMODE 64 support is added to the description of the example.

The following functions are not supported in AMODE 64:

- `advance()`
- `brk()`
- `compile()`

- `__console()`
- `__csplist`
- `ctdli()`
- `fortrc().__openMvsRel()`
- `__pcblist`
- `pthread_quiesce_and_get_np()`
- `re_comp()`
- `re_exec()`
- `regcmp()`
- `regex()`
- `sbrk()`
- `sock_debug_bulk_perf0()`
- `sock_do_bulkmode()`
- `step()`
- `tinit()`
- `tsched()`
- `tsetsubt()`
- `tsyncro()`
- `tterm()`
- `valloc()`

The following external variables are not supported in AMODE 64:

- `__loc1`
- `loc1`
- `loc2`
- `locs`

Standards

Each function description begins with a table to indicate the standards/extensions, language support, and dependencies.

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | | |

See the tables below for more details.

Standards and extensions

The "Standards / Extensions" column describes the supported standards and extensions.

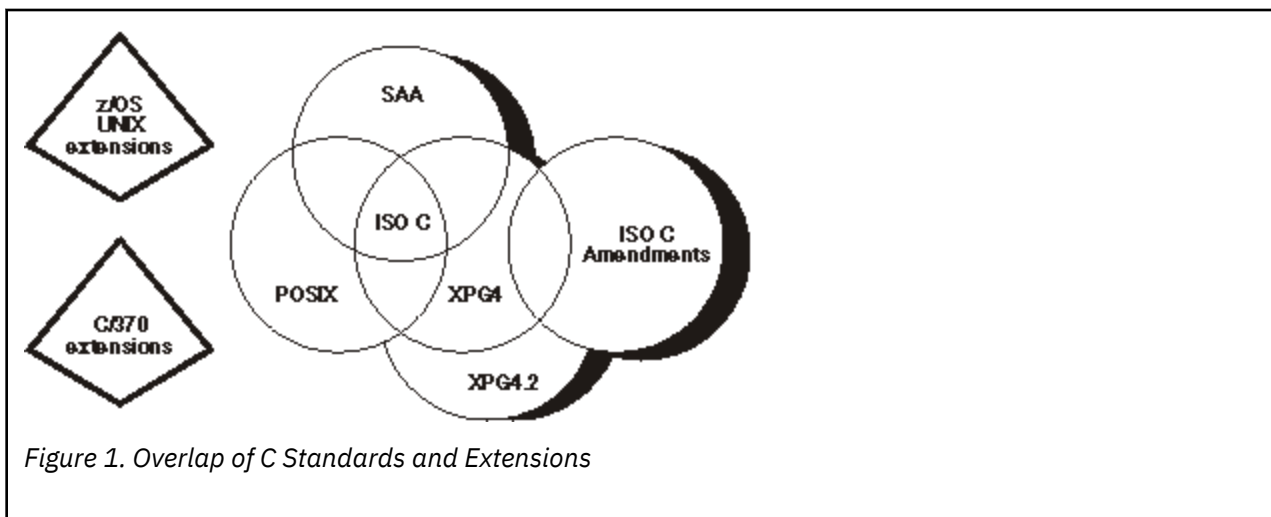

Note: By indicating a standard, we refer to the origin of the function, not necessarily the compliance. For example, functions that are enriched by features from XPG4 have XPG4 listed.

| Standards / Extensions | Refer to |
|------------------------|---|
| ISO C | ISO/IEC 9899:1990(E) |
| ISO C Amendment | A subset of the ISO/IEC 9899:1990/Amendment 1:1993(E) |
| POSIX.1 | ISO/IEC 9945-1:1990/IEEE POSIX 1003.1-1990 |

| Standards / Extensions | Refer to |
|--------------------------------------|--|
| POSIX.1a | A subset of IEEE POSIX 1003.1a, Draft 7, May 1992 |
| POSIX.2 | IEEE Portable Operating System Interface (POSIX) Part 2, P1003.2 draft 12 |
| POSIX.4a | A subset of IEEE POSIX 1003.4a, Draft 6, Feb. 26,1992 |
| POSIX.4b | A subset of IEEE 1003.4b |
| BSD 4.3 | Berkeley Software Distribution (BSD) 4.3 standard (also known as Berkeley sockets) |
| XPG4 | X/Open Common Applications Environment Specification, System Interfaces and Headers, Issue 4 |
| XPG4.2 | X/Open Common Applications Environment Specification, System Interfaces and Headers, Issue 4, Version 2 |
| SAA | IBM Systems Application Architecture® Common Programming Interface (SAA CPI) Level 2 definition of the C language |
| C Library | Functions that are extensions to the runtime library, before the Language Environment product |
| Language Environment | Functions that are extensions to the conventional standards |
| z/OS UNIX | Functions that provide z/OS UNIX support beyond the defined standards |
| Single UNIX Specification, Version 2 | IEEE Std 1003.1-1997 |
| Single UNIX Specification, Version 3 | IEEE Std 1003.1-2001 |
| ISO/ANSI C++ | ISO/ANSI C++ Standard (ISO/IEC 14882:1998(E)) |
| RFC2292 | Advanced Sockets API for IPv6 (draft-ietf-ipngwg-rfc2292bis-06.txt, dated February 25, 2002) Note: Not all of the support described in this draft is available on z/OS. |
| RFC2553 | Basic socket interface extensions for IPv6 (draft-ietf-ipngwg-rfc2253bis-05.txt, dated February 2002) Note: Not all of the support described in this draft is available on z/OS. |
| RFC3678 | Socket interface extensions for multicast source filters |
| ANSI/IEEE Standard P754 | IEEE standard for binary floating-point arithmetic |
| C99 | ISO/IEC 9899:1999(E) |

| Standards / Extensions | Refer to |
|----------------------------|--|
| C/C++ DFP | <ol style="list-style-type: none"> 1. ISO/IEC TR24732 -- Extensions for the programming language C to support decimal floating point arithmetic 2. ISO/IEC TR24733 -- Extensions for the programming language C++ to support decimal floating point arithmetic |
| C++ TR1 C99 | ISO/IEC DTR 19768 - Draft Technical Report on C++ library Extensions, chapter 8, C compatibility |
| C11 | ISO/IEC 9899:2011(E) |
| Runtime library extensions | Additional functions to the runtime library |

These standards do have some overlap, as illustrated in [Figure 1 on page 94](#).

The C library contains several functions that are extensions to the SAA CPI Level 2 definition. These library functions are available only with the runtime library extensions. As indicated, some of the *stub* routines for the extensions are available if they are ISO C/C++ compliant. They are made available for compatibility with Version 1; they may not be available in the future. (Within runtime libraries, a *stub routine* is a routine that contains the minimum lines of code required to locate a given routine at run time.)

Many of the symbols that are defined in headers are “protected” by a feature test macro. For information on the relationships between feature test macros and the standards, see [“Feature test macros” on page 3](#).

Language support

The "C or C++" column indicates the language support for each function.

| C or C++ | Description |
|----------|--|
| C only | The function is supported by the IBM z/OS C compiler only |
| C++ only | The function is supported by the IBM z/OS C++ compiler only. |
| both | The function is supported by both the IBM z/OS C and the IBM z/OS C++ compilers. |

Dependencies

The "Dependencies" column indicates the dependencies that are identified for each function. If the dependencies are not met, then the function fails, and returns an `errno` of `EMVSNORTL`. Functions defined by the standards that cannot fail, will cause abnormal termination and return Language Environment condition CEE5001.

| Dependencies | Description |
|--------------|--|
| POSIX(ON) | <ul style="list-style-type: none"> POSIX(ON) <i>required</i> refers to whether the enclave can run with the POSIX semantics. <p>POSIX is an application characteristic that is maintained at the enclave level. After you have established the characteristic during enclave initialization, you cannot change it.</p> <p>When you set POSIX to ON, you can use functions that are unique to POSIX, such as <code>pthread_create()</code>.</p> <p>One of the effects of POSIX(ON) is the enablement of POSIX signal handling semantics, which interact closely with the z/OS Language Environment condition handling semantics. Where ambiguities exist between ISO C/C++ and POSIX semantics, the POSIX runtime setting indicates that the POSIX semantics will be followed.</p> |

Using C include files from C++

If you need to use an old C header file in a C++ program, use `extern`, like this:

```
extern "C" {
    #include "myhdr.include"
}
```

Built-in functions

Built-in functions are ones for which the compiler generates inline code at compile time. Every call to a built-in function eliminates a runtime call to the function having the same name in the dynamic library.

Built-in functions are used by application code, while it is running, without reference to the dynamic library. Although built-in functions increase the size of a generated application slightly, this should be offset by the improved performance resulting from reducing the overhead of the dynamic calls. Built-in functions can be used with the System Programming C (SPC) Facilities to generate free-standing C applications.

Restriction: The SPC facility is not supported in AMODE 64.

Table 18 on page 96 shows all of the built-in functions. In the listing of library functions, each built-in function is labeled as such.

Table 18. Built-in library functions

| Built-in library functions | | | | |
|----------------------------|-----------|----------|-----------|-----------|
| abs() | alloca() | cabs() | cs() | decabs() |
| decchk() | decfix() | fabs() | fortrc() | memchr() |
| memcmp() | memcpy() | memset() | strcat() | strchr() |
| strcmp() | strcpy() | strlen() | strncat() | strncmp() |
| strncpy() | strrchr() | tsched() | wmemchr() | wmemcmp() |
| wmemcpy() | wmemset() | | | |

The built-in versions of these functions are accessed by preprocessor macros defined in the standard header files. They are not used unless the appropriate header file (such as `decimal.h`, `math.h`, `stdlib.h`, `string.h` or `wchar.h`) is included in the source file.

The built-in versions of functions `wmemchr()`, `wmemcmp()`, `wmemcpy()`, and `wmemset()` are only available under **ARCH(7)** when LP64 is not used.

Your program will use the built-in version of a standard function only if you include the associated standard header file. However, `decfix()`, `decabs()`, and `decchk()` are implemented only as built-in functions. They are not available without including the header file.

Note: When **NOOPT** or **COMPACT** is specified, the compiler might not expand all built-in functions.

If you are using the standard header file, but want to use the function in the dynamic library instead of the built-in function, you can force a call to the dynamic library by putting parentheses around the function name in your source code: `(memcpy)(buf1, buf2, len)`

The built-in functions are documented in [Using hardware built-in functions in z/OS XL C/C++ Programming Guide](#).

If you will never use the built-in version, you can also use `#undef` with the function name. For example, `#undef memcpy` causes all calls to `memcpy` in the compilation unit to make a dynamic call to the function rather than using the built-in version.

IEEE binary floating-point

Starting with OS/390 V2R6 (including the Language Environment and C/C++ components), support has been added for IEEE binary floating-point (IEEE floating-point) as defined by the ANSI/IEEE Standard 754-1985, IEEE Standard for Binary Floating-Point Arithmetic.

Notes:

1. You must have OS/390 Release 6 or higher to use the IEEE Binary Floating-Point instructions. In Release 6, the base control program (BCP) is enhanced to support the new IEEE Binary Floating-Point hardware in the IBM S/390® Generation 5 Server. This enables programs running on OS/390 Release 6 to use the IEEE Binary Floating-Point instructions and 16 floating-point registers. In addition, the BCP provides simulation support for all the new floating-point hardware instructions. This enables applications that make light use of IEEE Binary Floating-Point, and can tolerate the overhead of software simulation, to execute on OS/390 V2R6 without requiring an IBM S/390 Generation 5 Server.
2. The terms *binary floating point* and *IEEE binary floating point* are used interchangeably. The abbreviations BFP and HFP, which are used in some function names, refer to binary floating point and hexadecimal floating point respectively.
3. Under Hexadecimal Floating-Point format, the rounding mode is set to round toward 0. Under IEEE Binary Floating-Point format, the rounding mode is to round toward the nearest integer.

You can select the format of floating-point numbers that are produced in a compile unit to be either [IEEE floating point representation](#) or [hexadecimal floating point representation](#).

The C/C++ runtime library interfaces, which formerly supported only hexadecimal floating-point format, have been changed in OS/390 V2R6 to support both IEEE Binary Floating-Point and hexadecimal floating-point formats. These interfaces are documented in the *z/OS C/C++ Runtime Library Reference*.

The primary documentation for the IEEE Binary Floating-Point support is contained in *z/Architecture® Principles of Operation* and *z/OS XL C/C++ User's Guide*.

IEEE binary floating point support provides interoperability and portability between platforms. It is anticipated that the support will be most commonly used for new and ported applications and in emerging environments, such as Java. Customers should not migrate existing applications that use hexadecimal floating point to binary floating point, unless there is a specific reason.

IBM does not recommend mixing floating-point formats in an application. However, for applications which must handle both formats, the z/OS C/C++ runtime library does offer some support. Reference information for IEEE Binary Floating-Point can also be found in *z/OS XL C/C++ Language Reference*.

IEEE decimal floating-point

Starting with z/OS V1R9 (including the Language Environment and C/C++ components), support has been added for IEEE decimal floating-point as defined by the ANSI/IEEE Standard P754/D0.15.3, IEEE Standard for Floating-Point Arithmetic.

Note:

1. You must have z/OS V1R9 or higher to use IEEE decimal floating-point, the hardware must have the Decimal Floating Point Facility installed and the `__STDC_WANT_DEC_FP__` feature test macro must be defined.
2. The abbreviation DFP refers to IEEE decimal floating-point.
3. IEEE decimal floating-point is not supported in a CICS environment.

The compiler supports [IEEE decimal floating-point types](#). z/OS C/C++ runtime library interfaces, which support IEEE decimal floating-point numbers have been added for z/OS V1R9 and other existing interfaces have been updated to support DFP.

4. When one or more input values for a Decimal Floating Point (DFP) library function are not in the preferred Densely Packed Decimal (DPD) encoding, it is not defined whether or not the output values

are converted to the preferred DPD coding. Applications should not rely on the current behavior of library functions regarding the DPD recoding of output values.

Related information

- Reference information for IEEE floating-point can also be found in *z/OS XL C/C++ Language Reference*.
- The primary documentation for the IEEE decimal floating-point support is contained in *z/Architecture Principles of Operation* and *z/OS XL C/C++ User's Guide*.

External variables

The POSIX 1003.1 and X/Open CAE Specification 4.2 (XPG4.2) require that the C system header files define certain external variables. Additional variables are defined for use with POSIX or XPG4.2 functions. If you define one of the POSIX or XPG4 feature test macros and include one of these headers, the external variables will be defined in your program. These external variables are treated differently compared with other global variables in a multithreaded environment (values are thread-specific) and across a call to a fetched module (values are propagated).

To access the global variable values, the following must be specified during C/C++ compiles and z/OS bind:

Non-XPLINK (non-thread-safe)

To compile C code, the compiler must generate reentrant code for the code that is not naturally reentrant or generate object code for DLLs or DLL applications. The SCEEOBJ autocall library must be specified during the bind.

Non-XPLINK (thread-safe)

No additional options are required for either C or C++. The `_SHARE_EXT_VARS` feature test macro, or the necessary `_SHR_` prefixed feature test macros must be used.

Equivalently, the necessary thread-specific functions can be called directly (as documented below under each external variable).

XPLINK (non-thread-safe)

When you compile with XPLINK linkage, the C runtime library side-deck, member CELHS003 of the SCEELIB data set, must be included during the bind.

XPLINK (thread-safe)

When you compile with XPLINK linkage, the C runtime library side-deck, member CELHS003 of the SCEELIB dataset, must be included during the bind.

The `_SHARE_EXT_VARS` feature test macro, or the necessary `_SHR_` prefixed feature test macros must be used. Equivalently, the necessary thread-specific functions can be called directly (as documented in the later sections under each external variable).

LP64 (non-thread-safe)

When you compile in 64-bit addressing mode, the C runtime library side-deck, member CELQS003 of the SCEELIB dataset, must be included during the bind.

The `_SHARE_EXT_VARS` feature test macro, or the necessary `_SHR_` prefixed feature test macros must be used.

Equivalently, the necessary thread-specific functions can be called directly (as documented in the later sections under each external variable).

LP64 (thread-safe)

When you compile in 64-bit addressing mode, the C runtime library side-deck, member CELQS003 of the SCEELIB dataset, must be included during the bind.

The `_SHARE_EXT_VARS` feature test macro, or the necessary `_SHR_` prefixed feature test macros must be used.

Equivalently, the necessary thread-specific functions can be called directly (as documented in the later sections under each external variable).

Note: When you compile with XPLINK linkage or in 64-bit mode, z/OS UNIX invocation commands automatically include the side-deck.

errno

When a runtime library function fails, the function may do any of the following to identify the error:

- Set `errno` to a documented value.
- Set `errno` to a value that is not documented. You can use `strerror()` or `perror()` to get the message associated with the `errno`.
- Not set `errno`.
- Clear `errno`.

See also **errno.h**.

daylight

Daylight savings time flag set by `tzset()`. Note that other time zone sensitive functions such as `ctime()`, `localtime()`, `mktime()`, and `strftime()` implicitly call `tzset()`.

Note: Use the `__dlight()` function to access the thread-specific value of `daylight`.

See also `time.h`.

getdate_err

The variable is set to the value below when an error occurs in the `getdate()` function.

1. The `DATMSK` environment variable is `NULL` or undefined.
2. The template file cannot be opened for reading.
3. Failed to get file status information.
4. The template file is not a regular file.
5. An error was encountered while reading the template file.
6. Memory allocation failed (not enough memory available).
7. No line in the template file matches the input specification.
8. Non-valid input specification. For example, February 31; or a time that can not be represented in a `time_t` (representing the time is seconds since Epoch - midnight, January 1, 1970 (UTC)).
9. Unable to determine current time.

Any changes to `errno` are unspecified.

Note: This value is unique for z/OS UNIX.

The `getdate64()` interface affects the same pointer to the thread-specific value of `getdate_err` and uses the same `getdate_err` values as the `getdate()` interface.

Note: Use the `__gderr()` function to access the thread-specific value of `getdate_err`. The `getdate64()` function affects the same pointer to the thread-specific value of `getdate_err` as the `getdate()` function does.

See also `time.h`.

h_errno

An integer which holds the specific error code when the network name server encounters an error. The network name server is used by the `gethostbyname()` and `gethostbyaddr()` functions.

Notes:

- Use the `_h_errno()` function to access the thread-specific value of `h_errno`. See also `netdb.h`.
- This variable is kept for historical reasons. However, it is used only in connection with the functions `gethostbyaddr()` and `gethostbyname()`, which are obsolescent in Single UNIX Specification, Version 3, so that the `h_errno` variable may also be withdrawn in the future.

__loc1

Restriction: This external variable is not supported in AMODE 64

A global character pointer which is set by the `regex()` function to point to the first matched character in the input string. Use the `___loc1()` function to access the thread-specific value of `__loc1`.

Note: This variable is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use the interfaces supported by the `<regex.h>` header, which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001 Regular Expressions. See also `regex.h`.

If it is necessary to continue using this symbol in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3. See also `libgen.h`.

loc1

Restriction: This external variable is not supported in AMODE 64.

A pointer to characters matched by regular expressions used by `step()`. The value is not propagated across a call to a fetched module.

Note: This variable is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use the interfaces supported by the `<regex.h>` header, which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001 Regular Expressions. See also `regex.h`.

loc2

Restriction: This external variable is not supported in AMODE 64

A pointer to characters matched by regular expressions used by `step()`. The value is not propagated across a call to a fetched module.

Note: This variable is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use the interfaces supported by the `<regex.h>` header, which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001 Regular Expressions. See also `regex.h`.

locs

Restriction: This external variable is not supported in AMODE 64

Used by `advance()` to stop regular expression matching in a string. The value is not propagated across a call to a fetched module. See also `regex.h`.

Note: This variable is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use the interfaces supported by the `<regex.h>` header, which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001 Regular Expressions. See also `regex.h`.

optarg

Character pointer used by `getopt()` and `getopt_long()` for options parsing variables.

Notes:

- Use the `__opargf()` function to access the thread-specific value of `optarg`.
- This variable has been removed from `stdio.h` by Single UNIX Specification, Version 3 and is exposed for Version 3 only in `unistd.h`. See also `stdio.h` and `unistd.h`.

opterr

Error value used by `getopt()` and `getopt_long()`.

Notes:

- Use the `__operrf()` function to access the thread-specific value of `opterr`.
- This variable has been removed from `stdio.h` by Single UNIX Specification, Version 3 and is exposed for Version 3 only in `unistd.h`. See also `stdio.h` and `unistd.h`.

optind

Integer pointer used by `getopt()` and `getopt_long()` for options parsing variables.

Notes:

- Use the `__opindf()` function to access the thread-specific value of `optind`.
- This variable has been removed from `stdio.h` by Single UNIX Specification, Version 3 and is exposed for Version 3 only in `unistd.h`. See also `stdio.h` and `unistd.h`.

optopt

Integer pointer used by `getopt()` and `getopt_long()` for options parsing variables.

Notes:

- Use the `__opoptf()` function to access the thread-specific value of `optopt`.
- This variable has been removed from `stdio.h` by Single UNIX Specification, Version 3 and is exposed for Version 3 only in `unistd.h`. See also `stdio.h` and `unistd.h`.

signgam

Storage for sign of `lgamma()`. This function defaults to thread-specific. See also `math.h`.

stderr

Standard Error stream. The external variable will be initialized to point to the enclave-level stream pointer for the standard error file. There is no multithreaded function. See also `stdio.h`.

stdin

Standard Input stream. The external variable will be initialized to point to the enclave-level stream pointer for the standard input file. There is no multithreaded function. See also `stdio.h`.

stdout

Standard Output stream. The external variable will be initialized to point to the enclave-level stream pointer for the standard output file. There is no multithreaded function. See also `stdio.h`.

t_errno

An integer which holds the specific error code when a failure occurs in one of the X/Open Transport Interface (XTI) functions. Use the `__t_errno()` function to access the thread-specific value of `t_errno`.

Note: Use the `__t_errno()` function to access the thread-specific value of `t_errno`.

See also `xti.h`.

timezone

Long integer difference from UTC and standard time as set by `tzset()`. Note that other time zone sensitive functions such as `ctime()`, `localtime()`, `mktime()`, and `strftime()` implicitly call `tzset()`.

Note: Use the `__tzone()` function to access the thread-specific value of `timezone`.

See also `time.h`.

tzname

Character pointer to unsized array of timezone strings used by `tzset()` and `ctime()`. The `*tzname` variable contains the Standard and Daylight Savings time zone names. If the TZ environment variable is present and correct, `tzname` will be set from TZ. Otherwise `tzname` will be set from the LC_TOD locale category. See the `tzset()` function for a description. There is no multithreaded function. See also `time.h`.

The `__restrict__` macro

The `restrict` keyword is being made available in the form of a macro named `__restrict__` that can be used for coding before the availability of a compiler that is designed to support C99. Once the compiler support is available, only a recompile is necessary. Applications need to include `<features.h>` before using the `__restrict__` macro.

The `__NORETURN` macro

The `_Noreturn` keyword is being made available in the form of a macro named `__NORETURN`. Applications need to include `<features.h>` before using the `__NORETURN` macro.

The `__noreturn__` macro

The `_Noreturn` keyword is being made available in the form of a macro named `__noreturn__`, which can be used for coding before the availability of a compiler that is designed to support C11. Once the compiler support is available, only a recompile is necessary. Applications need to include `<features.h>` before using the `__noreturn__` macro.

Note: Open XL C/C++ for z/OS reserves `__noreturn__` as a keyword. To avoid name conflict, `__noreturn__` is not defined as a macro in `features.h` for Open XL C/C++ for z/OS.

abort() — Stop a program

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 C11 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdlib.h>

__noreturn__ void abort(void);
```

General description

Causes an abnormal program termination and returns control to the host environment. The `abort()` function flushes all buffers and closes all open files. Be aware that abnormal termination will *not* run the `atexit()` list functions.

If the `abort()` function is called and the user has a handler for `SIGABRT`, then `SIGABRT` is raised; however, `SIGABRT` is raised again when the handler associated with the default action is returned. The code path only passes through the user's handler once, even if the handler is reset. The same thing occurs if `SIGABRT` is ignored; abnormal termination occurs.

The `abort()` function will not result in program termination if `SIGABRT` is caught by a signal handler, and the signal handler does not return. You can avoid returning by “jumping” out of the handler with `setjmp()` and `longjmp()`. In IBM z/OS C programs, you can jump out of the handler with `sigsetjmp()` and `siglongjmp()`.

For more information see the process termination sections in the chapter “Using Runtime User Exits” in [z/OS XL C/C++ Programming Guide](#).

Special behavior for POSIX C: To obtain access to the special POSIX behavior for `abort()`, the POSIX runtime option must be set ON.

Calls to `abort()` raise the `SIGABRT` signal, using `pthread_kill()`, so that the signal is directed to the same thread. A `SIGABRT` signal generated by `abort()` cannot be blocked.

Under POSIX, the handler can use `siglongjmp()` to restore the environment at a place in the code where a `sigsetjmp()` was previously issued. In this way, an application can avoid the process for termination.

Special behavior for C++: If `abort()` is called from a IBM z/OS C++ program, the program will be terminated immediately, without leaving the current block. Functions passed to `atexit()`, and destructors for static and local (automatic) objects, will not be called.

By default, the IBM z/OS C++ function `terminate()` calls `abort()`.

Returned value

The abnormal termination return code for z/OS is 2000.

Example

CELEBA01

```
/* CELEBA01

This example tests for successful opening of the file myfile.
If an error occurs, an error message is printed and the program
ends with a call to the abort() function.

*/
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    FILE *stream;
    unlink("myfile.dat");
    if ((stream = fopen("myfile.dat", "r")) == NULL)
    {
        printf("Could not open data file\n");
        abort();
    }
    printf("Should not see this message\n");
}
}
```

abs(), absf(), absl() – Calculate integer absolute value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 C/C++ DFP C++ TR1 C99 | both | |

Format

```
#include <stdlib.h>

int abs(int n);
long abs(long n);           /* C++ only */

#include <math.h>

double abs(double n);       /* C++ only */
float abs(float n);         /* C++ only */
long double abs(long double n); /* C++ only */
float absf(float n);
long double absl(long double n);
```

DFP:

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 abs(_Decimal32 x); /* C++ only */
_Decimal64 abs(_Decimal64 x); /* C++ only */
_Decimal128 abs(_Decimal128 x); /* C++ only */
```

C++ TR1 C99:

```
#define _TR1_C99
#include <inttypes.h>
intmax_t abs(intmax_t n);

#define _TR1_C99
#include <stdlib.h>
long long abs(long long n);
```

General description

The functions `abs()`, `absf()`, and `absl()` return the absolute value of an argument *n*.

For the integer version of `abs()`, the minimum allowable integer is `INT_MIN+1`. (`INT_MIN` is a macro that is defined in the `limits.h` header file.) For example, with the IBM z/OS C/C++ compiler, `INT_MIN+1` is `-2147483648`.

For the double, float, and long double versions of `abs()`, the minimum allowable values are `DBL_MIN+1`, `FLT_MIN+1`, and `LDBL_MIN+1`, respectively. (The floating-point macro constants are defined in the `float.h` header file.)

If the value entered cannot be represented as an integer, the `abs()`, `absf()`, and `absl()` functions return the same value.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

Special behavior for C++: For C++ applications, `abs()` is also overloaded for the types `long`, `float`, and `long double`.

Returned value

The returned value is the absolute value, if the absolute value is possible to represent.

Otherwise the input value is returned.

There are no `errno` values defined.

Example

CELEBA02

```
/* CELEBA02

   This example calculates the absolute value of an integer
   x and assigns it to y.

*/
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    int x = -4, y;

    y = abs(x);
    printf("The absolute value of %d is %d.\n", x, y);
}
```

Output

The absolute value of -4 is 4.

accept() — Accept a new connection on a socket

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int accept(int socket, struct sockaddr *__restrict__ address,
           socklen_t *__restrict__ address_len);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>

int accept(int socket, struct sockaddr *address, int *address_len);
```

General description

The `accept()` call is used by a server to accept a connection request from a client. When a connection is available, the socket created is ready for use to read data from the process that requested the connection. The call accepts the first connection on its queue of pending connections for the given socket *socket*. The `accept()` call creates a new socket descriptor with the same properties as *socket* and returns it to the caller. If the queue has no pending connection requests, `accept()` blocks the caller unless *socket* is in nonblocking mode. If no connection requests are queued and *socket* is in nonblocking mode, `accept()` returns -1 and sets the error code to EWOULDBLOCK. The new socket descriptor cannot be used to accept new connections. The original socket, *socket*, remains available to accept more connection requests.

Parameter

Description

socket

The socket descriptor.

address

The socket address of the connecting client that is filled in by `accept()` before it returns. The format of *address* is determined by the domain that the client resides in. This parameter can be NULL if the caller is not interested in the client address.

address_len

Must initially point to an integer that contains the size in bytes of the storage pointed to by *address*. On return, that integer contains the size required to represent the address of the connecting socket. If this value is larger than the size supplied on input, then the information contained in `sockaddr` is truncated to the length supplied on input. If *address* is NULL, *address_len* is ignored.

The *socket* parameter is a stream socket descriptor created with the `socket()` call. It is usually bound to an address with the `bind()` call. The `listen()` call marks the socket as one that accepts connections and allocates a queue to hold pending connection requests. The `listen()` call places an upper boundary on the size of the queue.

The *address* parameter is a pointer to a buffer into which the connection requester's address is placed. The *address* parameter is optional and can be set to be the NULL pointer. If set to NULL, the requester's address is not copied into the buffer. The exact format of *address* depends on the addressing domain from which the communication request originated. For example, if the connection request originated in the AF_INET domain, *address* points to a **sockaddr_in** structure, or if the connection request originated in the AF_INET6 domain, *address* points to a **sockaddr_in6** structure. The **sockaddr_in** and **sockaddr_in6** structures are defined in `netinet/in.h`. The *address_len* parameter is used only if the address is not NULL. Before calling `accept()`, you must set the integer pointed to by *address_len* to the size of the buffer, in bytes, pointed to by *address*. On successful return, the integer pointed to by *address_len* contains the actual number of bytes copied into the buffer. If the buffer is not large enough to hold the address, up to *address_len* bytes of the requester's address are copied. If the actual length of the address is greater than

the length of the supplied **sockaddr**, the stored address is truncated. The **sa_len** member of the store structure contains the length of the untruncated address.

Notes:

1. This call is used only with SOCK_STREAM sockets. There is no way to screen requesters without calling `accept()`. The application cannot tell the system the requesters from which it will accept connections. However, the caller can choose to close a connection immediately after discovering the identity of the requester.
2. The `accept()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support”](#) on page 2123 for details.

A socket can be checked for incoming connection requests using the `select()` call.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` 1 feature test macro.

Returned value

If successful, `accept()` returns a nonnegative socket descriptor.

If unsuccessful, `accept()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EAGAIN

If during an `accept` call that changes identity, the UID of the new identity is already at MAXPROCUID, the `accept` call fails.

EBADF

The *socket* parameter is not within the acceptable range for a socket descriptor.

EFAULT

Using *address* and *address_len* would result in an attempt to copy the address into a portion of the caller's address space into which information cannot be written.

EINTR

A signal interrupted the `accept()` call before any connections were available.

EINVAL

`listen()` was not called for socket descriptor *socket*.

EIO

There has been a network or transport failure.

EMFILE

An attempt was made to open more than the maximum number of file descriptors allowed for this process.

EMVSEERR

Two consecutive `accept` calls that cause an identity change are not allowed. The original identity must be restored (`close()` the socket that caused the identity change) before any further accepts are allowed to change the identity

ENFILE

The maximum number of file descriptors in the system are already open.

ENOBUFS

Insufficient buffer space is available to create the new socket.

ENOTSOK

The *socket* parameter does not refer to a valid socket descriptor.

EOPNOTSUPP

The socket type of the specified socket does not support accepting connections.

EWOULDBLOCK

The socket descriptor *socket* is in nonblocking mode, and no connections are in the queue.

Example

The following are two examples of the `accept()` call. In the first, the caller wishes to have the requester's address returned. In the second, the caller does not wish to have the requester's address returned.

```
int clientsocket;
int s;
struct sockaddr clientaddress;
int address_len;
int accept(int s, struct sockaddr *addr, int *address_len);
/* socket(), bind(), and listen()
have been called */
/* EXAMPLE 1: I want the address now */
address_len = sizeof(clientaddress);
clientsocket = accept(s, &clientaddress, &address_len);
/* EXAMPLE 2: I can get the address later using getpeername() */
clientsocket = accept(s, (struct sockaddr *) 0,
(int *) 0);
```

accept4() — Accept a new connection on a socket

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int accept4(int sockfd, struct sockaddr *addr, socklen_t *addrlen, int flags);
```

General description

`accept4()` is used by a server to accept a connection request from a client. When a connection is available, the created socket is ready for use to read data from the process that requests the connection. The call accepts the first connection on its queue of pending connections for the given *socket*. `accept4()` creates a new socket descriptor with the same properties as *socket* and returns it to the caller. If the queue has no pending connection requests, `accept4()` blocks the caller unless *socket* is in nonblocking mode. If no connection requests are queued and *socket* is in nonblocking mode, `accept4()` returns -1 and sets the error code to `EWOULDBLOCK`. The new socket descriptor cannot be used to accept new connections. The original *socket* remains available to accept more connection requests. `accept4()` extends the `accept()` function by accepting the `SOCK_CLOEXEC` and `SOCK_NONBLOCK` flags.

Parameter

Description

socket

The socket descriptor

address

The socket address of the connecting client that is filled in by `accept4()` before it returns. The format of *address* is determined by the domain that the client resides in. This parameter can be NULL if the caller is not interested in the client address.

address_len

Must initially point to an integer that contains the size in bytes of the storage pointed to by *address*. On return, that integer contains the size that is required to represent the address of the connecting socket. If this value is larger than the size that is supplied on input, then the information that is contained in *sockaddr* is truncated to the length that is supplied on input. If *address* is NULL, *address_len* is ignored.

flags

If *flags* is 0, then `accept4()` is the same as `accept()`. The following values can be bitwise ORed in *flags* to obtain different behavior:

SOCK_NONBLOCK

Set the `O_NONBLOCK` file status flag on the new open file description. Using this flag saves extra calls to `fcntl()` to achieve the same result.

SOCK_CLOEXEC

Set the `close-on-exec` (`FD_CLOEXEC`) flag on the new file descriptor. See the description of the `O_CLOEXEC` flag in [open\(\)](#) for more information.

The *socket* parameter is a stream socket descriptor that is created with the `socket()` call. It is bound to an address with the `bind()` call. The `listen()` call marks the socket as one that accepts connections and allocates a queue to hold pending connection requests. The `listen()` call places an upper boundary on the size of the queue.

The *address* parameter is a pointer to a buffer into which the connection requester's address is placed. The *address* parameter is optional and can be set to be the NULL pointer. If set to NULL, the requester's address is not copied into the buffer. The exact format of *address* depends on the addressing domain from which the communication request originated. For example, if the connection request originated in the `AF_INET` domain, *address* points to a `sockaddr_in` structure, or if the connection request originated in the `AF_INET6` domain, *address* points to a `sockaddr_in6` structure. The `sockaddr_in` and `sockaddr_in6` structures are defined in `netinet/in.h`. The *address_len* parameter is used only if *address* is not NULL. Before calling `accept4()`, you must set the integer pointed to by *address_len* to the size of the buffer, in bytes, pointed to by *address*. On successful return, the integer pointed to by *address_len* contains the actual number of bytes that are copied into the buffer. If the buffer is not large enough to hold the address, up to *address_len* bytes of the requester's address are copied. If the actual length of the address is greater than the length of the supplied `sockaddr`, the stored address is truncated. The `sa_len` member of the store structure contains the length of the untruncated address.

Note: `accept4()` is used only with `SOCK_STREAM` sockets. There is no way to screen requesters without calling `accept4()`. The application cannot tell the system the requesters from which it accepts connections. However, the caller can choose to close a connection after discovering the identity of the requester.

A socket can be checked for incoming connection requests by using `select()`.

Returned value

If successful, `accept4()` returns a nonnegative socket descriptor.

If unsuccessful, `accept4()` returns -1 and sets `errno` to one of the following values:

Error Code**Description****EAGAIN**

If during an `accept` call that changes identity, the UID of the new identity is already at `MAXPROCUID`, the `accept` call fails.

EBADF

The *socket* parameter is not within the acceptable range for a socket descriptor.

EFAULT

Using *address* and *address_len* can result in an attempt to copy the address into a portion of the caller's address space into which information cannot be written.

EINTR

A signal interrupts the `accept4()` call before any connections are available.

EINVAL

`listen()` is not called for socket descriptor *socket*.

EIO

There is a network or transport failure.

EMFILE

An attempt is made to open more than the maximum number of file descriptors that are allowed for this process.

EMVSERR

Two consecutive `accept` calls that cause an identity change are not allowed. The original identity must be restored by closing the socket that caused the identity change before any further accepts are allowed to change the identity.

ENFILE

The maximum number of file descriptors in the system are already open.

ENOBUFS

Insufficient buffer space is available to create the new socket.

ENOTSOCK

The *socket* parameter does not refer to a valid socket descriptor.

EOPNOTSUPP

The socket type of the specified socket does not support accepting connections.

EWouldBlock

The socket descriptor *socket* is in nonblocking mode, and no connections are in the queue.

accept_and_recv() — Accept connection and receive first message

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

X/Open:

```
#define _OPEN_SYS_SOCKET_EXT2
#include <sys/socket.h>

int accept_and_recv(int socket, int *accept_socket,
                   struct sockaddr *remote_address,
                   socklen_t *remote_address_len,
                   struct sockaddr *local_address,
                   socklen_t *local_address_len,
                   void *buffer, size_t buffer_len);
```

General description

The `accept_and_recv()` function extracts the first connection on the queue of pending connections. It either reuses the specified socket (if **accept_socket* is not -1) or creates a new socket with the same socket type, protocol, and address family as the listening socket (if **accept_socket* is -1). It then returns the first block of data sent by the peer and returns the local and remote socket addresses associated with the connection.

The function takes the following arguments:

Parameter Description

socket

Specifies a socket that was created with `socket()`, has been bound to an address with `bind()`, and has issued a successful call to `listen()`.

accept_socket

Pointer to an `int` which specifies the socket on which to accept the incoming connection. The socket must not be bound or connected. Use of this parameter lets the application reuse the accepting socket. It is possible that the system may choose to reuse a different socket than the one the application specified by this argument. In this case, the system will set **accept_socket* to the socket actually reused.

A value of -1 for **accept_socket* indicates that the accepting socket should be assigned by the system and returned to the application in this parameter. It is recommended that a value of -1 be used on the first call to `accept_and_recv()`. For more details, see [“Usage notes” on page 113](#).

remote_address

Either a NULL pointer or a pointer to a `sockaddr` structure where the address of the connecting socket will be returned.

remote_address_len

Points to a `socklen_t`. On input, this specifies the length of the supplied `sockaddr` structure. On output, this contains the length of the stored address.

local_address

Either a NULL pointer or a pointer to a `sockaddr` structure where the address of the local socket will be returned.

local_address_len

Points to a `socklen_t`. On input, this specifies the length of the supplied `sockaddr` structure. On output, this contains the length of the stored address.

buffer

Either a NULL pointer, or a pointer to a buffer where the message should be stored. If this is a NULL pointer, no receive is performed, and `accept_and_recv()` completes when the incoming connection is received.

buffer_len

Specifies the length in bytes of the buffer pointed to by the *buffer* argument.

If **accept_socket* is not -1, the incoming connection will be accepted on the socket specified by **accept_socket*. The system may choose to reuse a different socket. If it does, the system will change **accept_socket* to reflect the socket actually used.

If *remote_address* is not a NULL pointer, the address of the peer for the accepted connection is stored in the *sockaddr* structure pointed to by *remote_address*, and the length of this address is stored in the object pointed to by *remote_address_len*. If the actual length of the address is greater than the length of the supplied socket address structure, the stored address will be truncated.

If *local_address* is not a NULL pointer, the address of the local socket associated with this connection is stored in the *sockaddr* structure pointed to by *local_address*, and the length of this address is stored in the object pointed to by *local_address_len*. If the actual length of the address is greater than the length of the supplied socket address structure, the stored address will be truncated.

Nonblocking mode is not supported for this function. If *O_NONBLOCK* is set on the socket file descriptor, the function will return with -1 and *errno* will be set to *EOPNOTSUPP*.

If the listen queue is empty of connection requests, *accept_and_recv()* will not return until an incoming connection is received.

If *buffer* is not NULL, *accept_and_recv* will not return until the first block of data on the connection has been received, otherwise *accept_and_recv()* returns 0 after the connection is established.

Note: The *accept_and_recv()* function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support”](#) on page 2123 for details.

Usage notes

1. On the first call to *accept_and_recv()*, it is recommended that the application set the socket pointed to by *accept_socket* to -1. This will cause the system to assign the accepting socket. The application then passes the assigned value into the next call to *accept_and_recv()* (by setting *accept_socket = socket_ptr*).

To take full advantage of the performance improvements offered by the *accept_and_recv()* function, a process/thread model different from the one where a parent accepts in a loop and spins off child process threads is needed. The parent/process thread is eliminated. Multiple worker processes/threads are created, and each worker process/thread then executes the *accept_and_recv()* function in a loop. The performance benefits of *accept_and_recv()* include fewer buffer copies, recycled sockets, and optimal scheduling.

Returned value

If successful, *accept_and_recv()* returns the number of bytes (zero or more) stored in the buffer pointed to by the *buffer* argument. Zero can be returned when *buffer* is NULL or when the client closes the socket without sending any data.

A partial success is achieved with **accept_socket* being assigned, a return value of -1 and *errno* set to one of the following values:

| | |
|-------------------|--------------------|
| Error Code | Description |
|-------------------|--------------------|

EINTRNODATA

The *accept_and_recv()* function was interrupted by a signal that was caught after a valid connection was established, but before the first block of data arrived.

EWOULDBLOCK

A new connection was established, but the *SO_RCVTIMEO* timeout value was reached before data was available.

If unsuccessful, *accept_and_recv()* sets **accepted_socket* to -1, returns -1 and sets *errno* to one of the following values:

**Error Code
Description****EBADF**

One of two errors occurred:

1. *socket* is not a valid descriptor.
2. *accept_socket* does not point to a valid descriptor.

ECONNABORTED

A connection has been aborted.

ECONNRESET

A connection was forcibly closed by a peer.

EFAULT

The data buffer pointed to by *accept_socket*, *remote_address*, *remote_address_len*, *local_address*, *local_address_len*, or *buffer* was not valid.

EINTR

The `accept_and_recv()` function was interrupted by a signal that was caught before a valid connection was established.

EINVAL

The *socket* is not accepting connections.

EIO

An I/O error occurred.

EISCONN

The *accept_socket* is either bound or connected already.

EMFILE

OPEN_MAX descriptors are already open in the calling process.

ENOBUFS

No buffer space is available.

ENOMEM

There was insufficient memory available to complete the operation.

ENOREUSE

Socket reuse is not supported.

ENOSR

There were insufficient STREAMS resources available for the operation to complete.

ENOTSOCK

The *socket* argument does not refer to a socket, or *accept_socket* does not point to a socket.

EOPNOTSUPP

One of errors occurred:

1. The type of the socket does not support accepting connections.
2. O_NONBLOCK is set for the socket and nonblocking is not supported for this function.

access() — Determine whether a file can be accessed

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

int access(const char *pathname, int how);
```

General description

Determines how a z/OS UNIX file can be accessed. When checking to see if a process has appropriate permissions, `access()` looks at the *real* user ID (UID) and group ID (GID), not the effective IDs.

pathname is the name of the file whose accessibility you want to test. The *how* argument indicates the access modes you want to test. The following symbols are defined in the `unistd.h` header file for use in the *how* argument:

F_OK

Tests whether the file exists.

R_OK

Tests whether the file can be accessed for reading.

W_OK

Tests whether the file can be accessed for writing.

X_OK

Tests whether the file can be accessed for execution.

You can take the bitwise inclusive-OR of any or all of the last three symbols to test several access modes at once. If you are using `F_OK` to test for the file's existence, you cannot use OR with any of the other symbols.

Returned value

If the specified access is permitted, `access()` returns 0.

If the given file cannot be accessed in the specified way, `access()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

The process does not have appropriate permissions to access the file in the specified way, or does not have search permission on some component of the *pathname* prefix.

EINVAL

The value of *how* is incorrect.

ELOOP

A loop exists in the symbolic links.

ENAMETOOLONG

pathname is longer than **PATH_MAX** characters. The **PATH_MAX** value is determined using `pathconf()`.

ENOENT

There is no file named *pathname*, or the *pathname* argument is an empty string.

ENOTDIR

Some component of the *pathname* prefix is not a directory.

EROFS

The argument *how* has specified write access for a file on a read-only file system.

Returned value for POSIX C

The following `errno` values behave differently when a program is running with `POSIX(ON)`:

Error Code**Description****ELOOP**

A loop exists in the symbolic links. This error is issued if the number of symbolic links detected in the resolution is greater than `POSIX_SYMLINK` (a value defined in the `limits.h` header file).

ENAMETOOLONG

pathname is longer than **PATH_MAX** characters, or some component of *pathname* is longer than **NAME_MAX**, when `_POSIX_NO_TRUNC` (defined in the `unistd.h` header file) is in effect. The **PATH_MAX** and **NAME_MAX** values are determined using `pathconf()`.

Example**CELEBA03**

```
/* CELEBA03
   The following example determines how a file is accessed.
*/

#define _POSIX_SOURCE
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
    char path[]="/";

    if (access(path, F_OK) != 0)
        printf("%s' does not exist!\n", path);
    else {
        if (access(path, R_OK) == 0)
            printf("You have read access to '%s'\n", path);
        if (access(path, W_OK) == 0)
            printf("You have write access to '%s'\n", path);
        if (access(path, X_OK) == 0)
            printf("You have search access to '%s'\n", path);
    }
}
```

Output: From a non-superuser:

```
You have read access to '/'
You have search access to '/'
```

acl_create_entry() — Add a new extended ACL entry to the ACL

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R3 |

Format

```
#define _OPEN_SYS    1
#include <sys/acl.h>

int acl_create_entry(lacl_t *acl_p, acl_entry_t entry_p, int version);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. ACLs are supported by the z/OS UNIX, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See [z/OS UNIX System Services Planning](#) for details.

The `acl_create_entry()` function creates a new extended ACL entry in the ACL pointed to by the contents of the pointer argument `acl_p`. The contents of the `acl_entry` are specified by `entry_p`. ACL working storage is allocated as needed. The first call to `acl_get_entry()` following the call to `acl_create_entry()` will obtain the first extended ACL entry in the ACL, as ordered by the system.

The version tells the function the version of ACL entry. See “[sys/acl.h — Manipulate ACL](#)” on page 67 for ACL entry mapping.

Returned value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the `acl_create_entry()` function returns -1 and sets `errno` to the corresponding value:

Error Code

Description

EINVAL

Argument `acl_p` does not point to a pointer to an ACL structure. Argument `entry_d` does not point to a valid extended ACL entry.

ENOMEM

The ACL working storage requires more memory than is available.

Related information

- “[sys/acl.h — Manipulate ACL](#)” on page 67

acl_delete_entry() – Delete an extended ACL entry from the ACL

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R3 |

Format

```
#define _OPEN_SYS 1
#include <sys/acl.h>

int acl_delete_entry(lacl_t acl_d, acl_entry_t entry_d);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. ACLs are supported by the z/OS UNIX, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See [z/OS UNIX System Services Planning](#) for details.

The `acl_delete_entry()` function removes the extended ACL entry indicated by `entry_d` in the ACL pointed to by argument `acl_d`. The first call to `acl_get_entry()` following the call to `acl_delete_entry()` will obtain the first extended ACL entry in the ACL, as ordered by the system.

Returned value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the `acl_delete_entry()` function returns -1 and sets `errno` to the corresponding value:

Error Code

Description

EINVAL

Argument `acl_d` does not point to a pointer to an ACL structure. Argument `entry_d` does not point to a valid extended ACL entry or not within the given ACL structure.

Related information

- [“sys/acl.h — Manipulate ACL” on page 67](#)

acl_delete_fd() – Delete an ACL by file descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R3 |

Format

```
#define _OPEN_SYS 1
#include <sys/acl.h>
```

```
int    acl_delete_fd (int fd, int type_d);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. ACLs are supported by the z/OS UNIX, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See [z/OS UNIX System Services Planning](#) for details.

The `acl_delete_fd()` function deletes the `type_d` ACL. That means that all extended ACL entries are deleted for `type_d` ACL. A file/dir subject must match the owner of the directory/file or the subject must have appropriate privileges.

The effective UID of the process must match the owner of the directory/file or the process must have appropriate privileges. If the `type_d` is the directory/file default and the object referred to by `fd` is not a directory, then the function will fail. An attempt to delete an ACL from a file that does not have that ACL is not considered an error.

Upon successful completion, the `acl_delete_fd()` will delete the type ACL associated with the file referred by argument `fd`. If unsuccessful, the type ACL associated with the file object referred by argument `fd` will not be changed.

Returned value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the `acl_delete_fd()` function returns -1 and sets `errno` to the corresponding value:

Error Code

Description

EBADF

The `fd` argument is not a valid file descriptor.

EINVAL

Argument `type_d` is not a valid ACL type.

ENOTDIR

The type specifies directory/file default ACL and the argument `fd` does not refer to a directory object.

EACCES

The process does not have appropriate privilege to delete the type ACL.

Related information

- [“sys/acl.h — Manipulate ACL” on page 67](#)
- [“acl_delete_file\(\) — Delete an ACL by file name” on page 119](#)

[acl_delete_file\(\) — Delete an ACL by file name](#)

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R3 |

Format

```
#define _OPEN_SYS    1
#include <sys/acl.h>

int    acl_delete_file (const char *path_p, int type_d);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. ACLs are supported by the z/OS UNIX, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See [z/OS UNIX System Services Planning](#) for details.

The `acl_delete_file()` function deletes the *type_d* ACL. That means that all extended ACL entries are deleted for *type_d* ACL. A file/directory always has base ACL entries so they cannot be deleted. The effective UID of the process must match the owner of the directory/file or the process must have appropriate privileges.

If the *type_d* is the directory/file default and the object referred to by *fd* is not a directory, then the function will fail. An attempt to delete an ACL from a file that does not have that ACL is not considered an error.

Upon successful completion, the `acl_delete_file()` will delete the type ACL associated with the file referred by argument *path_p*. If unsuccessful, the type ACL associated with the file object referred by argument *path_p* will not be changed.

Returned value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the `acl_delete_file()` function returns -1 and sets `errno` to the corresponding value:

Error Code

Description

EACCES

Search permission is denied for a component of the path prefix or the object exists and the subject does not have appropriate access rights.

EINVAL

Argument *type_d* is not a valid ACL type.

ENAMETOOLONG

The length of the path name argument exceeds `PATH_MAX`, or a path name component is longer than `NAME_MAX` and `{_POSIX_NO_TRUNC}` is in effect for that file. For symbolic links, the length of the path name string substituted for a symbolic link exceeds `PATH_MAX`. `PATH_MAX` and `NAME_MAX` values can be determined by using `pathconf()`.

ENOENT

The named object does not exist or the *path_p* argument points to an empty string.

ENOTDIR

The type specified was directory/file default but the argument *path_p* is not a directory or a component of the path prefix is not a directory.

Related information

- [“sys/acl.h — Manipulate ACL” on page 67](#)
- [“acl_delete_fd\(\) — Delete an ACL by file descriptor” on page 118](#)

acl_first_entry() – Return to beginning of ACL working storage

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R3 |

Format

```
#define _OPEN_SYS    1
#include <sys/acl.h>

int    acl_first_entry (lacl_t acl_d);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. ACLs are supported by the z/OS UNIX, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See [z/OS UNIX System Services Planning](#) for details.

A call to `acl_first_entry()` sets the internal ACL entry offset descriptor for the `acl_d` argument such that a subsequent call to `acl_get_entry()` using the same `acl_d` argument obtains the first extended ACL entry in the ACL.

Returned value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the `acl_init()` function returns -1 and sets `errno` to the corresponding value:

Error Code

Description

EINVAL

Argument `acl_d` does not point to an ACL structure.

Related information

- [“sys/acl.h – Manipulate ACL” on page 67](#)
- [“acl_get_entry\(\) – Get an ACL entry” on page 124](#)

acl_free() – Release memory allocated to an ACL data object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R3 |

Format

```
#define _OPEN_SYS    1
#include <sys/acl.h>
```

```
int      acl_free (lacl_t acl_d);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. ACLs are supported by the z/OS UNIX,TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See [z/OS UNIX System Services Planning](#) for details.

The `acl_free()` function frees any releasable memory currently allocated to the ACL data object identified by `acl_d`. Use of the object reference pointed to by `acl_d` after the memory has been released is undefined.

Returned value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the `acl_free()` function returns -1 and sets `errno` to the corresponding value:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

EINVAL
The value of the `acl_d` argument is not valid.

Related information

- [“sys/acl.h — Manipulate ACL” on page 67](#)
- [“acl_init\(\) — Initialize ACL working storage” on page 128](#)

acl_from_text() — Create an ACL from text

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R3 |

Format

```
#define _OPEN_SYS      1
#include <sys/acl.h>

int      acl_from_text (const char *buf_p, short OpType, acl_all_t ptr, char **ret);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. ACLs are supported by the z/OS UNIX, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See [z/OS UNIX System Services Planning](#) for details.

The `acl_from_text()` function converts the text form of an ACL referred to by `buf_p` into the `acl_t` form of an ACL. It parses both the extended and base ACL entries.

If successful, the structure that `ptr` points to will be updated with ACL entries for the 3 types of ACLs. The structure members that `ptr` points to must either be NULL or point to a valid `acl_t` structure. If the

structure member is not NULL, ACL entries contained in *buf_p* will be merged in. New storage for those structure members may be allocated as needed and in that case passed-in storage will be freed, so structure members may point to a different storage than the one originally supplied.

If *ptr* is NULL, the *acl_from_text* will fail. If the *buf_p* has no ACL entries (such as empty string, only empty lines, etc), *acl_from_text()* will fail with *errno* set to *EINVAL* and *ret* will point to the null terminator in *buf_p*.

Working storage is allocated for the individual ACLs structures as needed and need to be freed using *acl_free()*.

If the function is unsuccessful due to error encountered in parsing, *ret* will contain the address of beginning of extended/base ACL entry where the error was found in *buf_p* and *errno* will be set to *EINVAL*. Otherwise *ret* will be NULL.

The text form of the ACL referred to by *buf_p* may be incomplete or may be a non-valid ACL as defined by *acl_valid()*. The *buf_p* must be null terminated. The first call to *acl_get_entry()* following the call to *acl_from_text()* obtains the first entry in the ACL as ordered by the system.

For *OpType* = *ACL_DELETE*, the extended ACL entries will be updated with the flag bit to be removed from the ACL when *acl_set_fd()* or *acl_set_file()* is called. The base ACL entries are parsed but not put into the structure that *ptr* points to since you cannot delete base ACL entries.

The *buf_p* cannot have a mixture of ACL entry delimiters (newline and comma). All ACL entries in the *buf* must use the same delimiter, either a newline or comma. For a mixture of delimiters, *acl_from_text()* will fail with *errno* set to *EINVAL* and *ret* parameter will point to the delimiter in error.

acl_all_t :

index 0

access acl

index 1

file default acl

index 2

directory default acl

Valid text input format based on *OpType*:

tag

fdefault, default (access if nothing is specified)

type

user, group, other

id

uid, gid, username, groupname

perm

rxw (or '-' for no permission), octal (0-7) , +/^ (where + is turn on and ^ is turn off)

Pound sign (#) is used to designate a comment. When the input is separated by commas, everything past # is treated as a comment. When the input is separated by a newline, everything after # till the newline is considered a comment. Comments are ignored and are not stored in the buffer.

```
ACL_ADD      tag:type:id:perm    // extended ACL entry
ACL_MODIFY   type::perm          // base ACL entry
ACL_DELETE   tag:type:id         // extended ACL entry
```

Note: The extended ACL entries must have the type (group or user) and the id (uid/gid). The base ACL entries do not have a value for the id field. The id field or the lack of one is what distinguishes the base ACL entry from the extended ACL entry. The base ACL entries do not have the tag fields since they only apply to access ACL.

The `acl_from_text()` allows for trailing ACL entry separator (newline or comma). For relative permission settings, only one of '+' or '^' is allowed per ACL entry. When using relative permissions you must have at least one of r, w, or x. For example: +rw or ^rwx.

Returned value

Upon successful completion, the function returns a zero.

If any of the following conditions occur, the `acl_from_text()` function returns -1 and sets `errno` to the corresponding value:

Error Code

Description

EINVAL

Argument `buf_p` cannot be translated into an ACL.

ENOMEM

The ACL working storage requires more memory than is available.

E2BIG

The number of base ACL entries exceeded allowable 3.

The `ret` will contain the address in `buf_p` where the error was found.

Related information

acl_get_entry() — Get an ACL entry

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R3 |

Format

```
#define _OPEN_SYS    1
#include <sys/acl.h>

int    acl_get_entry (lacl_t acl_d, acl_entry_t *entry_p);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. ACLs are supported by the z/OS UNIX, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See [z/OS UNIX System Services Planning](#) for details.

The `acl_get_entry()` function obtains a descriptor to the next extended ACL entry of the ACL indicated by argument `acl_d`. Upon successful execution, the `acl_get_entry()` function returns a descriptor for the extended ACL entry via `entry_p`. Argument `acl_d` must refer to a valid `acl_t` structure.

The first call to `acl_get_entry()` following a call to `acl_first_entry()`, `acl_from_text()`, `acl_get_fd()`, `acl_get_file()`, `acl_set_fd()`, `acl_set_file()`, or `acl_valid()` obtains the first extended ACL entry in the ACL, as ordered by the system. Subsequent calls to `acl_get_entry()` obtain successive extended ACL entries, until

the last entry is obtained. After the last extended ACL entry has been obtained from the *acl_d* the value NULL is returned via *entry_p*.

To determine if ACL has any base ACL entries, check *acl_d->lacl_base*, which gives the number of base ACL entries present. Then the process can access the base ACL entries directly in the *acl_d*. (For example: *acl_d->lacl_base_entries[0].acl_type* is the type field of the first base ACL entry.)

Returned value

If the function successfully obtains a pointer to the extended ACL entry, the function returns a value of one. If the last extended ACL entry in the ACL has already been returned by a previous call to *acl_get_entry()* or if ACL has no extended ACL entries, the function returns a value of zero.

If any of the following conditions occur, the *acl_get_entry()* function returns -1 and sets *errno* to the corresponding value:

Error Code Description

EINVAL

Argument *acl_d* does not point to an ACL structure.

acl_get_fd() — Get ACL by file descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R3 |

Format

```
#define _OPEN_SYS 1
#include <sys/acl.h>

int  acl_get_fd (int fd, acl_type_t type_d, lacl_t acl_d, int *num);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. ACLs are supported by the z/OS UNIX, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See [z/OS UNIX System Services Planning](#) for details.

The *acl_get_fd()* function retrieves an ACL based on *type_d* argument for an object associated with the file descriptor *fd*. The ACL is retrieved into the supplied working storage pointed to by *acl_d*. For the *type_d* = *ACL_ACCESS*, *acl_get_fd()* will get both the base ACL entries and extended ACL entries. (The base ACL entries only apply to the *ACL_ACCESS* ACL.)

The working storage should be allocated using the *acl_init()* function. If the buffer is not big enough, the *acl_get_fd()* will fail with *errno*=*E2BIG* and *num* will be filled with the number of ACLs in the ACL pointed to by *fd*. The user can get a bigger *acl_t* structure buffer using the *num* value and reissue the *acl_get_fd()*.

If the object associated with the file descriptor does not have the specified ACL, then an ACL containing zero ACL entries will be returned. If the argument *fd* refers to an object other than a directory and the value of *type_d* is a directory/file default, then the function will fail.

The first call to `acl_get_entry()` following the call to `acl_get_fd()` obtains the first extended ACL entry in the ACL as ordered by the system.

The result of `acl_get_fd()` can be used to set that same ACL using `acl_set_fd()` or `acl_set_file()` using `OpType = ACL_ADD`.

Returned value

Upon successful completion, the function returns 0.

If any of the following conditions occur, the `acl_get_fd()` function returns a value of NULL and sets `errno` to the corresponding value:

Error Code
Description

EACCES
The required access to the file referred to by *fd* is denied.

EBADF
The *fd* argument is not a valid file descriptor.

EINVAL
Argument *type_d* is not a valid ACL type. Argument *acl_d* does not point to an ACL structure.

ENOTDIR
The type specified was directory/file default but the argument *fd* does not refer to a directory.

E2BIG
The supplied buffer is too small for all extended ACL entries. *num* value has the number of ACL entries that need to fit in the buffer.

acl_get_file() — Get ACL by file name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R3 |

Format

```
#define _OPEN_SYS    1
#include <sys/acl.h>

int  acl_get_file (const char *path_p, acl_type_t type_d, lacl_t acl_d, int *num);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. ACLs are supported by the z/OS UNIX, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See [z/OS UNIX System Services Planning](#) for details.

The `acl_get_file()` function retrieves an ACL based on *type_d* argument for an object associated with the object via file name. The ACL is retrieved into the specified working storage pointed to by *acl_d*. For the *type_d* = `ACL_ACCESS`, `acl_get_file()` will get both the base ACL entries and extended ACL entries. The base ACL entries only apply to the `ACL_ACCESS` ACL.

The working storage should be allocated using the `acl_init()` function. If the buffer is not big enough, the `acl_get_fd()` will fail with `errno=E2BIG` and *num* will be filled with the number of ACLs in the ACL pointed to by *fd*. The user can get a bigger `acl_t` structure buffer using the *num* value and reissue the `acl_get_fd()`.

If the object associated with the file descriptor does not have the specified ACL, then an ACL containing zero ACL entries will be returned. If the argument *fd* refers to an object other than a directory and the value of *type_d* is a directory/file default, then the function will fail.

The first call to `acl_get_entry()` following the call to `acl_get_fd()` obtains the first extended ACL entry in the ACL as ordered by the system. The result of `acl_get_fd()` can be used to set that same ACL using `acl_set_fd()` or `acl_set_file()` using `OpType = ACL_ADD`.

Returned value

Upon successful completion, the function returns 0.

If any of the following conditions occur, the `acl_get_file()` function returns a value of NULL and sets `errno` to the corresponding value:

Error Code

Description

EACCES

Search permission is denied for a component of the path prefix or the object exists and the subject does not have appropriate access rights.

EINVAL

Argument *type_d* is not a valid ACL type. Argument *acl_d* does not point to an ACL structure.

ENAMETOOLONG

The length of the path name argument exceeds `PATH_MAX`, or a path name component is longer than `NAME_MAX` and `{_POSIX_NO_TRUNC}` is in effect for that file. For symbolic links, the length of the path name string substituted for a symbolic link exceeds `PATH_MAX`. `PATH_MAX` and `NAME_MAX` values can be determined by using `pathconf()`.

ENOENT

The named object does not exist or the *path_p* argument points to an empty string.

ENOTDIR

The type specified was directory/file default but the argument *path_p* is not a directory or a component of the path prefix is not a directory.

E2BIG

The supplied buffer is too small for all extended ACL entries. *Num* value has the number of ACL entries that need to fit in the buffer.

acl_init() — Initialize ACL working storage

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R3 |

Format

```
#define _OPEN_SYS    1
#include <sys/acl.h>

lacl_t  acl_init (int count);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. ACLs are supported by the z/OS UNIX, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See [z/OS UNIX System Services Planning](#) for details.

The `acl_init()` function allocates and initializes working storage for an ACL of at least *count* extended ACL entries. A pointer to the working storage is returned. The working storage allocated to contain the ACL must be freed by a call to `acl_free()`. The working storage contains an ACL with no ACL entries. The count must be greater than 0.

The `acl_init()` function initializes fields in the *lacl_t* it returns. When those fields are destroyed (for example, using `memset` or overwriting storage), the results are unpredictable. To re-use the buffer, `acl_entry_delete()` all extended ACL entries and set `lacl_base = 0` or `acl_free()` the existing buffer and `acl_init()` for a new one.

Returned value

Upon successful completion, the function returns a pointer to the working storage.

If any of the following conditions occur, the `acl_init()` function returns NULL and sets `errno` to the corresponding value:

Error Code

Description

ENOMEM

The *lacl_t* to be returned requires more memory than is available.

EINVAL

The count is less than or equal to zero.

acl_set_fd() – Set an ACL by file descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R3 |

Format

```
#define _OPEN_SYS    1
#include <sys/acl.h>

int    acl_set_fd (int fd, acl_type_t type_d, lacl_t acl_d, short OpType,
                  acl_entry_t *entry_p);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. ACLs are supported by the z/OS UNIX, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See [z/OS UNIX System Services Planning](#) for details.

The `acl_set_fd()` function associates the `type_d` ACL with the object referred to by `fd`. The effective UID of the subject must match the owner of the object or the subject must have appropriate privileges.

If the `type_d` is the directory/file default and the object referred to by `fd` is not a directory, then the function will fail.

The `acl_set_fd()` function will succeed only if the ACL is valid as defined by the `acl_valid()` function.

Upon successful completion, `acl_set_fd()` will set the ACL of the object. For `type_d = ACL_ACCESS`, `acl_set_fd()` will also set the base ACL entries. The base ACL entries only apply to `ACL_ACCESS` ACL type, so for any other type the base ACL entries are ignored.

The `OpType` determines whether the ACL is updated or replaced.

OpType

Action

ACL_ADD

replace the whole ACL with the given extended and base ACL entries

ACL_MODIFY

update the ACL with the given extended and/or base ACL entries (if individual extended ACL entries are marked for deletion, then `ACL_MODIFY` removes them)

ACL_DELETE

delete from the ACL the specified extended ACL entries; marks the individual extended ACL entries for deletion (cannot delete base ACL entries)

If `OpType` is `ACL_MODIFY`, the setting will modify the existing extended ACL entries and add new ones if they do not exist. Both ACL entry's mask and value are used to determine ACL entry's permission to set.

If `OpType` is `ACL_ADD`, the existing ACL is replaced by the new one. Only extended ACL entry's value is used to determine permissions to set. The object's previous ACL will no longer be in effect. If the object had no ACL, a new one is added for both `ACL_MODIFY` and `ACL_ADD`.

Similarly, for `OpType = ACL_ADD`, base ACL entries are replaced with the new values specified (mask field is ignored). All three base ACL entries (`ACL_USER`, `ACL_GROUP`, and `ACL_OTHER`) must be specified. For `OpType = ACL_MODIFY`, the base ACL entries are modified with the specified values (both mask and value fields are used).

For Optype = ACL_MODIFY only the base ACL entries to be changed need to be specified. The Optype = ACL_DELETE does not apply to base ACL entries since they cannot be removed. Every file always has base ACL entries.

If the `acl_set_fd()` is unsuccessful, the ACL of the object referred to by argument *fd* is not changed.

The ordering of entries within ACL referred to by *acl_d* may be changed. The first call to `acl_get_entry()` following the call to `acl_set_fd()` obtains the first extended ACL entry in the ACL as ordered by the system.

Returned value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the `acl_set_file()` function returns a value of -1 and sets `errno` to the corresponding value:

Error Code

Description

EACCES

Search permission is denied for a component of the path prefix or the object exists and the subject does not have appropriate access rights.

E2BIG

The ACL has more extended ACL entries than is allowed.

ENOENT

The named object does not exist or the *path_p* argument points to an empty string.

EINVAL

Argument *acl_d* does not point to a valid ACL structure.

ENOSPC

The directory or file system that would contain the new ACL cannot be extended or the file system is out of space.

ENOTDIR

The *type_d* specified was directory/file default but the argument *path_p* does not refer to a directory.

ENAMETOOLONG

The length of the path name argument exceeds PATH_MAX, or a path name component is longer than NAME_MAX and {_POSIX_NO_TRUNC} is in effect for that file. For symbolic links, the length of the path name string substituted for a symbolic link exceeds PATH_MAX. PATH_MAX and NAME_MAX values can be determined by using `pathconf()`.

EMVSERR

Other internal RACF error (more information in `errno2`)

The function will return -2 and set `errno` to EINVAL if the base ACL entry is not unique or is not a valid type or for ACL_ADD, there are less than 3 base ACL entries. The *entry_p* will be NULL.

The function will return -3 and set `errno` to EINVAL if the extended ACL entry is not unique or is not a valid type. The *entry_p*, if not NULL, will point to the extended ACL entry in error.

acl_sort() – Sort the extended ACL entries

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R3 |

Format

```
#define _OPEN_SYS 1
#include <sys/acl.h>

int acl_sort(lacl_t acl_d);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. ACLs are supported by the z/OS UNIX, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See [z/OS UNIX System Services Planning](#) for details.

The `acl_sort()` function sorts the extended ACL entries in the following orders:

- ACL_USER lowest to highest uid
- ACL_GROUP lowest to highest gid

Returned value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the `acl_sort()` returns -1 and sets `errno` to the corresponding value:

Error Code

Description

EINVAL

Argument `acl_d` does not point to a valid ACL structure.

acl_to_text() – Convert an ACL to text

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R3 |

Format

```
#define _OPEN_SYS 1
#include <sys/acl.h>
```

```
char *    acl_to_text (const lacl_t acl_d, ssize_t *len_p, acl_type_t type_d,
                     char delim);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. ACLs are supported by the z/OS UNIX, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See [z/OS UNIX System Services Planning](#) for details.

The `acl_to_text()` function translates the extended ACL entries in an ACL pointed to by argument `acl_d` into a NULL terminated character string. This function allocates any memory necessary to contain the string and returns a pointer to the string. The memory allocated to contain the string must be freed. If the pointer `len_p` is not NULL, then the function returns the full length of the string (not including the NULL terminator) in the location pointed to by `len_p`. The `delim` parameter determines the delimiter used to separate the ACL entries (usually newline or comma).

The mask field in the base and extended ACL entry is ignored and only the ACL entry value field is used to display the ACL entry permissions.

For `acl_d` with no extended ACL entries, `acl_to_text()` returns NULL. When `acl_to_text()` cannot convert uid/gid to username/groupname, it leaves the uid/gid in the string.

The format of the text string:

```
<acl_entry>delim<acl_entry> ... <acl_entry>
```

where `acl_entry` may be:

```
base_acl_tag::permissions
user:user_name:permissions
group:group_name:permissions
default:user_name:permissions
```

base_acl_entry:
user, group, or other

permissions:
rwx (with '-' for no permission)

default:
fdefault - file default
default - directory default

Returned value

Upon successful completion, the function returns a pointer to the text form of an ACL.

If any of the following conditions occur, the `acl_to_text()` returns NULL and sets `errno` to the corresponding value:

| | |
|-------------------|--------------------|
| Error Code | Description |
|-------------------|--------------------|

| | |
|---------------|--|
| EINVAL | Argument <code>acl_d</code> does not point to a valid ACL structure. The ACL referenced by <code>acl_d</code> contains one or more improperly formed ACL entries, or for some other reason cannot be translated into the string form of ACL. |
|---------------|--|

| | |
|---------------|---|
| ENOMEM | The character string to be returned requires more memory than is available. |

acl_update_entry() — Update the extended ACL entry

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R3 |

Format

```
#define _OPEN_SYS    1
#include <sys/acl.h>

int acl_update_entry(lacl_t acl_d, acl_entry_t entry_s, acl_entry_t entry_d
                    int version);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the z/OS UNIX, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See *z/OS UNIX System Services Planning* for details.

The `acl_update_entry()` function updates the extended ACL entry `entry_s` with the values from `entry_d`. The `version` tells the function the version of ACL entry. See [“sys/acl.h — Manipulate ACL” on page 67](#) for ACL entry mapping.

Returned value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the `acl_create_entry()` function returns -1 and sets `errno` to the corresponding value:

Error Code

Description

EINVAL

Argument `entry_s` or `entry_d` do not point to a valid extended ACL entry. Argument `acl_d` does not point to a valid ACL structure.

Related information

- [“sys/acl.h — Manipulate ACL” on page 67](#)

acl_valid() – Validate an ACL

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R3 |

Format

```
#define _OPEN_SYS    1
#include <sys/acl.h>

int    acl_valid (lacl_t acl_d, acl_entry_t *entry_p);
```

General description

Use access control lists (ACLs) in conjunction with permission bits to control access to files and directories. Currently, ACLs are supported by the z/OS UNIX, TFS, and zFS file systems. You must know whether your security product supports ACLs and what rules are used when determining file access. See *z/OS UNIX System Services Planning* for details.

The `acl_valid()` function checks the access ACL, file default ACL, or directory default ACL referred to by the argument `acl_d` for validity.

The ACL_USER, ACL_GROUP, and ACL_OTHER can only exist once in base ACL entries. The ACL_OTHER only applies to base ACL entries.

The tag type (user, group) must contain valid values for the extended ACL entries. The qualifier field (uid, gid) must be unique among all extended ACL entries of the same ACL except for the extended ACL entries that are mapped for deletion (see ACL entry mapping in “[sys/acl.h – Manipulate ACL](#)” on page 67 for more information). The ordering of base and/or extended ACL entries within ACL referred by the `acl_d` may be changed.

The first call to `acl_get_entry()` following the call to `acl_valid()` obtains the first extended ACL entry in the ACL as ordered by the system.

Returned value

Upon successful completion, the function returns a value of zero.

If any of the following conditions occur, the location referred to by `entry_p` will be undefined and the `acl_valid()` function returns -1 and sets `errno` to the corresponding value:

Error Code

Description

EINVAL

Argument `acl_d` does not point to an ACL structure.

If any of the following conditions occur, the `acl_valid()` function will set the location referred to by `entry_p` to one of the ACL entries in error, return -2 and set `errno` to the appropriate value.

Error Code

Description

EINVAL

The ACL contains extended ACL entries that are not unique or is not a valid ACL entry type.

If any of the following conditions occur, the `acl_valid()` function will return -3 and set `errno` to the appropriate value.

Error Code

Description

EINVAL

The ACL contains base ACL entries that are not unique or is not a valid ACL entry type. Only one base ACL entry of the same tag type (ACL_USER, ACL_GROUP, ACL_OTHER) may exist.

acos(), acosf(), acosl() — Calculate arccosine

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#include <math.h>

double acos(double x);
float  acos(float x);           /* C++ only */
long double acos(long double x); /* C++ only */
float  acosf(float x);
long double acosl(long double x);
```

General description

Calculates the arccosine of x , expressed in radians, in the range 0 to π .

The value of x must be between -1 and 1 inclusive.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

Returned value

Special behavior for C/370: If x is less than -1 or greater than 1, the function sets `errno` to `EDOM` and returns 0. If the correct value would cause underflow, zero is returned and the value `ERANGE` is stored in `errno`.

Special behavior for XPG4.2: If successful, the function returns the arccosine of x , in the range $[0, \pi]$ radians.

If the value of x is not in the range $[-1,1]$, the function returns 0.0 and sets `errno` to the following value. No other errors will occur.

| Error Code | Description |
|------------|-------------|
|------------|-------------|

| | |
|-------------|--|
| EDOM | The value x is not in the range $[-1,1]$. |
|-------------|--|

Special behavior for IEEE: If successful, the function returns the arccosine of the argument x .

If x is less than -1 or greater than 1, the function sets `errno` to `EDOM` and returns `NaNQ` (Not a Number Quiet). No other errors will occur.

Example

CELEBA04

```

/* CELEBA04

   This example prompts for a value for x.
   It prints an error message if x is greater than 1 or
   less than -1; otherwise, it assigns the arccosine of
   x to y.

   */
#include <stdio.h>
#include <stdlib.h>
#include <math.h>
#define MAX 1.0
#define MIN -1.0

int main(void)
{
    double x, y;

    printf( "Enter x\n" );
    scanf( "%lf", &x );

    /* Output error if not in range */
    if ( x > MAX )
        printf( "Error: %f too large for acos\n", x );
    else if ( x < MIN )
        printf( "Error: %f too small for acos\n", x );
    else {
        y = acos( x );
        printf( "acos( %f ) = %f\n", x, y );
    }
}

```

Output

Expected result if 0.4 is entered:

```

Enter x
acos( 0.400000 ) = 1.159279

```

long double acoshl(long double x);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>
float acosh(float x);
long double acosh(long double x);
```

General description

The acosh functions compute the (nonnegative) arc hyperbolic cosine of x . A domain error occurs for arguments less than 1.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------|-----|------|
| acosh | X | X |
| acoshf | X | X |
| acoshl | X | X |

Returned value

If successful, `acosh()` returns the hyperbolic arccosine of its argument x .

If the value of x is less than 1.0, then the function returns 0.0 and sets `errno` to `EDOM`.

Special behavior for IEEE: If successful, the function returns the hyperbolic arccosine of its argument x .

If x is less than 1.0, the function sets `errno` to `EDOM` and returns `NaNQ`.

advance() — Pattern match given a compiled regular expression

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4 XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE
#include <regex.h>

int advance(const char *string, const char *expbuf);

extern char *loc2, *locs;
```

General description

Restriction: This function is not supported in AMODE 64.

The `advance()` function attempts to match an input string of characters with the compiled regular expression which was obtained by an earlier call to `compile()`.

The first parameter *string* is a pointer to a string of characters to be checked for a match.

expbuf is the pointer to the regular expression which was previously obtained by a call to `compile()`.

The external variable *loc2* will point to the next character in *string* after the last character that matched the regular expression.

The external variable *locs* can be optionally set to point to some point in the input regular expression string to cause the `advance()` function to exit its back up loop.

Note: The external variables *cirf*, *sed*, and *nbra* are reserved.

During the pattern matching operation, when `advance()` encounters a `*` or `{\}` sequence in the regular expression, it will advance its pointer to the string to be matched as far as possible and will recursively call itself trying to match the rest of the string to the rest of the regular expression. As long as there is no match, `advance()` will back up along the string until it finds a match or reaches the point in the string that

initially matched the * or `{\}`. It is sometime desirable to stop this backing up before the initial point in the string is reached. If the external character pointer *locs* is equal to the point in the string at some time during the back up process, `advance()` will break out of the loop that backs up and will return 0 (a failure indication).

Notes:

1. The application must provide the proper serialization for the `compile()`, `step()`, and `advance()` functions if they are run under a multithreaded environment.
2. The `compile()`, `step()`, and `advance()` functions are provided for historical reasons. These functions were part of the Legacy Feature in Single UNIX Specification, Version 2. They have been withdrawn and are not supported as part of Single UNIX Specification, Version 3. New applications should use the newer functions `fnmatch()`, `glob()`, `regcomp()` and `regexexec()`, which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001.

Returned value

If the initial substring of *string* matches the regular expression in *expbuf*, `advance()` returns nonzero.

If there is no match, `advance()` returns 0.

If there is a match, `advance()` sets an external character pointer, *loc2*, as a side effect. The variable *loc2* points to the next character in *string* after the last character that matched the regular expression.

`__ae_correstbl_query()` — Return coded character set ID type (ASCII and EBCDIC)

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R2 |

Format

```
#include <_Nascii.h>

__argument_t __ae_correstbl_query(void *search_argument, int src_arg_type,
                                   _AE_correstbl_t **ebcdic_entry_ptr,
                                   _AE_correstbl_t **ascii_entry_ptr);
```

General description

The `__ae_correstbl_query()` function is a method by which the user can obtain coded character set id (CCSID), type, and correspondence information from the EBCDIC/ASCII Correspondence and CCSID/Codeset Name Lookup Table, CEL4CTBL.

The user must provide the following:

Argument

Description

*search_argument

A Codeset Name or CCSID search argument.

src_arg_type

Specifies whether *search_argument* is a Codeset Name or a CCSID, using one of the defined values from `<_Nascii.h>`:

- `_AE_CODESET_SRCH_ARG`
- `_AE_CCSID_SRCH_ARG`

**ebcdic_entry_ptr

The address of an `_AE_correstbl_t` pointer for storing the EBCDIC table entry.

**ascii_entry_ptr

The address of an `_AE_correstbl_t` pointer for storing the ASCII table entry.

The function will then populate the supplied pointers with the address of `_AE_correstbl_t` structures containing the requested codeset's table entry as well as the address of the corresponding codeset's entry. However, not every EBCDIC codeset in the table has a corresponding ASCII encoding and vice versa. When a corresponding codeset does not exist, the pointer value returned in that argument is zero.

For consistency, the first `_AE_correstbl_t` pointer address argument will be populated with the EBCDIC entry address, and the second `_AE_correstbl_t` pointer will be populated with the ASCII entry address, regardless of which was the requested codeset and which was the corresponding codeset.

The `__argument_t` return value for `__ae_correstbl_query()` indicates the EBCDIC or ASCII type of the provided codeset.

Returned value

If successful, `__ae_correstbl_query()` returns either:

- `_AE_EBCDIC_TYPE`, when the requested entry is EBCDIC.
- `_AE_ASCII_TYPE`, when the requested entry is ASCII.

If unsuccessful, because the correspondence table cannot be loaded or the provided Codeset Name or CCSID is not valid, `__ae_correstbl_query()` returns `_AE_UNKNOWN_TYPE`.

aio_cancel() – Cancel an asynchronous I/O request

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 | both | OS/390 V2R7 |

Format

```
#define _XOPEN_SOURCE 500
#include <aio.h>

int aio_cancel(int fildev, struct aiocb *aiocbp);
```

General description

The `aio_cancel()` function attempts to cancel one or more asynchronous I/O requests currently outstanding against file descriptor *fildev*. The *aiocbp* argument points to an *aiocb* structure for a particular request to be canceled or is NULL to cancel all outstanding cancelable requests against *fildev*.

Normal asynchronous notification occurs for asynchronous I/O operations that are successfully canceled. The associated error status is set to ECANCELED and the return status is set to -1 for the canceled requests.

For requests that cannot be canceled, the normal asynchronous completion process takes place when their I/O completes. In this case the *aiocb* is not modified by `aio_cancel()`.

An asynchronous operation is cancelable if it is currently blocked or becomes blocked. Once an outstanding request can be completed it is allowed to complete. For example, an `aio_read()` will be cancelable if there is no data available at the time that `aio_cancel()` is called.

fildev must be a valid file descriptor, but when *aiocbp* is not NULL *fildev* does not have to match the file descriptor with which the asynchronous operation was initiated. For maximum portability, though, it should match.

The `aio_cancel()` function always waits for the request being canceled to either complete or be canceled. When control returns from `aio_cancel()`, the program may safely free the original request's *aiocb* and buffer. If a signal was specified on the original request, the signal handler for that request's I/O complete notification may run before, during, or after control returns from `aio_cancel()`, so coordination may be necessary between the signal handler and the caller of `aio_cancel()`. This is particularly unpredictable when `aio_cancel()` is called from a different thread than the original request, unless the original thread no longer exists.

Canceling all requests on a given descriptor does not stop new requests from being made or otherwise affect the descriptor. The program may start again or close the descriptor depending on why it issued the cancel.

An individual request can only be canceled once. Subsequent attempts to explicitly cancel the same request will fail with EALREADY.

Returned value

`aio_cancel()` returns one of the following values:

- AIO_CANCELED if the requested operations were canceled.
- AIO_NOTCANCELED if at least one of the requested operations cannot be canceled because it is in progress.

In this case, the state of the other operations, if any, referenced in the call to `aio_cancel()` is not indicated by the return value of `aio_cancel()`. The application can determine the status of these operations by using `aio_error()`.

- `AIO_ALLDONE` if all of the operations have already completed. This is returned when there are no outstanding requests found that match the criteria specified. This is also the result returned when a file associated with *fildev* does not support the asynchronous I/O function because there are no outstanding requests to be found that match the criteria specified.
- `-1` if there was an error. `aio_cancel()` sets `errno` to one of the following values:

Error Code

Description

EALREADY

The operation to be canceled is already being canceled.

EBADF

The *fildev* argument is not a valid file descriptor.

aio_error() — Retrieve error status for an asynchronous I/O operation

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 | both | OS/390 V2R7 |

Format

```
#define _XOPEN_SOURCE 500
#include <aio.h>

int aio_error(const struct aiocb *aiocbp);
```

General description

The `aio_error()` function returns the error status associated with the *aiocb* structure referenced by the *aiocbp* argument. The error status for an asynchronous I/O operation is the `errno` value that would be set by the corresponding `read()`, or `write()` operation. If the operation has not yet completed, then the error status will be equal to `EINPROGRESS`.

Returned value

If the asynchronous I/O operation has completed successfully, `aio_error()` returns 0.

If the asynchronous I/O operation has completed unsuccessfully, `aio_error()` returns the error status as described for `read()`, or `write()`.

If the asynchronous I/O operation has not yet completed, then `EINPROGRESS` is returned.

`aio_error()` does not set `errno`.

When the `errno` is returned is not `EINPROGRESS` and not zero, the `errno2` set by either `read()` or `write()` can be retrieved by using the `__errno2()` function.

aio_read() — Asynchronous read from a socket

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 | both | OS/390 V2R7 |

Format

```
#define _XOPEN_SOURCE 500
#include <aio.h>

int aio_read(struct aiocb *aiocbp);
```

General description

The `aio_read()` function initiates an asynchronous read operation as described by the `aiocb` structure (the asynchronous I/O control block).

The `aiocbp` argument points to the `aiocb` structure. This structure contains the following members:

- aio_fildes**
file descriptor
- aio_offset**
file offset
- aio_buf**
location of buffer
- aio_nbytes**
length of transfer
- aio_reqprio**
request priority offset
- aio_sigevent**
signal number and value
- aio_lio_opcode**
operation to be performed

The operation reads up to *aio_nbytes* from the socket or file associated with *aio_fildes* into the buffer pointed to by *aio_buf*. The call to *aio_read()* returns when the request has been initiated or queued to the file or device (even when the data cannot be delivered immediately).

Asynchronous I/O is currently only supported for sockets. The *aio_offset* field may be set but it will be ignored.

With a stream socket an asynchronous read may be completed when the first packet of data arrives and the application may have to issue additional reads, either asynchronously or synchronously, to get all the data it wants. A datagram socket has message boundaries and the operation will not complete until an entire message has arrived.

The *aiocbp* value may be used as an argument to *aio_error()* and *aio_return()* functions in order to determine the error status and return status, respectively, of the asynchronous operation. While the operation is proceeding, the error status retrieved by *aio_error()* is *EINPROGRESS*; the return status retrieved by *aio_return()* however is unpredictable.

If an error condition is encountered during the queueing, the function call returns without having initiated or queued the request.

When the operation completes asynchronously the program can be notified by a signal as specified in the *aio_sigevent* structure. It is significantly more efficient to receive these notifications with *sigwaitinfo()* or *sigtimedwait()* than to let them drive a signal handler. At this time the return and error status will have been updated to reflect the outcome of the operation. The *sigevent* structure's notification function fields are not supported. If a signal is not desired the program can occasionally poll the *aiocb* with *aio_error()* until the result is no longer *EINPROGRESS*.

Be aware that the operation may complete, and the signal handler may be delivered, before control returns from the call to *aio_read()*. Even when the operation does complete this quickly the return value from the call to *aio_read()* will be zero, reflecting the queueing of the I/O request not the results of the I/O itself.

An asynchronous operation may be canceled with *aio_cancel()* before its completion. Canceled operations complete with an error status of *ECANCELED* and any specified signal will be delivered. Due to timing, the operation may still complete naturally, either successfully or unsuccessfully, before it can be canceled by *aio_cancel()*.

If the file descriptor of this operation is closed, the operation will be deleted if it has not completed or is not just about to complete. Signals specified for deleted operations will not be delivered. *Close()* will wait for asynchronous operations in progress for the descriptor to be deleted or completed.

You may use *aio_suspend()* to wait for the completion of asynchronous operations.

Sockets must be in blocking state or the operation may fail with *EWOULDBLOCK*.

If the control block pointed by *aiocbp* or the buffer pointed to by *aio_buf* becomes an illegal address before the asynchronous I/O completion, then the behavior of *aio_read()* is unpredictable.

If the thread that makes the *aio_read()* request terminates before the I/O completes the *aiocb* structure will still be updated with the return and error status, and any specified signal will be delivered to the process in which the thread was running. If thread related storage was used on the request the results are quite unpredictable.

Simultaneous asynchronous operations using the same *aiocbp*, asynchronous operations using a non-valid *aiocbp*, or any system action, that changes the process memory space while asynchronous I/O is outstanding to that address range, will produce unpredictable results

Simultaneous *aio_read()* operations on the same socket should not be done in general. With stream sockets, the I/O complete notifications may not be delivered in the same order as the bytes to which they refer, and so the byte stream may appear out of order. With UDP sockets, each datagram will complete one *aio_read()* operation, but you should not use multiple *aio_reads* for UDP sockets because this can cause significantly more system overhead as data arrives than a single outstanding request would.

There are several sockets oriented extensions to asynchronous I/O available with the BPX1AIO callable service, such as asynchronous *accept()*, asynchronous *accept_and_recv()*, asynchronous forms of all

five pairs of read and write type operations, and receiving I/O completion notifications via an ECB, exit program, or through a message queue. The `<aio.h>` header contains all the structure fields, constants, and prototypes necessary to use BPX1AIO from a C program. These extensions are exposed when the `_AIO_OS390` feature test macro is defined. The BPX1AIO stub resides in SYS1.CSSLIB and must be bound with your program. For a more detailed description of asynchronous I/O services, see BPX1AIO in [z/OS UNIX System Services Programming: Assembler Callable Services Reference](#).

The `aio_lio_opcode` field is set to `LIO_READ` by the function `aio_read()`.

`_POSIX-PRIORITIZED_IO` is not supported. The `aio_reqprio` field may be set but it will be ignored.

`_POSIX-SYNCHRONIZED_IO` is not supported.

Returned value

If successful, `aio_read()` returns 0 to the calling process.

If unsuccessful, `aio_read()` returns -1 and sets `errno` to one of the following values:

Error Code Description

EAGAIN

The requested asynchronous I/O operation was not queued due to system resource limitations.

ENOSYS

The file associated with `aio_fildes` does not support the `aio_read()` function.

Each of the following conditions may be detected synchronously at the time of the call to `aio_read()`, or asynchronously. If any of the conditions below are detected synchronously, `aio_read()` returns -1 and sets the `errno` to the corresponding value. If any of the conditions below are detected asynchronously, the return status of the asynchronous operation is set to -1, and the error status of the asynchronous operation will be set to the corresponding value.

Error Code Description

EBADF

The `aio_fildes` argument is not a valid file descriptor open for reading.

EINVAL

`aio_sigevent` contains a non-valid value.

EWOULDBLOCK

The file associated with `aio_fildes` is in nonblocking state and there is no data available.

In the case where the `aio_read()` function successfully queues the I/O operation but the operation is subsequently canceled or encounters an error, the return status of the asynchronous operations is set to -1, and the error status of the asynchronous operation will be set to the error status normally set by the `read()` function call, or to the following value:

Error Code Description

ECANCELED

The requested I/O was canceled before the I/O completed due to an explicit call to `aio_cancel()`.

aio_return() — Retrieve status for an asynchronous I/O operation

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 | both | OS/390 V2R7 |

Format

```
#define _XOPEN_SOURCE 500
#include <aio.h>

int aio_return(const struct aiocb *aiocbp);
```

General description

The `aio_return()` function returns the return status associated with the *aiocb* structure referenced by the *aiocbp* argument. The return status for an asynchronous I/O operation is the value that would be set by the corresponding `read()` or `write()` operation. While the operation is proceeding, the error status retrieved by `aio_error()` is `EINPROGRESS`; the return status retrieved by `aio_return()` however is unpredictable. The `aio_return()` function may be called to retrieve the return status of a given asynchronous operation; once `aio_error()` has returned with 0.

Returned value

If the asynchronous I/O operation has completed successfully, `aio_return()` returns the status as described for `read()` or `write()`.

If the asynchronous I/O operation has not yet completed, then the return status is unpredictable. `aio_return()` does not set `errno`.

Related information

- [“aio.h — Asynchronous I/O operations” on page 16](#)
- [“aio_error\(\) — Retrieve error status for an asynchronous I/O operation” on page 147](#)
- [“aio_read\(\) — Asynchronous read from a socket” on page 148](#)
- [“aio_suspend\(\) — Wait for an asynchronous I/O request” on page 151](#)

aio_suspend() — Wait for an asynchronous I/O request

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 | both | OS/390 V2R7 |

Format

```
#define _XOPEN_SOURCE 500
#include <aio.h>

int aio_suspend(const struct aiocb *const list[],
               int nent, const struct timespec *timeout);
```

General description

The `aio_suspend()` function suspends the calling thread when the *timeout* is a NULL pointer until at least one of the asynchronous I/O operations referenced by the *list* argument has completed, or until a signal interrupts the function. Or, if *timeout* is not NULL, it is suspended until the time interval specified by *timeout* has passed. If the time interval indicated in the *timespec* structure pointed to by *timeout* passes before any of the I/O operations referenced by *list*, then `aio_suspend()` returns with an error. If any of the *aiocb* structures in the list correspond to completed asynchronous I/O operations (that is, the error status for the operation is not equal to EINPROGRESS) at the time of the call, the function returns without suspending the calling thread.

The *list* argument is an array of pointers to asynchronous I/O control blocks (AIOCBs). The *nent* argument indicates the number of elements in the array. Each *aiocb* structure pointed to will have been used in initiating an asynchronous I/O request. This array may contain NULL pointers, which are ignored. If this array contains pointers that refer to *aiocb* structures that have not been used in submitting asynchronous I/O or *aiocb* structures that are not valid, the results are unpredictable.

Returned value

If successful, `aio_suspend()` returns 0.

If unsuccessful, `aio_suspend()` returns -1. The application may determine which asynchronous I/O completed by scanning the associated error and return status using `aio_error()` or `aio_return()`, respectively. `aio_suspend()` sets `errno` to one of the following values:

Error Code

Description

EAGAIN

No asynchronous I/O indicated in the list referenced by *list* completed in the time interval indicated by *timeout*.

EINTR

A signal interrupted the `aio_suspend()` function. Note that, since each asynchronous I/O operation may possibly provoke a signal when it completes, this error return may be caused by the completion of one (or more) of the very I/O operations being awaited.

ENOSYS

z/OS UNIX System Services does not support the `aio_suspend()` function.

Usage notes

1. The AIOCBs represented by the list of AIOCB pointers must reside in the same storage key as the key of the invoker of `aio_suspend`. If the AIOCB Pointer List or any of the AIOCBs represented in the list are not accessible by the invoker an EFAULT may occur.
2. AIOCB pointers in the list with a value of zero will be ignored.
3. A timeout value of zero (seconds+nanoseconds) means that the `aio_suspend()` call will not wait at all. It will check for any completed asynchronous I/O requests. If none are found it will return with a EAGAIN. If at least one is found `aio_suspend()` will return with success.
4. A timeout value of a *timespec* with the `tv_sec` field set with INT_MAX, as defined in <limits.h>, will cause the `aio_suspend` service to wait until a asynchronous I/O request completes or a signal is received.

If the Macro `_AIO_OS390` is defined then the following may also apply.

5. The number of pointers to AIOCBs that use application supplied event control block (ECB) pointers for invocations of asynchronous I/O is limited to 253. There is no limit when not using the `_AIO_OS390` Feature Test Macro. See *z/OS UNIX System Services Programming: Assembler Callable Services Reference* under the BPX1AIO for information on supplying user-defined ECBs in the AIOCB data area.
6. The AIOCBs passed to `aio_suspend()` must not be freed or reused by other threads in the process while this service is still in progress. This service may use the AIOCBs even after the asynchronous I/O completes. This restriction excludes multiple threads from doing `aio_suspend()` on the same AIOCB at the same time. Modifying the AIOCB during an `aio_suspend()` will produce unpredictable results.
7. The use of these extensions will require macros from SYS1.CSSLIB. Make sure that it is included in the SYSLIB concatenation during the compile.

aio_write() — Asynchronous write to a socket

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 | both | OS/390 V2R7 |

Format

```
#define _XOPEN_SOURCE 500
#include <aio.h>

int aio_write(struct aiocb *aiocbp);
```

General description

The `aio_write()` function initiates an asynchronous write as described by the `aiocb` structure (the asynchronous I/O control block).

The `aiocbp` argument points to the `aiocb` structure. This structure contains the following members:

aio_fildes

file descriptor

aio_offset

file offset

aio_buf

location of buffer

aio_nbytes

length of transfer

aio_reqprio

request priority offset

aio_sigevent

signal number and value

aiowrite_opcode

operation to be performed

The operation will write *aio_nbytes* from the buffer pointed to by *aio_buf* to the socket or file associated with *aio_fildes*. The call to *aio_write()* returns when the request has been initiated or queued to the file or device (even when the data cannot be delivered immediately).

Asynchronous I/O is currently only supported for sockets. The *aio_offset* field may be set but it will be ignored.

The *aio_cbp* value may be used as an argument to *aio_error()* and *aio_return()* functions in order to determine the error status and return status, respectively, of the asynchronous operation. While the operation is proceeding, the error status retrieved by *aio_error()* is *EINPROGRESS*; the return status retrieved by *aio_return()* however is unpredictable.

If an error condition is encountered during the queueing, the function call returns without having initiated or queued the request.

When the operation completes asynchronously the program can be notified by a signal as specified in the *aio_sigevent* structure. It is significantly more efficient to receive these notifications with *sigwaitinfo()* or *sigtimedwait()* than to let them drive a signal handler. At this time the return and error status will have been updated to reflect the outcome of the operation. The *sigevent* structure's notification function fields are not supported. If a signal is not desired the program can occasionally poll the *aio_cbp* with *aio_error()* until the result is no longer *EINPROGRESS*.

Be aware that the operation may complete, and the signal handler may be delivered, before control returns from the call to *aio_read()*. Even when the operation does complete this quickly the return value from the call to *aio_read()* will be zero, reflecting the queueing of the I/O request not the results of the I/O itself.

An asynchronous operation may be canceled with *aio_cancel()* before its completion. Canceled operations complete with an error status of *ECANCELED* and any specified signal will be delivered. Due to timing, the operation may still complete naturally, either successfully or unsuccessfully, before it can be canceled by *aio_cancel()*.

If the file descriptor of this operation is closed, the operation will be deleted if it has not completed or is not just about to complete. Signals specified for deleted operations will not be delivered. *Close()* will wait for asynchronous operations in progress for the descriptor to be deleted or completed.

You may use *aio_suspend()* to wait for the completion of asynchronous operations.

Sockets must be in blocking state or the operation may fail with *EWouldBlock*.

If the control block pointed by *aio_cbp* or the buffer pointed to by *aio_buf* becomes an illegal address before the asynchronous I/O completion, then the behavior of *aio_read()* is unpredictable.

If the thread that makes the *aio_read()* request terminates before the I/O completes, the *aio_cbp* structure will still be updated with the return and error status, and any specified signal will be delivered to the process in which the thread was running. If thread related storage was used on the request the results are quite unpredictable.

Simultaneous asynchronous operations using the same *aio_cbp*, attempting asynchronous operations using a non-valid *aio_cbp*, or any system action, that changes the process memory space while asynchronous I/O is outstanding to that address range, will produce unpredictable results.

Simultaneous *aio_write()* operations on the same stream socket should not be done because the data may be transmitted on the network out of order. With UDP sockets each *aio_write* defines a single datagram and there is no implied order of arrival in UDP. Beware, though, of sending too many datagrams. If there is network congestion or the receiver is slow you can tie up a large amount of system storage with uncontrolled *aio_writes*, and eventually they may start to fail with *ENOBUFS*.

There are several sockets oriented extensions to asynchronous I/O available with the *BPX1AIO* callable service, such as asynchronous *accept()*, asynchronous *accept_and_recv()*, asynchronous forms of all five pairs of read and write type operations, and receiving I/O completion notifications via an ECB, exit program, or through a message queue. The *<aio.h>* header contains all the structure fields, constants,

and prototypes necessary to use BPX1AIO from a C program. These extensions are exposed when the `_AIO_OS390` feature test macro is defined. The BPX1AIO stub resides in SYS1.CSSLIB and must be bound with your program. For a more detailed description of asynchronous I/O services, see BPX1AIO in [z/OS UNIX System Services Programming: Assembler Callable Services Reference](#).

The `aio_lio_opcode` field is set to `LIO_WRITE` by the function `aio_write()`.

`_POSIX_PRIORITIZED_IO` is not supported. The `aio_reqprio` field may be set but it will be ignored.

`_POSIX_SYNCHRONIZED_IO` is not supported.

Returned value

If the I/O operation is successfully queued, `aio_write()` returns 0 to the calling process.

If the I/O operation is not queued, `aio_write()` returns -1 and sets `errno` to one of the following values:

Error Code Description

EAGAIN

The requested asynchronous I/O operation was not queued due to system resource limitations.

ENOSYS

The file associated with `aio_fildes` does not support the `aio_write()` function.

Each of the following conditions may be detected synchronously at the time of the call to `aio_write()`, or asynchronously. If any of the conditions below are detected synchronously, `aio_write()` returns -1 and sets the `errno` to the corresponding value. If any of the conditions below are detected asynchronously, the return status of the asynchronous operation is set to -1, and the error status of the asynchronous operation will be set to the corresponding value.

Error Code Description

EBADF

The `aio_fildes` argument is not a valid file descriptor open for writing.

EINVAL

The `aio_nbytes` is not a valid value or `aio_sigevent` contains a value that is not valid.

EWOULDBLOCK

The file associated with `aio_fildes` is in nonblocking state and there is no data available.

In the case where `aio_write()` successfully queues the I/O operation but the operation is subsequently canceled or encounters an error, the return status of the asynchronous operation is set to -1, and the error status of the asynchronous operation is set to the error status normally set by the `write()` function call, or to the following value:

Error Code Description

ECANCELED

The requested I/O was canceled before the I/O completed due to an explicit call to `aio_cancel()`.

alarm() — Set an alarm

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

unsigned int alarm(unsigned int seconds);
```

General description

Generates a SIGALRM signal after the number of seconds specified by the *seconds* parameter has elapsed. The SIGALRM signal delivery is directed at the calling thread.

seconds is the number of real seconds to wait before the SIGALRM signal is generated. Because of processor delays, the SIGALRM signal may be generated slightly later than this specified time. If *seconds* is zero, any previously set alarm request is canceled.

Only one such alarm can be active at a time. If you set a new alarm time, any previous alarm is canceled.

This function is supported only in a POSIX program.

Special behavior for XPG4: The `fork()` function clears pending alarms in the child thread. However, a new thread image created by one of the `exec` functions inherits the time left to an alarm in the old thread's image.

Special behavior for XPG4.2: `alarm()` will interact with the `setitimer()` function when the `setitimer()` function is used to set the 'real' interval timer (ITIMER_REAL).

`alarm()` does not interact with the `usleep()` function.

Returned value

If a prior alarm request has not yet completed, `alarm()` returns the number of seconds remaining until that request would have generated a SIGALRM signal.

If there are no prior alarm requests with time remaining, `alarm()` returns 0. Because `alarm()` is always successful, there is no failure return. If any failures are encountered that prevent `alarm()` from completing successfully, an abend is generated.

Example

CELEBA05

```
/* CELEBA05
   The following example generates a SIGALRM signal.
*/
#define _POSIX_SOURCE
#include <stdio.h>
#include <signal.h>
#include <time.h>
#include <unistd.h>
```

```

volatile int footprint=0;

void catcher(int signum) {
    puts("inside signal catcher!");
    footprint = 1;
}

main() {
    struct sigaction sact;
    volatile double count;
    time_t t;

    sigemptyset(&sact.sa_mask);
    sact.sa_flags = 0;
    sact.sa_handler = catcher;
    sigaction(SIGALRM, &sact, NULL);

    alarm(5); /* timer will pop in five seconds */

    time(&t);
    printf("before loop, time is %s", ctime(&t));
    for (count=0; (count<1e10) && (footprint == 0); count++);
    time(&t);
    printf("after loop, time is %s", ctime(&t));

    printf("the sum so far is %.0f\n", count);

    if (footprint == 0)
        puts("the signal catcher never gained control");
    else
        puts("the signal catcher gained control");
}

```

Output

```

before loop, time is Fri Jun 16 08:37:03 2006
inside signal catcher!
after loop, time is Fri Jun 16 08:37:08 2006
the sum so far is 17417558

```

aligned_alloc() — Allocating aligned memory blocks

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C11 | both | |

Format

```
#include <stdlib.h>
void *aligned_alloc( size_t alignment, size_t size );
```

General description

The `aligned_alloc` function allocates space for an object whose alignment is specified by `alignment`, whose size is specified by `size`, and whose value is indeterminate.

Special behavior for C++: The C++ keywords `new` and `delete` are not interoperable with `aligned_alloc()`, `calloc()`, `free()`, `malloc()`, `posix_memalign()`, or `realloc()`.

Note: To use the `aligned_alloc()` function, compile the source code with C11 standard based compilation.

Parameters

alignment

Specifies the alignment. The value of *alignment* is a power of two.

size

Number of bytes to allocate. The value of *size* is an integral multiple of alignment.

Returned Value

On success, returns the pointer to the beginning of newly allocated memory. To avoid a memory leak, the returned pointer must be deallocated with `free()` or `realloc()`.

If `size` was specified as 0, `aligned_alloc()` returns a null pointer.

On failure, returns a null pointer, it sets `errno` to one of the following values:

Error Code

EINVAL

The value of *alignment* or *size* is not supported.

ENOMEM

Insufficient memory is available

Example

CELEBM26

```
/* CELEBM26
This example prompts you allocate size (which is an integral multiple of alignment) bytes of
uninitialized storage.
If &aligned_alloc was successful, the example prints the address returned; otherwise, it prints
errno.
*/
#include <stdio.h>
#include <stdlib.h>
#include <errno.h>

int main(void)
{
    int *p1 = aligned_alloc(8, 8*sizeof *p1);
    if(!p1)
    {
        printf("aligned_alloc failed with errno = %d\n", errno);
        return -1;
    }
    else
    {
        printf("8-byte aligned addr: %p\n", (void*)p1);
        free(p1);
    }
}
```

```
return 0;
}
```

Output

One possible output is:

```
8-byte aligned addr: 22575D20
```

alloca() — Allocate storage from the stack

Standards

| Standards / Extensions | C or C++ | Dependencies |
|-------------------------|----------|--------------|
| Language Environment | both | OS/390 V2R6 |

Format

```
#include <stdlib.h>

void *alloca(unsigned int size);
```

General description

The built-in `alloca()` function obtains memory from the stack. This eliminates the need for an explicit `free()` as the memory is freed when the stack is collapsed.

If the `alloca()` function is unable to obtain the requested storage, control will not return to the caller. Instead the application will terminate due to an out of memory condition (if the reserve stack is available and the caller is not XPLINK), or it will terminate with an abend indicating that storage could not be obtained.

To avoid infringing on the user's name space, this nonstandard function is exposed only when you enable the [runtime library extensions](#) or [extended language level](#).

Note: Storage from an `alloca()` is done after a `setjmp()` (or any variation thereof) is freed on a `longjmp()` (or any variation thereof) to an XPLINK-compiled function, and not freed on a `longjmp()` to a NOXPLINK-compiled function. See the `longjmp()` family of functions for more details.

Returned value

If successful, `alloca()` returns the address of the requested storage.

arm_bind_thread() — Bind the current thread to a given transaction

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | |

Format

```
#include <sys/_Elmarm4.h>

arm_error_t arm_bind_thread(
/* [in]      */ arm_start_handle_t      start_handle,
/* [in]      */ arm_int32_t             flags,
/* [in]      */ arm_buffer4_t          *buffer4,
);
```

General description

Use arm_bind_thread() to indicate the current thread is performing processing on behalf of a given transaction, and no other transaction. This enables eWLM to collect resource usage and delay information for threads serving each class of work, and to adjust the resources given to threads to help them meet the goals assigned to those classes.

Any number of threads can bind to the same transaction at the same time. However a single thread cannot bind to more than one transaction at the same time. If a thread calls arm_bind_thread() when it is already bound to a transaction, the call is not honored and it returns a negative value to indicate an error.

A thread that calls arm_bind_thread() must call arm_unbind_thread() when it completes its processing on behalf of the transaction. (If arm_unbind_thread() is not called, then arm_stop_transaction() unbinds any threads that remain bound to the transaction. This exists for recovery purposes. Applications are expected to use arm_unbind_thread() as part of normal processing.)

start_handle

The handle returned by arm_start_transaction() for the transaction.

flags

Reserved for future use. The argument must be set to 0.

buffer4

A pointer to a buffer that identifies one or more sub-buffers containing additional data. Currently no sub-buffers are defined for this function so a null pointer should be passed. If a buffer is passed eWLM ignores it.

Returned value

On success, arm_bind_thread returns ARM_RC_SUCCESS. On failure, the errno and return code are set to indicate the error. See [“Return code” on page 161](#) for the list of all possible return codes.

| |
|--------------------|
| Error Code |
| Description |

EFAULT

A parameter of this service contained an address that was not accessible to the caller.

EINVAL

A parameter of this service contained a value that was not valid.

EMVSAARMERROR

An ARM error occurred. Refer to the return code for the specific error.

EPERM

The caller does not have the appropriate privileges. The return code is set to ARM_RC_AUTH_ERROR.

EMVSSAF2ERR

An error occurred in the security product.

Return code

The following list contains all possible return codes for the ARM function calls.

| |
|--------------------|
| Return Code |
| Description |

ARM_RC_APP_INPUT

User provided application id is invalid.

ARM_RC_APPL_INST_MAX

Maximum number of application instances per process is exceeded.

ARM_RC_APPL_INST_NAME

Application instance name is too long.

ARM_RC_APPL_MAX

Maximum number of registered applications is exceeded.

ARM_RC_APPL_NAME

Application name is missing or too long.

ARM_RC_AUTH_ERROR

User is not authorized to perform ARM calls.

ARM_RC_BLOCKED_MAX

Maximum number of blocked threads per transaction is exceeded.

ARM_RC_CORR_BAD_SIZE

Correlator size is not valid.

ARM_RC_CORR_EFAULT

Correlator return address is not valid.

ARM_RC_ENOMEM

Process or system is out of memory.

ARM_RC_FLAGS_EINVAL

Flags value is not valid.

ARM_RC_GRP_MAX

Maximum number of registered application groups is exceeded.

ARM_RC_GRP_NAME

Application group name is too long.

ARM_RC_HANDLE_EFAULT

Handle return address is not valid.

ARM_RC_MAXMEM

Maximum ARM services memory limit is exceeded.

ARM_RC_PARENT_CORR_INVAL

Parent correlator is not valid.

ARM_RC_PARENT_CORR_SZ

Parent correlator is too small.

ARM_RC_PARENT_CORR_VERSION

Parent correlator version is not correct.

ARM_RC_PROC_VAL_MSMTCH

Property values do not match property names.

ARM_RC_PROP_NAME

Transaction property name is too long.

ARM_RC_PROP_NAME_MAX

Too many property names are passed to ARM call.

ARM_RC_PROP_NAME_SUBBUF_MAX

Too many property name sub-buffers are passed to ARM call.

ARM_RC_PROP_VAL

Transaction property value is too long.

ARM_RC_PROP_VAL_MAX

Too many property values are passed to ARM call.

ARM_RC_PROP_VAL_SUBBUF_MAX

Too many property value sub-buffers are passed to ARM call.

ARM_RC_TIME_SUBBUF_MAX

Too many arrival time sub-buffers are passed to ARM call.

ARM_RC_TRAN_INPUT

User provided transaction type id is not valid.

ARM_RC_TRAN_MAX

Maximum number of transactions is exceeded.

ARM_RC_TRAN_STATUS_EINVAL

Invalid transaction status.

ARM_RC_TRAN_TYPE_INST_MAX

Maximum number of registered transaction type instances per process is exceeded.

ARM_RC_TRAN_TYPE_MAX

Maximum number of registered transaction types is exceeded.

ARM_RC_TRAN_TYPE_NAME

Transaction type name is missing or too long.

ARM_RC_UNKN_APPL_INST

Application instance is not found.

ARM_RC_UNKN_BLOCKED

Blocked thread is not valid for the specified transaction.

ARM_RC_UNKN_PARENT

Parent transaction is not a valid transaction.

ARM_RC_UNKN_PROC

The calling processing did not register an application instance.

ARM_RC_UNKN_TRAN

Transaction was not found for the calling process.

ARM_RC_UNKN_TRANCLASS_INST

Transaction class instance is not found.

ARM_RC_URI_NAME

URI value is too long.

ARM_RC_URI_SUBBUF_MAX

Too many URI value sub-buffers are passed to ARM call.

ARM_RC_VERSION_NAME

Application version name is too long.

arm_blocked() — Indicate the processing of a transaction is blocked

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | |

Format

```
#include <sys/_Elmarm4.h>

arm_error_t arm_blocked(
/* [in] */ arm_start_handle_t start_handle,
/* [in] */ arm_int32_t flags,
/* [in] */ arm_buffer4_t *buffer4,
/* [out] */ arm_block_handle_t *block_handle
);
```

General description

Use `arm_blocked()` to indicate that processing of a transaction is blocked waiting for a transaction in another application to complete. This helps to identify what portion of a transaction's response time is spent in its own application and what portion is spent in downstream applications.

start_handle

The handle returned by `arm_start_transaction()` for the transaction.

flags

Reserved for future use. The argument must be set to 0.

buffer4

A pointer to a buffer that identifies one or more sub-buffers containing additional data. Currently no sub-buffers are defined for this function so a null pointer should be passed. If a buffer is passed eWLM ignores it.

block_handle

A pointer to a 64-bit area where a handle that identifies the arm_blocked() call is returned. The handle must be passed to arm_unblocked(). The handle is valid only within the caller's process.

Returned value

On success, arm_blocked returns ARM_RC_SUCCESS. On failure, the errno and return code are set to indicate the error. See “Return code” on page 161 for the list of all possible return codes. On failure, the block_handle is set to a dummy value which can be used for later calls to other interfaces. Those interfaces will recognize that the block_handle contains a dummy value and return without performing any action.

Error Code**Description****EFAULT**

A parameter of this service contained an address that was not accessible to the caller.

EINVAL

A parameter of this service contained a value that was not valid.

EMVSARMERROR

An ARM error occurred. Refer to the return code for the specific error.

EPERM

The caller does not have the appropriate privileges. The return code is set to ARM_RC_AUTH_ERROR.

EMVSSAF2ERR

An error occurred in the security product.

arm_correlator_get_length() – Get the actual size of the transaction correlator

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | |

Format

```
#include <sys/_Elmarm4.h>

arm_error_t arm_correlator_get_length(
/* [in] */ arm_correlator_t *corr_ptr,
/* [out] */ arm_correlator_length_t **result_ptr
);
```

General description

Returns the actual size of a given correlator.

corr_ptr

Address of correlator.

result_ptr

Set to the address of the length of the correlator.

Returned value

On success, arm_correlator_get_length returns ARM_RC_SUCCESS. On failure, the errno and return code are set to indicate the error. See [“Return code” on page 161](#) for the list of all possible return codes.

Error Code

Description

EFAULT

A parameter of this service contained an address that was not accessible to the caller.

EINVAL

A parameter of this service contained a value that was not valid.

EMVARMERROR

An ARM error occurred. Refer to the return code for the specific error.

EPERM

The caller does not have the appropriate privileges. The return code is set to ARM_RC_AUTH_ERROR.

EMVSSAF2ERR

An error occurred in the security product.

arm_end_application() — Undefines an ARM application

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | |

Format

```
#include <sys/_Elmarm4.h>

arm_error_t arm_end_application(
/* [in/out] */ arm_appl_id_t  *application_id
/* [in]      */ arm_int32_t    flags,
/* [in]      */ arm_buffer4_t  *buffer4,
);
```

General description

Use `arm_end_application()` to close ARM API activity for a particular application. `arm_end_application()` invalidates the application handle returned by `arm_init_application()`, all transaction type handles associated with the application handle, and all transaction handles associated with those transaction types. Any further API calls using these handles will be rejected with a negative status return value. Information about transactions that were started and not yet stopped is discarded.

application_id

The handle passed to or returned by `arm_init_application()` for the application.

flags

Reserved for future use. The argument must be set to 0.

buffer4

A pointer to a buffer that identifies one or more sub-buffers containing additional data. Currently no sub-buffers are defined for this function so a null pointer should be passed. If a buffer is passed eWLM ignores it.

Returned value

On success, `arm_stop_transaction` returns `ARM_RC_SUCCESS`. On failure, the `errno` and return code are set to indicate the error. See “[Return code](#)” on page 161 for the list of all possible return codes.

Error Code

Description

EFAULT

A parameter of this service contained an address that was not accessible to the caller.

EINVAL

A parameter of this service contained a value that was not valid.

EMVSARMERROR

An ARM error occurred. Refer to the return code for the specific error.

EPERM

The caller does not have the appropriate privileges. The return code is set to `ARM_RC_AUTH_ERROR`.

EMVSSAF2ERR

An error occurred in the security product.

arm_get_correlator_max_length() — Get the max length of the transaction correlator

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | |

Format

```
#include <sys/_Elmarm4.h>

arm_int32_t arm_get_correlator_max_length();
```

General description

Returns the size of the buffer required for the correlator returned by arm_start_transaction().

Note: The size applies only to correlators returned by arm_start_transaction(). It does not necessarily apply to parent correlators received from other applications, which may have been created by another ARM implementation and may have a different maximum size. The ARM 2.0 and ARM 3.0 standards defined the maximum size of the correlator for any implementation as 168 bytes. However the proposed ARM 4.0 standard most likely will drop this restriction and implementations will be allowed to create a correlator of any length.

Returned value

On success, arm_iget_correlator_max_length returns a positive number representing the maximum correlator length. On failure, the errno and return code are set to indicate the error. See [“Return code” on page 161](#) for the list of all possible return codes.

Error Code**Description**

EFAULT

A parameter of this service contained an address that was not accessible to the caller.

EINVAL

A parameter of this service contained a value that was not valid.

EMVSARMERROR

An ARM error occurred. Refer to the return code for the specific error.

EPERM

The caller does not have the appropriate privileges. The return code is set to ARM_RC_AUTH_ERROR.

EMVSSAF2ERR

An error occurred in the security product.

arm_get_timestamp() — Get the current timestamp

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | |

Format

```
#include <sys/_Elmarm4.h>

arm_error_t arm_get_timestamp(
/* [out] */ arm_timestamp_t *timestamp
);
```

General description

Use `arm_get_timestamp()` to obtain the current time. If the application wants to pass the arrival time sub-buffer to `arm_start_transaction()`, it must call `arm_get_timestamp()` to capture the arrival time in a format that is compatible with the arrival time sub-buffer.

timestamp

Area where the current time is returned. The format of the timestamp is implementation-dependent.

Returned value

On success, `arm_get_timestamp` returns `ARM_RC_SUCCESS`. On failure, the `errno` and return code are set to indicate the error. See [“Return code” on page 161](#) for the list of all possible return codes.

Error Code

Description

EFAULT

A parameter of this service contained an address that was not accessible to the caller.

EINVAL

A parameter of this service contained a value that was not valid.

EMVSARMERROR

An ARM error occurred. Refer to the return code for the specific error.

EPERM

The caller does not have the appropriate privileges. The return code is set to `ARM_RC_AUTH_ERROR`.

EMVSSAF2ERR

An error occurred in the security product.

arm_init_application() — Defines an ARM application

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | |

Format

```
#include <sys/_Elmarm4.h>

arm_error_t arm_init_application(
/* [in] */ arm_string_t application_name,
/* [in] */ arm_string_t application_group_name,
/* [in] */ arm_string_t application_instance_name,
/* [in] */ arm_int32_t flags,
/* [in] */ arm_buffer4_t *buffer4,
/* [in/out] */ arm_appl_id_t *application_id
);
```

General description

Use `arm_init_application()` to define an application. This function must be called before any other ARM API calls. Typically it should be called during the application's initialization.

If an application exists as multiple processes, it must call `arm_init_application()` in each process. This is necessary for eWLM to understand how each process contributes to the application. Multiple applications can register from within one process. This is useful if external functions are packaged in the same process.

`arm_init_application()` is the ARM 4.0 equivalent of ARM 2.0's `arm_init` function.

application_name

The name used generically to identify the application. The maximum length is 128 characters including the null string terminator.

application_group_name

The name of a group of application instances to which this instance belongs. The maximum length is 256 characters including the null string terminator. If no value is desired, a null pointer should be passed.

application_instance_name

The name of this instance of the application. The maximum length is 256 characters including the null string terminator. If no value is desired, a null pointer should be passed.

flags

One flag is defined. `ARM_INIT_FLAG_ID_INPUT` indicates whether the application id is an input (flag is one) or an output (flag is zero). See the application id parameter below. All other flag bits are reserved and must be zero.

buffer4

A pointer to a buffer that identifies one or more sub-buffers containing additional data. Currently no sub-buffers are defined for this function so a null pointer should be passed. If a buffer is passed, eWLM ignores it.

application_id

A pointer to a 64-bit area handle that identifies the application. The application can define its own handle and pass it as input or it can have eWLM generate a handle and return it. The choice is indicated by the flag `ARM_INIT_FLAG_ID_INPUT`. The handle must be passed to `arm_init_transaction_type()` and `arm_end_application()`. The handle is defined only within the caller's process.

Returned value

On success, `arm_init_application` returns `ARM_RC_SUCCESS`. On failure, the `errno` and return code are set to indicate the error. See [“Return code” on page 161](#) for the list of all possible return codes. On failure, the `application_id` is set to a dummy value which can be used for later calls to other interfaces. Those interfaces will recognize that the `application_id` contains a dummy value and return without performing any action.

Error Code

Description

EFAULT

A parameter of this service contained an address that was not accessible to the caller.

EINVAL

A parameter of this service contained a value that was not valid.

EMVSARMERROR

An ARM error occurred. Refer to the return code for the specific error.

EPERM

The caller does not have the appropriate privileges. The return code is set to `ARM_RC_AUTH_ERROR`.

EMVSSAF2ERR

An error occurred in the security product.

arm_init_transaction_type() — Defines and initializes an ARM transaction type

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | |

Format

```
#include <sys/_Elmarm4.h>

arm_error_t arm_init_transaction_type(
/* [in]      */ arm_appl_id_t   *application_id,
/* [in]      */ arm_string_t    transaction_name,
/* [in]      */ arm_int32_t     flags,
/* [in]      */ arm_buffer4_t   *buffer4,
/* [in/out] */ arm_appl_id_t    *transaction_type_id
);
```

General description

Use `arm_init_transaction_type()` to define a transaction classtype. A transaction type represents a type of transaction that is executed by an application. A transaction type must be defined before transactions of that type can be measured using `arm_start_transaction()` and `arm_stop_transaction()`.

A transaction type consists of a transaction type name and a list of up to 20 transaction property names. Multiple transaction types with the same transaction type name and different transaction property names are allowed. It is the complete set of names that determines the uniqueness of a transaction type.

It is recommended that transaction types be defined during the application's initialization. eWLM expects transaction types to represent broad categories of work so that ordinarily there will be few of them. Detailed transaction identification should be done using the transaction-level properties.

Transaction types also can be defined as needed, during the application's processing of transactions. The ARM implementation must check whether there is an existing definition of the same type to prevent duplicates. Since this adds further overhead into mainline processing, this approach is not recommended.

Transaction classtype definitions remain valid for the life of the application (i.e. until it calls `arm_end_application()` or its process terminates).

arm_init_application_type() is the ARM 4.0 equivalent of ARM 2.0's arm_getid function.

application_id

The handle passed to or returned by arm_init_application() for the application associated with this transaction type.

transaction_name

The name used to identify the transaction type. The maximum length is 128 characters including the null string terminator. Classification rules in the eWLM policy can use the transaction type name to categorize transactions into eWLM service classes and report classes.

flags

One flag is defined. ARM_INIT_FLAG_ID_INPUT indicates whether the transaction type id is an input (flag is one) or an output (flag is zero). See the transaction type id parameter below. All other flag bits are reserved and must be zero.

buffer4

A pointer to a buffer that identifies one or more sub-buffers containing additional data. A null value can be specified if no additional data is required.

transaction_type_id

A pointer to a 64-bit handle that identifies the transaction type. The application can define its own handle and pass it as input or it can have eWLM generate a handle and return it. The choice is indicated by the flag ARM_INIT_FLAG_ID_INPUT. The handle must be passed to arm_start_transaction(). The handle is defined only within the caller's process. If eWLM is asked to generate a handle and the transaction type name and the transaction property names (in the user data buffer) match the names passed on a previous arm_init_transaction_type() call, the handle value that is returned will be the same as the previous call.

Returned value

On success, arm_init_application returns ARM_RC_SUCCESS. On failure, the errno and return code are set to indicate the error. See [“Return code” on page 161](#) for the list of all possible return codes. On failure, the application_id is set to a dummy value which can be used for later calls to other interfaces. Those interfaces will recognize that the application_id contains a dummy value and return without performing any action.

Error Code**Description****EFAULT**

A parameter of this service contained an address that was not accessible to the caller.

EINVAL

A parameter of this service contained a value that was not valid.

EMVSARMERROR

An ARM error occurred. Refer to the return code for the specific error.

EPERM

The caller does not have the appropriate privileges. The return code is set to ARM_RC_AUTH_ERROR.

EMVSSAF2ERR

An error occurred in the security product.

arm_start_transaction() — Mark the start of an ARM transaction

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | |

Format

```
#include <sys/_Elmarm4.h>

arm_error_t arm_start_transaction(
/* [in] */ arm_appl_id_t *transaction_id,
/* [in] */ arm_correlator_t *parent_correlator_ptr,
/* [in] */ arm_int32_t flags,
/* [in] */ arm_buffer4_t *buffer4,
/* [out] */ arm_start_handle_t *start_handle,
/* [out] */ arm_correlator_t *current_correlator_ptr
);
```

General description

Use `arm_start_transaction()` to mark the beginning of execution of a transaction. The transaction must be identified as a member of a transaction type that was previously defined by `arm_init_transaction_type()`. There can be any number of transactions executing simultaneously.

transaction_id

The handle passed to or returned by `arm_init_transaction_type()` for the transaction type.

parent_correlator_ptr

A pointer to the parent correlator for this transaction. If there is no parent correlator, a null value should be passed.

flags

One flag bit is defined: `ARM_START_FLAG_TRACE_REQUEST` requests tracing of the transaction. Currently eWLM has no support to trace transactions and ignores the flag. All other flag bits are reserved and must be zero.

buffer4

A pointer to a buffer that identifies one or more sub-buffers with additional data. A null value can be specified if no additional data is required.

start_handle

A pointer to a 64-bit area where a handle that identifies the transaction is returned. The handle must be passed to other transaction-level interfaces such as `arm_stop_transaction()`. The handle is valid only within the caller's process.

current_correlator_ptr

A pointer to a buffer into which eWLM will store a correlator for the transaction. The length of the buffer must be at least the length returned from the `arm_get_correlator_max_length()` function.

Returned value

On success, `arm_init_application` returns `ARM_RC_SUCCESS`. On failure, the `errno` and return code are set to indicate the error. See “Return code” on page 161 for the list of all possible return codes. On failure, the `application_id` is set to a dummy value which can be used for later calls to other interfaces. Those interfaces will recognize that the `application_id` contains a dummy value and return without performing any action.

Error Code

Description

EFAULT

A parameter of this service contained an address that was not accessible to the caller.

EINVAL

A parameter of this service contained a value that was not valid.

EMVSARMERROR

An ARM error occurred. Refer to the return code for the specific error.

EPERM

The caller does not have the appropriate privileges. The return code is set to `ARM_RC_AUTH_ERROR`.

EMVSSAF2ERR

An error occurred in the security product.

arm_stop_transaction() — Mark the end of an ARM transaction

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | |

Format

```
#include <sys/_Elmarm4.h>

arm_error_t arm_stop_transaction(
/* [in] */ arm_start_handle_t start_handle,
/* [in] */ arm_int32_t transaction_status,
/* [in] */ arm_int32_t flags,
/* [in] */ arm_buffer4_t *buffer4,
);
```

General description

Use `arm_stop_transaction()` to mark the end of execution of a transaction.

If any threads are bound to the transaction, `arm_stop_transaction()` unbinds them. If the transaction is in a blocked state due to outstanding `arm_blocked()` calls, then `arm_stop_transaction()` considers the transaction to be unblocked at the time it is stopped. This cleanup processing exists for recovery purposes. Applications are expected to use `arm_unbind_thread()` and `arm_unblocked()` as part of normal processing.

start_handle

The handle returned by `arm_start_transaction()` for the transaction.

transaction_status

The completion code of the transaction.

ARM_STATUS_GOOD

Transaction successful.

ARM_STATUS_ABORT

Transaction aborted This value indicates there was a fundamental failure in the system; for example, a communications timeout or a database operation error.

ARM_STATUS_FAILED

Transaction failed. This value indicates the system worked properly but the transaction was not successful; for example, when making an airline reservation, no seats are available on the requested flight.

ARM_STATUS_UNKNOWN

Transaction status is unknown.

flags

Reserved for future use. The argument must be set to 0.

buffer4

A pointer to a buffer that identifies one or more sub-buffers containing additional data. A null pointer can be passed if no additional data is required. The proposed ARM4 standard defines a metric values sub-buffer for this function but eWLM does not process metrics. If a buffer is passed eWLM ignores it.

Returned value

On success, `arm_end_application` returns `ARM_RC_SUCCESS`. On failure, the `errno` and return code are set to indicate the error. See [“Return code” on page 161](#) for the list of all possible return codes.

Error Code

Description

EFAULT

A parameter of this service contained an address that was not accessible to the caller.

EINVAL

A parameter of this service contained a value that was not valid.

EMVSARMERROR

An ARM error occurred. Refer to the return code for the specific error.

EPERM

The caller does not have the appropriate privileges. The return code is set to `ARM_RC_AUTH_ERROR`.

EMVSSAF2ERR

An error occurred in the security product.

arm_unbind_thread() — Unbind the current thread to a given transaction

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | |

Format

```
#include <sys/_Elmarm4.h>

arm_error_t arm_unbind_thread(
/* [in] */ arm_start_handle_t start_handle,
/* [in] */ arm_int32_t flags,
/* [in] */ arm_buffer4_t *buffer4,
);
```

General description

Use `arm_unbind_thread()` to indicate the current thread is no longer performing processing on behalf of a given transaction.

If `arm_unbind_thread()` is not called, then `arm_stop_transaction()` unbinds any threads that remain bound to the transaction. This exists for recovery purposes. Applications are expected to use `arm_unbind_thread()` as part of normal processing.

start_handle

The handle returned by `arm_start_transaction()` for the transaction.

flags

Reserved for future use. The argument must be set to 0.

buffer4

A pointer to a buffer that identifies one or more sub-buffers containing additional data. Currently no sub-buffers are defined for this function so a null pointer should be passed. If a buffer is passed eWLM ignores it.

Returned value

On success, `arm_unbind_thread` returns `ARM_RC_SUCCESS`. On failure, the `errno` and return code are set to indicate the error. See [“Return code” on page 161](#) for the list of all possible return codes.

Error Code

Description

EFAULT

A parameter of this service contained an address that was not accessible to the caller.

EINVAL

A parameter of this service contained a value that was not valid.

EMVSARMERROR

An ARM error occurred. Refer to the return code for the specific error.

EPERM

The caller does not have the appropriate privileges. The return code is set to ARM_RC_AUTH_ERROR.

EMVSSAF2ERR

An error occurred in the security product.

arm_unblocked() — Indicate the processing of a transaction is no longer blocked

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | |

Format

```
#include <sys/_Elmarm4.h>

arm_error_t arm_unblocked(
/* [in]      */ arm_start_handle_t   start_handle,
/* [in]      */ arm_block_handle_t   block_handle,
/* [in]      */ arm_int32_t          flags,
/* [in]      */ arm_buffer4_t        *buffer4,
);
```

General description

Use arm_unblocked() to indicate that processing of a transaction is no longer blocked.

If arm_unblocked() is not called, then arm_stop_transaction() considers the transaction to be unblocked at the time it is stopped. This exists for recovery purposes. Applications are expected to use arm_unblocked() as part of normal processing.

start_handle

The handle returned by `arm_startarm_start_transaction()` for the transaction.

block_handle

The handle returned by `arm_blocked()`.

flags

Reserved for future use. The argument must be set to 0.

buffer4

A pointer to a buffer that identifies one or more sub-buffers containing additional data. Currently no sub-buffers are defined for this function so a null pointer should be passed. If a buffer is passed eWLM ignores it.

Returned value

On success, `arm_unblocked` returns `ARM_RC_SUCCESS`. On failure, the `errno` and return code are set to indicate the error. See [“Return code” on page 161](#) for the list of all possible return codes.

Error Code**Description****EFAULT**

A parameter of this service contained an address that was not accessible to the caller.

EINVAL

A parameter of this service contained a value that was not valid.

EMVSAARMERROR

An ARM error occurred. Refer to the return code for the specific error.

EPERM

The caller does not have the appropriate privileges. The return code is set to `ARM_RC_AUTH_ERROR`.

EMVSSAF2ERR

An error occurred in the security product.

arm_update_transaction() — Update a given transaction

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | |

Format

```
#include <sys/_Elmarm4.h>

arm_error_t arm_update_transaction(
/* [in] */ arm_start_handle_t start_handle,
/* [in] */ arm_int32_t flags,
/* [in] */ arm_buffer4_t *buffer4,
);
```

General description

arm_update_transaction() does not perform any function in the eWLM developer's edition. A future edition of eWLM may support a version of arm_update_transaction() that can be used to log problem determination data associated with the transaction.

start_handle

The handle returned by arm_start_transaction() for the transaction.

flags

Reserved for future use. The argument must be set to 0.

buffer4

A pointer to a buffer that identifies one or more sub-buffers containing additional data. A null pointer can be passed if no additional data is required. The proposed ARM4 standard defines a metric values sub-buffer for this function but eWLM does not process metrics. If a buffer is passed eWLM ignores it.

Returned value

On success, arm_update_transaction returns ARM_RC_SUCCESS. On failure, the errno and return code are set to indicate the error. See [“Return code” on page 161](#) for the list of all possible return codes.

Error Code

Description

EFAULT

A parameter of this service contained an address that was not accessible to the caller.

EINVAL

A parameter of this service contained a value that was not valid.

EMVSARMERROR

An ARM error occurred. Refer to the return code for the specific error.

EPERM

The caller does not have the appropriate privileges. The return code is set to ARM_RC_AUTH_ERROR.

EMVSSAF2ERR

An error occurred in the security product.

asctime(), asctime64() — Convert time to character string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```
#include <time.h>

char *asctime(const struct tm *timeptr);

#define _LARGE_TIME_API
#include <time.h>

char asctime64(const struct tm *timeptr);
```

General description

Converts time stored as a structure, pointed to by *timeptr*, to a character string. The *timeptr* value can be obtained from a call to `gmtime()` or `localtime()`. Both functions return a pointer to a `tm` structure defined in “time.h — Time and date” on page 75.

The string result that `asctime()` produces contains exactly 26 characters and has the format:

```
"%.3s %.3s%3d %.2d:%.2d:%.2d %d\n"
```

The following is an example of the string returned:

```
Fri Jun 16 02:03:55 2006\n\0
```

Notes:

1. The calendar time returned by a call to the `time()` function begins at epoch, which was at 00:00:00 Coordinated Universal Time (UTC), January 1, 1970.
2. The `asctime()` function uses a 24-hour clock format.
3. The days are abbreviated to: Sun, Mon, Tue, Wed, Thu, Fri, and Sat.
4. The months are abbreviated to: Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, and Dec.
5. All fields have a constant width.
6. Dates with only one digit are preceded either with a zero or a blank space.
7. The newline character (`\n`) and the NULL character (`\0`) occupy the last two positions of the string.
8. The `asctime()`, `ctime()`, and other time functions can use a common, statically allocated buffer for holding the return string. Each call to one of these functions may possibly destroy the result of the previous call.

The function `asctime64()` will behave exactly like `asctime()` except it will support a structured date beyond 03:14:07 UTC on January 19, 2038 with a limit of 23:59:59 UTC on December 31, 9999.

Returned value

If successful, `asctime()` returns a pointer to the resulting character string.

If the function is unsuccessful, it returns `NULL`.

Example

CELEBA06

```
/* CELEBA06

   This example polls the system clock and prints a message
   giving the current time.

*/
#include <time.h>
#include <stdio.h>

int main(void)
{
    struct tm *newtime;
    time_t ltime;

    /* Get the time in seconds */
    time(&ltime);
    /* Break it down & store it in the structure tm */
    newtime = localtime(&ltime);

    /* Print the local time as a string */
    printf("The current date and time are %s",
           asctime(newtime));
}
```

Output

```
The current date and time are Fri Jun 16 13:29:51 2006
```

asctime_r(), asctime64_r() – Convert date and time to a character string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 Language Environment | both | OS/390 V2R8 |

Format

```
#define _XOPEN_SOURCE 500
#include <time.h>
```

```
char *asctime_r(const struct tm *__restrict__ tm, char *__restrict__ buf);
```

```
#define _LARGE_TIME_API
#include <time.h>
```

```
char *asctime64_r(const struct tm *__restrict__ tm, char *__restrict__ buf);
```

General description

The `asctime_r()` function converts the broken-down time in the structure pointed to by *tm* into a character string that is placed in the user-supplied buffer pointed to by *buf* (which contains at least 26 bytes) and then returns *buf*.

The function `asctime64_r()` will behave exactly like `asctime_r()` except it will support a structured date beyond 03:14:07 UTC on January 19, 2038 with a limit of 23:59:59 UTC on December 31, 9999.

Returned value

If successful, `asctime_r()` returns a pointer to a character string containing the date and time. This string is pointed to by the argument *buf*.

If unsuccessful, `asctime_r()` returns NULL.

There are no documented errno values.

asin(), asinf(), asinl() — Calculate arcsine

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#include <math.h>

double asin(double x);
float asin(float x);           /* C++ only */
long double asin(long double x); /* C++ only */
float asinf(float x);
long double asinl(long double x);
```

General description

Calculates the arcsine of x , in the range $-\pi/2$ to $\pi/2$ radians.

The value of x must be between -1 and 1 .

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

Returned value

If x is less than -1 or greater than 1 , the function sets `errno` to `EDOM`, and returns `0`. Otherwise, it returns a nonzero value.

If the correct value would cause an underflow, `0` is returned and the value `ERANGE` is stored in `errno`.

Special behavior for IEEE: If successful, the function returns the arcsine of its argument x .

If x is less than -1 or greater than 1 , the function sets `errno` to `EDOM` and returns `NaNQ`. No other errors will occur.

Example

CELEBA07

```
/* CELEBA07

This example prompts for a value for x.
It prints an error message if x is greater than 1 or
less than -1; otherwise, it assigns the arcsine of
x to y.

*/
#include <stdio.h>
#include <stdlib.h>
```

```

#include <math.h>
#define MAX 1.0
#define MIN -1.0

int main(void)
{
    double x, y;

    printf( "Enter x\n" );
    scanf( "%lf", &x );

    /* Output error if not in range */
    if ( x > MAX )
        printf( "Error: %f too large for asin\n", x );
    else if ( x < MIN )
        printf( "Error: %f too small for asin\n", x );
    else {
        y = asin( x );
        printf( "asin( %f ) = %f\n", x, y );
    }
}

```

Output

```

Enter x
0.2 is entered
asin( 0.200000 ) = 0.201358

```

asinh(), asinhf(), asinhl() — Calculate hyperbolic arcsine

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <math.h>

double asinh(double x);
```

C99:

```
#define _ISOC99_SOURCE
#include <math.h>

float asinhf(float x);
long double asinhl(long double x);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

float asinh(float x);
long double asinh(long double x);
```

General description

The asinh() functions return the hyperbolic arcsine of its argument x.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------|-----|------|
| asinh | X | X |
| asinhf | X | X |
| asinhl | X | X |

Returned value

`asinh()` returns the hyperbolic arcsine of its argument x . The function is always successful.

asprintf(), vasprintf() – Print to allocated string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <stdio.h>

int asprintf(char **strp, const char *fmt, ...);
int vasprintf(char **strp, const char *fmt, va_list ap);
```

General description

`asprintf()` and `vasprintf()` are analogs of `sprintf()` and `vsprintf()`, except that they allocate a string that is large enough to hold the output including the terminating NULL byte, and return a pointer to it via the first argument. This pointer must be passed to `free()` to release the allocated storage when it is no longer needed.

Returned value

If successful, `asprintf()` and `vasprintf()` return the number of bytes that are printed, same as `sprintf()`.

If memory allocation is not possible, or some other error occurs, `asprintf()` and `vasprintf()` return -1 and the content of `strp` is undefined.

- [“vprintf\(\) — Format and print data to stdout” on page 1974](#)

assert() — Verify condition

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <assert.h>

void assert(int expression);
```

General description

The `assert()` macro inserts diagnostics into a program. If the expression (which will have a scalar type) is false (that is, compares equal to 0), a diagnostic message of the form shown below is printed to `stderr`, and `abort()` is called to abnormally end the program. The `assert()` macro takes no action if the expression is true (nonzero).

Without a compiler that is designed to support C99, or when compiling C++ code, the diagnostic message has the following format:

```
Assertion failed: expression, file filename, line line-number.
```

With a compiler that is designed to support C99, or when compiling C++ code, the diagnostic message has the following format:

```
Assertion failed: expression, file filename, line line-number, function function-name.
```

If you define `NDEBUG` to any value with a `#define` directive or the compiler option to define macros, the C/C++ preprocessor expands all `assert()` invocations to void expressions.

Note: The `assert()` function is a macro. Using the `#undef` directive with the `assert()` macro results in undefined behavior. The `assert()` macro uses `__FILE__`, `__LINE__` and, with a compiler that is designed to support C99, `__func__`...

Returned value

`assert()` returns no values.

Example

CELEBA08

```
/* CELEBA08

   In this example, the assert() macro tests the string argument for a
   null string and an empty string, and verifies that the length argument
   is positive before proceeding.

*/
#include <stdio.h>
#include <assert.h>

void analyze(char *, int);
int main(void)
{
    char *string1 = "ABC";
    char *string2 = "";
    int length = 3;

    analyze(string1, length);
    printf("string1 %s is not null or empty, "
           "and has length %d \n", string1, length);
    analyze(string2, length);
    printf("string2 %s is not null or empty, "
           "and has length %d\n", string2, length);
}

void analyze(char *string, int length)
{
    assert(string != NULL);      /* cannot be NULL */
    assert(*string != '\0');     /* cannot be empty */
    assert(length > 0);         /* must be positive */
}
```

Output without a compiler that is designed to support C99

```
String1 ABC is not NULL or empty, and has length 3
Assertion failed: *string != '\0', file: CELEBA08 C      A1, line: 26
```

Output with a compiler that is designed to support C99

```
String1 ABC is not NULL or empty, and has length 3
Assertion failed: *string != '\0', file: CELEBA08 C      A1, line: 26 in function analyze
```

atan(), atanf(), atanl(), atan2(), atan2f(), atan2l() – Calculate arctangent

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#include <math.h>

double atan(double x);
float atan(float x);           /* C++ only */
long double atan(long double x); /* C++ only */
float atanf(float x);
long double atanl(long double x);

double atan2(double y, double x);
float atan2(float y, float x);   /* C++ only */
long double atan2(long double y, long double x); /* C++ only */
float atan2f(float y, float x);
long double atan2l(long double y, long double x);
```

General description

The `atan()` and `atan2()` functions calculate the arctangent of x and y/x , respectively.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

Restriction: The `atan2f()` function does not support the `_FP_MODE_VARIABLE` feature test macro.

Returned value

Returns a value in the range $-\pi/2$ to $\pi/2$ radians.

The `atan2()` functions return a value in the range $-\pi$ to π radians. If both arguments of `atan2()` are zero, the function sets `errno` to `EDOM`, and returns 0. If the correct value would cause underflow, zero is returned and the value `ERANGE` is stored in `errno`.

Special behavior for IEEE: If successful, `atan2()` returns the arctangent of y/x .

If both arguments of `atan2()` are zero, the function sets `errno` to `EDOM` and returns 0. No other errors will occur.

Example

CELEBA09

```
/* CELEBA09 */
#include <math.h>
#include <stdio.h>

int main(void)
```

```
{
    double a,b,c,d;

    c = 0.45;
    d = 0.23;

    a = atan(c);
    b = atan2(c,d);

    printf("atan( %f ) = %f\n", c, a);
    printf("atan2( %f, %f ) = %f\n", c, d, b);
}
```

Output

```
atan( 0.450000 ) = 0.422854
atan2( 0.450000, 0.230000 ) = 1.098299
```

Note: To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

Returns a value in the range $-\pi/2$ to $\pi/2$ radians.

If both arguments of `atan2()` are zero, the function sets `errno` to `EDOM` and returns 0. No other errors will occur.

Example

CELEBA15

```
/* CELEBA15
   This example illustrates the atand64() and atan2d64() functions.
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal64 a,b,c,d;

    c = 0.45DD;
    d = 0.23DD;

    a = atand64(c);
    b = atan2d64(c,d);

    printf("atand64( %Df ) = %Df\n", c, a);
    printf("atan2d64( %Df, %Df ) = %Df\n", c, d, b);
}
```

atanh(), atanhf(), atanh() – Calculate hyperbolic arctangent

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <math.h>

double atanh(double x);
```

C99:

```
#define _ISOC99_SOURCE
#include <math.h>

float atanhf(float x);
long double atanh1(long double x);
```

C++ TR1 C99

```
#define _TR1_C99
#include <math.h>
float atanh(float x);
long double atanh(long double x);
```

General description

The `atanh()` function returns the hyperbolic arctangent of its argument x .

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|---------------------|-----|------|
| <code>atanh</code> | X | X |
| <code>atanhf</code> | X | X |
| <code>atanhl</code> | X | X |

Returned value

If successful, `atanh()` returns the hyperbolic arctangent of its argument x .

`atanh()` fails, returns 0.0 and sets `errno` to one of the following values:

Error Code

Description

EDOM

The x argument has a value greater than 1.0.

ERANGE

The x argument has a value equal to 1.0.

Special behavior for IEEE: If successful, the function returns the hyperbolic arctangent of its argument x .

If the absolute value of x is greater than 1.0, `atanh()` sets `errno` to `EDOM` and returns `NaNQ`. If the value of x is equal to 1.0, the function sets `errno` to `ERANGE` and returns `+HUGE_VAL`.

atanhd32(), atanh64(), atanh128() - Calculate hyperbolic arctangent

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.10 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 atanh32(_Decimal32 x);
_Decimal64 atanh64(_Decimal64 x);
_Decimal128 atanh128(_Decimal128 x);
_Decimal32 atanh(_Decimal32 x); /* C++ only */
_Decimal64 atanh(_Decimal64 x); /* C++ only */
_Decimal128 atanh(_Decimal128 x); /* C++ only */
```

General description

The `atanh()` function returns the hyperbolic arctangent of its argument x .

These functions work in IEEE decimal floating-point format. See [“IEEE decimal floating-point” on page 97](#) for more information.

Note: To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

If successful, the function returns the hyperbolic arctangent of its argument x .

If the absolute value of x is greater than 1.0, atanh() sets errno to EDOM and returns NaNQ. If the value of x is equal to 1.0, the function sets errno to ERANGE and returns +HUGE_VAL_D32, +HUGE_VAL_D64 or +HUGE_VAL_D128.

Example

CELEBA16

```
/* CELEBA16

   This example illustrates the atanh32() function.
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal32 x, y;

    x = 0.5DF;
    y = atanh32(x);

    printf("atanh32(%Hf) = %Hf\n", x, y);
}
```

__atanpid32(), __atanpid64(), __atanpid128() - Calculate arctangent(x)/pi

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | z/OS V1.10 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>
```

```
_Decimal32 __atanpid32(_Decimal32 x);
_Decimal64 __atanpid64(_Decimal64 x);
_Decimal128 __atanpid128(_Decimal128 x);
```

General description

Calculates the value of $\arctangent(x)/\pi$.

These functions work in IEEE decimal floating-point format. See [“IEEE decimal floating-point” on page 97](#) for more information.

Note: To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

Returns the calculated value expressed in radians.

Example

CELEBA17

```
/* CELEBA17
   This example illustrates the __atanpid64() function.
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal64 x, y;

    x = 5.0DD;
    y = __atanpid64(x);

    printf("__atanpid64(%Df) = %Df\n", x, y);
}
```

atexit() — Register program termination function

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdlib.h>

int atexit(void (*func)(void));
```

General description

Records a function, pointed to by *func*, that the system calls at normal program termination. Termination is a result of `exit()` or returning from `main()`, regardless of the language of the `main()` routine. Process termination started by `_exit()` or by a terminating signal under Language Environment is not included.

The functions are executed in the reverse order that they were registered. The registered function must return to ensure that all registered functions are called. The functions registered with `atexit()` are started before streams and files are closed. You may specify a number of functions to the limit set by the `ATEXIT_MAX` constant, which is defined in `<limits.h>`.

Under z/OS UNIX services only, when a process ends, the address space is ended; otherwise, the address space persists.

Special behavior for IBM z/OS C

The C Library `atexit()` function has the following restrictions:

- Any function registered by a fetched module that has been released is removed from the list at the time of `release()`. See `fetch()`, `fetchep()`, and `release()` for details about fetching and releasing modules.
- Any function registered in an explicitly loaded DLL (using `dllload()`) that has been freed (using `dllfree()`) is removed from the list. But, if the DLL in question has also been implicitly loaded, then the function is NOT removed from the `atexit` list.
- All C Library library functions can be used in a registered routine except `exit()`.
- When a program is running under CICS control, if an `EXEC CICS RETURN` command or an `EXEC CICS XCTL` command is issued, the `atexit()` list that has been previously registered is not run.
- Use of the `system()` library function within `atexit()` may result in undefined behavior.
- Use of non-C subroutines or functions in the `atexit()` list will result in undefined behavior.
- The `atexit()` list will not be run when `abort()` is called.

Special behavior for IBM z/OS C++

- All of the behaviors listed under "Special Behavior for IBM z/OS C".
- Because C and C++ linkage conventions are incompatible, `atexit()` cannot receive C++ function pointers. If you attempt to pass a C++ function pointer to `atexit()`, the compiler will flag it as an error. To use the C++ `atexit()` function, you must ensure that all functions registered for `atexit()` have C linkage by declaring them as `extern "C"`.
- You can use `try`, `throw`, and `catch` in a function registered for `atexit()`. However, by the time an `atexit()` function is driven, all stack frames will have collapsed. As a result, the only `catch` clauses available for `throw` will be the ones coded in the `atexit()` function. If those `catch` clauses cannot handle the thrown object, `terminate()` will be called.

Special behavior for XPG4.2: The maximum number of functions that can be registered is specified by the symbol `ATEXIT_MAX` which is defined in the `limits.h` header.

Returned value

If successful, `atexit()` returns 0.

If unsuccessful, `atexit()` returns nonzero.

Example

CELEBA10

```

/* CELEBA10

   This example uses the atexit() function to call the function goodbye()
   at program termination.

   */
#include <stdlib.h>
#include <stdio.h>

#ifdef __cplusplus      /* the __cplusplus macro is      */
extern "C" void goodbye(void); /* automatically defined by the */
#else                  /* C++/MVS compiler      */
void goodbye(void);
#endif

int main(void)
{
    int rc;

    rc = atexit(goodbye);
    if (rc != 0)
        printf("Error in atexit");
    exit(0);
}

void goodbye(void)
/* This function is called at normal program termination */
{
    printf("The function goodbye was called \
at program termination\n");
}

```

Output

```
The function goodbye was called at program termination
```

__atoe() — ISO8859-1 to EBCDIC string conversion

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```

#include <unistd.h>

int __atoe(char *string);

```

General description

The __atoe() function converts an ISO8859-1 character string *string* to its EBCDIC equivalent. The conversion is performed using the codeset page associated with the current locale. The input character string up to, but not including, the NULL is changed from an ISO8859-1 representation to that of the current locale.

The argument *string* points to the ISO8859-1 character string to be converted to its EBCDIC equivalent.

Returned value

If successful, __atoe() converts the input ISO8859-1 character string to its equivalent EBCDIC value, and returns the length of the converted string.

If unsuccessful, __atoe() returns -1 and sets errno to one of the following values:

Error Code
Description

EINVAL
The current locale does not describe a single-byte character set.

ENOMEM
There is insufficient storage to complete the conversion process.

Note: This function may internally call iconv_open() and iconv(). The errnos returned by these functions are propagated without modification.

Related information

- [“unistd.h — Implementation-specific functions” on page 77](#)
- [“iconv\(\) — Code conversion” on page 824](#)
- [“iconv_open\(\) — Allocate code conversion descriptor” on page 828](#)

__atoe_l() — ISO8859-1 to EBCDIC conversion operation

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <unistd.h>

int __atoe_l(char *bufferptr, int leng);
```

General description

The __atoe_l() function converts *leng* ISO8859-1 bytes in the buffer pointed to by *bufferptr* to their EBCDIC equivalent. The conversion is performed using the codeset page associated with the current locale.

The argument *bufferptr* points to a buffer containing the ISO8859-1 bytes to be converted to their EBCDIC equivalent. The input buffer is treated as sequence of bytes, and all bytes in the input buffer are converted, including any imbedded NULLs.

Returned value

If successful, `__atoe_l()` converts the input IOS8859-1 bytes to their equivalent EBCDIC value, and returns the number of bytes that were converted.

If unsuccessful, `__atoe_l()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

The current locale does not describe a single-byte character set.

ENOMEM

There is insufficient storage to complete the conversion process.

Note: This function may internally call `iconv_open()` and `iconv()`. The `errno`s returned by these functions are propagated without modification.

atof() — Convert character string to double

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdlib.h>

double atof(const char *nptr);
```

General description

The `atof()` function converts the initial portion of the string pointed to by `nptr` to a 'double'. This is equivalent to

```
strtod(nptr, (char**)NULL)
```

The double value is either hexadecimal floating point or binary floating point, depending on the floating point mode of the thread invoking the `atof()` function. This function uses `_isBF()` to determine the floating point mode of the invoking thread.

See the [“fscanf Family of Formatted Input Functions” on fscanf\(\), scanf\(\), sscanf\(\) — Read and format data](#) for a description of special infinity and NaN sequences recognized by z/OS formatted input functions, including `atof()` and `strtod()` in IEEE Binary Floating-Point mode.

Returned value

The `atof()` function returns the converted value if the value can be represented, otherwise the return value is undefined.

Related information

atoi() — Convert character string to integer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdlib.h>

int atoi(const char *nptr);
```

General description

The `atoi()` function converts the initial portion of the string pointed to by `nptr` to a 'int'. This is equivalent to

```
(int)strtol(nptr, NULL, 10)
```

Returned value

There are no documented `errno` values.

Related information

atol() — Convert character string to long

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdlib.h>

long int atol(const char *nptr);
```

General description

The `atol()` function converts the initial portion of the string pointed to by *nptr* to a 'long int'. This is equivalent to

```
strtol(nptr, (char**)NULL, 10)
```

Returned value

The `atol()` function returns the converted value if the value can be represented, otherwise the return value is undefined.

atoll() – Convert character string to signed long long

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _ISOC99_SOURCE
#include <stdlib.h>
long long atoll(const char *nptr);
```

Compile requirement: Use of this function requires the long long data type. See [z/OS XL C/C++ Language Reference](#) for information on how to make long long available.

General description

atoll() converts the initial portion of the string pointed to by *nptr* to a 'long long int'. This is equivalent to strtoll(*nptr*, (char **)NULL, 10).

Returned value

If successful, atoll() returns the converted signed long long value, represented in the string. If unsuccessful, it returns an undefined value.

Related information

- [“stdlib.h – Standard library functions” on page 65](#)
- [“atof\(\) – Convert character string to double” on page 201](#)
- [“atoi\(\) – Convert character string to integer” on page 202](#)

- [“strtoul\(\) – Convert string to unsigned integer” on page 1773](#)
- [“strtol\(\) – Convert character string to long” on page 1768](#)

__authenticate() – Authenticate the specified user’s credentials

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <unistd.h>

int __authenticate(unsigned int Auth_cred_type, int *User_name_length,
                  char *User_name, int Pass_length, char *Pass, int New_pass_length,
```

```
char *New_pass, int *Idt_buffer_length, char *Idt_buffer_ptr,
int *Idt_length, char **Msg_buffer_ptr, int Appl_id_length,
char *Appl_id, unsigned int *Option_flags);
```

General description

The `__authenticate()` function authenticates a user by using passwords, password phrases, PassTickets, or Identity Tokens (IDTs). It also optionally generates an IDT, which is used for follow-on authentications. The `__authenticate()` function authenticates the user's credentials only. `__authenticate()` does not create a security context (ACEE) or modify the caller's process or thread identity.

Auth_cred_type

Identifies the type of credentials to be used for authentication. It can be specified to the following values:

AUTH_USER_ID

The *User_name* parameter that is specified by the caller is passed to RACF for the authentication.

AUTH_ID_TOKEN

The IDT from the location that is specified by the *Idt_buffer_ptr* parameter is passed to RACF for authentication.

Note: When both AUTH_USER_ID and AUTH_ID_TOKEN are specified, both the *userid* and IDT are passed to RACF. If the *userid* that is associated with the IDT does not match the *User_name* parameter, the authentication fails.

User_name_length

When AUTH_USER_ID is specified for the *Auth_cred_type* parameter, it specifies the length of the *User_name* parameter string.

Returned length of the *User_name* parameter string that is returned when authenticating with only an IDT. The name is obtained from a temporary ACEE that is created by RACF. The caller must specify the maximum *userid* length of 8 characters to accommodate all possible *userid* sizes. `authenticate()` does not modify the *User_name_length* parameter that is specified by the caller to indicate the length of the returned *User_name* parameter string.

User_name

Supplied *userid* when *Auth_cred_type* specifies AUTH_USER_ID.

Returned *userid* when *Auth_cred_type* specifies AUTH_ID_TOKEN and AUTH_USER_ID is not specified.

This parameter is an input/output parameter, the storage must be writable.

Pass_length

Contains the length of the *Pass* parameter. This length must be between 1 and 8 characters for a password or PassTicket or between 9 and 100 characters for a password phrase. A length of zero indicates that *Pass* is to be ignored.

Pass

Contains left-justified, the password, PassTicket, or password phrase that is to be verified.

New_pass_length

Contains the length of *New_pass*. This length must be between 1 and 8 characters for a password or between 9 and 100 characters for a password phrase. A length of zero indicates that *New_pass* is to be ignored.

New_pass

Contains left-justified, the new password or password phrase.

Idt_buffer_length

Contains supplied length of the buffer that is pointed to by *Idt_buffer_ptr*. If the supplied buffer is smaller than the IDT that is built by RACF, `__authenticate()` fails with -1 and EINVAL, and JrBuffTooSmall and the required length is returned in the *Idt_length* parameter. In this situation, the caller must allocate a larger buffer and recall `__authenticate()`.

__authenticate()

Idt_buffer_ptr

Contains supplied address of the buffer that can be used for input or output of an IDT.

When AUTH_ID_TOKEN is specified for the *Auth_cred_type* parameter, the buffer contains an IDT that `__authenticate()` passes to RACF to be authenticated.

When only AUTH_USER_ID is specified for the *Auth_cred_type* parameter and AUTH_BUILD_IDT is specified for the *Option_flags* parameter, if an IDT is generated, `__authenticate()` copies the generated IDT into the buffer.

In both cases, if an IDT is copied into the buffer, the AUTH_RETURNED_IDT flag in the *Option_flags* parameter is set by `__authenticate()` and returned to the caller.

Idt_length

Contains the address of IDT length.

When AUTH_ID_TOKEN is specified for the *Auth_cred_type* parameter, this parameter supplies the length of the IDT whose location is specified by the *Idt_buffer_ptr* parameter. In this case, when AUTH_USER_ID is specified for the *Auth_cred_type* parameter and AUTH_BUILD_IDT is specified for the *Option_flags* parameter, the length must be zero.

When AUTH_ID_TOKEN is specified for the *Auth_cred_type* parameter and RACF refreshes the IDT while authenticating the IDT that is supplied by the caller, this parameter returns the length of the IDT that is copied into the location that is specified by the *Idt_buffer_ptr* parameter. In this case, when AUTH_USER_ID is specified for the *Auth_cred_type* parameter and AUTH_BUILD_IDT is specified for the *Option_flags* parameter, the size of the created IDT that is generated by RACF is returned.

Note: The *Idt_length* parameter can be both supplied and returned for the same `__authenticate()` call depending on the previous conditions being met or not.

Msg_buffer_ptr

Contains the address of a pointer of a message buffer if any messages are returned by RACF. All message buffers for one `__authenticate()` call are located in a contiguous piece of storage and the caller is responsible for freeing the buffer storage by using `free()`. The AUTH_MSGRTRN option in the *Option_flags* parameter must be specified to have messages returned.

Appl_id_length

Contains the length of the *Appl_id* parameter. This length must be between 1 and 8 characters. A length of zero indicates the *Appl_id* parameter is to be ignored.

Appl_id

Contains left-justified, the APPLID that identifies the name of the application that requests authentication. If *Appl_id* is not specific (*Appl_id_length* of zero), the application ID defaults to OMVSAPPL.

Option_flags

Contains the `__authenticate()` options. If no options are required, specify 0 for this parameter.

The following values are valid for this parameter:

AUTH_BUILD_IDT

Requests that an ID Token is built by RACF and returned to the caller. This option is valid when only AUTH_USER_ID is specified (AUTH_ID_TOKEN is not specified) for the *Auth_cred_type* parameter. The ID Token is returned to the caller in the buffer that is pointed to by the *Idt_buffer_ptr* parameter and its length is returned in the *Idt_length* parameter.

AUTH_RETURN_USERNAME

Requests that the userid that is associated with the ID Token that is used for authentication be returned in the field that is specified by the *User_name* parameter. This option is valid when only AUTH_ID_TOKEN is specified (AUTH_USER_ID is not specified) for the *Auth_cred_type* parameter and the *User_name_length* parameter contains a value of 8. If those conditions are not met, the request fails. The length of the returned *User_name* is returned in the *User_name_length* parameter.

AUTH_MSGRTRN

Controls the *MSGRTRN* parameter that is specified on the RACROUTE REQUEST=VERIFY call that is made by `__authenticate()`.

When *AUTH_MSGRTRN* is not specified, *MSGRTRN*=NO is specified for the resulting RACROUTE REQUEST=VERIFY by default. Messages are not returned in a buffer but are issued by RACF using TPUT.

When *AUTH_MSGRTRN* is specified, *MSGRTRN*=YES is specified for RACROUTE REQUEST=VERIFY. The address of the message buffer that is obtained by RACF is returned in the *Msg_buffer_ptr* parameter.

AUTH_RETURNED_IDT

Returned by `__authenticate()` to indicate that an IDT is copied into the location that is specified by the *Idt_buffer_ptr* parameter. The length of that IDT is returned in the *Idt_length* parameter. This occurs when the caller requests to build a new IDT or authenticates with an IDT and RACF refreshes the IDT in response to changes of system or user settings. *AUTH_RETURNED_IDT* must not be specified by the caller. Otherwise, `__authenticate()` fails with -1, EINVAL, and JrBadOptnFlags.

Returned value

If successful, `__authenticate()` returns a value of 0.

If unsuccessful, `__authenticate()` returns a value of -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

Permission is denied.

EINVAL

The parameter is incorrect.

ESRCH

No such process or thread exists.

EMVSSAFEXTRERR

SAF/RACF extract error.

EMVSSAF2ERR

SAF/RACF error.

EMVSEXPIRE

The password for the specified resource is expired.

EMVSPASSWORD

The new password or password phrase that is specified is not valid.

Usage notes

- If a profile is defined in the FACILITY class protecting the BPX.DAEMON resource, all programs that are loaded into the caller's address space must be controlled programs by the installed security product (such as RACF). If `__authenticate` detects that a load of a nonprogram control program is done, it fails with an `errno` of EMVSERR and an `errnojr` of JRENVDIRTY. For more information, see [Establishing the correct level of security for daemons in z/OS UNIX System Services Planning](#).
- To request RACF to return messages in a buffer, the *AUTH_MSGRTRN* option in the *Option_flags* parameter must be specified with the *Msg_buffer_ptr* parameter. If the *AUTH_MSGRTRN* option is not specified, the *Msg_buffer_ptr* parameter is ignored and `__authenticate()` does not request RACF to return messages resulting from the request. When not returning messages, RACF issues the messages by using TPUT. For more information about messages returned by RACF, see the MSGSP and MSGRTRN parameters in [RACROUTE \(standard form\)](#) in *z/OS Security Server RACROUTE Macro Reference*.

- When a message buffer address is returned to the caller in the *Msg_buff_ptr* parameter, the caller is responsible to free the storage it points to. The format of the buffer is defined by RACF. The area consists of two fullwords followed by the message itself in write-to-operator (WTO) parameter list format. The first word is the length of the area including the two-fullword header; the second word points to the next message area, if there is one, or contains zero if no more message areas exist. See MSGRTRN and MSGSP parameters in *RACROUTE (standard form)* in *z/OS Security Server RACROUTE Macro Reference* for more information about messages that are returned by RACF.
- The minimum size of an IDT is 1024 bytes. See *Activating and using the IDTA parameter in RACROUTE REQUEST=VERIFY and initACEE* in *z/OS Security Server RACROUTE Macro Reference* for more information about IDTs.
- `__authenticate` accepts and returns signed IDTs only. See *Activating and using the IDTA parameter in RACROUTE REQUEST=VERIFY and initACEE* in *z/OS Security Server RACROUTE Macro Reference* for more information about signed and unsigned IDTs.
- The *Idt_buffer_length* and *Idt_buffer_ptr* parameters detail the length and location of the buffer that is supplied by the caller for storing IDTs. The *Idt_length* parameter details the length of an IDT that is located in the IDT buffer. The caller specifies the *Idt_length* when supplying an IDT for authentication. The system returns the *Idt_length* when either building a new IDT or for an IDT that is refreshed by RACF when authenticating with an IDT. When the system returns a new or refreshed IDT, the AUTH_RETURNED_IDT flag in the *Option_flags* parameter is set and returned to the caller to indicate a created or refreshed IDT is returned.

`__a2e_l()` — Convert characters from ASCII to EBCDIC

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | z/OS V1R2 |

Format

```
#include <unistd.h>

size_t __a2e_l(char *bufptr, size_t szLen)
```

General description

The `__a2e_l()` function converts *szLen* characters in *bufptr* from ASCII to EBCDIC, returning the number of characters converted if successful or -1 if not. Conversion occurs in place in the buffer. `__a2e_l()` is not sensitive to the locale, and only converts between ISO8859-1 and IBM-1047.

Note: This function is valid for applications compiled XPLINK only.

Returned value

If successful, `__a2e_l()` returns the number of characters converted.

If unsuccessful, `__a2e_l()` returns -1 and sets `errno` to the following value:

Error Code

Description

EINVAL

The pointer to *bufptr* is NULL or *szLen* is a negative value.

Related information

__a2e_s() — Convert string from ASCII to EBCDIC

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | z/OS V1R2 |

Format

```
#include <unistd.h>

size_t __a2e_s(char *string)
```

General description

The `__a2e_s()` function converts a string from ASCII to EBCDIC, returning the string length if successful or -1 if not. Conversion occurs in place in the string. `__a2e_s()` is not sensitive to the locale, and only converts between ISO8859-1 and IBM-1047.

Note: This function is valid for applications compiled XPLINK only.

Returned value

If successful, `__a2e_s()` returns the string length.

If unsuccessful, `__a2e_s()` returns -1 and sets `errno` to the following value:

Error Code

Description

EINVAL

The pointer to string is NULL.

a64l() — Convert base 64 string representation to long integer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

long a64l(const char *string);
```

General description

The a64l() function converts a string representation of a base 64 number into its corresponding long value. It scans the string from left to right with the least significant character on the left, decoding each character as a 6-bit base 64 number. If the string pointed to by *string* contains more than six characters, a64l() uses only the first six. If the first six characters of the string contain a NULL character, a64l() uses only the characters preceding the first NULL. The following characters are used to represent digits:

| Character | Digit Represented |
|-----------|-------------------|
| . | 0 |
| / | 1 |
| 0-9 | 2-11 |
| A-Z | 12-37 |
| a-z | 38-63 |

Returned value

If successful, a64l() returns the long value resulting from conversion of the input string.
If the string pointed to by *string* is NULL, a64l() returns 0.
There are no errno values defined.

basename() – Return the last component of a path name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <libgen.h>
```

```
char *basename(char *path);
```

General description

The `basename()` function takes the pathname pointed to by *path* and returns a pointer to the final component of the pathname, deleting any trailing '/' characters.

If the string consists entirely of the '/' character, `basename()` returns a pointer to the string "/".

If *path* is a NULL pointer or points to an empty string, `basename()` returns a pointer to the string ".". The `basename()` function may modify the string pointed to by *path*.

Examples:

| Input String | Output String |
|--------------|---------------|
| "/usr/lib" | "lib" |
| "/usr/" | "usr" |
| "/" | "/" |

Returned value

If successful, `basename()` returns a pointer to the final component of *path*.

There are no `errno` values defined.

Related information

- [“libgen.h — Pattern matching functions” on page 34](#)

bcmp() — Compare bytes in memory

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <strings.h>

int bcmp(const void *s1, const void *s2, size_t n);
```

General description

The `bcmp()` function compares the first *n* bytes of the area pointed to by *s1* with the area pointed to by *s2*.

Note: The `bcmp()` function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The `memcmp()` function is preferred for portability.

Returned value

If *s1* and *s2* are identical, `bcmp()` returns 0. Otherwise, `bcmp()` returns nonzero. Both areas are assumed to be at least *n* bytes long.

If the value of *n* is zero, `bcmp()` returns 0.

There are no errno values defined.

bcopy() — Copy bytes in memory

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <strings.h>

void bcopy(const void *s1, void *s2, size_t n);
```

General description

The `bcopy()` function copies *n* bytes from the area pointed to by *s1* to the area pointed to by *s2* using the `memcpy()` function.

Note: The `bcopy()` function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The `memmove()` function is preferred for portability.

Returned value

`bcopy()` returns no values.

There are no errno values defined.

bind() — Bind a name to a socket

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int bind(int socket, const struct sockaddr *address, socklen_t address_len);
```

Berkeley Sockets

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>

int bind(int socket, struct sockaddr *address, int address_len);
```

General description

The `bind()` function binds a unique local name to the socket with descriptor *socket*. After calling `socket()`, a descriptor does not have a name associated with it. However, it does belong to a particular address family as specified when `socket()` is called. The exact format of a name depends on the address family.

Parameter

Description

socket

The socket descriptor returned by a previous `socket()` call.

address

The pointer to a **sockaddr** structure containing the name that is to be bound to *socket*.

address_len

The size of *address* in bytes.

The *socket* parameter is a socket descriptor of any type created by calling `socket()`.

The *address* parameter is a pointer to a buffer containing the name to be bound to *socket*. The *address_len* parameter is the size, in bytes, of the buffer pointed to by *address*. For `AF_UNIX`, this function creates a file that you later need to unlink besides closing the socket.

Socket Descriptor Created in the `AF_INET` Domain

If the socket descriptor *socket* was created in the `AF_INET` domain, the format of the name buffer is expected to be **sockaddr_in**, as defined in the include file `netinet/in.h`:

```
struct in_addr
{
    ip_addr_t s_addr;
};

struct sockaddr_in {
    unsigned char sin_len;
    unsigned char sin_family;
    unsigned short sin_port;
    struct in_addr sin_addr;
    unsigned char sin_zero[8];
};
```

```
};
```

The *sin_family* field must be set to AF_INET.

The *sin_port* field is set to the port to which the application must bind. It must be specified in network byte order. If *sin_port* is set to 0, the caller leaves it to the system to assign an available port. The application can call `getsockname()` to discover the port number assigned.

The *sin_addr.s_addr* field is set to the Internet address and must be specified in network byte order. On hosts with more than one network interface (called multihomed hosts), a caller can select the interface to which it is to bind. Subsequently, only UDP packets and TCP connection requests from this interface (which match the bound name) are routed to the application. If this field is set to the constant INADDR_ANY, as defined in `netinet/in.h`, the caller is requesting that the socket be bound to all network interfaces on the host. Subsequently, UDP packets and TCP connections from all interfaces (which match the bound name) are routed to the application. This becomes important when a server offers a service to multiple networks. By leaving the address unspecified, the server can accept all UDP packets and TCP connection requests made for its port, regardless of the network interface on which the requests arrived.

The *sin_zero* field is not used and must be set to all zeros.

Socket Descriptor Created in the AF_INET6 Domain If the socket descriptor *socket* was created in the AF_INET6 domain, the format of the name buffer is expected to be **sockaddr_in6**, as defined in the include file `netinet/in.h`. The structure is defined as follows:

```
struct sockaddr_in6 {
    uint8_t      sin6_len;
    sa_family_t  sin6_family;
    in_port_t    sin6_port;
    uint32_t     sin6_flowinfo;
    struct in6_addr sin6_addr;
    uint32_t     sin6_scope_id;
};
```

The *sin6_len* field is set to the size of this structure. The SIN6_LEN macro is defined to indicate the version of the `sockaddr_in6` structure being used.

The *sin6_family* field identifies this as a `sockaddr_in6` structure. This field overlays the *sa_family* field when the buffer is cast to a `sockaddr` structure. The value of this field must be AF_INET6.

The *sin6_port* field contains the 16-bit UDP or TCP port number. This field is used in the same way as the *sin_port* field of the `sockaddr_in` structure. The port number is stored in network byte order.

The *sin6_flowinfo* field is a 32-bit field that contains the traffic class and the flow label.

The *sin6_addr* field is a single `in6_addr` structure. This field holds one 128-bit IPv6 address. The address is stored in network byte order.

The *sin6_scope_id* field is a 32-bit integer that identifies a set of interfaces as appropriate for the scope of the address carried in the *sin6_addr* field. For a link scope *sin6_addr*, *sin6_scope_id*, this would be an interface index. For a site scope *sin6_addr*, *sin6_scope_id*, this would be a site identifier.

Socket Descriptor Created in the AF_UNIX Domain

If the socket descriptor *socket* is created in the AF_UNIX domain, the format of the name buffer is expected to be `sockaddr_un`, as defined in the include file **un.h**.

```
struct sockaddr_un {
    unsigned char sun_len;
    unsigned char sun_family;
    char          sun_path[108];    /* pathname */
};
```

The *sun_family* field is set to AF_UNIX.

The *sun_path* field contains the NULL-terminated pathname, and *sun_len* contains the length of the pathname.

Notes:

1. For AF_UNIX, when a bind is issued, a file is created with a mode of 660. In order to allow other users to access this file, a `chmod()` should be issued to modify this mode if desired.
2. For AF_UNIX, when closing sockets that were bound, you should also use `unlink()` to delete the file created at `bind()` time.
3. The pathname the client uses on the `bind()` must be unique.
4. The `sendto()` call must specify the pathname associated with the server.
5. For AF_INET or AF_INET6, the user must have appropriate privileges to bind to a port in the range from 1 to 1023.

Special Behavior for C++

To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

Note: The `bind()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support”](#) on page 2123 for details.

Returned value

If successful, `bind()` returns 0.

If unsuccessful, `bind()` returns -1 and sets `errno` to one of the following values:

Error Code**Description****EACCES**

Permission denied.

EADDRINUSE

The address is already in use. See the `SO_REUSEADDR` option described under [“getsockopt\(\) — Get the options associated with a socket”](#) on page 778 and the `SO_REUSEADDR` described under the [“setsockopt\(\) — Set options associated with a socket”](#) on page 1573 for more information.

EADDRNOTAVAIL

The address specified is not valid on this host. For example, the Internet address does not specify a valid network interface.

EAFNOSUPPORT

The address family is not supported (it is not AF_UNIX, AF_INET, or AF_INET6).

EBADF

The *socket* parameter is not a valid socket descriptor.

EINVAL

One of three conditions may apply:

- The socket is already bound to an address—for example, trying to bind a name to a socket that is already connected.
- The socket was shut down.
- An incorrect parameter was passed on the `bind()` invocation.

Check the parameter values passed and ensure they are specified as described above.

EIO

There has been a network or transport failure.

ENOBUFS

`bind()` is unable to obtain a buffer due to insufficient storage.

ENOTSOCK

The descriptor is for a file, not for a socket.

EOPNOTSUPP

The socket type of the specified socket does not support binding to an address.

EPERM

The user is not authorized to bind to the port specified.

The following are for AF_UNIX only:

Error Code**Description****EACCES**

A component of the path prefix denies search permission, or the requested name requires writing in a directory with a mode that denies write permission.

EDESTADDRREQ

The *address* argument is a NULL pointer.

EIO

An I/O error occurred.

ELOOP

Too many symbolic links were encountered in translating the pathname in *address*.

ENAMETOOLONG

A component of a pathname exceeded **NAME_MAX** characters, or an entire pathname exceeded **PATH_MAX** characters.

ENOENT

A component of the pathname does not name an existing file or the pathname is an empty string.

ENOTDIR

A component of the path prefix of the pathname in *address* is not a directory.

EROFS

The name would reside on a read-only file system.

Example

The following are examples of the `bind()` call. It is a good idea to zero the structure before using it to ensure that the name requested does not set any reserved fields.

AF_INET Domain Example

The following example illustrates the `bind()` call binding to interfaces in the AF_INET domain. The Internet address and port must be in network byte order. To put the port into network byte order, the `htons()` utility routine is called to convert a short integer from host byte order to network byte order. The *address* field is set using another utility routine, `inet_addr()`, which takes a character string representing the dotted-decimal address of an interface and returns the binary Internet address representation in network byte order.

```
int rc;
int s;
struct sockaddr_in myname;
/* Bind to a specific interface in the Internet domain */
/* make sure the sin_zero field is cleared */
memset(&myname, 0, sizeof(myname));
myname.sin_family = AF_INET;
myname.sin_addr.s_addr = inet_addr("129.5.24.1");
/* specific interface */
myname.sin_port = htons(1024);
:
rc = bind(s, (struct sockaddr *) &myname,
sizeof(myname));
/* Bind to all network interfaces in the Internet domain */
/* make sure the sin_zero field is cleared */
memset(&myname, 0, sizeof(myname));
myname.sin_family = AF_INET;
myname.sin_addr.s_addr = INADDR_ANY; /* specific interface */
myname.sin_port = htons(1024);
:
rc = bind(s, (struct sockaddr *) &myname,
sizeof(myname));
/* Bind to a specific interface in the Internet domain.
   Let the system choose a port */
*/
```

```
/* make sure the sin_zero field is cleared */
memset(&myname, 0, sizeof(myname));
myname.sin_family = AF_INET;
myname.sin_addr.s_addr = inet_addr("129.5.24.1");
/* specific interface */
myname.sin_port = 0;
:
rc = bind(s, (struct sockaddr *) &myname,
sizeof(myname));
```

AF_UNIX Domain Example

The following example illustrates the `bind()` call binding to interfaces in the AF_UNIX domain.

```
/* Bind to a name in the UNIX domain */
struct sockaddr_un myname;
char socket_name[]="/tmp/socket.for._";
:
memset(&myname, 0, sizeof(myname));
myname.sun_family = AF_UNIX;
strcpy(myname.sun_path,socket_name);
myname.sun_len = sizeof(myname.sun_path);
:
rc = bind(s, (struct sockaddr *) &myname, SUN_LEN(&myname));
```

bind2addrsel() - Bind with source address selection

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| RFC 5014 | both | |

Format

```
#define _OPEN_SYS SOCK_IPV6
#include <netinet/in.h>

int bind2addrsel(int sd, const struct sockaddr *dstaddr, socklen_t dstaddrlen);
```

General description

The `bind2addrsel()` function binds a socket to a source address and port that is appropriate to communicate with a given destination address. The source address is selected by the TCP stack according to either the default preference flags or the flags previously expressed by the application by use of the `setsockopt() IPV6_ADDR_PREFERENCES` call on this socket. If the bind is successful, the application can call `getsockname()` to determine the address and port selected. The application can then call `inet6_is_srcaddr()` to determine if the bound local address meets its preferences. For more information on source address selection, see *z/OS Communications Server: IPv6 Network and Appl Design Guide*.

Argument**Description****sd**

The socket to bind to a stack-selected source address and port.

dstaddr

A non-NULL pointer to a `sockaddr_in6` structure initialized as follows:

- Clear the entire structure for `sizeof(struct sockaddr_in6)`.
- `sin6_family` must be set to `AF_INET6`.
- Set `sin6_len` to the correct length for `AF_INET6`.
- Set `sin6_addr` to a 128-bit IPv6 destination address with which the local node wants to communicate.
- The `sin6_scope_id` must be set if the address is link-local.

dstaddrlen

The size of the `sockaddr` structure passed as argument.

Returned value

If successful, `bind2addrsel()` returns 0.

If unsuccessful, `bind2addrsel()` returns -1 and sets `errno` to one of the following values:

Error Code**Description****EADDRNOTAVAIL**

The destination address is a multicast address but the socket type is `SOCK_STREAM` or there are no ephemeral ports available to satisfy the bind request.

EAFNOSUPPORT

The address family specified in the address structure is not supported.

EBADF

The socket descriptor is incorrect.

EHOSTUNREACH

The destination address is not reachable because there is no route.

EINVAL

One of the input parameters was not valid.

EIO

There has been a network or transport failure.

ENOBUFS

A buffer could not be obtained.

ENOTSOCK

The `sd` parameter does not refer to a valid socket descriptor.

EOPNOTSUPP

The socket domain type is not supported.

EPROTOTYPE

The socket protocol is not TCP or UDP.

brk() — Change space allocation

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int brk(void *addr);
```

General description

Restriction: This function is not supported in AMODE 64.

The `brk()` function is used to change the space allocated for the calling process. The change is made by setting the process's break value to `addr` and allocating the appropriate amount of space. The amount of allocated space increases as the break value increases. The newly-allocated space is set to 0. However, if the application first decrements and then increments the break value, the contents of the reallocated space are not zeroed.

The storage space from which the `brk()` and `sbrk()` functions allocate storage is separate from the storage space that is used by the other memory allocation functions (`malloc()`, `calloc()`, etc.). Because this storage space must be a contiguous segment of storage, it is allocated from the initial heap segment only and thus is limited to the initial heap size specified for the calling program or the largest contiguous segment of storage available in the initial heap at the time of the first `brk()` or `sbrk()` call. Since this is a separate segment of storage, the `brk()` and `sbrk()` functions can be used by an application that is using the other memory allocation functions. However, it is possible that the user's region may not be large enough to support extensive usage of both types of memory allocation.

Prior usage of the `brk()` function has been limited to specialized cases where no other memory allocation function performed the same function. Because the `brk()` function may be unable to sufficiently increase the space allocation of the process when the calling application is using other memory functions, the use of other memory allocation functions, such as `mmap()`, is now preferred because it can be used portably with all other memory allocation functions and with any function that uses other allocation functions. Applications that require the use of `brk()` and/or `sbrk()` should refrain from using the other memory allocation functions and should be run with an initial heap size that will satisfy the maximum storage requirements of the program. The `brk()` function is not supported from a multithreaded environment, it will return in error if it is invoked in this environment.

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use `malloc()` instead of `brk()` or `sbrk()`.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

If successful, `brk()` returns 0.

If unsuccessful, brk() returns -1 and sets errno to one of the following values:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

| | |
|--------|--|
| ENOMEM | The requested change would allocate more space than allowed for the calling process. |
|--------|--|

bsd_signal() — BSD version of signal()

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <signal.h>

void (*bsd_signal(int sig, void (*func)(int)))(int);
```

General description

The bsd_signal() function provides a partially compatible interface for programs written to use the BSD form of the signal() function.

BSD signal() differs from ISO C/C++ signal() in that the **SA_RESTART** flag is set and the **SA_RESETHAND** is cleared when bsd_signal() is used. Whereas for signal() both of these flags are cleared and **_SA_OLD_STYLE** is set.

There are three functions available for establishing a signal's action, signal(), bsd_signal(), and sigaction(). The sigaction() function is the strategic way to establish a signal's action. The bsd_signal() and signal() functions are provided for compatibility with BSD and ISO C/C++, respectively.

The argument sig is the signal type. See Table 57 on page 1606 for a list of the supported signal types or refer to the <signal.h> header. The argument func is the signal action. It may be set to **SIG_DFL**, **SIG_IGN**, or the address of a signal catching function that takes one input argument.

Special Behavior for C++

Because C and C++ linkage conventions are incompatible, bsd_signal() cannot receive a C++ function pointer as the start routine function pointer. If you attempt to pass a C++ function pointer to bsd_signal(), the compiler will flag it as an error. You can pass a C or C++ function to bsd_signal() by declaring it as extern "C".

Usage notes

1. The use of the SIGTHSTOP and SIGTHCONT signal is not supported with this function.
2. The bsd_signal() function has been marked obsolescent in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The sigaction() function is preferred for portability.

Returned value

If successful, `bsd_signal()` returns the previous action established for this signal type.
If unsuccessful, `bsd_signal()` returns **SIG_ERR** and sets `errno` to one of the following values:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

| | |
|---------------|--|
| EINVAL | The value of the argument <i>sig</i> was not a valid signal type, or an attempt was made to catch a signal that cannot be caught, or ignore a signal that cannot be ignored. |
|---------------|--|

Related information

bsearch() – Search arrays

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdlib.h>

void *bsearch(const void *key, const void *base, size_t num, size_t size,
              int (*compare)(const void *element1, const void *element2));
```

General description

Performs a binary search of an array of *num* elements, each of *size* bytes.
The pointer *base* points to the initial element of the array to be searched. *key* points to the object containing the value being sought. The array must be sorted in ascending key sequence, according to the comparison function. Otherwise, undefined behavior occurs.
The *compare* parameter is a pointer to a function you must supply. It compares two array elements and returns a value specifying their relationship. The `bsearch()` function calls this function one or more times during the search, passing the key and the pointer to one array element on each call. The function compares the elements and then returns one of the following values:

| Value | Meaning |
|-------|--|
| < 0 | Object pointed to by key is less than the array element. |

= 0

Object pointed to by key is equal to the array element.

> 0

Object pointed to by key is greater than the array element.

Special Behavior for C++

Because C++ and C linkage conventions are incompatible, `bsearch()` cannot receive C++ function pointers. If you attempt to pass a C++ function pointer to `bsearch()`, the compiler will flag it as an error. To use the C++ `bsearch()` function, you must ensure that the *compare* function has C linkage by declaring it as `extern "C"`.

Returned value

If successful, `bsearch()` returns a pointer to a matching element of the array. If two or more elements are equal, the element pointed to is not specified.

If unsuccessful finding the key, `bsearch()` returns NULL.

Example**CELEBB01**

```

/* CELEBB01

This example performs a binary search on the argv array of pointers o
to the program arguments and finds the position of the argument PATH.
It first removes the program name from argv, and then sorts the array
alphabetically before calling bsearch().

The functions compare1 and compare2 compare the values pointed to by
arg1 and arg2, and they return the result to bsearch().

*/
#include <stdlib.h>
#include <stdio.h>
#include <string.h>

#ifdef __cplusplus /* the __cplusplus macro is */
extern "C" {      /* automatically defined by the */
#endif           /* C++/MVS compiler */
    int compare1(const void *arg1, const void *arg2);
    int compare2(const void *arg1, const void *arg2);
#ifdef __cplusplus
}
#endif

int main(int argc, char *argv[])
{
    char **result;
    char *key = "PATH";
    int i;
    argv++;
    argc--;

    /* sort to ensure that the input is ordered */
    qsort((char *)argv, argc, sizeof(char *), compare1);

    result = (char**)bsearch(key, (void *)argv, argc, sizeof(char *),
                           compare2);
    if (result != NULL) {
        printf("The key <%s> was found.\n", *result);
    }
    else printf("Match not found\n");
}

int compare1(const void *arg1, const void *arg2)
{
    return (strcmp(*(char **)arg1, *(char **)arg2));
}

int compare2(const void *arg1, const void *arg2) {

```

```
    return (strcmp((char *)arg1, *(char **)arg2));
}
```

Input

```
progname Is there PATH in this sentence?
```

Output

```
The key <PATH> was found.
```

btowc() — Convert single-byte character to wide-character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C C99 Single UNIX Specification, Version 3 | both | z/OS V1R2 |

Format

```
#include <wchar.h>

wint_t btowc(int c);
```

General description

The `btowc()` function determines whether `c` constitutes a valid (one-byte) character in the initial shift state.

The behavior of this wide-character function is affected by the `LC_CTYPE` category of the current locale. If you change the category, undefined results can occur.

Returned value

If successful, `btowc()` returns the wide-character representation of the character `c`.

If `c` has the value `EOF` or if `(unsigned char)c` does not constitute a valid (one-byte) character in the initial shift state, `btowc()` returns `WEOF`.

There are no documented `errno` values.

Related information

bzero() – Zero bytes in memory

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <strings.h>

void bzero(void *s, size_t n);
```

General description

The `bzero()` function places *n* zero-valued bytes in the area pointed to by *s*.

Note: The `bzero()` function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The `memset()` function is preferred for portability.

Returned value

`bzero()` returns no values.

There are no `errno` values defined for `bzero()`.

Related information

- [“strings.h – String operations” on page 67](#)
- [“bcmp\(\) – Compare bytes in memory” on page 211](#)
- [“bcopy\(\) – Copy bytes in memory” on page 212](#)
- [“memset\(\) – Set buffer to value” on page 1069](#)

c16rtomb() – Convert a char16_t character to a multibyte character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| ISO C Amendment C11 | both | z/OS V2R1 |

Format

```
#include <uchar.h>

size_t c16rtomb(char * restrict s, char16_t c16, mbstate_t * restrict ps);
```

General description

The `c16rtomb()` function converts a wide character of type `char16_t` to a multibyte character, and returns the number of bytes stored in `s` (including any shift sequences).

If `s` is not a null pointer, the `c16rtomb()` function determines the number of bytes needed to represent the multibyte character that corresponds to the wide character given by `c16` (including any shift sequences), and stores the multibyte character representation in the array whose first element is pointed to by `s`. At most `MB_CUR_MAX` bytes are stored. If the `c16` is a null wide character, a null byte is stored, preceded by any shift sequence needed to restore the initial shift state; the resulting state described is the initial conversion state.

If `s` is a null pointer, the `c16rtomb()` function is equivalent to the call `c16rtomb(buf, L'\0', ps)`, where `buf` is an internal buffer.

If `ps` is a null pointer, `c16rtomb()` uses its own internal object to track the shift state. Otherwise `*ps` must be a valid `mbstate_t` object. An `mbstate_t` object `*ps` can be initialized to the initial state by assigning 0 to it, or by calling `c16rtomb(NULL, L'\0', ps)`.

Usage notes

1. To use the `c16rtomb()` function, compile the source code with [C11 standard based compilation](#).
2. The result `s` for stateful multibyte encodings, such as EBCDIC MBCS, might leave out shift bytes according to the conversion state. The first DBCS character in the output sequence has only shift-out character, and the following characters have neither shift-out nor shift-in. The ending shift-in will not be produced until an SBCS character or a null wide character is encountered.
3. The `c16rtomb()` function only supports the CCSIDs that are provided by Unicode Services.
4. The Unicode combining characters are not supported, and will be converted to substitute character of target CCSID.
5. The result of converting multiple string alternately in one thread by using multiple `mbstate_t` objects (including the internal one) is undefined.

Returned value

The `c16rtomb()` function returns the number of bytes stored in the array object (including any shift sequences). When `c16` is not a valid wide character, an encoding error occurs. The function stores the value of the macro `EILSEQ` in `errno` and returns `(size_t)-1`; the conversion state is unspecified.

Example

```
#include <stdio.h>
#include <stdlib.h>
#include <uchar.h>

int main(void)
{
    char16_t in = u'a';
    mbstate_t st = 0;
    char out[MB_CUR_MAX];
    int rc, i;
    rc = c16rtomb(out, in, &st);
    if (rc < 0) {
        perror("c16rtomb() fails to convert");
        exit(-1);
    }
    printf(" c16: 0x%04x \n", in);
    printf(" return code: %d \n", rc);
    printf(" mb character: ");
    for (i=0; i<rc; i++)
        printf(" 0x%02x", out[i]);
    printf("\n");
    return 0;
}
```

Output:

```
c16: 0x0061
return code: 1
mb character: 0x81
```

c32rtomb() — Convert a char32_t character to a multibyte character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| ISO C Amendment C11 | both | z/OS V2R1 |

Format

```
#include <uchar.h>

size_t c32rtomb(char * restrict s, char32_t c32, mbstate_t * restrict ps);
```

General description

The `c32rtomb()` function converts a wide character of type `char32_t` to a multibyte character, and returns the number of bytes stored in the `s` (including any shift sequences).

If `s` is not a null pointer, the `c32rtomb()` function determines the number of bytes needed to represent the multibyte character that corresponds to the wide character given by `c32` (including any shift sequences), and stores the multibyte character representation in the array whose first element is pointed to by `s`. At most `MB_CUR_MAX` bytes are stored. If the `c32` is a null wide character, a null byte is stored, preceded by any shift sequence needed to restore the initial shift state; the resulting state described is the initial conversion state.

If `s` is a null pointer, the `c32rtomb()` function is equivalent to the call `c32rtomb(buf, L'\0', ps)`, where `buf` is an internal buffer.

If `ps` is a null pointer, `c32rtomb()` uses its own internal object to track the shift state. Otherwise `*ps` must be a valid `mbstate_t` object. An `mbstate_t` object `*ps` can be initialized to the initial state by assigning 0 to it, or by calling `c32rtomb(NULL, L'\0', ps)`.

Usage notes

1. To use the `c32rtomb()` function, compile the source code with [C11 standard based compilation](#).
2. The result `s` for stateful multibyte encodings, such as EBCDIC MBCS, might leave out shift bytes according to the conversion state. The first DBCS character in the output sequence has only shift-out

character, and the following characters have neither shift-out nor shift-in. The ending shift-in will not be produced until an SBCS character or a null wide character is encountered.

3. The `c32rtomb()` function only supports the CCSIDs that are provided by Unicode Services.
4. The Unicode combining characters are not supported, and will be converted to substitute character of target CCSID.
5. The result of converting multiple string alternately in one thread by using multiple `mbstate_t` objects (including the internal one) is undefined.

Returned value

The `c32rtomb()` function returns the number of bytes stored in the array object (including any shift sequences). When `c32` is not a valid wide character, an encoding error occurs. The function stores the value of the macro `EILSEQ` in `errno` and returns `(size_t)-1`; the conversion state is unspecified.

Example

```
#include <stdio.h>
#include <stdlib.h>
#include <uchar.h>

int main(void)
{
    char32_t in = U'a';
    mbstate_t st = 0;
    char out[MB_CUR_MAX];
    int rc, i;
    rc = c32rtomb(out, in, &st);
    if (rc < 0) {
        perror("c32rtomb() fails to convert");
        exit(-1);
    }
    printf(" c32: 0x%04x \n", in);
    printf(" return code: %d \n", rc);
    printf(" mb character: ");
    for (i=0; i<rc; i++)
        printf(" 0x%02x", out[i]);
    printf("\n");
    return 0;
}
```

Output:

```
c32: 0x00000061
return code: 1
mb character:  0x81
```

__cabend() – Terminate the process with an abend

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | AMODE 64 |

Format

```
#include <ctest.h>

void __cabend(int abendcode, int reasoncode, int clean_up);
```

General description

Causes an abnormal process termination and returns an abend code.

Note: When TRAP(OFF) is specified, __cabend() behaves as if clean_up was set to 0.

Parameter

Description

abendcode

Numeric value for the user abend code.

reasoncode

Numeric value of the reason code.

clean_up

Specifies whether normal process cleanup should be performed with the type of dump the user requires.

0 - Issue the abend without cleanup

1 - Issue the abend with cleanup honoring the TERMTHDACT runtime option that the user has specified

2 - Issue the abend with cleanup honoring the TERMTHDACT runtime option for system dump of the user address space but always suppressing the CEEDUMP

3 - Issue the abend with cleanup honoring the TERMTHDACT runtime option but always suppressing both the system dump and the CEEDUMP

4 - Issue the abend with cleanup honoring the TERMTHDACT runtime option for CEEDUMP but always suppressing the system dump

5 - Issue the abend with cleanup forcing a system dump of the user address space but not specifying the TERMTHDACT runtime option

cabs(), cabsf(), cabsl() – Calculate the complex absolute value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--|
| C99 Single UNIX Specification, Version 3 | both | z/OS V1R7 a compiler that is designed to support C99 |

Format

```
#include <complex.h>

double cabs(double complex z);
float cabsf(float complex z);
long double cabsl(long double complex z);
```

General description

The `cabs()` family of functions compute the complex absolute value (also called norm, modules, or magnitude) of `z`.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|--------------------|-----|------|
| <code>cabs</code> | X | X |
| <code>cabsf</code> | X | X |
| <code>cabsl</code> | X | X |

Returned value

The `cabs` functions return the complex absolute value.

Example

```
/*
 * This example calculates the complex absolute
 * value of complex number 'z'
 */
#include <complex.h>
#include <stdio.h>

void main()
{
    double complex z=3.5 + I*2.21;
    double res;

    res = cabs(z);
    printf("cabs(%f + I*%f) = %f\n",creal(z), cimag(z),res);
}

/*
 * Output:
 * cabs(3.5 + I*2.21) = 4.139336
 */
```

cacos(), cacosf(), cacosl() – Calculate the complex arc cosine

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--|
| C99 Single UNIX Specification, Version 3 | both | z/OS V1R7 a compiler that is designed to support C99 |

Format

```
#include <complex.h>

double complex cacos(double complex z);
float complex cacosf(float complex z);
long double complex cacosl(long double complex z);
```

General description

The cacos() family of functions compute the complex arc cosine of z, with branch cuts outside the interval [-1, +1] along the real axis.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------|-----|------|
| cacos | X | X |
| cacosf | X | X |
| cacosl | X | X |

Returned value

The cacos() family of functions return the complex arc cosine value, in the range of a strip, mathematically unbounded along the imaginary axis and in the interval [0, π] along the real axis.

Example

```
/*
 * This example calculates the complex arc-cosine of
 * complex number 'z'
 */
#include <complex.h>
#include <stdio.h>

void main()
{
    long double complex z1=3.5 + I*2.21;
    double complex zd=(double complex)z1;
    float complex zf=(float complex)z1;
    long double resl;
    double resd;
    float resf;
    char *func = "cacos";

    printf("Example of the %s complex function\n",func);
    resd = cacos(zd);
    resf = cacosf(zf);
    resl = cacosl(z1);
    printf("\t%s(%f + I*%f) = %f\n",func, creal(zd), cimag(zd),resd);
    printf("\t%sf(%f + I*%f) = %f\n",func, crealf(zf), cimagf(zf),resf);
    printf("\t%s1(%Lf + I*%Lf) = %Lf\n",func, creall(z1), cimagl(z1),resl);
}
```

Output:

```
Example of the cacos complex function
cacos(3.500000 + I*2.210000) = 0.576628
cacoshf(3.500000 + I*2.209999) = 0.576627
cacoshl(3.500000 + I*2.210000) = 0.576628
```

cacosh(), cacoshf(), cacoshl() — Calculate the complex arc hyperbolic cosine

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--|
| C99 Single UNIX Specification, Version 3 | both | z/OS V1R7 a compiler that is designed to support C99 |

Format

```
#include <complex.h>

double complex cacosh(double complex z);
float complex cacoshf(float complex z);
long double complex cacoshl(long double complex z);
```

General description

The `cacosh()` family of functions compute the complex arc hyperbolic cosine of z , with a branch cut at values less than 1 along the real axis.

Note: The following table shows the viable formats for these functions. See “[IEEE binary floating-point](#)” on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------------------|-----|------|
| <code>cacosh</code> | X | X |
| <code>cacoshf</code> | X | X |
| <code>cacoshl</code> | X | X |

Returned value

The `cacosh()` family of functions return the complex arc hyperbolic cosine value, in the range of a half-strip, non-negative value along the real axis and in the interval $[-i\pi, +i\pi]$ along the imaginary axis.

Example

For an example of a similar function see `cacos()`, `cexp()` or `cpow()`.

calloc() – Reserve and initialize storage

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdlib.h>

void *calloc(size_t num, size_t size);
```

General description

Reserves storage space for an array of *num* elements, each of length *size* bytes. The `calloc()` function then gives all the bits of each element an initial value of 0.

`calloc()` returns a pointer to the reserved space. The storage space to which the returned value points is aligned for storage of any type of object.

This function is also available to C applications in free-standing System Programming C (SPC) Facilities applications.

Special behavior for C++: The C++ keywords `new` and `delete` are not interoperable with `aligned_alloc()`, `calloc()`, `free()`, `malloc()`, `posix_memalign()`, or `realloc()`.

Note: To use the `aligned_alloc()` function, compile the source code with [C11 standard based compilation](#).

Returned value

If successful, `calloc()` returns the pointer to the area of memory reserved.

If there is not enough space to satisfy the request or if *num* or *size* is 0, `calloc()` returns NULL. If `calloc()` returns NULL because there is not enough storage, it sets `errno` to one of the following values:

Error Code Description

ENOMEM

Insufficient memory is available

Example

CELEBC01

```
/* CELEBC01

This example prompts for the number of array entries required
and then reserves enough space in storage for the entries.

If &calloc. is successful, the example prints out each entry;
otherwise, it prints out an error message.

*/
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    long * array;      /* start of the array */
    long * index;      /* index variable */
    int    i;          /* index variable */
    int    num;         /* number of entries in the array */

    printf( "Enter the number of elements in the array\n" );
    scanf( "%i", &num );

    /* allocate num entries */
    if ( (index = array = (long *)calloc( num, sizeof( long ))) != NULL )
    {
        for ( i = 0; i < num; ++i )          /* put values in array */
            *index++ = i;                    /* using pointer notation */

        for ( i = 0; i < num; ++i )          /* print the array out */
            printf( "array[ %i ] = %i\n", i, array[i] );
    }
    else
    { /* out of storage */
        printf( "Out of storage\n" );
        abort();
    }
}
```

Output

```
Enter the size of the array
array[ 0 ] = 0
array[ 1 ] = 1
array[ 2 ] = 2
```

carg(), cargf(), cargl() – Calculate the argument

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--|
| C99 Single UNIX Specification, Version 3 | both | z/OS V1R7 a compiler that is designed to support C99 |

Format

```
#include <complex.h>

double carg(double complex z);
float cargf(float complex z);
long double cargl(long double complex z);
```

General description

The `carg()` family of functions compute the argument (phase angle) of z , with a branch cut along the negative real axis.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|--------------------|-----|------|
| <code>carg</code> | X | X |
| <code>cargf</code> | X | X |
| <code>cargl</code> | X | X |

Returned value

The `carg()` family of functions return the value of the argument in the interval $[-\pi, +\pi]$.

Example

For an example of a similar function see `cacos()`, `cexp()` or `cpow()`.

casin(), casinf(), casinl() – Calculate the complex arc sine

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--|
| C99 Single UNIX Specification, Version 3 | both | z/OS V1R7 a compiler that is designed to support C99 |

Format

```
#include <complex.h>

double complex casin(double complex z);
float complex casinf(float complex z);
long double complex casinl(long double complex z);
```

General description

The `casin()` family of functions compute the complex arc sine of z , with branch cuts outside the interval $[-1, +1]$ along the real axis.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|---------------------|-----|------|
| <code>casin</code> | X | X |
| <code>casinf</code> | X | X |
| <code>casinl</code> | X | X |

Returned value

The `casin()` family of functions return the complex arc sine value, in the range of a strip, mathematically unbounded along the imaginary axis and in the interval $[-\pi/2, +\pi/2]$ along the real axis.

casinh(), casinhf(), casinhl() – Calculate the complex arc hyperbolic sine

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--|
| C99 Single UNIX Specification, Version 3 | both | z/OS V1R7 a compiler that is designed to support C99 |

Format

```
#define _ISOC99_SOURCE
#include <complex.h>

double complex casinh(double complex z);
float complex casinhf(float complex z);
long double complex casinhl(long double complex z);
```

General description

The `casinh()` family of functions compute the complex arc hyperbolic sine of z , with branch cuts outside the interval $[-i, +i]$ along the imaginary axis.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------------------|-----|------|
| <code>casinh</code> | X | X |
| <code>casinhf</code> | X | X |
| <code>casinhl</code> | X | X |

Returned value

The `casinh()` family of functions return the complex arc hyperbolic sine value, in the range of a strip, mathematically unbounded along the real axis and in the interval $[-i\pi/2, +i\pi/2]$ along the imaginary axis.

Example

For an example of a similar function see `cacos()`, `cexp()` or `cpow()`.

catan(), catanf(), catanl() – Calculate the complex arc tangent

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--|
| C99 Single UNIX Specification, Version 3 | both | z/OS V1R7 a compiler that is designed to support C99 |

Format

```
#include <complex.h>

double complex catan(double complex z);
```

```
float complex catanf(float complex z);
long double complex catanl(long double complex z);
```

General description

The `catan()` family of functions compute the complex arc tangent of z , with branch cuts outside the interval $[-i, +i]$ along the imaginary axis.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|---------------------|-----|------|
| <code>catan</code> | X | X |
| <code>catanf</code> | X | X |
| <code>catanl</code> | X | X |

Returned value

The `catan()` family of functions return the complex arc tangent value, in the range of a strip, mathematically unbounded along the imaginary axis and in the interval $[-\pi/2, +\pi/2]$ along the real axis.

Example

For an example of a similar function see `cacos()`, `cexp()` or `cpow()`.

catanh(), catanhf(), catanhl() — Calculate the complex arc hyperbolic tangent

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--|
| C99 Single UNIX Specification, Version 3 | both | z/OS V1R7 a compiler that is designed to support C99 |

Format

```
#include <complex.h>

double complex catanh(double complex z);
float complex catanhf(float complex z);
long double complex catanhl(long double complex z);
```

General description

The `catanh()` family of functions compute the complex arc hyperbolic tangent of z , with branch cuts outside the interval $[-1, +1]$ along the real axis.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------------------|-----|------|
| <code>catanh</code> | X | X |
| <code>catanhf</code> | X | X |
| <code>catanhl</code> | X | X |

Returned value

The `catanh()` family of functions return the complex arc hyperbolic tangent value, in the range of a strip, mathematically unbounded along the real axis and in the interval $[-i\pi/2, +i\pi/2]$ along the imaginary axis.

Example

For an example of a similar function see `cacos()`, `cexp()` or `cpow()`.

catclose() — Close a message catalog descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <nl_types.h>

int catclose(nl_catd catd);
```

General description

The `catclose()` function closes the message catalog identified by `catd`. If a catalog is opened more than once in the same process, a use count is incremented. `catclose()` decrements this use count. When the use count reaches zero then the file descriptor for that catalog is closed.

Returned value

If successful, `catclose()` returns 0.

If unsuccessful, `catclose()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

The catalog descriptor is not valid.

EINTR

`catclose()` was interrupted by a signal.

Related information

- [“nl_types.h — National languages” on page 52](#)
- [“catgets\(\) — Read a program message” on page 239](#)
- [“catopen\(\) — Open a message catalog” on page 240](#)

catgets() — Read a program message

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <nl_types.h>

char *catgets(nl_catd catd, int set_id, int msg_id, const char *s);
```

General description

The `catgets()` function attempts to read message `msg_id`, in set `set_id`, from the message catalog identified by `catd`. The `catd` argument is a message catalog descriptor returned from an earlier call to `catopen()`. The `s` argument points to a default message string which will be returned by `catgets()` if it cannot retrieve the identified message.

When message source files are processed by the `gencat` command, the CODESET used to create them is saved in the resulting message catalog. The `catgets()` function interrogates this CODESET value to see if it differs from the CODESET value of the current locale. If it does differ then `catgets()` uses the `iconv()` function to convert the message text coming from the message catalog into the codeset of the current locale. The default message string (`s`) is not affected by this conversion. If `iconv()` does not support the conversion specified by the two CODESETs then the default message string is returned.

Returned value

If the identified message is retrieved successfully, `catgets()` returns a pointer to an internal buffer area containing the NULL-terminated message string.

If unsuccessful, `catgets()` returns `s` and sets `errno` to one of the following values:

Error Code Description

EBADF

The *catd* argument is not a valid message catalog descriptor open for reading.

EINTR

The read operation was terminated due to the receipt of a signal, and no data was transferred.

Special behavior for z/OS UNIX Services:

Error Code Description

EINVAL

May be returned for several reasons:

- The message catalog identified by *catd* is not a valid message catalog, or has been corrupted. Ensure that the message catalog was created using the z/OS UNIX *gencat* command.
- *iconv()* does not support the conversion between the codeset of the message catalog and that of the current locale. To check the codeset that the message catalog was created in, look for the codeset name at offset 28 into the message catalog.

ENOMSG

The message identified by *set_id* and *msg_id* is not in the message catalog.

Related information

- [“nl_types.h — National languages” on page 52](#)
- [“catclose\(\) — Close a message catalog descriptor” on page 238](#)
- [“catopen\(\) — Open a message catalog” on page 240](#)

catopen() — Open a message catalog

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <nl_types.h>

nl_catd catopen(const char *name, int oflag);
```

General description

The *catopen()* function opens a message catalog and returns a message catalog descriptor. The *name* argument specifies the name of the message catalog to be opened. If *name* contains a */*, then *name* specifies a complete name for the message catalog. Otherwise, the environment variable *NLSPATH* is used with *name* substituted for *%N* (see the XBD specification, Chapter 6, Environment Variables). If *NLSPATH* does not exist in the environment, or if a message catalog cannot be found in any of the components specified by *NLSPATH*, then the default path of */usr/lib/nls/msg/%L/%N* is used. The *%L* component of this default path is replaced by the setting of *LC_MESSAGES* if the value of *oflag* is

NL_CAT_LOCALE, or the LANG environment variable if oflag is 0. A change in the setting of the LANG or LC_MESSAGES will have no effect on existing open catalogs.

A message catalog descriptor remains valid in a process until that process closes it, or a successful call to one of the exec functions. When a message catalog is opened the FD_CLOEXEC flag will be set. See [“fcntl\(\) — Control open file descriptors” on page 483](#). Portable applications must assume that message catalog descriptors are not valid after a call to one of the exec functions.

If a catalog is opened more than once in the same process, a use count is incremented. When the use count reaches zero, by using catclose() to close the catalog, then the file descriptor for that catalog is closed.

Returned value

If successful, catopen() returns a message catalog descriptor for use on subsequent calls to catgets() and catclose().

If unsuccessful, catopen() returns (nl_catd)-1 and sets errno to one of the following values:

Error Code
Description

- EACCES**
Search permission is denied for the component of the path prefix of the message catalog or read permission is denied for the message catalog.
- EMFILE**
OPEN_MAX file descriptors are currently open in the calling process.
- ENAMETOOLONG**
The length of the path name of the message catalog exceeds **PATH_MAX**, or a path name component is longer than **NAME_MAX**.
- ENFILE**
Too many files are currently open in the system.
- ENOENT**
The message catalog does not exist or the name argument points to an empty string.
- ENOMEM**
Insufficient storage space is available.
- ENOTDIR**
A component of the path prefix of the message catalog is not a directory.

cbt(), cbtft(), cbttl() — Calculate the cube root

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <math.h>

double cbrt(double x);
```

C99:

```
#define _ISOC99_SOURCE
#include <math.h>

float cbrtf(float x);
long double cbrtl(long double x);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

float cbrt(float x);
long double cbrt(long double x);
```

General description

The cbrt() function calculates the real cube root of its argument x.

Note: The following table shows which functions work in IEEE Binary Floating-Point format and which work in hexadecimal floating-point format. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------|-----|------|
| cbrt | X | X |
| cbrtf | X | X |
| cbrtl | X | X |

Returned value

The cbrt functions return x to the 1/3 power.
cbrt() does not fail.

Related information

- [“math.h — Floating-point math functions” on page 40](#)

cbtrd32(), cbtrd64(), cbtrd128() – Calculate the cube root

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.11 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 cbtrd32(_Decimal32 x);
_Decimal64 cbtrd64(_Decimal64 x);
```

```

_Decimal128 cbrtd128(_Decimal128 x);

_Decimal32  cbrt(_Decimal32 x);      /* C++ only */
_Decimal64  cbrt(_Decimal64 x);      /* C++ only */
_Decimal128 cbrt(_Decimal128 x);     /* C++ only */

```

General description

The `cbrt()` function calculates the real cube root of its argument `x`.

Notes:

1. These functions work in IEEE decimal floating-point format. See [“IEEE decimal floating-point” on page 97](#) IEEE Decimal Floating-Point for more information.
2. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Example

```

/* CELEBC52

   This example illustrates the cbrtd64() function.
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

void main(void)
{
    _Decimal64 x, y;

    x = 1000.0DD;
    y = cbrtd64(x);

    printf("cbrtd64( %Df ) = %Df\n", x, y);
}

```

Returned value

The `cbrt` functions return `x` to the $1/3$ power.

`cbrt()` does not fail.

Related information

- [“math.h — Floating-point math functions” on page 40](#)

cclass() — Return characters in a character class

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C Library | both | |

Format

```

#include <collate.h>

int cclass(char *class, coll_t **list);

```

General description

Finds all the collating elements of the class, *class*. The list is updated to point to the array of collating elements found. The list is valid until the next call to `setlocale()`.

The function supports user-defined character classes. In C Library programs, the function also supports POSIX.2 character classes.

Returned value

If successful, `cclass()` returns the number of elements in the list pointed to by *list*.

If the first argument specifies a class that does not exist in the LC_CTYPE category of the current locale, `cclass()` returns -1.

Example

CELEBC02

```
/* CELEBC02
*/

#include <stdio.h>
#include <collate.h>

int main(void)
{
    collat_t *list;      /* ptr to the digit class collation weights */
    int      weights;    /* no. of class collation class weights found */
    int      i;

    weights = cclass("digit", &list);

    printf("weights=%d\n", weights);
    for (i=0; i<weights; i++)
        printf("(list + %d) = %d\n", i, *(list + i) );
}
```

ccos(), ccosf(), ccosl() – Calculate the complex cosine

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--|
| C99 Single UNIX Specification, Version 3 | both | z/OS V1R7 a compiler that is designed to support C99 |

Format

```
#include <complex.h>

double complex ccos(double complex z);
float complex ccosf(float complex z);
long double complex ccosl(long double complex z);
```

General description

The ccos() family of functions compute the complex cosine of z.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------|-----|------|
| ccos | X | X |
| ccosf | X | X |
| ccosl | X | X |

Returned value

The ccos() family of functions return the complex cosine value.

Example

For an example of a similar function see cacos(), cexp() or cpow().

ccosh(), ccoshf(), ccoshl() – Calculate the complex hyperbolic cosine

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--|
| C99 Single UNIX Specification, Version 3 | both | z/OS V1R7 a compiler that is designed to support C99 |

Format

```
#define _ISOC99_SOURCE
#include <complex.h>

double complex ccosh(double complex z);
float complex ccoshf(float complex z);
long double complex ccoshl(long double complex z);
```

General description

The `ccosh()` family of functions compute the complex hyperbolic cosine of z .

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|---------------------|-----|------|
| <code>ccosh</code> | X | X |
| <code>ccoshf</code> | X | X |
| <code>ccoshl</code> | X | X |

Returned value

The `ccosh()` family of functions return the complex hyperbolic cosine value.

Example

For an example of a similar function see `cacos()`, `cexp()` or `cpow()`.

__CcsidType() – Return coded character set ID type

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R2 |

Format

```
#include <_Ccsid.h>

__csType __CcsidType(__ccsid_t Ccsid);
```

General description

__CcsidType() returns a __csType value which indicates the corresponding coded character set ID type.

Returned value

If *Ccsid* is valid, __CcsidType() returns one of the following __csType values, which are defined in <_Ccsid.h>:

- _CSTYPE_EBCDIC
- _CSTYPE_ASCII
- _CSTYPE_UCS2
- _CSTYPE_UTF8
- _CSTYPE_UTF16
- _CSTYPE_UTF32

If *Ccsid* is not valid, __CcsidType() returns _CSTYPE_INVALID.

Related information

cds() – Compare double and swap

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C Library | both | |

Format

```
#include <stdlib.h>

int cds(cds_t *oldptr, cds_t *curptr, cds_t newwords);
```

General description

The `cds()` built-in function compares the 8-byte value pointed to by *oldptr* to the 8-byte value pointed to by *curptr*. If they are equal, the 8-byte value *newwords* is copied into the location pointed to by *curptr*. If they are unequal, the value pointed to by *curptr* is copied into the location pointed to by *oldptr*.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

The function uses the COMPARE DOUBLE AND SWAP (CDS) instructions, which can be used in multiprogramming or multiprocessing environments to serialize access to counters, flags, control words, and other common storage areas. For a detailed description, see [Function support table on number representation and instruction](#).

Returned value

`cds()` returns 0 if the 8-byte value pointed to by *oldptr* is equal to the 8-byte value pointed to by *curptr*. Otherwise `cds()` returns 1.

cdump() — Request a main storage dump

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C Library | both | |

Format

```
#include <ctest.h>

int cdump(char *dumptitle);
```

General description

1. Creates a display of the activation stack, by calling `trace` in the same way as the `ctrace()` function does.
2. Displays the Language Environment-formatted dump.
3. If the source file was compiled with `TEST (SYM)`, `cdump()` displays the contents of the user's variables. The output is identified with *dumptitle*. See the CEE3DMP Language Environment callable service in [z/OS Language Environment Programming Guide](#) to determine where the output is written to.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

When `cdump()` is invoked from a user routine, the C/C++ library issues an OS SNAP macro to obtain a dump of virtual storage. The first invocation of `cdump()` results in a SNAP identifier of 0. For each successive invocation, the ID is increased by one to a maximum of 256, after which the ID is reset to 0.

The output of the dump is directed to the CEESNAP data set. The DD definition for CEESNAP is as follows:

```
//CEESNAP DD SYSOUT= *
```

If the data set is not defined, or is not usable for any reason, `cdump()` returns a failure code of 1. This occurs even if the call to `CEE3DMP` is successful. For more information see "Debugging C/C++ Routines " in [z/OS Language Environment Debugging Guide](#).

Returned value

If successful, `cdump()` returns 0.

If unsuccessful, `cdump()` returns nonzero.

Related information

ceil(), ceilf(), ceill() — Round up to integral value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#include <math.h>

double ceil(double x);
float ceil(float x);           /* C++ only */
long double ceil(long double x); /* C++ only */
float ceilf(float x);
long double ceill(long double x);
```

General description

Computes the smallest integer that is greater than or equal to x .

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

Returned value

Returns the calculated value as a double, float, or long double value.

If there is an overflow, the function sets `errno` to `ERANGE` and returns `HUGE_VAL`.

Special behavior for IEEE: The `ceil()` functions are always successful.

Example

CELEBC04

```
/* CELEBC04

This example sets y to the smallest integer greater than
1.05, and then to the smallest integer greater than -1.05.

The results are 2.0 and -1.0, respectively.

*/
#include <math.h>
#include <stdio.h>
int main(void)
{
    double y, z;

    y = ceil(1.05);          /* y = 2.0 */
    z = ceil(-1.05);         /* z = -1.0 */
    printf("y = %f\n z = %f\n", y, z);
}
```

ceild32(), ceild64(), ceild128() — Round up to integral value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 ceild32(_Decimal32 x);
_Decimal64 ceild64(_Decimal64 x);
_Decimal128 ceild128(_Decimal128 x);
_Decimal32 ceil(_Decimal32 x); /* C++ only */
_Decimal64 ceil(_Decimal64 x); /* C++ only */
_Decimal128 ceil(_Decimal128 x); /* C++ only */
```

General description

Computes the smallest integer that is greater than or equal to x.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

These functions are always successful.

Example

```

/* CELEBC50

   This example illustrates the ceild32() function.

   This example sets y to the smallest integer greater than
   1.05, and then to the smallest integer greater than -1.05.

   The results are 2.0 and -1.0, respectively.

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal32 y, z;

    y = ceild32(+1.05DF);      /* y = +2.0 */
    z = ceild32(-1.05DF);      /* z = -1.0 */

    printf("ceild32(+1.05) = % Hf\n"
           "ceild32(-1.05) = % Hf\n", y, z);
}

```

__certificate() — Register, deregister, or authenticate a digital certificate

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | OS/390 V2R7 |

Format

```

#define _OPEN_SYS
#include <unistd.h>

int __certificate(int function_code,
                  int certificate_length,
                  char *certificate,...);

```

General description

The `__certificate()` function allows the user to register or deregister a digital certificate with or from the userid that is associated with the current security environment, or to authenticate a security environment using a digital certificate in lieu of a userid/password combination.

The function takes at least the following arguments:

function_code

Specifies one of the following functions:

__CERTIFICATE_REGISTER

Register the passed certificate to the user. No new security environment is created, and no authentication of the user is done.

__CERTIFICATE_DEREGISTER

Deregister the passed certificate from the user. Certificate must have been previously registered to the user.

__CERTIFICATE_AUTHENTICATE

As of z/OS V1R4, authenticate the passed certificate for this caller. The certificate must have already been registered.

certificate_length

The length of the digital certificate. A zero length will cause -1 return value with errno set to EINVAL.

certificate

The certificate must be a single BER encoded X.509 certificate. PKCS7, PEM, or Base64 encoded certificates are allowed.

Note: Only a single BER encoded X.509 certificate is supported for the authenticate function.

As of z/OS V1R4, the __CERTIFICATE_AUTHENTICATE function code requires the following additional parameters to be specified on the function call:

buflen (size_t)

Specifies the size of the buffer pointed to by buf. Up to buflen bytes of userid (including the NULL terminator) will be copied into the buffer. Note that truncation may occur if the buffer is too small. The buffer size should be large enough for any userid on the system. A value less than 1 will cause -1 return value with errno set to EINVAL.

buf (char *)

Pointer to character buffer where __certificate() will place the userid associated with the digital certificate. A value of NULL will cause -1 return value with errno set to EINVAL.

Usage notes

1. The __certificate function is intended for servers that support the automatic registration of certificates for clients they are supporting (on the World Wide Web for example).
2. The __CERTIFICATE_REGISTER function code will associate the passed certificate with whatever user identity is present. If the task level identity is present the certificate is associated with the task. Task level security can be created by pthread_security_np(), __login() or by any other means of creating a task level ACEE. If no task level identity (ACEE) is present, the certificate will be associated with the address space identity.
3. The __certificate() function calls the z/OS z/OS UNIX System Services BPX1SEC service. For a more detailed description of the BPX1SEC service, see [z/OS UNIX System Services Programming: Assembler Callable Services Reference](#).

Restrictions

A security manager supporting digital certificate registration and deregistration must be installed and operational.

Returned value

If successful, __certificate() returns 0.

If unsuccessful, __certificate() returns -1 and sets errno to one of the following values:

Error Code

Description

EACCES

Permission is denied.

EINVAL

A parameter is not valid.

EMVSERR

An MVS environmental error or internal error occurred.

EMVSSAF2ERR

An error occurred in the security product. Certificate is already defined for another process or certificate is not valid or certificate does not meet required format. Also, realized when an internal error has occurred.

ENOSYS

The function is not implemented or installed.

EPERM

The operation was not permitted. Calling process may not be authorized in BPX.DAEMON facility class.

Use `__errno2()` to obtain a more detailed reason code (in most cases) when `__certificate()` fails.

cexp(), cexpf(), cexpl() — Calculate the complex exponential

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--|
| C99 Single UNIX Specification, Version 3 | both | z/OS V1R7 a compiler that is designed to support C99 |

Format

```
#include <complex.h>

double complex cexp(double complex z);
float complex cexpf(float complex z);
long double complex cexpl(long double complex z);
```

General description

The `cexp()` family of functions compute the complex base-e exponential of `z`.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|--------------------|-----|------|
| <code>cexp</code> | X | X |
| <code>cexpf</code> | X | X |
| <code>cexpl</code> | X | X |

Returned value

The cexp() family of functions return the complex base-e exponential value.

Example

```
/*
 * This example illustrates the complex exponential
 * function
 */
#include <complex.h>
#include <stdio.h>

void main()
{
    double complex z=6.0146 + I*(-2.41958),
               res;

    res = cexp(z);
    printf("cexp(%f + (%f)*I) = %f + (%f)*I\n",creal(z),
    cimag(z),creal(res),cimag(res));
}

Output:

cexp(6.014600 + (-2.419580)*I) = -307.216850 + (-270.545937)*I
```

cfgetispeed() – Determine the input baud rate

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <termios.h>

speed_t cfgetispeed(const struct termios *termpr);
```

General description

Extracts the input baud rate from the termios structure indicated by **termpr*. The termios structure contains information about a terminal. A program should first use tcgetattr() to get the termios structure, and then use cfgetispeed() to extract the speed from the structure. The program can then use cfgetispeed() to set a new baud rate in the structure and tcsetattr() to pass the changed value to the system.

Although in a z/OS UNIX application valid speeds can be set with `cfsetispeed()` and passed to the system with `tcsetattr()`, the speed has no effect on the operation of a pseudoterminal. However, the operation will have an effect if issued for an OCS remote terminal.

Returned value

`cfgetispeed()` returns a code indicating the baud rate; see [Table 19 on page 255](#). These codes are defined in the `termios.h` header file and have an unsigned integer type.

There are no documented `errno` values.

Table 19. Baud Rate Codes

| | |
|---------------|-------------|
| B0 | Hang up |
| B50 | 50 baud |
| B75 | 75 baud |
| B110 | 110 baud |
| B134 | 134.5 baud |
| B150 | 150 baud |
| B200 | 200 baud |
| B300 | 300 baud |
| B600 | 600 baud |
| B1200 | 1200 baud |
| B1800 | 1800 baud |
| B2400 | 2400 baud |
| B4800 | 4800 baud |
| B9600 | 9600 baud |
| B19200 | 19,200 baud |
| B38400 | 38,400 baud |

Example

CELEBC05

```
/* CELEBC05

   This example determines the speed of stdin.

*/
#define _POSIX_SOURCE
#include <termios.h>
#include <stdio.h>

char *see_speed(speed_t speed) {
    static char  SPEED[20];
    switch (speed) {
        case B0:      strcpy(SPEED, "B0");
                       break;
        case B50:     strcpy(SPEED, "B50");
                       break;
        case B75:     strcpy(SPEED, "B75");
                       break;
        case B110:    strcpy(SPEED, "B110");
                       break;
        case B134:    strcpy(SPEED, "B134");
                       break;
        case B150:    strcpy(SPEED, "B150");
```

```

        case B200:      break;
                        strcpy(SPEED, "B200");
                        break;
        case B300:      strcpy(SPEED, "B300");
                        break;
        case B600:      strcpy(SPEED, "B600");
                        break;
        case B1200:     strcpy(SPEED, "B1200");
                        break;
        case B1800:     strcpy(SPEED, "B1800");
                        break;
        case B2400:     strcpy(SPEED, "B2400");
                        break;
        case B4800:     strcpy(SPEED, "B4800");
                        break;
        case B9600:     strcpy(SPEED, "B9600");
                        break;
        case B19200:    strcpy(SPEED, "B19200");
                        break;
        case B38400:    strcpy(SPEED, "B38400");
                        break;
        default:        sprintf(SPEED, "unknown (%d)", (int) speed);
    }
    return SPEED;
}

main() {
    struct termios term;
    speed_t speed;

    if (tcgetattr(0, &term) != 0)
        perror("tcgetattr() error");
    else {
        speed = cfgetispeed(&term);
        printf("cfgetispeed() says the speed of stdin is %s\n",
               see_speed(speed));
    }
}
```

Output

```
cfgetispeed() says the speed of stdin is B0
```

cfgetospeed() — Determine the output baud rate

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <termios.h>

speed_t cfgetospeed(const struct termios *term_ptr);
```

General description

Extracts the output baud rate from the `termios` structure indicated by *term_ptr*. The `termios` structure contains information about a terminal. A program should first use `tcgetattr()` to get the `termios` structure, and then use `cfgetospeed()` to extract the speed from the structure. The program can then use `cfsetospeed()` to set a new baud rate in the structure and `tcsetattr()` to pass the changed value to the system.

Although in a z/OS UNIX application valid speeds can be set with `cfsetospeed()` and passed to the system with `tcsetattr()`, the speed has no effect on the operation a pseudoterminal. However, the operation will have an effect if issued for an OCS remote terminal.

Returned value

`cfgetospeed()` returns a code indicating the baud rate. The codes are defined in the `termios.h` header file and have an unsigned integer type. [Table 19 on page 255](#) shows the codes to set the baud rate.

There are no documented `errno` values.

Example

CELEBC06

```
/* CELEBC06

   This example determines the speed of stdout.

*/
#define _POSIX_SOURCE
#include <termios.h>
#include <stdio.h>

char *see_speed(speed_t speed) {
    static char SPEED[20];
    switch (speed) {
        case B0:      strcpy(SPEED, "B0");
                       break;
        case B50:     strcpy(SPEED, "B50");
                       break;
        case B75:     strcpy(SPEED, "B75");
                       break;
        case B110:    strcpy(SPEED, "B110");
                       break;
        case B134:    strcpy(SPEED, "B134");
                       break;
        case B150:    strcpy(SPEED, "B150");
                       break;
        case B200:    strcpy(SPEED, "B200");
                       break;
        case B300:    strcpy(SPEED, "B300");
                       break;
        case B600:    strcpy(SPEED, "B600");
                       break;
        case B1200:   strcpy(SPEED, "B1200");
                       break;
        case B1800:   strcpy(SPEED, "B1800");
                       break;
        case B2400:   strcpy(SPEED, "B2400");
                       break;
        case B4800:   strcpy(SPEED, "B4800");
                       break;
        case B9600:   strcpy(SPEED, "B9600");
                       break;
        case B19200:  strcpy(SPEED, "B19200");
                       break;
```

```

    case B38400:    strcpy(SPEED, "B38400");
                    break;
    default:        sprintf(SPEED, "unknown (%d)", (int) speed);
    }
    return SPEED;
}

main() {
    struct termios term;
    speed_t speed;

    if (tcgetattr(1, &term) != 0)
        perror("tcgetattr() error");
    else {
        speed = cfgetospeed(&term);
        printf("cfgetospeed() says the speed of stdout is %s\n",
               see_speed(speed));
    }
}
```

Output

```
cfgetospeed() says the speed of stdout is B0
```

cfsetispeed() — Set the input baud rate in the termios

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <termios.h>

int cfsetispeed(struct termios *termpptr, speed_t speed);
```

General description

Specifies a new input baud rate for the `termios` control structure, `*termpptr`. `cfsetispeed()` records this new baud rate in the control structure but does not actually change the terminal device file. The program must call `tcsetattr()` to modify the terminal device file to reflect the settings in the `termios` structure.

A program should first use `tcgetattr()` to get the `termios` structure. Then it should use `cfsetispeed()` to set the speed in `termios` and `tcsetattr()` to pass the modified `termios` structure to the system.

Although in a z/OS UNIX application valid speeds can be set with `cfsetispeed()` and passed to the system with `tcsetattr()`, the speed has no effect on the operation of a pseudoterminal. However, the operation will have an effect if issued for an OCS remote terminal.

The *speed* argument indicates the new baud rate with one of the following codes, defined in the `termios.h` header file. The codes have an unsigned integer type. [Table 19 on page 255](#) shows the codes to set the baud rate.

Returned value

If successful, `cfsetispeed()` sets the baud rate in the control structure and returns 0.

If unsuccessful, `cfsetispeed()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

An unsupported value for *speed*

Example

CELEBC07

```
/* CELEBC07

   This example specifies a new input baud rate.

*/
#define _POSIX_SOURCE
#include <termios.h>
#include <stdio.h>

main() {
    struct termios term;

    if (tcgetattr(0, &term) != 0)
        perror("tcgetattr() error");
    else if (cfsetispeed(&term, B0) != 0)
        perror("cfsetispeed() error");
    else if (tcsetattr(0, TCSANOW, &term) != 0)
        perror("tcsetattr() error");
}
```

__chattr(), __chattr64() — Change the attributes of a file or directory

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R2 |

Format

__chattr:

```

#define _OPEN_SYS_FILE_EXT 1
#include <sys/stat.h>

int __chattr(char* pathname, attrib_t *attributes, int attributes_len);

```

__chattr64:

```

#define _LARGE_TIME_API
#define _OPEN_SYS_FILE_EXT 1
#include <sys/stat.h>

int __chattr64(char *pathname, attrib64_t *attributes, int attributes_len);

```

Compile requirement: Use of the __chattr64 function requires the long long data type. For more information on how to make the long long data type available, see [z/OS XL C/C++ Language Reference](#).

General description

The __chattr() function modifies the attributes that are associated with a file. It can be used to change the mode, owner, access time, modification time, change time, reference time, audit flags, general attribute flags, file tag, and file format and size. The file to be impacted is defined by the *pathname* argument.

The *attributes* argument is the address of an `attrib_t` structure that is used to identify the attributes to be modified and the new values desired. The `attrib_t` type is an `f_attributes` structure as defined in `<sys/stat.h>` for use with the __chattr() function. For proper behavior the user should ensure that this structure has been initialized to zeros before it is populated. Available elements of the `f_attributes` structure are defined in [Table 20 on page 262](#):

Table 20. Struct *f_attributes* Element Descriptions

| Element | Data Type | General Description |
|--|-----------|-----------------------------------|
| Bit Flags Indicating Which Attributes to Change | | |
| att_modechg:1 | int | 1=Change to mode indicated |
| att_ownerchg:1 | int | 1=Change to Owner indicated |
| att_setgen:1 | int | 1=Set General Attributes |
| att_trunc:1 | int | 1=Truncate Size |
| att_atimechg:1 | int | 1=Change the Atime |
| att_atimetod:1 | int | 1=Change Atime to Cur.Time |
| att_mtimechg:1 | int | 1=Change the Mtime |
| att_mtimetod:1 | int | 1=Change Mtime to Cur.Time |
| att_maaudit:1 | int | 1=Modify auditor audit info |
| att_muaudit:1 | int | 1=Modify user audit info |
| att_ctimechg:1 | int | 1=Change the Ctime |
| att_ctimetod:1 | int | 1=Change Ctime to Cur.Time |
| att_reftimechg:1 | int | 1=Change the RefTime |
| att_reftimetod:1 | int | 1=Change RefTime to Cur.Time |
| att_filefmtchg:1 | int | 1=Change File Format |
| att_filetagchg:1 | int | 1=Change File Tag |
| att_seclabelchg:1 | int | 1=Change Seclabel |
| Modified Values for Indicated Attributes to Change | | |
| att_mode | mode_t | File Mode |
| att_uid | int | User ID of the owner of the file |
| att_gid | int | Group ID of the Group of the file |
| att_sharelibmask:1 | int | 1=Shared Library Mask |
| att_noshareasmask:1 | int | 1=No Shareas Flag Mask |
| att_apfauthmask:1 | int | 1=APF Authorized Flag Mask |
| att_progctlmask:1 | int | 1=Prog. Controlled Flag Mask |
| att_sharelib:1 | int | 1=Shared Library Flag |
| att_noshareas:1 | int | 1=No Shareas Flag |
| att_apfauth:1 | int | 1=APF Authorized Flag |
| att_progctl:1 | int | 1=Program Controlled Flag |
| att_size | off_t | File size |
| att_atime | time_t | Time of last access |
| att_mtime | time_t | Time of last data modification |
| att_auditoraudit | int | Area for auditor audit info |

Table 20. Struct *f_attributes* Element Descriptions (continued)

| Element | Data Type | General Description |
|---------------|-----------------|---------------------------------|
| att_useraudit | int | Area for user audit info |
| att_ctime | time_t | Time of last file status change |
| att_reftime | time_t | Reference Time |
| att_filefmt | char | File Format |
| att_filetag | struct file_tag | File Tag |
| att_seclabel | char | Security Label |

Note: If you set `att_nodelfilesmask`, `att_sharelibmask`, `att_nodelfiles`, `att_sharelib`, `att_noshareasmask`, `att_apfauthmask`, `att_progctlmask`, `att_noshareas`, `att_apfauth` or `att_progctl`, then `att_setgen` must also be set. The `att_setgen` flag is a required indicator when setting "general" attributes.

The `__chattr64()` function behaves exactly like `__chattr()` except `__chattr64()` uses struct `attrib64_t` instead of struct `attrib_t` to support time beyond 03:14:07 UTC on January 19, 2038.

The type of `attrib64_t` is an `f_attributes64` structure as defined in `<sys/stat.h>` for use with the `__chattr64()` function.

The use of the `f_attributes64` structure is exactly like `f_attributes` structure except that the types of `att_atime`, `att_mtime`, `att_ctime`, and `att_reftime` are `time64_t`.

Returned value

If successful, `__chattr()` returns 0.

If unsuccessful, `__chattr()` returns -1 and sets `errno` to one of the following values:

Error Code Description

EACCES

The calling process did not have appropriate permissions. Possible reasons include:

- The calling process was attempting to set access time or modification time to current time, and the effective UID of the calling process does not match the owner of the file; the process does not have write permission for the file; or the process does not have appropriate privileges.
- The calling process was attempting to truncate the file, and it does not have write permission for the file.

ECICS

An attempt was made to change file tag attributes under non-OTE CICS and file tagging is not supported in that environment.

EFBIG

The calling process was attempting to change the size of a file, but the specified length is greater than the maximum file size limit for the process.

EINVAL

The attributes structure containing the requested changes is not valid.

ELOOP

A loop exists in symbolic links that were encountered during resolution of the *pathname* argument. This error is issued if more than 24 symbolic links are detected in the resolution of *pathname*.

ENAMETOOLONG

pathname is longer than 1023 characters, or a component of the *pathname* is longer than 255 characters. (File name truncation is not supported.)

ENOENT

No file named *pathname* was found.

ENOTDIR

Some component of *pathname* is not a directory.

EPERM

The operation is not permitted for one of the following reasons:

- The calling process was attempting to change the mode or the file format but the effective UID of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges.
- The calling process was attempting to change the owner but it does not have appropriate privileges.
- The calling process was attempting to change the general attribute bits but it does not have write permission for the file.
- The calling process was attempting to set a time value (not current time) but the effective UID does not match the owner of the file, and it does not have appropriate privileges.
- The calling process was attempting to set the change time or reference time to current time but it does not have write permission for the file.
- The calling process was attempting to change auditing flags but the effective UID of the calling process does not match the owner of the file and the calling process does not have appropriate privileges.
- The calling process was attempting to change the Security Auditor's auditing flags but the user does not have auditor authority.

EROFS

pathname specifies a file that is on a read-only file system.

Example

```
#define _POSIX_SOURCE 1
#define _OPEN_SYS_FILE_EXT 1
#include <stdio.h>
#include <fcntl.h>
#include <sys/stat.h>

int main(int argc, char *argv[]) {

    int fd;
    attrib_t myAtt;
    struct stat attr;
    char filename[] = "chattr.testfile";

    /* Create an empty file */
    if ( (fd = creat(filename, S_IRWXU | S_IRGRP | S_IROTH)) < 0) {
        perror("Failed to create testfile");
        exit(1);
    }
    close(fd);

    /* Clear myAtt structure */
    memset(&myAtt, 0, sizeof(myAtt));

    /* Update myAtt to request file tag change and set file tag values */
    myAtt.att_filetagchg = 1;
    myAtt.att_filetag.ft_ccsid = 12345;
    myAtt.att_filetag.ft_txtflag = 1;

    /* Change Attributes */
    if ( __chattr(filename, &myAtt, sizeof(myAtt)) != 0 ) {
        perror("Failed to change attributes for testfile");
        exit(2);
    }
}
```

```

/* Verify Change */
if ( stat(filename,&attr) !=0 ) {
    perror("Failed to acquire statistics for testfile");
    exit(3);
}

if ((attr.st_tag.ft_ccsid == 12345)
    && (attr.st_tag.ft_txtflag == 1)) {
    printf("File attributes changed successfully\n");
}
}

```

__chattrrat(), __chattrrat64() — Change the attributes of a file or directory

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

__chattrrat:

```

#define _OPEN_SYS_FILE_EXT 1
#include <sys/stat.h>
#include <fcntl.h>

int __chattrrat(int dirfd, char *pathname, attrib_t *attributes, int attributes_len, int flags);

```

__chattrrat64:

```

#define _LARGE_TIME_API
#define _OPEN_SYS_FILE_EXT 1
#include <sys/stat.h>
#include <fcntl.h>

int __chattrrat64(int dirfd, char *pathname, attrib64_t *attributes, int attributes_len, int flags);

```

Compile requirement: Use of the __chattrrat64 function requires the long long data type. For more information on how to make the long long data type available, see [z/OS XL C/C++ Language Reference](#).

General description

__chattrrat() modifies the attributes that are associated with a file. It can be used to change the mode, owner, access time, modification time, change time, reference time, audit flags, general attribute flags, file tag, and file format and size. The file to be impacted is defined by the *pathname* argument.

The __chattrrat() function operates in the same way as __chattr().

The __chattrrat64() function behaves exactly like __chattrrat() except that __chattrrat64() uses struct attrib64_t instead of struct attrib_t to support time beyond 03:14:07 UTC on January 19, 2038. The type of attrib64_t is an f_attributes64 structure as defined in <sys/stat.h> for use with the __chattrrat64() function.

The use of the `f_attributes64` structure is exactly like `f_attributes` structure except that the types of `att_atime`, `att_mtime`, `att_ctime`, and `att_reftime` are `time64_t`.

Parameter Description

pathname

If *pathname* is relative, then it is interpreted relative to the directory referred to by the file descriptor *dirfd* (rather than relative to the current working directory of the calling process, as is done by `__chattr()` for a relative path name).

If *pathname* is relative and *dirfd* is the special value `AT_FDCWD`, then *pathname* is interpreted relative to the current working directory of the calling process (same as `__chattr()`).

If *pathname* is absolute, then *dirfd* is ignored.

If *pathname* is a symbolic link, operate on the link itself instead of dereferencing it. (By default, `__chattrat()` dereferences symbolic links.)

attributes

The *attributes* argument is the address of an `attrib_t` structure that is used to identify the attributes to be modified and the new values desired. The `attrib_t` type is an `f_attributes` structure as defined in `<sys/stat.h>` for use with the `__chattrat()` function. For proper behavior, you must ensure that this structure is initialized to zeros before it is populated. For available elements of the `f_attributes` structure, see [Table 20 on page 262](#).

flags

flags can either be 0 or include the following flag: `AT_SYMLINK_NOFOLLOW`.

Returned value

If successful, `__chattrat()` and `__chattrat64()` return 0.

If unsuccessful, `__chattrat()` and `__chattrat64()` return -1 and set `errno` to one of the following values:

Error Code Description

EACCES

The calling process did not have appropriate permissions. Possible reasons include:

- The calling process attempts to set access time or modification time to current time, and the effective UID of the calling process does not match the owner of the file; the process does not have write permission for the file; or the process does not have appropriate privileges.
- The calling process attempts to truncate the file, and it does not have write permission for the file.

EBADF

- *pathname* is relative but *dirfd* is `AT_FDCWD` or a valid file descriptor.
- *fd* is not a valid file descriptor.

EBUSY

The file is opened by a remote NFS client with a share reservation that conflicts with the requested operation.

EFBIG

The calling process attempts to change the size of a file, but the specified length is greater than the maximum file size limit for the process.

EINVAL

- The attributes structure containing the requested changes is not valid.
- Invalid value in *flags*.
- *pathname* is NULL, *dirfd* is not `AT_FDCWD`, and *flags* contains `AT_SYMLINK_NOFOLLOW`.

ELOOP

A loop exists in symbolic links that are encountered during resolution of the *pathname* argument.
More than 24 symbolic links are detected in the resolution of *pathname*.

EMVSERR

An MVS environmental error or internal error occurs.

ENAMETOOLONG

pathname is longer than 1023 characters, or a component of the *pathname* is longer than 255 characters. (File name truncation is not supported.)

ENOENT

No file that is named *pathname* is found.

ENOSYS

The function is not supported for the specified file.

ENOTDIR

Some component of *pathname* is not a directory.

EPERM

The operation is not permitted for one of the following reasons:

- The calling process attempts to change the mode or the file format but the effective UID of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges.
- The calling process attempts to change the owner but it does not have appropriate privileges.
- The calling process attempts to change the general attribute bits but it does not have write permission for the file.
- The calling process attempts to set a time value (not current time) but the effective UID does not match the owner of the file, and it does not have appropriate privileges.
- The calling process attempts to set the change time or reference time to current time but it does not have write permission for the file.
- The calling process attempts to change auditing flags but the effective UID of the calling process does not match the owner of the file and the calling process does not have appropriate privileges.
- The calling process attempts to change the Security Auditor's auditing flags but the user does not have auditor authority.

EROFS

pathname specifies a file that is on a read-only file system.

chaudit() — Change audit flags for a file by path

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _OPEN_SYS 1
#include <sys/stat.h>

int chaudit(const char *pathname, unsigned int flags,
            unsigned int option);
```

General description

Changes the audit flags for a file to indicate the type of requests the security product should audit. `chaudit()` can change user audit flags or security auditor audit flags, depending on the *option* specified.

pathname is the name of the file for which the audit flags are to be changed.

flags is the setting for the audit flags:

AUDTREADFAIL

Audit the failing read requests.

AUDTREADSUCC

Audit the successful read requests.

AUDTWRITEFAIL

Audit the failing write requests.

AUDTWritesucc

Audit the successful write requests.

AUDTEXECFAIL

Audit the failing execute or search requests.

AUDTEXECsucc

Audit the successful execute or search requests. The bitwise inclusive-OR of any or all of these can be used to set more than one type of auditing.

option indicates whether the user audit flags or the security-auditor audit flags are to be changed:

AUDT_USER (0)

Change user flags. The user must be the file owner or have appropriate authority to change the user audit flags for a file.

AUDT_AUDITOR (1)

Change security auditor audit flags. The user must have security-auditor authority to modify the security auditor audit flags for a file.

Returned value

If successful, `chaudit()` returns 0.

If unsuccessful, `chaudit()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

The calling process does not have permission to search some component of *pathname*.

EINVAL

option is not `AUDT_USER` or `AUDT_AUDITOR`.

ELOOP

A loop exists in symbolic links. This error is issued if the number of symbolic links detected in the resolution of *pathname* is greater than `POSIX_SYMLINK` (a value defined in the `limits.h` header file).

ENAMETOOLONG

pathname is longer than `PATH_MAX` characters or a component of *pathname* is longer than `NAME_MAX` characters while `_POSIX_NO_TRUNC` is in effect. For symbolic links, the length of

the *pathname* string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values are determined using `pathconf()`.

ENOENT

There is no file named *pathname*, or *pathname* is an empty string.

ENOTDIR

A component of the path prefix is not a directory.

EPERM

The effective user ID (UID) of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges.

EROFS

pathname specifies a file that is on a read-only file system.

Example

CELEBC09

```
/* CELEBC09

   This example changes the audit flags.

*/

#define _OPEN_SYS
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _OPEN_SYS
#include <stdio.h>

main() {
    int fd;
    char fn[]="chaudit.file";

    if ((fd = creat(fn, S_IRUSR|S_IWUSR)) < 0)
        perror("creat() error");
    else {
        close(fd);
        if (chaudit(fn, AUDTREADFAIL, AUDT_USER) != 0)
            perror("chaudit() error");
        unlink(fn);
    }
}
```

chdir() – Change the working directory

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

int chdir(const char *pathname);
```

General description

Makes *pathname* your new working directory.

Returned value

If successful, chdir() changes the working directory and returns 0.
If unsuccessful, chdir() does not change the working directory, returns -1, and sets errno to one of the following values:

Error Code

Description

- EACCES**
The process does not have search permission on one of the components of *pathname*.
- ELOOP**
A loop exists in symbolic links. This error is issued if the number of symbolic links detected in the resolution of *pathname* is greater than POSIX_SYMLLOOP (a value defined in the limits.h header file).
- ENAMETOOLONG**
pathname is longer than **PATH_MAX** characters, or some component of *pathname* is longer than **NAME_MAX** characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the *pathname* string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values are determined using pathconf().
- ENOENT**
pathname is an empty string, or the specified directory does not exist.
- ENOTDIR**
Some component of *pathname* is not a directory.

Example

CELEBC10

```
/* CELEBC10 */
#define _POSIX_SOURCE
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
    if (chdir("/tmp") != 0)
        perror("chdir() to /tmp failed");
}
```

```

    if (chdir("/chdir/error") != 0)
        perror("chdir() to /chdir/error failed");
}

```

Output

```
chdir() to /chdir/error failed: No such file or directory
```

__check_resource_auth_np() — Determine access to MVS resources

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```

#include <unistd.h>

int __check_resource_auth_np( char *principal_uuid,
                             char *cell_uuid,
                             char *userid,
                             char *security_class,
                             char *entity_name,
                             int access_type);

```

General description

The `__check_resource_auth_np()` function is used to check the access that a user has to an MVS resource.

For authorization to use this function, the caller must have read permission to the BPX.SERVER Facility class, or if BPX.SERVER is not defined, the caller must be a superuser (UID=0).

The user identity can be specified in several forms. The identities are scanned in the following order , and the access check is made with the first identity that is found:

- `userid`
- Principal UUID and if known, a cell UUID
- Caller's thread-level (task) security context, if one exists
- Caller's process-level (address space) security context

Note:

- When no identity is specified by the caller and the caller's task has an ACEE that is created with `pthread_security_np()` for a SURROGATE (nonpassword) client, both the task and address space level ACEEs are used in determining the type of access that is permitted to a resource.
- The `__check_resource_auth_np()` function supports the general resources only. In particular, the `security_class` parameter cannot specify DATASET. For system that uses RACF, the class name that is specified must be in the RACF class descriptor table.

The parameters that are supported are:

principal_uuid

Specifies a 36-byte principal UUID. A value of NULL indicates that no principal UUID is specified.

cell_uuid

Specifies a 36-byte cell UUID. A value of NULL indicates that no cell UUID is specified.

userid

Specifies a user ID. A value of NULL indicates that no user ID is specified. The *userid* must be 1-8 characters in length.

security_class

Specifies the name of a class of resources. The access check is made on a resource in this security class. The *security_class* must be 1-8 characters in length.

entity_name

Specifies the name of a resource profile name. The access check is made on the resource that is specified by the resource profile name. The *entity_name* must be 1-246 characters in length.

access

Specifies a numeric value that identifies the type of access to check for. Possible access values are:

__READ_RESOURCE

Check if the specified user has read access to the resource.

__UPDATE_RESOURCE

Check if the specified user has update access to the resource.

__CONTROL_RESOURCE

Check if the specified user has control access to the resource.

__ALTER_RESOURCE

Check if the specified user has altered access to the resource.

Returned value

If successful, `__check_resource_auth_np()` returns 0.

If unsuccessful, `__check_resource_auth_np()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

One of the following errors is detected:

- *access_type* that is specified is undefined.
- *userid* is not 1 to 8 characters in length.
- *security_class* is not 1 to 8 characters in length.
- *entity_name* is not 1 to 246 characters in length.

EMVSERR

An MVS internal or environmental error occurred.

EMVSSAF2ERR

One of the following errors was detected:

- Received an unexpected return code for the security product.

- The security product detected an error in the input parameters.
- An internal error occurred in the security product.

ENOSYS

One of the following errors was detected:

- No security product is installed on the system.
- The security product does not have support for this function.

EPERM

One of the following errors was detected:

- The caller is not permitted to use this service.
- Do not have the *access_type* that is specified to the resource.
- Not permitted in address spaces where a load from an unauthorized library has been performed.

ESRCH

One of the following errors was detected:

- No mapping exists between a UUID and *userid*.
- The resource that is specified is not defined to the security product.
- The DCEUUIDS class is not active.
- The *userid* is not defined to the security product.

CheckSchEnv() — Check WLM scheduling environment

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <sys/_wlm.h>

int CheckSchEnv(const char *sched_env,
                const char *system_name);
```

General description

The CheckSchEnv() function provides the ability for an application to connect to check the WLM scheduling environment.

***sched_env**

Points to a 16 byte character string that represents the WLM scheduling environment to be queried. If the environment name is less than 16 characters, the name should be right padded with blanks.

***sys_name**

Points to a 8 bytes character string that represents the system name to be queried. If the system name is less than 8 characters, the name should be right padded with blanks.

Returned value

If successful, CheckSchEnv() returns 0.

If unsuccessful, CheckSchEnv() returns -1 and sets errno to one of the following values:

Error Code
Description

EFAULT

An argument of this function contained an address that was not accessible to the caller.

EINVAL

An argument of this function contained an incorrect value.

EMVSSAF2ERR

An error occurred in the security product.

EMVSWLMERROR

The WLM check scheduling environment failed. Use __errno2() to obtain the WLM service reason code for the failure.

EPERM

The calling thread's address space is not permitted to the BPX.WLMSEVER Facility class. The caller's address space must be permitted to the BPX.WLMSEVER Facility class if it is defined. If BPX.WLMSEVER is not defined, the calling process is not defined as a superuser (UID=0).

chmod() – Change the mode of a file or directory

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <sys/stat.h>

int chmod(const char *pathname, mode_t mode);
```

General description

Changes the mode of the file or directory specified in *pathname*.

The *mode* argument is created with one of the following symbols defined in the `sys/stat.h` header file.

Any mode flags that are not defined will be turned off, and the function will be allowed to proceed.

S_IRGRP

Read permission for the file's group.

S_IROTH

Read permission for users other than the file owner.

S_IRUSR

Read permission for the file owner.

S_IRWXG

Read, write, and search or execute permission for the file's group. `S_IRWXG` is the bitwise inclusive-OR of `S_IRGRP`, `S_IWGRP`, and `S_IXGRP`.

S_IRWXO

Read, write, and search or execute permission for users other than the file owner. `S_IRWXO` is the bitwise inclusive-OR of `S_IROTH`, `S_IWOTH`, and `S_IXOTH`.

S_IRWXU

Read, write, and search, or execute, for the file owner; `S_IRWXG` is the bitwise inclusive-OR of `S_IRUSR`, `S_IWUSR`, and `S_IXUSR`.

S_ISGID

Privilege to set group ID (GID) for execution. When this file is run through an `exec` function, the effective group ID of the process is set to the group ID of the file. The process then has the same authority as the file owner, rather than the authority of the actual invoker.

S_ISUID

Privilege to set the user ID (UID) for execution. When this file is run through an `exec` function, the effective user ID of the process is set to the owner of the file. The process then has the same authority as the file owner, rather than the authority of the actual invoker.

S_ISVTX

The sticky bit indicating shared text. Keep loaded as an executable file in storage.

S_IWGRP

Write permission for the file's group.

S_IWOTH

Write permission for users other than the file owner.

S_IWUSR

Write permission for the file owner.

S_IXGRP

Search permission (for a directory) or execute permission (for a file) for the file's group.

S_IXOTH

Search permission for a directory, or execute permission for a file, for users other than the file owner.

S_IXUSR

Search permission (for a directory) or execute permission (for a file) for the file owner.

Special behavior for XPG4.2: If a directory is writable and the mode bit `S_ISVTX` is set on the directory, a process may remove or rename files within that directory only if one or more of the following is true:

- The effective user ID of the process is the same as that of the owner ID of the file.
- The effective user ID of the process is the same as that of the owner ID of the directory.
- The process has appropriate privileges.

A process can set mode bits only if the effective user ID of the process is the same as the file's owner or if the process has appropriate privileges (superuser authority). `chmod()` automatically clears the `S_ISGID` bit in the file's mode bits if all these conditions are true:

- The calling process does not have appropriate privileges, that is, superuser authority (UID=0).
- The group ID of the file does not match the group ID or supplementary group IDs of the calling process.
- One or more of the S_IXUSR, S_IXGRP, or S_IXOTH bits of the file mode are set to 1.

Returned value

If successful, chmod() marks for update the st_ctime field of the file and returns 0.

If unsuccessful, chmod() returns -1 and sets errno to one of the following values:

Error Code

Description

EACCES

The process does not have search permission on some component of the *pathname* prefix.

ELOOP

A loop exists in symbolic links. This error is issued if the number of symbolic links detected in the resolution of *pathname* is greater than POSIX_SYMLINK_MAX (a value defined in the limits.h header file).

ENAMETOOLONG

pathname is longer than **PATH_MAX** characters, or some component of *pathname* is longer than **NAME_MAX** characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the *pathname* string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values are determined using pathconf().

ENOENT

There is no file named *pathname*, or the *pathname* argument is an empty string.

ENOTDIR

Some component of the *pathname* prefix is not a directory.

EPERM

The effective user ID (UID) of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges (superuser authority).

EROFS

pathname is on a read-only file system.

Example

CELEBC11

```
/* CELEBC11

   This example changes the permission from the file owner to the file's
   group.

*/
#define _POSIX_SOURCE
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
    char fn[] = "./temp.file";
    FILE *stream;
    struct stat info;

    if ((stream = fopen(fn, "w")) == NULL)
        perror("fopen() error");
    else {
        fclose(stream);
        stat(fn, &info);
        printf("original permissions were: %08x\n", info.st_mode);
        if (chmod(fn, S_IRWXU|S_IRWXG) != 0)
            perror("chmod() error");
        else {
            stat(fn, &info);
```

```

        printf("after chmod(), permissions are: %08x\n", info.st_mode);
    }
    unlink(fn);
}
}

```

Output

```

original permissions were: 030001b6
after chmod(), permissions are: 030001f8

```

chown() — Change the owner or group of a file or directory

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```

#define _POSIX_SOURCE
#include <unistd.h>

int chown(const char *pathname, uid_t owner, gid_t group);

```

General description

Changes the owner or group (or both) of a file. *pathname* is the name of the file whose owner or group you want to change. *owner* is the user ID (UID) of the new owner of the file. *group* is the group ID (GID) of the new group for the file.

If `_POSIX_CHOWN_RESTRICTED` is defined in the `unistd.h` header file, a process can change the group of a file only if one of these is true:

1. The process has appropriate privileges.
2. Or all of the following are true:
 - a. The effective user ID of the process is equal to the user ID of the file owner.
 - b. The *owner* argument is equal to the user ID of the file owner or `(uid_t) -1`,
 - c. The *group* argument is either the effective group ID or a supplementary group ID of the calling process.

If *pathname* is a regular file and one or more of the S_IXUSR, S_IXGRP, or S_IXOTH bits of the file mode are set, chown() clears the set-user-ID (S_ISUID) and set-group-ID (S_ISGID) bits of the file mode and returns successfully.

If *pathname* is not a regular file and one or more of the S_IXUSR, S_IXGRP, or S_IXOTH bits of the file mode are set, chown() clears the set-user-ID (S_ISUID) and set-group-ID (S_ISGID) bits of the file.

When chown() completes successfully, it marks the st_ctime field of the file to be updated.

Special behavior for XPG4.2: If *owner* or *group* is specified as (uid_t) -1 or (gid_t) -1 respectively, the corresponding ID of the file is unchanged.

Returned value

If successful, chown() updates the owner, group, and change time for the file and returns 0.

If unsuccessful, chown() returns -1 and sets errno to one of the following values:

Error Code Description

EACCES

The process does not have search permission on some component of the *pathname* prefix.

EINTR

Added for XPG4.2: The chown() function was interrupted by a signal which was caught.

EINVAL

owner or *group* is not a valid user ID (UID) or group ID (GID).

EIO

Added for XPG4.2: An I/O error occurred while reading or writing to the file system.

ELOOP

A loop exists in symbolic links. This error is issued if the number of symbolic links detected in the resolution of *pathname* is greater than POSIX_SYMLINK_MAX (a value defined in the limits.h header file).

ENAMETOOLONG

pathname is longer than **PATH_MAX** characters, or some component of *pathname* is longer than **NAME_MAX** characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the *pathname* string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values can be determined using pathconf().

ENOENT

There is no file named *pathname*, or the *pathname* argument is an empty string.

ENOTDIR

Some component of the *pathname* prefix is not a directory.

EPERM

The effective user ID of the calling process does not match the owner of the file, or the calling process does not have appropriate privileges, that is, superuser authority (UID=0).

EROFS

pathname is on a read-only file system.

Example

CELEBC12

```
/* CELEBC12
   This example changes the owner and group of a file.
*/
#define _POSIX_SOURCE
#include <unistd.h>
#include <sys/stat.h>
#include <sys/types.h>
#undef _POSIX_SOURCE
```

```
#include <stdio.h>

main() {
    char fn[] = "./temp.file";
    FILE *stream;
    struct stat info;

    if ((stream = fopen(fn, "w")) == NULL)
        perror("fopen() error");
    else {
        fclose(stream);
        stat(fn, &info);
        printf("original owner was %d and group was %d\n", info.st_uid,
              info.st_gid);
        if (chown(fn, 25, 0) != 0)
            perror("chown() error");
        else {
            stat(fn, &info);
            printf("after chown(), owner is %d and group is %d\n",
                  info.st_uid, info.st_gid);
        }
        unlink(fn);
    }
}
```

Output

```
original owner was 0 and group was 0
after chown(), owner is 25 and group is 0
```

chpriority() — Change the scheduling priority of a process

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _OPEN_SOURCE 2
#include <sys/resource.h>

int chpriority(int which, id_t who, int prioritytype, int priority);
```

General description

The `chpriority()` function changes the scheduling priority of a process, process group or user.

Processes are specified by the values of the *which* and *who* arguments. The *which* argument may be one of the following values: `PRIO_PROCESS`, `PRIO_PGRP`, or `PRIO_USER`, indicating that the *who* argument is to be interpreted as a process ID, a process group ID, or a user ID, respectively. A 0 (zero) value for the *who* argument specifies the current process, process group or user ID.

If more than one process is specified, the `chpriority()` function changes the priorities of all of the specified processes.

The default priority is 0; negative priorities cause more favorable scheduling. The range of legal priority values is -20 to 19. If the `CPRIO_ABSOLUTE` value is specified for the *prioritytype* argument and the priority value specified to `chpriority()` is less than the system's lowest supported priority value, the system's lowest supported value is used; if it is greater than the system's highest supported value, the system's highest supported value is used. If the `CPRIO_RELATIVE` value is specified on the *prioritytype* argument, request for values above or below the legal limits result in the priority value being set to the corresponding limit.

The changing of a process's scheduling priority value has the equivalent effect of a process's nice value, since they both represent the process's relative CPU priority. For example, changing one's scheduling priority value using the `chpriority()` function to its maximum value (19) has the equivalent effect of increasing one's nice value to its maximum value $2^{\{NZERO\}-1}$, and will be reflected on the `nice()`, `getpriority()`, `chpriority()`, and `setpriority()` functions.

Only a process with appropriate privilege can lower its priority. In addition to lowering the priority value, a process with appropriate privilege has the ability to change the priority of any process regardless of the process's saved set-user-ID value.

Returned value

If successful, `chpriority()` returns 0.

If unsuccessful, `chpriority()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCESS

The priority is being changed to a lower value and the current process does not have the appropriate privilege.

EINVAL

The value of the *which* argument was not recognized, or the value of the *who* argument is not a valid process ID, process group ID or user ID, or the value of the *prioritytype* argument was not recognized.

ENOSYS

The system does not support this function.

EPERM

A process was located, but the save set-user-ID of the executing process does not match the saved set-user-ID of the process whose priority is to be changed.

ESRCH

No process could be located using the *which* and *who* argument values specified.

Related information

- [“sys/resource.h — XSI resource operations” on page 70](#)
- [“getpriority\(\) — Get process scheduling priority” on page 756](#)

chroot() — Change root directory

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4 XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE
#include <unistd.h>

int chroot(const char *path);
```

General description

The *path* argument points to a path name naming a directory. The `chroot()` function causes the named directory to become the root directory, that is the starting point for path searches for path names beginning with `/`. The process's working directory is unaffected by `chroot()`. Only a superuser can request `chroot()`.

The dot-dot entry in the root directory is interpreted to mean the root directory. Thus, dot-dot cannot be used to access files outside the subtree rooted at the root directory.

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

If successful, `chroot()` changes the root directory, and returns 0.

If unsuccessful, `chroot()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

Search permission is denied for a component of *path*

ELOOP

A loop exists in symbolic links. This error is issued if the number of symbolic links detected in the resolution of path name is greater than `POSIX_SYMLLOOP` (a value defined in the `limits.h` header file).

ENAMETOOLONG

Path name is longer than **PATH_MAX** characters, or some component of path name is longer than **NAME_MAX** characters while `_POSIX_NO_TRUNC` is in effect. For symbolic links, the length of the path name string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values are determined using `pathconf()`.

ENOENT

A component of *path* does not name an existing directory or *path* is an empty string.

ENOTDIR

A component of the *path* name is not a directory.

EPERM

The effective user ID does not have appropriate privileges.

cimag(), cimagf(), cimagl() — Calculate the complex imaginary part

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--|
| C99 Single UNIX Specification, Version 3 | both | z/OS V1R7 a compiler that is designed to support C99 |

Format

```
#include <complex.h>

double cimag(double complex z);
float cimagf(float complex z);
long double cimagl(long double complex z);
```

General description

The cimag() family of functions compute the imaginary part of z.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------|-----|------|
| cimag | X | X |
| cimagf | X | X |
| cimagl | X | X |

Returned value

The cimag() family of functions return the imaginary part value (as a real).

Example

For an example of a similar function see cacos(), cexp() or cpow().

clearenv() — Clear environment variables

Standards

| Standards / Extensions | C or C++ | Dependencies |
|-------------------------------------|----------|--------------|
| POSIX.1a Language Environment | both | |

Format

POSIX - C only:

```
#define _POSIX1_SOURCE 2
#include <env.h>

int clearenv(void);
```

Non-POSIX:

```
#include <stdlib.h>

int clearenv(void);
```

General description

Clears all environment variables from the environment table and frees the associated storage.

`clearenv()` also resets all behavior modified by IBM z/OS C/C++ specific environment variables back to their defaults. For example, if a binary file was opened, then it would support seeking by byte offsets, regardless of record format. If the file is a Variable Record format MVS DASD file, then clearing the environment variable causes seeking by encoded values the next time it is opened.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

For details about environment variables, see “Using Environment Variables” in [z/OS XL C/C++ Programming Guide](#).

Special behavior for POSIX C: `clearenv()` can change the value of the pointer `environ`. Therefore, a copy of that pointer made before a call to `clearenv()` may no longer be valid after the call to `clearenv()`.

Returned value

If successful, `clearenv()` returns 0.

If unsuccessful, `clearenv()` returns nonzero and sets `errno` to one of the following values:

Error Code

Description

ENOMEM

The process requires more space than is available.

Example

CELEBC13

```

/* CELEBC13

   This C/MVS example needs to be run with POSIX(ON).
   It clears the process environment variable list.

*/
#define _POSIX_SOURCE 1
#include <env.h>
#include <stdio.h>

extern char **environ;

int count_env() {
    int num;

    for (num=0; environ[num] != NULL; num++);
    return num;
}

main() {
    printf("before clearenv(), there are %d environment variables\n",
        count_env());
    if (clearenv() != 0)
        perror("clearenv() error");
    else {
        printf("after clearenv(), there are %d environment variables\n",
            count_env());
        setenv("var1", "value1", 1);
        setenv("var-two", "Value Two", 1);
        printf("after setenv()'s, there are %d environment variables\n",
            count_env());
        if (clearenv() != 0)
            perror("clearenv() error");
        else
            printf("after clearenv(), there are %d environment variables\n",
                count_env());
    }
}

```

Output

```

before clearenv(), there are 9 environment variables
after clearenv(), there are 0 environment variables
after setenv()'s, there are 2 environment variables
after clearenv(), there are 0 environment variables

```

CELEBC14

```

/* CELEBC14

   This example is for a non-POSIX environment, and thus will work under
   C++/MVS.

*/
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    char *x;

    /* set 3 environment variables to "Y" */
    setenv("_EDC_ANSI_OPEN_DEFAULT", "Y", 1);
    setenv("_EDC_BYTE_SEEK", "Y", 1);
    setenv("_EDC_COMPAT", "3", 1);

    /* query the setting of _EDC_BYTE_SEEK */
    x = getenv("_EDC_BYTE_SEEK");

    if (x != NULL)
        printf("_EDC_BYTE_SEEK = %s\n", x);
    else
        printf("_EDC_BYTE_SEEK is undefined\n");
}

```

```
/* clear the environment variable table */
clearenv();

/* query the setting of _EDC_BYTE_SEEK */
x = getenv("_EDC_BYTE_SEEK");

if (x != NULL)
    printf("_EDC_BYTE_SEEK = %s\n",x);
else
    printf("_EDC_BYTE_SEEK is undefined\n");
}
```

Output

```
_EDC_BYTE_SEEK = Y
_EDC_BYTE_SEEK is undefined
```

clearerr() – Reset error and end of file (EOF)

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```
#include <stdio.h>

void clearerr(FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

void clearerr_unlocked (FILE *stream);
```

General description

Resets the error indicator and EOF indicator for the stream that `stream` points to. Generally, the indicators for a stream remain set until your program calls `clearerr()` or `rewind()`.

`clearerr_unlocked()` is functionally equivalent to `clearerr()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking

thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

clearerr() returns no values.

Example

CELEBC15

```
/* CELEBC15

This example reads a data stream and then checks that a read
error has not occurred.

*/
#include <stdio.h>

int main(void)
{
    char string[100];
    FILE *stream;
    int eofvalue;

    stream = fopen("myfile.dat", "r");

    /* scan an input stream until an end-of-file character is read */
    while (!feof(stream))
        fscanf(stream,"%s",&string[0]);

    /* print EOF value: will be nonzero */
    eofvalue=feof(stream);
    printf("feof value=%i\n",eofvalue);

    /* print EOF value-after clearerr, will be equal to zero */
    clearerr(stream);
    eofvalue=feof(stream);
    printf("feof value=%i\n",eofvalue);
}
```

clock() — Determine processor time

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <time.h>

clock_t clock(void);
```

General description

Approximates the processor time used by the program, since the beginning of an implementation-defined time period that is related to the program invocation. To measure the time spent in a program, call the `clock()` function at the start of the program, and subtract its returned value from the value returned by subsequent calls to `clock()`. Then, to obtain the time in seconds, divide the value returned by `clock()` by `CLOCKS_PER_SEC`.

If you use the `system()` function in your program, do not rely on `clock()` for program timing, because calls to `system()` may reset the clock.

In a multithread POSIX C application, if you are creating threads with a function that is based on a POSIX.4a draft standard, the `clock()` function is thread-scoped.

Returned value

If the time is available and can be represented, `clock()` returns the calculated time.

If unsuccessful, `clock()` returns `(clock_t)-1`. `clock()` may return -1 when running with STIMER REAL TQE present on MVS/ESA Version 3 Release 1 Modification 2 (or earlier) system.

Special behavior for XPG4: If `_XOPEN_SOURCE` or `_XOPEN_SOURCE_EXTENDED` are defined when your application is compiled, `CLOCKS_PER_SEC` is defined as 1000000. Also, in this case, the following C/370 pragma in the `<time.h>` header is used to compile your application:

```
#pragma map ( clock(), "@@OCLCK")
```

Because of this pragma, when your application executes, it will attempt to access an XPG4 version of `clock()` which returns a `clock_t` value in units of 1000000 `CLOCKS_PER_SEC`. The XPG4 version of `clock()` is only available if `POSIX(ON)` is specified for execution of your application.

If `_XOPEN_SOURCE` or `_XOPEN_SOURCE_EXTENDED` are defined when you compile your program AND your application is run with `POSIX(OFF)`, `clock()` will return `(clock_t) -1`.

If neither `_XOPEN_SOURCE` or `_XOPEN_SOURCE_EXTENDED` are defined when you compile your application, the historical C/370 value of `CLOCKS_PER_SEC` will be used and `clock()` calls in your application will be mapped to the historical C/370 version of `clock()` which returns a `clock_t` value in historical C/370 `CLOCKS_PER_SEC` units whether your application executes with `POSIX(ON)` or `POSIX(OFF)`.

Example

```
/* This example prints the time elapsed since the program was invoked. */
#include <time.h>
#include <stdio.h>

double time1, timedif; /* use doubles to show small values */

int main(void)
{
    time1 = (double) clock(); /* get initial time */
    time1 = time1 / CLOCKS_PER_SEC; /* in seconds */
    :
    /* call clock a second time */
    timedif = ( ((double) clock()) / CLOCKS_PER_SEC) - time1;
    printf("The elapsed time is %f seconds\n", timedif);
}
```

clock_gettime() — Retrieve the time of the specified clock

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1-2001 POSIX.1-2008 Single UNIX Specification, Version 2 | both | |

Format

```
#define _XOPEN_SOURCE 500
#include <time.h>
int clock_gettime(clockid_t clockid, struct timespec *tp);
```

General description

The clock_gettime() function retrieves the time of the specified clock identifier. The clockid argument specifies the clock identifier, which can be one of the following values:

CLOCK_MONOTONIC

Clock that represents monotonic time since some unspecified starting point.

CLOCK_REALTIME

System-wide real-time clock.

The tp argument is a timespec structure that is defined in <time.h>:

```
struct timespec {
    time_t    tv_sec;        /* seconds */
    long      tv_nsec;       /* nanoseconds */
};
```

Returned value

If successful, clock_gettime() returns 0.

If unsuccessful, clock_gettime() returns -1 and sets errno to one of the following values:

Error Code

Description

EFAULT

tp points outside the accessible address space.

EINVAL

clockid does not refer to a valid instance of a clock object or is not supported.

EMVSTODNOTSET

System TOD clock is not set.

- [“time.h — Time and date” on page 75](#)

clog(), clogf(), clogl() – Calculate the complex natural logarithm

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--|
| C99 Single UNIX Specification, Version 3 | both | z/OS V1R7 a compiler that is designed to support C99 |

Format

```
#include <complex.h>

double complex clog(double complex z);
float complex clogf(float complex z);
long double complex clogl(long double complex z);
```

General description

The `clog()` family of functions compute the complex natural (base-e) logarithm of `z`, with a branch cut along the negative real axis.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|--------------------|-----|------|
| <code>clog</code> | X | X |
| <code>clogf</code> | X | X |
| <code>clogl</code> | X | X |

Returned value

The `clog()` family of functions return the complex natural logarithm value, in the range of a strip, mathematically unbounded along the real axis and in the interval $[-i\pi, +i\pi]$ along the imaginary axis.

Example

For an example of a similar function see `cacos()`, `cexp()` or `cpow()`.

clone() – Create a child process

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | AMODE 64 |

Format

```
#define _XPLATFORM_SOURCE
#include <sched.h>

int clone(int (*fn)(void *), void *stack, int flags, void *arg, ...);
```

General description

`clone()` create a new ("child") process, in a manner similar to `fork()`.

Comparing to `fork()`, `clone()` provides more precise control over what pieces of execution context are shared between the calling process and the child process. For example, by using `clone()`, the caller can control whether the two processes share the same namespace and the same parent process ID.

When the child process is created with `clone()`, it commences execution by calling the function that is pointed to by the argument `fn`. (This differs from `fork()`, where execution continues in the child from the point of the `fork()` call.) The `arg` argument is passed as the argument of the function `fn`. The stack argument is ignored.

When the `fn(arg)` function returns, the child process terminates. The integer that is returned by `fn` is the exit status for the child process. The child process might also terminate explicitly by calling `exit()` or after receiving a fatal signal.

`clone()` allow a flags bit mask that modifies its behavior and allows the caller to specify what is shared between the calling process and the child process. The `flags` mask is specified as a bitwise-OR of zero or more of the following constants:

CLONE_NEWIPC

- If `CLONE_NEWIPC` is set, then create the process in a new IPC namespace.
- If `CLONE_NEWIPC` is not set, (as with `fork()`), the process is created in the same IPC namespace as the calling process.

CLONE_NEWNS

- If `CLONE_NEWNS` is set, the cloned child is started in a new mount namespace, initialized with a copy of the namespace of the parent.
- If `CLONE_NEWNS` is not set, the child lives in the same mount namespace as the parent.

CLONE_PARENT

- If `CLONE_PARENT` is set, the parent of the new child (as returned by `getppid()`) is the same as that of the calling process.
- If `CLONE_PARENT` is not set, (as with `fork()`), the child's parent is the calling process.

The parent process that is returned by `getppid()` is signaled when the child terminates, so if `CLONE_PARENT` is set, the parent of the calling process, rather than the calling process itself, is signaled.

The `CLONE_PARENT` flag cannot be used in clone calls by the global `init` process (PID 1 in the initial PID namespace) and `init` processes in other PID namespaces.

CLONE_NEWPID

- If `CLONE_NEWPID` is set, create the process in a new PID namespace.
- If `CLONE_NEWPID` is not set, (as with `fork()`), the process is created in the same PID namespace as the calling process. This flag cannot be specified in `CLONE_PARENT`.

CLONE_NEWUTS

- If `CLONE_NEWUTS` is set, create the process along with a new UTS namespace, whose identifiers are initialized by duplicating the identifiers from the UTS namespace of the calling process.
- If `CLONE_NEWUTS` is not set, (as with `fork()`), the process is created in the same UTS namespace as the calling process.

Usage note

A child termination signal can be specified in the *flag* parameter. SIGCHLD is the only supported signal and it must be specified.

If a UNIX set-user-ID or set-group-ID privileged program that switched the caller's effective UID or GID invokes the clone service, the child process that is created inherits the privilege of the set-user-ID or setgroup-ID program.

The child process is a duplicate of the process that calls the clone service (called the calling process), except for the following:

- The child process has a unique process ID (PID) in its namespace and each of any ancestor namespaces, that does not match any active process group ID.
- The child has a different parent process ID (the process ID of the process that calls `clone()`) unless `CLONE_PARENT` is specified. If the new process is created in a PID namespace other than the PID namespace of the caller, the child appears to have no parent process (PPID=0) from its view within the namespace.
- The child is created in the same namespaces as the calling process, unless one or more of the `CLONE_NEWxxx` flags are set or a prior call to `unshare()` or `setns()` with flag `CLONE_NEWPID` was issued by the calling process.
- The child has its own copy of the parent's file descriptors. Each file descriptor in the child refers to the same open file description as the corresponding file descriptor in the parent.
- The child has its own copy of the parent's open directory streams. Each child's open directory stream can share directory stream positioning with the corresponding parent's directory stream.
- If the file has its `FD_CLOFORK` flag set on, it is not inherited by the child process. This flag is set with a call to `fcntl()`.
- The process and system utilization times for the child are set to zero.
- The following elements in the `tms` structure are set to 0 in the child:
 - `tms_utime`
 - `tms_stime`
 - `tms_cutime`
 - `tms_cstime`

For more information about these elements, see [“times\(\) — Get process and child process times” on page 1867](#).

- The child does not inherit any file locks previously set by the parent.
- The child process has no alarms set (similar to the results of a call to `alarm()` with an argument value of `Wait_time` specified as 0).
- The child has no pending signals.
- The child process has only a single thread. That thread is a copy of the thread in the parent that called `clone()`. The child process has a different thread ID. If the parent process was multithreaded (invoked `pthread_create()` at least once), the child process can only safely invoke `async-signal-safe` functions before it invokes an `exec()` family function. (This restriction also applies to any process created as the result of the child invoking `clone()` before it invokes an `exec()` family function because the child process is considered multithreaded.) The child process does not inherit `pthread` attributes or `pthread` security environment. See [Table 28 on page 578](#) for a list of `async-signal-safe` functions.

When the clone requests the process to be added in one or more new namespaces (one of the `CLONE_NEWxxx` flags was specified) the caller must be authorized by being a superuser or having, at least, `READ` access to the `CONTAINERS` resource in the `UNIXPRIV` class.

The child process inherits all key 8 shared memory segments that are attached to the calling process. The internal values of the number of processes that are attached to each shared memory segment (`shm_nattch`) are incremented. The function `clone()` only supports the propagation of key 8 storage;

therefore, `clone()` does not propagate to the child any shared memory segments that reside in a storage key other than key 8.

The child address space inherits the following address space attributes of the parent address space:

- Region size
- Time limit

The child process inherits the `MEMLIMIT` of the calling process.

If the parent process is multithreaded, it is the responsibility of the application to ensure that the application data is in a consistent state when the `clone()` occurs. For example, mutexes that are used to serialize updates to application data may need to be locked before the `clone()` and unlocked afterward.

For more information on `clone()`, see [z/OS UNIX System Services Programming: Assembler Callable Services Reference](#).

You can use MVS memory files from a z/OS UNIX program. However, use of the `clone()` function from the program removes access from a hiperspace memory file for the child process. Use of an `exec` function from the program clears a memory file when the process address space is cleared.

The child process that results from a `clone()` in a multithreaded environment can only invoke `async-signal-safe` functions.

An `async-signal-safe` function is defined as a function that might be invoked, without restriction, from signal-catching functions.

Interoperability restriction: For POSIX resources, `clone()` behaves as described. But in general, MVS resources that exist in the parent do not exist in the child. This is true for open streams in MVS data sets and assembler-accessed MVS facilities, such as `STIMERS`. In addition, MVS allocations (through `JCL`, `SVC99`, or `ALLOCATE`) are not passed to the child process.

Special behavior for z/OS UNIX System Services:

1. A prior loaded copy of an HFS program in the same address space is reused under the same circumstances that apply to the reuse of a prior loaded MVS unauthorized program from an unauthorized library by the MVS XCTL service with the following exceptions:
 - If the calling process is in `Ptrace` debug mode, a prior loaded copy is not reused.
 - If the calling process is not in `Ptrace` debug mode, but the only prior loaded usable copy that is found of the HFS program is in storage modifiable by the caller, the prior copy is not reused.
2. If the specified file name represents an external link or a sticky bit file, the program is loaded from the caller's MVS load library search order. For an external link, the external name is only used if the name is eight characters or less, otherwise the caller receives an error from the `loadhfs` service. For a sticky bit program, the file name is used if it is eight characters or less. Otherwise, the program is loaded from the HFS.
3. If the calling task is in a WLM enclave, the resulting task in the new process image is joined to the same WLM enclave. This allows WLM to manage the old and new process images as one 'business unit of work' entity for system accounting and management purposes.

Returned value

If successful, the process ID of the child process is returned to the calling (parent) process.

If unsuccessful, -1 is returned and no child process is created, `errno` is set to indicate the error.

Error Code

Description

EAGAIN

The required resources to create another process are not available, or the maximum number of processes that are allowed to run is reached.

EINVAL

The argument *flags* is not valid (A bit other than the supported flags is on, or the child termination signal is not SIGCHLD, or both CLONE_NEWPID and CLONE_PARENT are specified), or CLONE_PARENT is specified from an INIT process, or CLONE_NEWPID specified, however a setns CLONE_NEWPID is done for the current process.

ENOMEM

The process requires more space than is available.

ENOSPC

A system limit is reached.

EPERM

The calling process does not have appropriate privileges.

close() — Close a file

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

int close(int filde);
```

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int close(int socket);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <unistd.h>

int close(int socket);
```

General description

Closes a file descriptor, *filde*. This frees the file descriptor to be returned by future open() calls and other calls that create file descriptors. The *filde* argument must represent a z/OS UNIX file.

close

When the last open file descriptor for a file is closed, the file itself is closed. If the file's link count is 0 at that time, its space is freed and the file becomes inaccessible.

When the last open file descriptor for a pipe or FIFO file is closed, any data remaining in the pipe or FIFO file is discarded.

close() unlocks (removes) all outstanding record locks that a process has on the associated file.

Behavior for sockets: close() call shuts down the socket associated with the socket descriptor *socket*, and frees resources allocated to the socket. If *socket* refers to an open TCP connection, the connection is closed. If a stream socket is closed when there is input data queued, the TCP connection is reset rather than being cleanly closed.

Parameter Description

socket

The descriptor of the socket to be closed.

Note: All sockets should be closed before the end of your process. You should issue a shutdown() call before you issue a close() call for a socket.

For AF_INET and AF_INET6 stream sockets (SOCK_STREAM) using SO_LINGER socket option, the socket does not immediately end if data is still present when a close is issued. The following structure is used to set or unset this option, and it can be found in **sys/socket.h**.

```
struct linger {
    int l_onoff;      /* zero=off, nonzero=on */
    int l_linger;     /* time is seconds to linger */
};
```

If the l_onoff switch is nonzero, the system attempts to deliver any unsent messages. If a linger time is specified, the system waits for *n* seconds before flushing the data and terminating the socket.

For AF_UNIX, when closing sockets that were bound, you should also use unlink() to delete the file created at bind() time.

Special behavior for XPG4.2: If a STREAMS-based *fildes* is closed and the calling process was previously registered to receive a SIGPOLL signal for events associated with that STREAM, the calling process will be unregistered for events associated with the STREAM. The last close() for a STREAM causes the STREAM associated with *fildes* to be dismantled. If O_NONBLOCK is not set and there have been no signals posted for the STREAM, and if there is data on the module's write queue, close() waits for an unspecified time (for each module and driver) for any output to drain before dismantling the STREAM. The time delay can be changed using an I_SETCLTIME ioctl() request. If the O_NONBLOCK flag is set, or if there are any pending signals, close() does not wait for output to drain, and dismantles the STREAM immediately.

Note: z/OS UNIX services do not supply any STREAMS devices or pseudodevices. See [“open\(\) — Open a file” on page 1157](#) for more information.

If *fildes* refers to the manager side of a pseudoterminal, a SIGHUP signal is sent to the process group, if any, for which the subsidiary side of the pseudoterminal is the controlling terminal.

If *fildes* refers to the subsidiary side of a pseudoterminal, a zero-length message will be sent to the manager.

If *fildes* refers to a socket, close() causes the socket to be destroyed. If the socket is connection-oriented and the SO_LINGER option is set for the socket and the socket has untransmitted data, then close() will block for up to the current linger interval until all data is transmitted.

Returned value

If successful, close() returns 0.

If unsuccessful, close() returns -1 and sets errno to one of the following values:

Error Code Description

EAGAIN

The call did not complete because the specified socket descriptor is currently being used by another thread in the same process.

For example, in a multithreaded environment, `close()` fails and returns `EAGAIN` when the following sequence of events occurs (1) thread is blocked in a `read()` or `select()` call on a given file or socket descriptor and (2) another thread issues a simultaneous `close()` call for the same descriptor.

EBADF

fildev is not a valid open file descriptor, or the *socket* parameter is not a valid socket descriptor.

EBUSY

The file cannot be closed because it is blocked.

EINTR

`close()` was interrupted by a signal. The file may or may not be closed.

EIO

Added for XPG4.2: An I/O error occurred while reading from or writing to the file system.

ENXIO

fildev does not exist. The minor number for the file is incorrect.

Example

```
#define _POSIX_SOURCE
#include <fcntl.h>
#include <unistd.h>
#include <stdio.h>
#include <string.h>

main() {
    int fd;
    char out[20]="Test string";
    if ((fd = creat("./myfile", S_IRUSR | S_IWUSR)) < 0)
        perror("creat error");
    else {
        if (write(fd, out, strlen(out)+1) == -1)
            perror("write() error");

        if (fd = 0) perror("write() error");
        close(fd);
    }
}
```

closedir() — Close a directory

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <dirent.h>

int closedir(DIR *dir);
```

General description

Closes the directory indicated by *dir*. It frees the buffer that `readdir()` uses when reading the directory stream.

Returned value

If successful, `closedir()` returns 0.
If unsuccessful, `closedir()` returns -1 and sets `errno` to one of the following values:

Error Code
Description

EBADF
dir does not refer to an open directory stream.

EINTR
`closedir()` was interrupted by a signal. The directory may or may not be closed.

Example

CELEBC18

```
/* CELEBC18

   This example closes a directory.

*/
#define _POSIX_SOURCE
#include <dirent.h>
#include <sys/types.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
    DIR *dir;
    struct dirent *entry;
    int count;

    if ((dir = opendir("/")) == NULL)
        perror("opendir() error");
    else {
        count = 0;
        while ((entry = readdir(dir)) != NULL) {
```

```

        printf("directory entry %03d: %s\n", ++count, entry->d_name);
    }
    closedir(dir);
}
}

```

Output

```

directory entry 001: .
directory entry 002: ..
directory entry 003: bin
directory entry 004: dev
directory entry 005: etc
directory entry 006: lib
directory entry 007: tmp
directory entry 008: u
directory entry 009: usr

```

closelog() — Close the control log

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```

#define _XOPEN_SOURCE_EXTENDED 1
#include <syslog.h>

void closelog(void);

```

General description

The `closelog()` function closes the log file.

Returned value

`closelog()` neither accepts an input nor returns a result. The system control log is closed for this process.

No errors are defined.

clrmemf() — Clear memory files

Standards

| Standards / Extensions | C or C++ | Dependencies |
|-------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <stdio.h>

int clrmemf(int level);
```

General description

Removes memory files created by the current program and any program that was called using a non-POSIX system() call. clrmemf() can remove memory files regardless of whether they are open or not.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

The argument *level* indicates which memory files are to be removed. The level can be one of the following:

- __LOWER**
Removes memory files that were created in other programs and called from this program using system().
- __CURRENT**
Removes only the memory files created at the current level.
- __CURRENT_LOWER**
Removes all the memory files created by the current program and by all the programs called at the current level.

Special behavior for multiple shared PIC1 C environments: Only files created by the C environment from which the clrmemf() function is called will be cleared.

Returned value

If successful, clrmemf() returns 0.
If unsuccessful, clrmemf() returns nonzero.

Example

```
/*
   In this example, when Program2 calls clrmemf(__CURRENT) only
   A3.FILE and A4.FILE will be removed.
*/
```

```

/***** Program1 *****/
:
:   fp1 = fopen ("A1.FILE", "w,type=memory(hiperspace)");
:   fp2 = fopen ("A2.FILE", "w,type=memory(hiperspace)");
:   system("Program2");
:
/***** Program2 *****/
:
:   fp3 = fopen("A3.FILE", "w,type=memory");
:   fp4 = fopen("A4.FILE", "w,type=memory");
:   system("Program3");
:
:   clrmemf(__CURRENT);
:
/***** Program3 *****/
:
:   fp5 = fopen("A5.FILE", "w,type=memory");
:   fp6 = fopen("A6.FILE", "w,type=memory");
:
:

```

__cnvblk() — Convert block

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```

#define _XOPEN_SOURCE
#include <unistd.h>

void __cnvblk(char bits[8], char bytes[64], int flag);

```

General description

The `__cnvblk()` function maps an 8 character array, *bits*, of bits to or from a 64 character array, *bytes*, of bytes depending on the value of *flag*.

If the value of *flag* is 0, `__cnvblk()` sets all bytes in the *bytes* array to 0x00 for which the corresponding bits in the *bits* array have value 0, and it sets all bytes in the *bytes* array to 0x01 for which the corresponding bits in the *bits* array have value 1.

If the value of *flag* is **not** 0, `__cnvblk()` sets all bits in the *bits* array to 0 for which corresponding bytes in the *bytes* array have value 0x00, and it sets all bits in the *bits* array to 1 for which the corresponding bytes in the *bytes* array have value 0x01.

This function may be used to prepare input to `setkey()` or `encrypt()` functions and to map results back to 8 bit characters.

Returned value

If the value of *flag* is zero, `__cnvblk()` functions without error checking.

If the value of *flag* is nonzero, `__cnvblk()` checks for errors, and if found, sets `errno` to one of the following values:

Error Code Description

EINVAL

The value of a byte in the array *bytes* is not 0x00 or 0x01.

Note: Because `__cnvblk()` returns no values, applications wishing to check for errors should set `errno` to 0, call `__cnvblk()`, then test `errno` and, if it is nonzero, assume an error has occurred.

collequiv() — Return a list of equivalent collating elements

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <collate.h>

int collequiv(collel_t c, collel_t **list);
```

General description

Finds all the collating elements whose primary weight is the same as the primary weight of *c*. It then updates the list to point to the first element of the array in which all the found elements are stored. The list of elements is valid until the next call to `setlocale()`, with categories `LC_ALL`, `LC_COLLATE`, or `LC_CTYPE`.

Another call to `collequiv()` may override the current list.

For information about the effect of `setlocale()` and `locale.h`, see “Internationalization: Locales and Character Sets” in [z/OS XL C/C++ Programming Guide](#).

Returned value

If successful, `collequiv()` returns the number of collating elements found.

If the value of *c* is not in the valid range of collating elements in the current locale, `collequiv()` returns -1.

Notes:

1. If the collating element passed is specified with the weight of `IGNORE` in the `LC_COLLATE` category, the list returned will contain all the characters specified as `IGNORE`.
2. The list will only contain characters defined in the charmap file in the current locale.

Example

CELEBC22

```
/* CELEBC22

This example prints the collating elements that have an
equivalent weight as the collating element passed in
```

```

    argv[1].

    */
#include "stdio.h"
#include "locale.h"
#include "collate.h"
#include "stdlib.h"
#include "wctype.h"
#include "wchar.h"

main(int argc, char *argv[]) {
    collet_t e, *rp;
    int i;

    setlocale(LC_ALL, "");
    if ((e = strtocoll(argv[1])) == (collet_t)-1) {
        printf("'%'s' collating element not defined\n", argv[1]);
        exit(1);
    }
    if ((i = collequiv(e, &rp)) == -1) {
        printf("Invalid collating element '%s'\n", argv[1]);
        exit(1);
    }
    for (; i-- > 0; rp++) {
        if (ismccollet(*rp))
            printf("'%'s' ", colltostr(*rp));
        else if (iswprint(*rp))
            printf("'%'lc' ", *rp);
        else
            printf("'%'x' ", *rp);
    }
}

```

collorder() — Return list of collating elements

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```

#include <collate.h>

int collorder(collet_t **list);

```

General description

Finds the number of collating elements in the collate order list and sets a pointer to the list. The list returned is valid until another call to `setlocale()`.

Notes:

1. Collating elements specified with the weight of IGNORE in the LC_COLLATE category are defined as having the lowest weight.
2. The list will only contain characters defined in the charmap file in the current locale.

Example

CELEBC23

```
/* CELEBC23

   This example creates a list of all the collating elements using
   the &collo. function.

*/
#include <stdio.h>
#include <locale.h>
#include <collate.h>
#include <wchar.h>
#include <wctype.h>

main(int argc, char *argv[]) {
    collat_t e, *rp;
    int i;

    setlocale(LC_ALL, "TEXAN.IBM-1024");
    i = collorder(&rp);
    for (; i-- > 0; rp++) {
        if (ismccollet(*rp))
            printf("%s' ", colltostr(*rp));
        else if (iswprint(*rp))
            printf("%lc' ", *rp);
        else
            printf("%x' ", *rp);
    }
}
```

collrange() – Calculate the range list of collating elements

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <collate.h>

int collrange(collel_t start, collel_t end, collel_t **list);
```

General description

Finds a list of collating elements whose primary weights are between the *start* and *end* points, inclusive. The number returned is the number of elements in the list, whose pointer is returned.

This value will be zero if the end point collates earlier than the *start* point. The list returned is valid until the next call to `setlocale()`.

Returned value

If successful, `collrange()` returns the number of elements in the list, whose pointer is returned.

If either *start* or *end* are out of range, `collrange()` returns -1.

Notes:

1. Collating elements specified with the weight of IGNORE in the LC_COLLATE category are defined having the lowest weight. Therefore, such elements can only be specified as the starting collating element.
2. The list will only contain characters defined in the charmap file in the current locale.

Example

CELEBC24

```
/* CELEBC24

   This example prints the collating elements in the range
   between the start and end points passed in
   argv[1] and argv[2], using the
   &collrap. function.

*/
#include <stdio.h>
#include <locale.h>
#include <collate.h>
#include <stdlib.h>
#include <wctype.h>
#include <wchar.h>

main(int argc, char *argv[]) {
    collel_t s, e, *rp;
    int i;

    setlocale(LC_ALL, "TEXAN.IBM-1024");
    if ((s = strtocoll(argv[1])) == (collel_t)-1) {
        printf("%s' collating element not defined\n", argv[1]);
        exit(1);
    }
    if ((e = strtocoll(argv[2])) == (collel_t)-1) {
        printf("%s' collating element not defined\n", argv[2]);
        exit(1);
    }
}
```

```
if ((i = collrange(s, e, &rp)) == -1) {
    printf("Invalid range for '%s' to '%s'\n", argv[1], argv[2]);
    exit(1);
}
for (; i-- > 0; rp++) {
    if (ismccollet(*rp))
        printf("%s' ", colltostr(*rp));
    else if (iswprint(*rp))
        printf("%lc' ", *rp);
    else
        printf("%x' ", *rp);
}
}
```

Related information

colltostr() – Return a string for a collating element

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <collate.h>
char *colltostr(collet_t c);
```

General description

Converts c to the string of the collating element. The colltostr() function is the inverse of strtocoll().

An application program can use the returned array from collrange() or collequiv(), calling ismccollet() on each element, only calling colltostr() if ismccollet() is true for the element. The string returned is valid until another call to setlocale().

Returned value

If a value is passed representing a single character or a value that is not in range, colltostr() returns NULL.

Example

CELEBC25

```
/* CELEBC25
```

This example prints all the collating elements in the collating sequence, using the `&colltop` function to get the string for the multi-character collating elements.

```
*/
#include <collate.h>
#include <locale.h>
#include <stdio.h>
#include <wchar.h>
#include <wctype.h>

main(int argc, char *argv[]) {
    collat_t e, *rp;
    int i;

    setlocale(LC_ALL, "");
    i = collorder(&rp);
    for (; i-- > 0; rp++) {
        if (ismccollet(*rp))
            printf("%s' ", colltostr(*rp));
        else if (iswprint(*rp))
            printf("%lc' ", *rp);
        else
            printf("%x' ", *rp);
    }
}
```

compile() — Compile regular expression

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4 XPG4.2 | both | |

Format

```
#define INIT declarations
#define GETC() getc_code
#define PEEK() peek_code
#define UNGETC() ungetc_code
#define RETURN(ptr) return_code
#define ERROR(val) error_code

#define _XOPEN_SOURCE
#include <regex.h>

char *compile(char *instring, char *expbuf, const char *endbuf, int eof);
```

General description

Restriction: This function is not supported in AMODE 64.

The `compile()` function takes as input a simple regular expression and produces a compiled expression that can be used with the `step()` and `advance()` functions.

The first parameter *instring* is never used explicitly by `compile()`. It is a pointer to a character string defining a source regular expression. It is useful for programs that pass down different pointers to input characters. Programs which invoke functions to input characters or have characters in an external array can pass down **(char *)0** for this parameter.

expbuf is a pointer to the place where the compiled regular expression will be placed.

endbuf points to one more than the highest address where the compiled regular expression may be placed. If the compiled expression cannot fit in (*endbuf-expbuf*) bytes, a call to `ERROR(50)` is made. (See "Returned Value" below.)

eof is the character which marks the end of the regular expression.

The z/OS UNIX services implementation of the `compile()` function does **not** accept internationalized simple expressions as input. Internationalized simple expressions (for example, `[[=c=]]` (an equivalence class)) may yield unpredictable results.

Programs must have the following five macros declared before the **#include <regexp.h>** statement. The macros `GETC()`, `PEEK()` and `UNGETC()` operate on the regular expression given as input to `compile()`.

GETC()

This macro returns the value of the next character (byte) in the regular expression pattern. Successive calls to `GETC()` should return successive characters of the regular expression.

PEEK()

This macro returns the next character (byte) in the regular expression pattern. Immediate successive calls to `PEEK()` should return the same byte, which should also be the next character returned by `GETC()`.

UNGETC(c)

This macro causes the argument *c* to be returned by the next call to `GETC()`. No more than one character is ever needed and this character is guaranteed to be the last character read by `GETC()`. The value of the macro `UNGETC()` is always ignored.

RETURN(ptr)

This macro is used on normal exit of the `compile()` function. The value of the argument *ptr* is a pointer to the character after the last character of the compiled regular expression.

ERROR(val)

This macro is the abnormal return from `compile()`. The argument *val* is an error number. (See "Returned Value" below for meanings.) This call should never return.

Notes:

1. z/OS UNIX services do not provide any default macros if the above user macros are not provided.
2. Each program that includes the **<regexp.h>** must have a **#define** statement for `INIT`. It is used for dependent declarations and initializations. For example, it can be used to set a variable to point to the beginning of the regular expression so that this variable can be used in the declarations for `GETC()`, `PEEK()`, and `UNGETC()`.
3. The external variables *cirf*, *sed*, and *nbra* are reserved.
4. The application must provide the proper serialization for the `compile()`, `step()`, and `advance()` functions if they are run under a multithreaded environment.

Simple regular expressions

A Simple Regular Expression (SRE) specifies a set of character strings. The simplest form of regular expression is a string of characters with no special meaning. A small set of special characters, known as metacharacters, do have special meaning when encountered in patterns.

Expression Meaning

c

The character *c* where *c* is not a special character.

|c

The character *c* where *c* is any special character. For example, *a\ . e* is equivalent to *a . e*.

^

The beginning of the string being compared

\$

The dollar symbol matches the end of the string.

.

The period symbol matches any one character.

[string]

A string within square brackets specifies any of the characters in *string*. Thus, *[abc]*, if compared to other strings, would match any which contained *a*, *b*, or *c*.

The *]* (right bracket) can be used alone within a pair of brackets, but only if it immediately follows either the opening left bracket or if it immediately follows *[^*.

Ranges may be specified as *c-c*. The hyphen symbol, within square brackets, means "through". It fills in the intervening characters according to the collating sequence. For example, *[a-z]* is equivalent to *[abc...xyz]*. If the end character in the range is lower in collating sequence to the start character, then only the range start and range end characters are accepted in the search pattern. For example, *[9-1]* is equivalent to *[91]*. Note that ranges in Simple Regular Expressions are only valid if the LC_COLLATE category is set to the C locale.

The *-* (hyphen) can be used by itself, but only if it is the first or last character in the expression. For example, the expression *[]a-f]* matches either the *]* or one of the characters *a* through *f*.

[^string]

The caret symbol, when inside square brackets, negates the characters within the square brackets. Thus, *[^abc]*, if compared to other strings, would *fail* to match any which contains even one *a*, *b*, or *c*.

Note: Characters *.*, ***, *[*, and ** (period, asterisk, left square bracket, and backslash, respectively) have special meaning, except when they appear within square brackets (*[]*), or are preceded by **.

The asterisk symbol indicates 0 or more of any preceding characters. For example, *(a*e)* will match any of the following: *e*, *ae*, *aae*, *aaae*, The longest leftmost match is chosen.

rx

The occurrence of regular expression *r* followed by the occurrence of regular expression *x*.

\{m\} \{m,\} \{m,u\}

Integer values enclosed in *\{\}* indicate the number of times to apply the preceding regular expression. *m* is the minimum number and *u* is the maximum number. *u* must be less than 256. If you specify only *m*, it indicates the exact number of times to apply the regular expression.

\{m,\} is equivalent to *\{m,255\}*. They both match *m* or more occurrences of the expression. The ***** (asterisk) operation is equivalent to *\{0,\}*.

The maximum number of occurrences is matched.

\(r\)

The regular expression *r*. The *\(* and *\)* sequences are ignored.

\n

When *|n* (where $1 \leq n \leq 9$) appears in a concatenated regular expression, it stands for the regular expression *x*, where *x* is the *n*th regular expression enclosed in *\(* and *\)* sequences that appeared

earlier in the concatenated regular expression. For example, in the pattern `\(c\)onc\(\(ate\)n\2`, the `\2` is equivalent to `ate`, giving *concatenate*.

The character `^` at the beginning of an expression permits a successful match only immediately after a newline or at the beginning of each of the string to which a match is to be applied. The character `$` at the end of an expression requires a trailing newline.

Notes:

1. The `compile()` function is physically embedded in the **regex.h** header. This header will be protected from multiple invocations just like other C headers.
2. The `compile()`, `step()`, and `advance()` functions are provided for historical reasons. These functions were part of the Legacy Feature in Single UNIX Specification, Version 2. They have been withdrawn and are not supported as part of Single UNIX Specification, Version 3. New applications should use the newer functions `fnmatch()`, `glob()`, `regcomp()` and `regexexec()`, which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001.

Returned value

If successful, `compile()` exits using the user-provided macro `RETURN(ptr)`. The value of the argument *ptr* is a pointer to the character after the last character of the compiled regular expression.

If unsuccessful, `compile()` exits using the user-provided macro `ERROR(val)`. The argument *val* is an error number identifying the error. The following error numbers are defined:

Errcode

Description String

| | |
|-----------|---|
| 11 | Range endpoint too large |
| 16 | Bad number |
| 25 | <code>\digit</code> out of range |
| 36 | Illegal or missing delimiter |
| 41 | No remembered search string |
| 42 | <code>\(\)</code> imbalance |
| 43 | Too many <code>\(</code> |
| 44 | More than two numbers given in <code>\{ \}</code> |
| 45 | <code>}</code> expected after <code>\</code> |
| 46 | First number exceeds second in <code>\{ \}</code> |
| 49 | <code>[]</code> imbalance |
| 50 | Regular expression overflow |

confstr() — Get configurable variables

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <unistd.h>

size_t confstr(int name, char *buf, size_t len);
```

General description

The `confstr()` function provides a method for applications to get configuration-defined string values. Its use and purpose are similar to the `sysconf()` function, but it is used where string values rather than numeric values are returned.

The *name* argument represents the system variable to be queried. It may be any one of the following symbolic constants, defined in `<unistd.h>`:

_CS_PATH

Request the value of the **PATH** environment variable that will find all standard utilities.

_CS_POSIX_V6_ILP32_OFF32_CFLAGS

Request the value of the set of initial options to be given to the c99 utility to build an application using a programming model with 32-bit types.

_CS_POSIX_V6_ILP32_OFF32_LDFLAGS

Request the value of the set of final options to be given to the c99 utility to build an application using a programming model with 32-bit types.

_CS_POSIX_V6_ILP32_OFF32_LIBS

Request the value of the set of libraries to be given to the c99 utility to build an application using a programming model with 32-bit int, long, pointer, and off_t types.

_CS_POSIX_V6_ILP32_OFFBIG_CFLAGS

Request the value of the set of initial options to be given to the c99 utility to build an application using a programming model with 32-bit int, long, and pointer types, and an off_t type using at least 64 bits.

_CS_POSIX_V6_ILP32_OFFBIG_LDFLAGS

Request the value of the set of final options to be given to the c99 utility to build an application using a programming model with 32-bit int, long, and pointer types, and an off_t type using at least 64 bits.

_CS_POSIX_V6_ILP32_OFFBIG_LIBS

Request the value of the set of libraries to be given to the c99 utility to build an application using a programming model with 32-bit int, long, and pointer types, and an off_t type using at least 64 bits.

_CS_POSIX_V6_LP64_OFF64_CFLAGS

Request the value of the set of initial options to be given to the c99 utility to build an application using a programming model with 32-bit int and 64-bit long, pointer, and off_t types.

_CS_POSIX_V6_LP64_OFF64_LDFLAGS

Request the value of the set of final options to be given to the c99 utility to build an application using a programming model with 32-bit int and 64-bit long, pointer, and off_t types.

_CS_POSIX_V6_LP64_OFF64_LIBS

Request the value of the set of libraries to be given to the c99 utility to build an application using a programming model with 32-bit int and 64-bit long, pointer, and off_t types.

_CS_POSIX_V6_LPBIG_OFFBIG_CFLAGS

Request the value of the set of initial options to be given to the c99 utility to build an application using a programming model with an int type using at least 32 bits and long, pointer, and off_t types using at least 64 bits.

_CS_POSIX_V6_LPBIG_OFFBIG_LDFLAGS

Request the value of the set of final options to be given to the c99 utility to build an application using a programming model with an int type using at least 32 bits and long, pointer, and off_t types using at least 64 bits.

_CS_POSIX_V6_LPBIG_OFFBIG_LIBS

Request the value of the set of libraries to be given to the c99 utility to build an application using a programming model with an int type using at least 32 bits and long, pointer, and off_t types using at least 64 bits.

_CS_POSIX_V6_WIDTH_RESTRICTED_ENVS

Request the list of names of programming environments supported by the implementation in which the widths of the blksize_t, cc_t, mode_t, nfd_t, pid_t, ptrdiff_t, size_t, speed_t, ssize_t, suseconds_t, tflag_t, useconds_t, wchar_t, and wint_t types are no greater than the width of type long.

z/OS UNIX services use the following constant:

_CS_SHELL

Request the fully qualified name of the default shell.

If the *len* argument is not zero, and if the *name* argument has a configuration-defined value, confstr() copies that value into the buffer pointed to by the *buf* argument. If the value to be returned is longer than *len* bytes, including the . terminating NULL, then confstr() truncates the string to *len*-1 bytes and NULL-terminates the results. The application can detect that the string was truncated by comparing the value returned by confstr() with *len*.

If the *len* argument is zero, and the *buf* argument is a NULL pointer, then confstr() still returns the integer value defined below, but does not return a string. If the *len* argument is zero, but the *buf* argument is not a NULL pointer the results are unspecified.

Returned value

If *name* has a configuration-defined value, confstr() returns the size of the buffer that would be needed to hold the entire configuration-defined string value. If this return value is greater than *len*, the string returned in *buf* is truncated.

If *name* does not have a configuration-defined value, confstr() returns 0 and leaves errno unchanged.

If *name* is not valid, confstr() returns 0 and sets errno to one of the following values:

Error Code**Description****EINVAL**

The value of the *name* argument is not valid.

conj(), conjf(), conjl() — Calculate the complex conjugate

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--|
| C99 Single UNIX Specification, Version 3 | both | z/OS V1R7 a compiler that is designed to support C99 |

Format

```
#include <complex.h>

double complex conj(double complex z);
float complex conjf(float complex z);
long double complex conjl(long double complex z);
```

General description

The `conj()` family of functions compute the complex conjugate of `z` by reversing the sign of its imaginary part.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|--------------------|-----|------|
| <code>conj</code> | X | X |
| <code>conjf</code> | X | X |
| <code>conjl</code> | X | X |

Returned value

If successful, they return the complex conjugate value.

Example

```
/*
 * This example illustrates the complex conjugate function
 */
#include <complex.h>
#include <stdio.h>

void main()
{
    long double complex z = -2.99 - I*3.99, zres;
    zres = conjl(z);
    printf("The complex conjugate of %Lf + %Lf*I is %Lf + %Lf*I\n",creall(z), cimagl(z), zres);
}

Output
The complex conjugate of -2.990000 + -3.990000*I is -2.990000 + 3.990000*I
```

connect() — Connect a socket

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int connect(int socket, const struct sockaddr *address, socklen_t address_len);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>

int connect(int socket, struct sockaddr *address, int address_len);
```

General description

For stream sockets, the connect() call attempts to establish a connection between two sockets. For datagram sockets, the connect() call specifies the peer for a socket. The *socket* parameter is the socket used to originate the connection request. The connect() call performs two tasks when called for a stream socket. First, it completes the binding necessary for a stream socket (in case it has not been previously bound using the bind() call). Second, it attempts to make a connection to another socket.

Note: For the X/Open socket function, the *socket* description applies to *socket*, *address* to *address*, and *address_len* to *address_len*. **const** is added to **struct sockaddr**.

Parameter
Description

socket
The socket descriptor.

address
The pointer to a socket address structure containing the address of the socket to which a connection will be attempted.

address_len
The size of the socket address pointed to by *address* in bytes.

The connect() call on a stream socket is used by the client application to establish a connection to a server. The server must have a passive open pending. A server that is using sockets must successfully call

`bind()` and `listen()` before a connection can be accepted by the server with `accept()`. Otherwise, `connect()` returns -1 and the error code is set to `ECONNREFUSED`.

If *socket* is in blocking mode, the `connect()` call blocks the caller until the connection is set up, or until an error is received. If *socket* is in non-blocking mode, the `connect` returns immediately with a return code of -1 and an `errno` of `EINPROGRESS`. The caller can test the completion of the connection setup by calling `select()` and testing for the ability to write to the socket.

When called for a datagram socket, `connect()` specifies the peer with which this socket is associated. This gives the application the ability to use data transfer calls reserved for sockets that are in the connected state. In this case, `read()`, `write()`, `readv()`, `writv()`, `send()`, and `recv()` calls are then available in addition to `sendto()`, `recvfrom()`, `sendmsg()`, and `recvmsg()` calls. Stream sockets can call `connect()` only once, but datagram sockets can call `connect()` multiple times to change their association. Datagram sockets can dissolve their association by connecting to an incorrect address, such as the NULL address (all fields zeroed).

The *address* parameter is a pointer to a buffer containing the name of the peer to which the application needs to connect. The *address_len* parameter is the size, in bytes, of the buffer pointed to by *address*.

Servers in the AF_INET domain: If the server is in the `AF_INET` domain, the format of the name buffer is expected to be `sockaddr_in`, as defined in the include file `netinet/in.h`.

```
struct in_addr
{
    ip_addr_t s_addr;
};

struct sockaddr_in {
    unsigned char  sin_len;
    unsigned char  sin_family;
    unsigned short sin_port;
    struct in_addr sin_addr;
    unsigned char  sin_zero[8];
};
```

The *sin_family* field must be set to `AF_INET`. The *sin_port* field is set to the port to which the server is bound. It must be specified in network byte order. The *sin_zero* field is not used and must be set to all zeros.

Servers in the AF_INET6 domain: If the server is in the `AF_INET6` domain, the format of the name buffer is expected to be `sockaddr_in6`, as defined in the `netinet/in.h`:

```
struct sockaddr_in6 {
    uint8_t char  sin6_len;
    sa_family_t  sin6_family;
    in_port_t    sin6_port;
    uint32_t     sin6_flowinfo;
    struct in6_addr sin6_addr;
    uint32_t     sin6_scope_id;
};
```

The *sin6_family* must be set to `AF_INET6`.

Servers in the AF_UNIX domain: If the server is in the `AF_UNIX` domain, the format of the name buffer is expected to be `sockaddr_un`, as defined in the include file `un.h`.

```
struct sockaddr_un {
    unsigned char  sun_len;
    unsigned char  sun_family;
    char          sun_path[108]; /* path name */
};
```

The *sun_family* field is set to `AF_UNIX`. The *sun_path* field contains the NULL-terminated path name, and *sun_len* contains the length of the path name.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` 1 feature test macro.

Note: The connect() function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support”](#) on page 2123 for details.

Returned value

If successful, connect() returns 0.

If unsuccessful, connect() returns -1 and sets errno to one of the following values:

Error Code

Description

EADDRNOTAVAIL

The specified address is not available from the local machine.

EAFNOSUPPORT

The address family is not supported.

EALREADY

The socket descriptor *socket* is marked nonblocking, and a previous connection attempt has not completed.

EBADF

The *socket* parameter is not a valid socket descriptor.

ECONNREFUSED

The connection request was rejected by the destination host.

EFAULT

Using *address* and *address_len* would result in an attempt to copy the address into a portion of the caller's address space to which data cannot be written.

EINTR

The attempt to establish a connection was interrupted by delivery of a signal that was caught. The connection will be established asynchronously.

EINVAL

The *address_len* parameter is not a valid length.

EIO

There has been a network or a transport failure.

EISCONN

The socket descriptor *socket* is already connected.

ENETUNREACH

The network cannot be reached from this host.

ENOTSOCK

The descriptor refers to a file, not a socket.

EOPNOTSUPP

The *socket* parameter is not of type SOCK_STREAM.

EPERM

connect() caller was attempting to extract a user's identity and the caller's process was not verified to be a server. To be server-verified, the caller's process must have permission to the BPX.SERVER profile (or superuser and BPX.SERVER is undefined) and have called either the __passwd() or pthread_security_np() services before calling connect() to propagate identity.

EPROTOTYPE

The protocol is the wrong type for this socket.

ETIMEDOUT

The connection establishment timed out before a connection was made.

The following are for AF_UNIX only:

Error Code

Description

EACCES

Search permission is denied for a component of the path prefix, or write access to the named socket is denied.

EIO

An I/O error occurred while reading from or writing to the file system.

ELOOP

Too many symbolic links were encountered in translating the path name in *address*.

ENAMETOOLONG

A component of a path name exceeded NAME_MAX characters, or an entire path name exceeded PATH_MAX characters.

ENOENT

A component of the path name does not name an existing file or the path name is an empty string.

ENOTDIR

A component of the path prefix of the path name in *address* is not a directory.

Example

The following are examples of the connect() call. The Internet address and port must be in network byte order. To put the port into network byte order, the htons() utility routine is called to convert a short integer from host byte order to network byte order. The *address* field is set using another utility routine, inet_addr(), which takes a character string representing the dotted-decimal address of an interface and returns the binary Internet address representation in network byte order. Finally, it is a good idea to zero the structure before using it to ensure that the name requested does not set any reserved fields. These examples could be used to connect to the servers shown in the examples listed with the call, [“bind\(\) — Bind a name to a socket” on page 213](#).

```
int s;
struct sockaddr_in inet_server;
struct sockaddr_un unix_server;
int rc;
int connect(int s, struct sockaddr *name, int namelen);

/* Connect to server bound to a specific interface in the
Internet domain */
/* make sure the sin_zero field is cleared */
memset(&inet_server, 0, sizeof(inet_server));
inet_server.sin_family = AF_INET;
inet_server.sin_addr.s_addr = inet_addr("129.5.24.1");
/* specific interface */
inet_server.sin_port = htons(1024);
:
rc = connect(s, (struct sockaddr *) &inet_server,
sizeof(inet_server));

/* Connect to a server bound to a name in the UNIX domain */
/* make sure the sun_addr, sun_port, sun_nodeid fields are cleared
*/
memset(&unix_server, 0, sizeof(unix_server));
unix_server.sun_family = AF_UNIX;
strncpy(unix_server.sun_path, "mysocket");
unix_server.sun_len = sizeof(unix_server.sun_len);
strncpy(mvsservername.sunix_name, "APPL", 8);
:
rc = connect(s, (struct sockaddr *)
&unix_server, sizeof(unix_server));
```

ConnectExportImport() — WLM connect for export or import use

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | OS/390 V2R9 |

Format

```
#include <sys/__wlm.h>

unsigned long ConnectExportImport(const char *subsystype,
                                const char *subsysname);
```

AMODE 64:

```
#include <sys/__wlm.h>

unsigned int ConnectExportImport(const char *subsystype,
                                const char *subsysname);
```

General description

Provides the ability for an application to connect to WLM to use the ExportWorkUnit(), UndoExportWorkUnit(), ImportWorkUnit(), and UndoImportWorkUnit() functions.

Note that if you need to use the CreateWorkUnit() function, you should use ConnectWorkMgr() instead.

The ConnectExportImport() function uses the following parameters:

***subsystype**

Points to a NULL-terminated character string containing the subsystem type by which to identify the connector. The export and import functions do not use the string. A meaningful string should be used since it can appear in WLM DATA IPCS reports. The character string can be up to 4 bytes in length.

***subsysname**

Points to a NULL-terminated character string containing the subsystem name by which to identify the connector. The export and import functions do not use the string. A meaningful string should be used since it can appear in WLM DATA IPCS reports. The character string can be up to 8 bytes in length.

Returned value

If successful, ConnectExportImport() returns 0.

If unsuccessful, ConnectExportImport() returns -1 and sets errno to one of the following values:

Error Code

Description

EFAULT

An argument of this function contained an address that was not accessible to the caller.

EINVAL

An argument of this function contained a value that is not correct.

EMVSWLMERROR

A WLM service failed. Use __errno2() to obtain the WLM service reason code for the failure.

ConnectServer() — Connect to WLM as a server manager

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <sys/ __wlm.h>

unsigned long ConnectServer(const char *subsystype,
                           const char *subsysname,
                           const char *applenv,
                           int *paralleleu);
```

AMODE 64:

```
#include <sys/ __wlm.h>

unsigned int ConnectServer(const char *subsystype,
                           const char *subsysname,
                           const char *applenv,
                           int *paralleleu);
```

General description

The ConnectServer function provides the ability for an application to connect to WLM as a WLM server manager to perform WLM server manager functions.

***subsystype**

Points to a NULL-terminated character string containing the generic subsystem type (CICS, IMS, WEB, etc.). This is the primary category under which WLM classification rules are grouped. The character string can be up to 4 bytes in length.

***subsysname**

Points to a NULL-terminated character string containing the subsystem name used for classifying work requests. The character string can be up to 8 bytes in length.

***applenv**

Points to a NULL-terminated character string that contains the name of the application environment under which work requests are processed. The character string can be up to 32 bytes in length.

***paralleleu**

Points to an integer which contains the maximum number of tasks within the address space which will be created to process concurrent work requests.

Returned value

If successful, ConnectServer() returns a nonzero value representing a WLM connect token.

If unsuccessful, ConnectServer() returns -1 and sets errno to one of the following values:

Error Code

Description

EFAULT

An argument of this function contained an address that was not accessible to the caller.

EINVAL

An argument of this function contained an incorrect value.

EMVSSAF2ERR

An error occurred in the security product.

EMVSWLMERROR

The WLM connect failed. Use __errno2() to obtain the WLM service reason code for the failure.

EPERM

The calling thread's address space is not permitted to the BPX.WLMSERVER Facility class. The caller's address space must be permitted to the BPX.WLMSERVER Facility class if it is defined. If BPX.WLMSERVER is not defined, the calling process is not defined as a superuser (UID=0).

                           const char *subsys_name);
```

AMODE 64:

```
#include <sys/_wlm.h>
```

```
unsigned int ConnectWorkMgr(const char *subsysname,
                           const char *subsysname);
```

General description

The ConnectServer function provides the ability for an application to connect to WLM as a WLM work manager to perform WLM work manager functions.

*subsysname

Points to a NULL-terminated character string containing the generic subsystem type (CICS, IMS, WEB, etc.). This is the primary category under which WLM classification rules are grouped. The character string can be up to 4 bytes in length.

*subsysname

Points to a NULL-terminated character string containing the subsystem name used for classifying work requests. The character string can be up to 8 bytes in length.

Returned value

If successful, ConnectServer() returns a nonzero value representing a WLM connect token.

If unsuccessful, ConnectServer() returns -1 and sets errno to one of the following values:

Error Code

Description

EFAULT

An argument of this function contained an address that was not accessible to the caller.

EINVAL

An argument of this function contained an incorrect value.

EMVSSAF2ERR

An error occurred in the security product.

EMVSWLMERROR

The WLM connect failed. Use __errno2() to obtain the WLM service reason code for the failure.

EPERM

The calling thread's address space is not permitted to the BPX.WLMSEVER Facility class. The caller's address space must be permitted to the BPX.WLMSEVER Facility class if it is defined. If BPX.WLMSEVER is not defined, the calling process is not defined as a superuser (UID=0).

__console() – Console communication services

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <sys/__messag.h>

int __console(struct __cons_msg *cons, char *modstr, int *concmd);
```

General description

The `__console()` function is used to communicate with the operator's console. The `__console()` function allows users to send messages to the operator's console and to wait on a modify/stop request from the console.

The parameters supported are:

cons

If the argument is not NULL, it points to a structure specifying the message that is to be sent to the operator's console. If the argument is NULL then no message is sent.

modstr

Specifies the string where `__console()` returns the data entered at the operator's console. If `modstr` is not NULL the invoker will wait until an operator MODIFY's the invoking job and specifies 'APPL=' parameter. The length of `modstr` should be 128-byte. See [z/OS MVS System Commands](#) for more information on the MODIFY console command. If the argument is NULL then the `__console()` function will not wait on operator console commands.

concmd

If a console command was issued against the invoking job, the `__console()` function will set the command type. Valid types are, `_CC_modify` (function received a modify request) and `_CC_stop` (function received a stop request).

The `cons` structure is defined in the `<sys/__messag.h>` header and has the following format.

```
struct __cons_msg {
    short __reserved0;
    char __reserved1[2];
    union {
        struct {
            int __msg_length;
            char *__msg;
            char __reserved2[8];
        } __f1;
    } __format;
};
```

__reserved0

Reserved for future use.

__reserved1[2]

Reserved for future use.

__format.__f1.__msg_length

Length of message, not including the NULL terminator.

__format.__f1.__msg

A character string containing the message to be sent to the operator console.

__format.__f1.__reserved2[8]

Reserved for future use.

Note: The length of the message must be between 1 and 17850 characters for invokers with appropriate privileges, and between 1 and 17780 for invokers without appropriate privileges. The number of lines written to the console is limited to 255. In the case of an unprivileged user, one of those lines is used for the message ID and the invoker's login name. If the message length is exceeded, no lines are written and the service returns an EINVAL. If the number of lines is exceeded, the service returns an EINTR, but the first 255 lines are written to the console.

Returned value

If successful, __console() returns 0.

If unsuccessful, __console() returns -1 and sets errno to one of the following values:

Error Code**Description****EFAULT**

One of the following errors was detected:

- All or part of the cons structure is not addressable by the caller.
- All or part of the modstr string is not addressable by the caller.

EINTR

__console() was interrupted by a signal.

EINVAL

The cons structure contains errors.

EMVSERR

z/OS environmental or internal error has occurred.

Example**CELEBC41**

```
/* CELEBC41

   This example prints a simple message to the console using the
   __console() function.

*/
#include <sys/__messag.h>
#include <errno.h>
#include <string.h>
#include <stdio.h>

int main(int argc, char** argv) {
    struct __cons_msg cmsg;
    char buf[256] = "A message on the console";
    int rc;
    int cmsg_cmd = 0;

    /* fill in the __cons_msg structure */
    cmsg.__format.__f1.__msg = buf;
    cmsg.__format.__f1.__msg_length = strlen(buf);

    rc = __console(&cmsg, NULL, &cmsg_cmd);
    if(rc == -1) {
        printf("__console() failed\n");
        printf("%s\n", strerror(errno));
    }
    else {
        printf("__console() successful. Check console for message.\n");
    }

    return 0;
}
```

__console2() — Enhanced console communication services

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | OS/390 V2R10 |

Format

```
#include <sys/_messag.h>

int __console2(struct __cons_msg2 *cons, char *modstr, int *concmd);
```

General description

The `__console2()` function is used to communicate with the operator console. The `__console2()` function allows users to send messages to the operator console with the ability to specify routing codes and message descriptor codes, wait on a modify or stop request from the console, and to delete messages from operator console using either a message ID or token.

The `__console2()` function parameters are as follows:

cons

Specifies the address of the structure containing the console communication information. The mapping of the structure is provided below. If this parameter is NULL, then no message is sent to the operator console and no messages are deleted from the console.

modstr

Address of a 128-byte buffer that is to be used to receive a string of EBCDIC data from the console MODIFY command. All characters that appear to the right of the "APPL=" are placed into this buffer, left justified. The data returned is folded to uppercase. If this parameter is NULL, then the `__console2()` function does not wait on operator console commands.

concmd

Address of a 32-bit integer where the `__console2()` function returns the type of command that was issued on the console. If this parameter is set to NULL, the `__console2()` function will fail with EFAULT. The command types are:

_CC_modify

Function received a modify request.

_CC_stop

Function received a stop request.

The console communication information is specified in a structure pointed to by the `cons` parameter. The structure contains the following fields:

__cm2_format

Specifies the format of the structure. This field must be set to one of the following:

__CONSOLE_FORMAT_2

Used to indicate structure format 2.

__CONSOLE_FORMAT_3

Used to indicate structure format 3.

__cm2_msglength

The length of the message to be written to the console. A value of zero indicates that no message is to be sent to the operator console.

Notes:

1. The length of the message must be between 1 and 17850 characters for authorized users, and between 1 and 17780 for unauthorized users. The number of lines written to the console is limited to 255. In the case of an unauthorized user, one of those lines is used for the message ID and the user ID of the user. If the message length is exceeded, no lines are written and the service returns an EINVAL error code. If the number of lines is exceeded, the service returns an EINVAL error code, but the first 255 lines are written to the console.
2. An authorized user is one with appropriate privileges, as described in the "Authorization" topic in *z/OS UNIX System Services Programming: Assembler Callable Services Reference*.

__cm2_msg

Pointer to a NULL terminated string containing the message to be written to the console. A value of NULL indicates no message is to be sent to the operator console.

__cm2_routcde

Pointer to an unsigned integer array containing the routing codes to be assigned to the message. The array is terminated by a zero value. Allowable routing codes are 1 to 128 for authorized users, and 1 to 28 for unauthorized users. For more information on routing codes, see *z/OS MVS Programming: Authorized Assembler Services Reference SET-WTO*.

Note: An authorized user is one with appropriate privileges, as described in the "Authorization" topic in *z/OS UNIX System Services Programming: Assembler Callable Services Reference*.

__cm2_descr

Pointer to an unsigned integer array containing the message descriptor codes to be assigned to the message. The array is terminated by a zero value. Allowable descriptor codes are 1 to 13. Descriptor codes 1 through 6, 11, and 12 are mutually exclusive. Codes 7 through 10, and 13 can be assigned in combination with any other code. For more information on descriptor codes, see *z/OS MVS Programming: Authorized Assembler Services Reference SET-WTO*.

__cm2_mcsflag

Specifies one or more of the following flags:

__CONSOLE_HRDCPY

Queue the message for hard copy only. The message will not be displayed on the console.

__cm2_token

Specifies a 4-byte token to be associated with this message. This field is used to identify a group of messages which can be deleted using the DOM feature of the `__console2()` function. The token must be unique within an address space and can be any value. A token value of zero indicates no token is specified and the message issued will not be associated with any token.

__cm2_msgid

An unsigned 32-bit integer field where the `__console2()` function will place the message ID associated with the message last sent to the console. This message ID can be used to delete a message when it is no longer needed by specifying it using the DOM feature of the `__console2()` function. A value of NULL indicates that the message ID is not to be returned.

Note: The value returned in `__cm2_msgid` is an internal message identifier associated with the message written to the console. The value is not text and it should not be confused with any textual part of a message that might otherwise be considered a message ID.

__cm2_dom_token

Specifies a 4-byte token which represents a message or group of messages to be deleted from the console. All messages previously issued with this token will be deleted from the console. This field is mutually exclusive with `__cm2_dom_msgid`. A value of zero indicates that no token is specified.

__cm2_dom_msgid

Pointer to an unsigned integer array containing message IDs to be deleted from the console. A maximum of 60 message IDs can be in the array. The array is terminated by a zero value. The array

terminator is not part of the 60 message IDs. This field is mutually exclusive with `__cm2_dom_token`. A value of NULL indicates that no message IDs are specified.

The console communication information structure includes the following additional fields when using the `__CONSOLE_FORMAT_3` format. These fields are not available when using the `__CONSOLE_FORMAT_2` format.

__cm2_mod_cartptr

Pointer to the 8-byte command and response token (CART) returned by a MODIFY or STOP command.

__cm2_mod_consldptr

Pointer to the 4-byte console ID returned by a MODIFY or STOP command.

__cm2_msg_cart

Specifies an 8-byte CART to be used on WTO when the message is issued.

__cm2_msg_consld

Specifies a 4-byte console ID to be used on WTO when the message is issued.

Note: All operations can be done in a single request. The order of operation is to issue messages, delete messages, and then wait for a MODIFY or STOP command.

Returned value

If successful, `__console2()` returns 0.

If unsuccessful, `__console2()` returns -1 and sets `ERRNO` to one of the following values:

Error Code

Description

EFAULT

The `__console2()` function was unable to address all or part of the *cons* structure, all or part of the routing codes array, all or part of the descriptor codes array, all or part of the array of DOM message IDs, all or part of the *modstr*, or the *concmd* parameter was NULL.

Another possible cause is that `__cm2_msgid` points to storage which is not accessible.

EINTR

The `__console2()` function was interrupted by a signal.

EINVAL

The structure pointed to by *cons* contains errors.

For example, mutually exclusive parameters were specified, a non-valid routing code was specified, a non-valid descriptor code or mutually exclusive descriptor codes were specified, or there were more than 60 entries in the array of DOM message IDs.

EMVSERR

A z/OS environmental or internal error has occurred. Use the `__errno2()` function to obtain diagnostic information that will help determine the cause of the problem.

EPERM

An unauthorized user specified a routing code in the range 29 through 128. Only authorized (superuser) users (UID=0) can specify routing codes in that range.

Example

CELEBC42

```
/* CELEBC42

This example prints a simple message to the console using the
__console2() function. A routing and descriptor code are also
assigned to the message.

*/
#include <sys/__messag.h>
#include <errno.h>
```

```

#include <string.h>
#include <stdio.h>

int main(int argc, char** argv) {
    struct __cons_msg2 cmsg;
    char buf[256] = "A message on the console";
    int rc;
    int cmsg_cmd;
    unsigned int cmsg_rout[2] = {1,0};
    unsigned int cmsg_desc[2] = {12,0};

    /* Fill in the __cons_msg2 struct */
    cmsg.__cm2_format = __CONSOLE_FORMAT_2;
    cmsg.__cm2_msg = buf;
    cmsg.__cm2_msglength = strlen(buf);
    cmsg.__cm2_routcde = cmsg_rout;
    cmsg.__cm2_descr = cmsg_desc;
    cmsg.__cm2_token = 0;
    cmsg.__cm2_msgid = NULL;
    cmsg.__cm2_dom_token = 0;

    rc = __console2(&cmsg, NULL, &cmsg_cmd);
    if(rc == -1) {
        printf("__console2() failed\n");
        printf("%s\n", strerror(errno));
    }
    else {
        printf("__console2() successful. Check console for message\n");
    }

    return 0;
}

```

ContinueWorkUnit() — Continue WLM work unit

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```

#include <sys/__wlm.h>

int ContinueWorkUnit(wlmetok_t *enclavetoken);

```

General description

The ContinueWorkUnit function provides the ability for an application to create a WLM work unit that represents a continuation of the work unit associated with the current home address space.

***enclavetoken**

Points to a data field of type wlmetok_t where the ContinueWorkUnit() function is to return the WLM work unit enclave token.

Returned value

If successful, ContinueWorkUnit() returns 0.

If unsuccessful, ContinueWorkUnit() returns -1 and sets errno to one of the following values:

**Error Code
Description****EFAULT**

An argument of this function contained an address that was not accessible to the caller.

EINVAL

An argument of this function contained an incorrect value.

EMVSSAF2ERR

An error occurred in the security product.

EMVSWLMERROR

The WLM create enclave failed. Use `__errno2()` to obtain the WLM service reason code for the failure.

EPERM

The calling thread's address space is not permitted to the BPX.WLMSERVER Facility class. The caller's address space must be permitted to the BPX.WLMSERVER Facility class if it is defined. If BPX.WLMSERVER is not defined, the calling process is not defined as a superuser (UID=0).

__convert_id_np() — Convert between DCE UUID and user ID

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <unistd.h>

int __convert_id_np(int function_code,
                   char *principal_uuid,
                   char *cell_uuid,
                   char *userid);
```

General description

The `__convert_id_np()` function is used to retrieve the DCE UUID associated with a userid or the userid associated with a DCE UUID.

This function is intended for DCE servers which process requests from multiple clients. For example, DCE RPC requests from clients are identified by a DCE UUID only. This function enables servers to extract the userid of the requester.

The parameters supported are:

function_code

Identifies whether extracting a userid or UUID. Possible function codes are:

__GET_USERID

Return the userid associated with the specified UUIDs.

__GET_UUID

Return the UUIDs associated with the specified userid.

principal_uuid

When *__GET_USERID* is specified, *principal_uuid* contains the UUID of the user for the specified userid. When *__GET_UUID* is specified, *principal_uuid* returns the extracted UUID for the userid specified. The caller must provide a 36-byte field for the returned *principal_uuid*.

cell_uuid

When *__GET_USERID* is specified, *cell_uuid* should contain the cell UUID if known. If not known, *cell_uuid* must be NULL. When *__GET_UUID* is specified, *cell_uuid* will return the extracted cell UUID, if it is defined for the specified userid. The caller must provide a 36-byte field for the returned *cell_uuid*.

userid

When *__GET_USERID* is specified, *userid* will return the extracted userid for the specified UUID. The caller must provide a 9 byte field for the returned userid. When *__GET_UUID* is specified, *userid* contains the userid for whom the UUID should be extracted. The userid must be 1 to 8 characters in length.

Returned value

If successful, *__convert_id_np()* returns 0.

If unsuccessful, *__convert_id_np()* returns -1 and sets *errno* to one of the following values:

Error Code

Description

EINVAL

One of the following errors was detected:

- *function_code* specified is undefined.
- *__GET_UUID* was specified and *userid* is not in the range 1 to 8 characters long.
- *__GET_USERID* was specified and *userid* was not 9 character long

EMVSERR

An MVS environmental or internal error occurred.

EMVSSAF2ERR

One of the following errors was detected:

- Received an unexpected return code for the security product.
- The security product detected an error in the input parameters.
- An internal error occurred in the security product.

ENOSYS

One of the following errors was detected:

- No security product is installed on the system.
- The security product does not have support for this function.

ESRCH

One of the following errors was detected:

- No mapping exists between a UUID and Userid.
- No mapping exists between a Userid and UUID.
- The DCEUUIDS class is not active.
- `__GET_UUID` was specified and no cell UUID is defined for the userid.
- The userid is not defined to the security product.

copysign(), copysignf(), copysignl() – Copy the sign from one floating-point number to another

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| Language Environment C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | OS/390 V2R6 |

Format

```
#define _AIX_COMPATIBILITY
#include <math.h>
#include <float.h>

double copysign(double x, double y);
```

C99:

```
#define _ISOC99_SOURCE
#include <math.h>
#include <float.h>

float copysignf(float x, float y);
long double copysignl(long double x, long double y);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

float copysign(float x, float y);
long double copysign(long double x, long double y);
```

General description

The `copysign` functions produce a value with the magnitude of `x` and the sign of `y`.

Restriction: The `copysignf()` function does not support the `_FP_MODE_VARIABLE` feature test macro.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|------------------------|-----|------|
| <code>copysign</code> | X | X |
| <code>copysignf</code> | X | X |

| Function | Hex | IEEE |
|-----------|-----|------|
| copysignl | X | X |

Returned value

The copysign functions return a value with the magnitude of *x* and the sign of *y*.

copysignd32(), copysignd64(), copysignd128() — Copy the sign from one floating-point number to another

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 copysignd32(_Decimal32 x, _Decimal32 y);
_Decimal64 copysignd64(_Decimal64 x, _Decimal64 y);
_Decimal128 copysignd128(_Decimal128 x, _Decimal128 y);

_Decimal32 copysign(_Decimal32 x, _Decimal32 y); /*C++ only */
_Decimal64 copysign(_Decimal64 x, _Decimal64 y); /*C++ only */
_Decimal128 copysign(_Decimal128 x, _Decimal128 y); /*C++ only */
```

General description

The copysign functions produce a value with the magnitude of *x* and the sign of *y*.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

The copysign functions return a value with the magnitude of *x* and the sign of *y*.

Example

```
/* CELEBC47
```

```
This example illustrates the copysignd64() function.

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal64 x = 1.2DD, y = -1.0DD , z;

    z = copysignd64(x, y);

    printf("The result of copysignd64(%Df,%Df) is %Df\n",x,y,z);
}
```

cos(), cosf(), cosl() — Calculate cosine

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#include <math.h>

double cos(double x);
float cos(float x);           /* C++ only */
long double cos(long double x); /* C++ only */
float cosf(float x);
long double cosl(long double x);
```

General description

Calculates the cosine of x. The value x is expressed in radians.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

Returned value

Returns the calculated value.

If x is outside prescribed limits, the value is not calculated. Instead, the function returns 0 and sets the `errno` to `ERANGE`. If the correct value would cause an underflow, zero is returned and the value `ERANGE` is stored in `errno`.

Special behavior for XPG4.2: The following error is added:

Error Code

Description

EDOM

The argument exceeded an internal limit for the function (approximately 2^{50}).

Example

CELEBC26

```
/* CELEBC26

   This example calculates y to be the cosine of
   x.

*/
#include <math.h>
#include <stdio.h>

int main(void)
{
    double x, y;

    x = 7.2;
    y = cos(x);

    printf("cos( %lf ) = %lf\n", x, y);
}
```

Output

```
cos( 7.200000 ) = 0.608351
```

cosd32(), cosd64(), cosd128() – Calculate cosine

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 cosd32(_Decimal32 x);
_Decimal64 cosd64(_Decimal64 x);
_Decimal128 cosd128(_Decimal128 x);

_Decimal32 cos(_Decimal32 x); /* C++ only */
_Decimal64 cos(_Decimal64 x); /* C++ only */
_Decimal128 cos(_Decimal128 x); /* C++ only */
```

General description

Calculates the cosine of x . The value x is expressed in radians.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

Returns the calculated value.

If x is outside prescribed limits, the value is not calculated. Instead, the function returns 0 and sets `errno` to `EDOM`.

Example

```
/* CELEBC48

   This example illustrates the cosd128() function.

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal128 x, y;

    x = 7.2DL;
    y = cosd128(x);

    printf("cosd128(%DDf) = %DDf\n", x, y);
}
```

cosh(), coshf(), coshl() — Calculate hyperbolic cosine

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#include <math.h>

double cosh(double x);
float cosh(float x);           /* C++ only */
long double cosh(long double x); /* C++ only */
float coshf(float x);
long double coshl(long double x);
```

General description

Calculates the hyperbolic cosine of x . The value x is expressed in radians.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

Returned value

If the result overflows, the function returns +HUGE_VAL and sets `errno` to `ERANGE`.

Example

CELEBC27

```
/* CELEBC27
   This example calculates y to be the hyperbolic cosine of x.
*/
#include <math.h>
#include <stdio.h>

int main(void)
{
    double x,y;

    x = 7.2;
    y = cosh(x);

    printf("cosh( %lf ) = %lf\n", x, y);
}
```

Output

```
cosh( 7.200000 ) = 669.715755
```

coshd32(), coshd64(), coshd128() - Calculate hyperbolic cosine

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.10 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 coshd32(_Decimal32 x);
_Decimal64 coshd64(_Decimal64 x);
_Decimal128 coshd128(_Decimal128 x);
_Decimal32 cosh(_Decimal32 x); /* C++ only */
_Decimal64 cosh(_Decimal64 x); /* C++ only */
_Decimal128 cosh(_Decimal128 x); /* C++ only */
```

General description

Calculates the hyperbolic cosine of x . The value x is expressed in radians.

These functions work in IEEE decimal floating-point format. See [“IEEE decimal floating-point” on page 97](#) for more information.

Note: To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

If the result overflows, the function returns +HUGE_VAL_D32, +HUGE_VAL_D64 or +HUGE_VAL_D128 and sets `errno` to `ERANGE`.

Example

CELEBC51

```
/* CELEBC51
```

This example illustrates the coshd128() function.

This example calculates y to be the hyperbolic cosine of x.

```
*/
#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal128 x, y;

    x = 7.2DL;
    y = coshd128(x);

    printf("coshd128( %Ddf ) = %Ddf\n", x, y);
}

__cospid32(), __cospid64(), __cospid128() — Calculate cosine of pi * x

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 __cospid32(_Decimal32 x);
_Decimal64 __cospid64(_Decimal64 x);
_Decimal128 __cospid128(_Decimal128 x);
```

General description

Calculates the cosine of pi * x. The value x is expressed in radians.

Notes:

- 1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- 2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

Returns the calculated value.

If x is outside the prescribed limits, the value is not calculated. Instead, the function either returns 1, or returns 0 and sets errno to ERANGE.

Example

```
/* CELEBC49

   This example illustrates the __cospid32() function.

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal32 x, y;

    x = 1.0DF;
    y = __cospid32(x);

    printf("__cospid32(%Hf) = %Hf\n", x, y);
}
```

__cotan(), __cotanf(), __cotanl() — Calculate cotangent

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | z/OS V1R5 |

Format

```
#include <math.h>

double __cotan(double x);
float __cotanf(float x);
long double __cotanl(long double x);
```

General description

The __cotan functions compute the cotangent of x.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------|-----|------|
| __cotan | X | X |
| __cotanf | X | X |
| __cotanl | X | X |

Returned value

The __cotan functions return the cotangent of x.

Related information

- [“math.h — Floating-point math functions”](#) on page 40

__cpl() — CPL interface service

Standards

| Standards / Extensions | C or C++ | Dependencies |
|-------------------------|----------|--------------|
| Language Environment | both | OS/390 V2R9 |

Format

```
#include <sys/__cpl.h>

int __cpl(int functioncode, int bufferlen, char *buffer);
```

General description

__cpl() is an interface to the BPX1CPL assembler callable service. __cpl() allows callers with appropriate system authorization facility (SAF) access to perform functions related to coupling facilities (CFs) and the structures that reside in them, such as sizing CF structures and querying CF and structure attributes.

functioncode

A value that specifies what function BPX1CPL will perform. The following function codes are defined.

- CPL_QUERY (equates to a value of 1)
- CPL_CFSIZER (equates to a value of 2)
- CPL_CFSIZER_W_LVL (equates to a value of 3)
- CPL_CFSIZER_VPL (equates to a value of 4)
- CPL_IXLCSF (equates to a value of 5)
- CPL_IXLMSG (equates to a value of 6)
- CPL_IXCQUERY (equates to a value of 7)

bufferlen

The length of the input/output storage area (*buffer*) for BPX1CPL

buffer

Storage area for input/output for BPX1CPL

For more information on parameters and behavior of BPX1CPL, please refer to [z/OS UNIX System Services Programming: Assembler Callable Services Reference](#).

Returned value

If successful, `__cpl()` returns 0.

If unsuccessful, `__cpl()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EFAULT

One of the parameters contained an address that was not accessible to the caller.

EINVAL

The *functioncode* parameter contains a value that is not correct.

EMVSCPLERROR

A `__cpl()` service failed.

EMVSERR

A z/OS environmental or internal error has occurred.

ENOMEM

Not enough space is available.

ENOSYS

The `__cpl()` service failed because the system is not at the correct level.

EPERM

The calling thread's address space is not permitted.

Usage notes

1. Access to `__cpl()` is controlled using SAF class profile BPX.CF. Requestors must have read access to this profile.
2. CFLevel8 or higher is required to use the structure size computation function. Because structure size is a function of CFLevel, all structure size computations that are performed by a given `__cpl()` call apply to the same CFLevel.

cpow(), cpowf(), cpowl() – Calculate the complex power

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--|
| C99 Single UNIX Specification, Version 3 | both | z/OS V1R7 a compiler that is designed to support C99 |

Format

```
#include <complex.h>

double complex cpow(double complex x, double complex y);
float complex cpowf(float complex x, float complex y);
long double complex cpowl(long double complex x, long double complex y);
```

General description

The cpow() family of functions computes the complex value of x to the power of y, with a branch cut for the first parameter along the negative real axis.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------|-----|------|
| cpow | X | X |
| cpowf | X | X |
| cpowl | X | X |

Returned value

The cpow() family of functions return the complex power value.

Example

```
/*
 * This example illustrates the complex power of complex number 'z'
 */
#include <complex.h>
#include <stdio.h>

void main()
{
    long double complex z1=-0.5 + I*0.5,  zpowl=(long double complex)3.0;
    double complex zd=(double complex)z1, zpowd=(double complex)zpowl;
    float complex zf=(float complex)zd,  zpowf=(float complex)zpowl;

    long double resl;
    double resd;
    float resf;

    printf("Illustrates the cpow function. Expected result is 0.25 in all cases\n");
    resd = cpow(zd,zpowd);
    resf = cpowf(zf,zpowf);
    resl = cpowl(z1,zpowl);
    printf("\tcpow(%f + I*%f,%f + I*%f) = %f\n",creal(zd), cimag(zd),
                                                creal(zpowd), cimag(zpowd), resd);
    printf("\tcpowf(%f + I*%f,%f + I*%f) = %f\n",crealf(zd), cimagf(zd),
                                                crealf(zpowf), cimagf(zpowf), resf);
    printf("\tcpowl(%Lf + I*%Lf,%Lf + I*%Lf) = %Lf\n",creall(z1), cimagl(z1),
                                                creall(zpowl), cimagl(zpowl), resl);
}
Output
Illustrates the cpow function. Expected result is 0.25
cpow(-0.500000 + I*0.500000,3.000000 + I*0.000000) = 0.250000
cpowf(-0.500000 + I*0.500000,3.000000 + I*0.000000) = 0.250000
cpowl(-0.500000 + I*0.500000,3.000000 + I*0.000000) = 0.250000
```

Related information

- [“complex.h — Complex math functions”](#) on page 85
- [“cabs\(\), cabsf\(\), cabsl\(\) — Calculate the complex absolute value”](#) on page 228

cproj(), cprojf(), cprojl() – Calculate the projection

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--|
| C99 Single UNIX Specification, Version 3 | both | z/OS V1R7 a compiler that is designed to support C99 |

Format

```
#include <complex.h>

double complex cproj(double complex z);
float complex cprojf(float complex z);
long double complex cprojl(long double complex z);
```

General description

The `cproj()` family of functions compute a projection of `z` onto the Riemann sphere: `z` projects to `z` except that all complex infinities (even those with one infinite part and one NaN part) project to positive infinity on the real axis. If `z` has an infinite part, then `cproj(z)` is equivalent to:

`INFINITY + I * copysign(0.0, cimag(z))`

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|---------------------|-----|------|
| <code>cproj</code> | X | X |
| <code>cprojf</code> | X | X |
| <code>cprojl</code> | X | X |

Returned value

The `cproj()` family of functions return the value of the projection onto the Riemann sphere.

For a variable `z` of complex type, `z == creal(z) + cimag(z)*I`.

Special behavior for hex: On hexadecimal floating point mode, `cproj(z)` family of functions always returns `z`.

Example

```
#include <complex.h>
#include <stdio.h>

/*
 * Illustrates complex function cproj().
 *
 * NOTE:      When compiled in HEX(FLOAT), cproj(z) should
 *            always return z
 */

#define INFINITEL 1.0L/0.0L    /* An infinite number */

void InitReal ( long double complex *z, long double RealPart)
{
    union LongDoubleComplexMap {
        long double complex w;
        long double ldarray[2];
    }
```

```

    }z1;

    z1.w = *z;
    z1.ldarray[0] = RealPart;
    *z = z1.w;
}

main() {
    long double complex z,w;
    z = 2.5 + I*(-3.999);

    printf("Illustrates function cproj() ");

#ifdef __BFP__
    printf ("(IEEE mode)");
#else
    printf ("(HFP mode)");
#endif

    printf("\n\n z = %Lf + I*%Lf\n\n",creall(z), cimagl(z));
    w = cprojl(z);
    printf(" cproj(z) = %Lf + I*%Lf\n",creall(w), cimagl(w));

    printf(" Initializing z(real) with infinity ...\n");
    InitReal(z,INFINITEL);
    printf(" z = %Lf + %Lf*I\n",creall(z),cimagl(z));

    w = cprojl(z);
    printf(" cproj(z) = %Lf + %Lf*I\n",creall(w),cimagl(w));
}

```

Output

```

Illustrates function cproj() (IEEE mode)

z = 2.500000 + I*-3.999000

cproj(z) = 2.500000 + I*-3.999000
Initializing z(real) with infinity ...
z = INF + -3.999000*I
cproj(z) = INF + -0.000000*I

```

creal(), crealf(), creall() – Calculate the complex real part

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--|
| C99 Single UNIX Specification, Version 3 | both | z/OS V1R7 a compiler that is designed to support C99 |

Format

```
#include <complex.h>
```

```
double creal(double complex z);
float crealf(float complex z);
long double creall(long double complex z);
```

General description

The `creal()` family of functions compute the real part of `z`.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|---------------------|-----|------|
| <code>creal</code> | X | X |
| <code>crealf</code> | X | X |
| <code>creall</code> | X | X |

Returned value

The `creal()` family of functions return the real part value (as a real).

Example

For an example of a similar function see `cacos()`, `cexp()` or `cpow()`.

Related information

creat() – Create a new file or rewrite an existing one

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <fcntl.h>

int creat(const char *pathname, mode_t mode);
```

General description

The function call: `creat(pathname, mode)` is equivalent to the call:

```
open(pathname, O_CREAT|O_WRONLY|O_TRUNC, mode);
```

Thus the file named by *pathname* is created, unless it already exists. The file is then opened for writing only, and is truncated to zero length. See “[open\(\) — Open a file](#)” on page 1157 for further information.

The *mode* argument specifies the file permission bits to be used in creating the file. Here is a list of symbols that can be used for a mode:

S_IRGRP

Read permission for the file's group.

S_IROTH

Read permission for users other than the file owner.

S_IRUSR

Read permission for the file owner.

S_IRWXG

Read, write, and search, or execute permission for the file's group. S_IRWXG is the bitwise inclusive-OR of S_IRGRP, S_IWGRP, and S_IXGRP.

S_IRWXO

Read, write, and search, or execute permission for users other than the file owner. S_IRWXO is the bitwise inclusive-OR of S_IROTH, S_IWOTH, and S_IXOTH.

S_IRWXU

Read, write, and search, or execute, for the file owner; S_IRWXG is the bitwise inclusive-OR of S_IRUSR, S_IWUSR, and S_IXUSR.

S_ISGID

Privilege to set group ID (GID) for execution. When this file is run through an exec function, the effective group ID of the process is set to the group ID of the file, so that the process has the same authority as the file owner rather than the authority of the actual invoker.

S_ISUID

Privilege to set the user ID (UID) for execution. When this file is run through an exec function, the effective user ID of the process is set to the owner of the file, so that the process has the same authority as the file owner rather than the authority of the actual invoker.

S_ISVTX

Indicates shared text. Keep loaded as an executable file in storage.

S_IWGRP

Write permission for the file's group.

S_IWOTH

Write permission for users other than the file owner.

S_IWUSR

Write permission for the file owner.

S_IXGRP

Search permission (for a directory) or execute permission (for a file) for the file's group.

S_IXOTH

Search permission for a directory, or execute permission for a file, for users other than the file owner.

S_IXUSR

Search permission (for a directory) or execute permission (for a file) for the file owner.

Large file support for z/OS UNIX files: Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the [long long data type support](#) enabled and define the `_LARGE_FILES` feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are

enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the `_LARGE_FILES` feature test macro as well.

Returned value

If successful, `creat()` returns a file descriptor for the open file.

If unsuccessful, `creat()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

One of the following error conditions exists:

- The process did not have search permission on a component in *pathname*.
- The file exists but the process did not have appropriate permissions to open the file in the way specified by the flags.
- The file does not exist, and the process does not have write permission on the directory where the file is to be created.
- `O_TRUNC` was specified, but the process does not have write permission on the file.

EINTR

`open()` was interrupted by a signal.

EISDIR

pathname is a directory, and *options* specifies write or read/write access.

ELOOP

A loop exists in symbolic links. This error is issued if the number of symbolic links detected in the resolution of *pathname* is greater than `POSIX_SYMLINK_MAX`.

EMFILE

The process has reached the maximum number of file descriptors it can have open.

ENAMETOOLONG

pathname is longer than `PATH_MAX` characters or some component of *pathname* is longer than `NAME_MAX` characters while `_POSIX_NO_TRUNC` is in effect. For symbolic links, this error occurs if the length of a *pathname* string substituted for a symbolic link in the *pathname* argument exceeds `PATH_MAX`. The `PATH_MAX` and `NAME_MAX` values can be determined with `pathconf()`.

ENFILE

The system has reached the maximum number of file descriptors it can have open.

ENOENT

`O_CREAT` is specified, and either the path prefix does not exist or the *pathname* argument is an empty string.

ENOSPC

The directory or file system intended to hold a new file has insufficient space.

ENOTDIR

A component of *pathname* is not a directory.

EOVERFLOW

The named file is a regular file and the size of the file cannot be represented correctly in an object of type `off_t`.

EROFS

pathname is on a read-only file system.

Example

CELEBC28

```
/* CELEBC28
```

This example creates a file.

```

*/
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
    char fn[]="creat.file", text[]="This is a test";
    int fd;

    if ((fd = creat(fn, S_IRUSR | S_IWUSR)) < 0)
        perror("creat() error");
    else {
        write(fd, text, strlen(text));
        close(fd);
        unlink(fn);
    }
    return(fd);
}

```

CreateWorkUnit() — Create WLM work unit

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```

#include <sys/__wlm.h>

int CreateWorkUnit(wlmetok_t *enclavetoken,
                  server_classify_t classify,
                  char *arrival_time,
                  char *func_name);

```

General description

The CreateWorkUnit function provides the ability for an application to create a WLM work unit.

***enclavetoken**

Points to a data field of type wlmetok_t where the CreateWorkUnit() function is to return the WLM work unit enclave token.

***classify**

Points to a server_classify_t structure that contains the classification information for the work request macro.

***arrival_time**

Address of a doubleword (unsigned long long) field that contains the arrival time of the work request in STCK format.

***func_name**

Points to a NULL-terminated character string that represents the descriptive function name of the associated work request.

Returned value

If successful, CreateWorkUnit() returns a pointer to work unit enclave token of type wlmelok_t.

If unsuccessful, CreateWorkUnit() returns -1 and sets errno to one of the following values:

Error Code**Description****EFAULT**

An argument of this function contained an address that was not accessible to the caller.

EINVAL

An argument of this function contained an incorrect value.

EMVSSAF2ERR

An error occurred in the security product.

EMVSWLMERROR

The WLM create failed. Use __errno2() to obtain the WLM service reason code for the failure.

EPERM

The calling thread's address space is not permitted to the BPX.WLMSEVER Facility class. The caller's address space must be permitted to the BPX.WLMSEVER Facility class if it is defined. If BPX.WLMSEVER is not defined, the calling process is not defined as a superuser (UID=0).

crypt() — String encoding function

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <unistd.h>

char *crypt(const char *key, const char *salt);
```

General description

The `crypt()` function encodes the string pointed to by the *key* argument. It perturbs the Data Encryption Standard (DES) encryption algorithm with the first two characters in the string pointed to by the *salt* argument to perform this encoding. The first two *salt* characters must be chosen from the set:

```
a b c d e f g h i j k l m n o p q r s t u v w x y z
A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
0 1 2 3 4 5 6 7 8 9 . /
```

This function can be called from any thread.

Returned value

If successful, `crypt()` returns a pointer to a thread specific encoded string. The first two characters of the returned value are those of the *salt* argument.

Notes:

1. The return value of `crypt()` points to a thread-specific buffer which is overwritten each time `crypt()` is called from the same thread.
2. The values returned by `crypt()` are not portable to other X/Open-conforming systems.

If unsuccessful, `crypt()` returns a NULL pointer and sets `errno` to indicate the error.

Special behavior for z/OS UNIX Services: The `crypt()` function will set `errno` to one of the following values:

Error Code

Description

EINVAL

First two characters of *salt* argument are not from the *salt* set.

ENOMEM

Storage for `crypt()` output buffer is not available for thread from which `crypt()` has been invoked.

Related information

cs() – Compare and swap

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <stdlib.h>

int cs(cs_t *oldptr, cs_t *curptr, cs_t newword);
```

General description

The `cs()` built-in function compares the 4-byte value pointed to by *oldptr* to the 4-byte value pointed to by *curptr*. If they are equal, the 4-byte value, *newword*, is copied into the location pointed to by *curptr*. If they are unequal, the value pointed to by *curptr* is copied into the location pointed to by *oldptr*.

If this function is used in a multi-threading environment, then it is the users responsibility to protect the *oldptr* variable. The user can create a local variable per thread to contain this value or provide locking code to protect the global variable used. The *oldptr* variable may not reflect the *curptr* variable if the *curptr* variable changes via another thread before the user has a chance to examine *oldptr*.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

The function uses the COMPARE SWAP (CS) instructions, which can be used in multiprogramming or multiprocessing environments to serialize access to counters, flags, control words, and other common storage areas. For a detailed description, refer to the appendixes in the *z/Architecture Principles of Operation* on number representation and instruction.

Returned value

`cs()` returns 0 if the 4-byte value pointed to by *oldptr* is equal to the 4-byte value pointed to by *curptr*.

If the value is not equal, `cs()` returns 1.

Related information

- *z/Architecture Principles of Operation*
- [“stdlib.h – Standard library functions” on page 65](#)

csid() – Character set ID for multibyte character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <stdlib.h>

int csid(const char *c)
```

External entry point: @@CSID, __csid;

General description

Determines the character set identifier for the specified multibyte character pointed to by *c*, that begins in the initial shift state.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

Returned value

If successful, `csid()` returns the character-set identifier for the multibyte character.

If the character is not valid, `csid()` returns -1.

Note: The multibyte character passed must begin in the initial shift state.

Example

CELEBC29

```
/* CELEBC29

   This example checks character set ID for a character.

*/
#include "locale.h"
#include "stdio.h"
#include "stdlib.h"

main() {
    char *string = "A";
    int    rc;

    rc = csid(string);
    printf("character '%s' is in character set id %i\n", string, rc);
}
```

Output

```
character 'A' is in character set id 0
```

Related information

- [“stdlib.h — Standard library functions” on page 65](#)

csin(), csinf(), csinl() — Calculate the complex sine

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--|
| C99 Single UNIX Specification, Version 3 | both | z/OS V1R7 a compiler that is designed to support C99 |

Format

```
#include <complex.h>

double complex csin(double complex z);
float complex csinf(float complex z);
long double complex csinl(long double complex z);
```

General description

The csin() family of functions compute the complex sine of z.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------|-----|------|
| csin | X | X |
| csinf | X | X |
| csinl | X | X |

Returned value

The csin() family of functions return the complex sine value.

Example

For an example of a similar function see cacos(), cexp() or cpow().

csinh(), csinhf(), csinhl() – Calculate the complex hyperbolic sine

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--|
| C99 Single UNIX Specification, Version 3 | both | z/OS V1R7 a compiler that is designed to support C99 |

Format

```
#include <complex.h>

double complex csinh(double complex z);
float complex csinhf(float complex z);
long double complex csinhl(long double complex z);
```

General description

The `csinh()` family functions compute the complex hyperbolic sine of z .

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|---------------------|-----|------|
| <code>csinh</code> | X | X |
| <code>csinhf</code> | X | X |
| <code>csinhl</code> | X | X |

Returned value

The `csinh()` family functions return the complex hyperbolic sine value.

Example

For an example of a similar function see `cacos()`, `cexp()` or `cpow()`.

Related information

__CSNameType() — Return codeset name type

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R2 |

Format

```
#include <_Ccsid.h>

__csType __CSNameType(char *codesetName);
```

General description

The `__CSNameType()` function returns a `__csType` value which indicates the corresponding codeset name type.

Returned value

If *codesetName* is valid, `__CSNameType()` returns one of the following `__csType` values, which are defined in `<_Ccsid.h>`:

- `_CSTYPE_EBCDIC`
- `_CSTYPE_ASCII`
- `_CSTYPE_UCS2`
- `_CSTYPE_UTF8`
- `_CSTYPE_UTF16`
- `_CSTYPE_UTF32`

If *codesetName* is not valid, `__CSNameType()` returns `_CSTYPE_INVALID`.

Related information

csnap() — Request a condensed dump

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <ctest.h>

int csnap(char *dumptitle);
```

General description

Creates a display of the activation stack, including the Dynamic Storage Area (DSA), for each presently active function. Other environmental control blocks that may be required by IBM Service are also displayed. Under Language Environment, these consist of the Common Anchor Area (CAA) and the IBM z/OS C++ CAA information. The output is identified with *dumptitle*. See the CEE3DMP Language Environment callable service in [z/OS Language Environment Programming Guide](#) to determine where the output is written to.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

Returned value

If successful, `csnap()` returns 0.

If unsuccessful, `csnap()` returns nonzero.

Example

```
#include <ctest.h>

int main(void) {
    int rc;
    rc = csnap("Sample csnap output");
}
```

Related information

- [z/OS Language Environment Programming Guide](#)

- [“ctrace\(\) — Request a traceback” on page 363](#)

__csplist — Retrieve CSP parameters

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | C only | |

Format

```
#include <csp.h>

__csplist;
```

General description

Restriction: This function is not supported in AMODE 64.

__csplist is a macro intended to be used to access the parameter list passed from Cross System Product (CSP) to your C Library program. The macro evaluates to the address of the first element of the parameter list. You can use array indexing to extract the subsequent parameters, casting each parameter to the expected type, as shown in the example below. If no parameters are passed, __csplist[0] equals NULL.

You must include the `#pragma runopts(plist(ims))` directive if CSP is used to invoke a IBM z/OS C program.

argc will always be 1.

If you are expecting an integer and then a structure of type `s_type`, you should have the statements:

```
int_var = (int *) __csplist[0];
s_var   = (s_type *) __csplist[1];
```

Related information

- [“csp.h — Define __csplist macro” on page 17](#)

csqrt(), csqrtf(), csqrtl() – Calculate the complex square root

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--|
| C99 Single UNIX Specification, Version 3 | both | z/OS V1R7 a compiler that is designed to support C99 |

Format

```

#include <complex.h>

double complex csqrt(double complex z);
float complex csqrtf(float complex z);
long double complex csqrtl(long double complex z);

```

General description

The `csqrt()` family of functions compute the complex square root of z , with a branch cut along the negative real axis.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|---------------------|-----|------|
| <code>csqrt</code> | X | X |
| <code>csqrtf</code> | X | X |
| <code>csqrtl</code> | X | X |

Returned value

The `csqrt()` family of functions return the complex square root value, in the range of the right half-plane (including the imaginary axis).

Example

For an example of a similar function see `cacos()`, `cexp()` or `cpow()`.

Related information

ctan(), ctanf(), ctanl() – Calculate the complex tangent

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--|
| C99 Single UNIX Specification, Version 3 | both | z/OS V1R7 a compiler that is designed to support C99 |

Format

```
#include <complex.h>

double complex ctan(double complex z);
float complex ctanf(float complex z);
long double complex ctanl(long double complex z);
```

General description

The `ctan()` family of functions compute the complex tangent of z .

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|--------------------|-----|------|
| <code>ctan</code> | X | X |
| <code>ctanf</code> | X | X |
| <code>ctanl</code> | X | X |

Returned value

The `ctan()` family of functions return the complex tangent value.

Example

For an example of a similar function see `cacos()`, `cexp()` or `cpow()`.

ctanh(), ctanhf(), ctanhl() — Calculate the complex hyperbolic tangent

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--|
| C99 Single UNIX Specification, Version 3 | both | z/OS V1R7 a compiler that is designed to support C99 |

Format

```
#include <complex.h>

double complex ctanh(double complex z);
float complex ctanhf(float complex z);
long double complex ctanhl(long double complex z);
```

General description

The `ctanh()` family of functions compute the complex hyperbolic tangent of z .

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|---------------------|-----|------|
| <code>ctanh</code> | X | X |
| <code>ctanhf</code> | X | X |
| <code>ctanhl</code> | X | X |

Returned value

The `ctanh()` family of functions return the complex hyperbolic tangent value.

Example

For an example of a similar function see `cacos()`, `cexp()` or `cpow()`.

ctdli() — Call to DL/I

Standards

| Standards / Extensions | C or C++ | Dependencies |
|-------------------------|----------|--------------|
| Language Environment | both | |

Format

C only:

```
#pragma runopts(env(IMS),plist(OS))
#include <ims.h> /* or #include <cics.h> */

#define _CTDLI_PARMCOUNT /* First arg is an explicit parameter count */
int ctdli(int parmcount, const char *function, ...);
```

```

or

#define _CTDLI_NOPARMCOUNT          /*Parameter count is implicit in varargs */
int ctdli(const char *function,...);

```

C++:

```

#include <ims.h>                                /* or #include <cics.h> */

int ctdli(int parmcount, const char *function, ...);

or

#define _CTDLI_NOPARMCOUNT
int ctdli(const char *function, ...);

```

General description

Restriction: This function is not supported in AMODE 64.

Invokes DL/I facilities. The *parmcount* argument is optional. The *parmcount* value specifies the number of arguments in the variable argument list for the ctdli() call to function.

In C, when specifying a *parmcount*, use the _CTDLI_PARMCOUNT feature test macro. Otherwise, for C or C++, define _CTDLI_NOPARMCOUNT and make *function* the first argument. If the compile unit contains both types of call (sometimes passing *parmcount* and sometimes not), and if you want to avoid messages when compiling with the checkout option, define _CTDLI_NOPARMCOUNT and always cast the first argument to (const char *).

The *function* argument specifies the DL/I function you want to perform. Because the format of the ctdli() call depends on the function selected, all of the variations are not given here. For complete details on the available functions, refer to the COBOL publications.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

To invoke ctdli() from an IMS transaction, you need to specify the target operating system release that generates object code to run under the Information Management System (IMS) subsystem and specify that the original operating system parameter list should be available and the parameters are passed without restructuring, and the standard calling conventions of the operating system are used..

Returned value

The Program Control Block (PCB) status field (2 bytes) is stored as an unsigned int and used as the returned value for ctdli().

If the PCB status field contains blanks (hex '4040'), ctdli() returns 0.

Example

```

/* The following program demonstrates the use of the ctdli() function.
   It is a skeleton of a message processing program that calls ctdli()
   to retrieve messages and data.

   Specify the target release that generates object code to run under the Information
   Management System (IMS) subsystem
   and specify that the original operating system parameter list should be available and the
   parameters are passed without restructuring, and
   the standard calling conventions of the operating system are used.
*/
#ifdef __cplusplus
#pragma runopts(env(ims),plist(os))
#endif

#include <stdlib.h>
#include <ims.h>

```

```
#define n      20          /* I/O area size - Application dependent */
typedef struct {PCB_STRUCT(10)} PCB_10_TYPE;

int main(void)
{
    /* Function codes for ctdli */
    static const char func_GU[4]  = "GU  ";
    static const char func_ISRT[4] = "ISRT";

    char ssa_name[] = "ORDER    (ORDERKEY    = 666666)";

    int rc;

    char msg_seg_io_area[n];
    char db_seg_io_area[n];
    char alt_msg_seg_out[n];

    PCB_STRUCT_8_TYPE *alt_pcb;
    PCB_10_TYPE *db_pcb;
    IO_PCB_TYPE *io_pcb;

    io_pcb = (IO_PCB_TYPE *) (__pcblist)[0];
    alt_pcb = __pcblist[1];
    db_pcb = (PCB_10_TYPE *) __pcblist[2];
:
    /* Get first message segment from message region */
    rc = ctdli(func_GU, io_pcb, msg_seg_io_area);
:
    /* Get the data from the database having the specified key value */
    rc = ctdli(func_GU, db_pcb, db_seg_io_area, ssa_name);
:
    /* Build output message in program's I/O area */
    rc = ctdli(func_ISRT, alt_pcb, alt_msg_seg_out);
:
:
}
```

#include <unistd.h>

char *ctermid(char *string);
```

General description

string points to a memory location where the ctermid() function stores the name of the current controlling terminal. The memory location must be able to hold at least L_ctermid characters, where L_ctermid is a symbol defined in the stdio.h header file.

ctermid() returns a string that can be used as a path name to refer to the controlling terminal for the current process. If *string* is not NULL, ctermid() stores the path name in the specified location and returns the value of *string*. Otherwise, ctermid() uses a location of its own and returns a pointer to that location.

The path name returned can be used to access the controlling terminal, if the process has a controlling terminal.

Returned value

`ctermid()` is always successful; it returns a string that can be used as a path name to refer to the controlling terminal for the current process.

There are no documented `errno` values.

Example

CELEBC32

```
/* CELEBC32

   This example refers to the controlling terminal for
   the current process.

*/
#define _POSIX_SOURCE
#include <unistd.h>
#include <stdio.h>

main() {
    char termid[1025];

    if (ctermid(termid) == NULL)
        perror("ctermid() error");
    else
        printf("The control terminal is %s\n", termid);
}
```

Output

```
The control terminal is /dev/tty
```

ctest() — Start debug tool

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <ctest.h>

int ctest(char *command);
```

General description

Invokes the Debug Tool from your application program. The parameter *command* is a character pointer to a list of valid Debug Tool commands, that `ctest()` uses to invoke Debug Tool.

If you choose not to compile your program with hooks, you can use well-placed `ctest()` function calls instead. (A *hook* is a conditional exit that transfers control to the debugger, when the code is run under the debugger.) You would create a hook when you compile with the `TEST` option, causing the exit to be in your generated code waiting to run. A hook has minimal effect on a program that is running without the debugger.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

Returned value

If successful, `ctest()` returns 0.
If unsuccessful, `ctest()` returns nonzero.

Examples

To let the debug tool gain control of your program, issue the command: `ctest(NULL)`.
To display the call chain from within a program and then let the program continue execution, issue the function call: `ctest("list calls; go;")`. To set a breakpoint from within a `ctest()` call, try:

```
char *cmd = "at line 17 list my_struct; go;";
ctest(cmd);
```

ctime(), ctime64() – Convert time to character string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```
#include <time.h>

char *ctime(const time_t *timer);

#define _LARGE_TIME_API
#include <time.h>

char *ctime64 (const time64_t *timer);
```

General description

Converts the calendar time pointed to by *timer* to local time in the form of a character string. A value for *timer* is usually obtained by a call to the `time()` function.

The `ctime()` function is equivalent to the function call: `asctime(localtime(timer))`

The function `ctime64()` will behave exactly like `ctime()` except it will convert a `time64_t` value pointing to a calendar time beyond 03:14:07 UTC on January 19, 2038 with a limit of 23:59:59 UTC on December 31, 9999.

Returned value

If successful, `ctime()` returns a pointer to a date and time string. The string returned by `ctime()` contains exactly 26 characters and has the format:

```
"%.3s %.3s%3d %.2d:%.2d:%.2d %d\n"
```

For example: `Mon Jul 16 02:03:55 1987\n\0`

If an error occurs, `ctime()` returns no value.

Notes:

1. This function is sensitive to time zone information which is provided by:
 - The TZ environmental variable when POSIX(ON) and TZ is correctly defined, or by the _TZ environmental variable when POSIX(OFF) and _TZ is correctly defined.
 - The LC_TOD category of the current locale if POSIX(OFF) or TZ is not defined.

The time zone external variables `tzname`, `timezone`, and `daylight` declarations remain feature test protected in `time.h`.
2. The calendar time returned by a call to the `time()` function begins at epoch, which was at 00:00:00 Coordinated Universal Time (UTC), January 1, 1970.
3. The `ctime()` function uses a 24-hour clock format.
4. The days are abbreviated to: Sun, Mon, Tue, Wed, Thu, Fri, and Sat.
5. The months are abbreviated to: Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, and Dec.
6. All fields have a constant width.
7. Dates with only one digit are padded with a blank space. Single digit time values are padded with a zero.
8. The newline character (`\n`) and the NULL character (`\0`) occupy the last two positions of the string.
9. The `asctime()`, `ctime()`, and other time functions may use a common, statically allocated buffer for holding the return string. Each call to one of these functions may destroy the result of the previous call.

When neither TZ nor _TZ is defined, the current locale is interrogated for time zone information. If neither TZ nor _TZ is defined and LC_TOD time zone information is not present in the current locale, a default value is applied to local time. POSIX programs simply default to Coordinated Universal Time (UTC), while non-POSIX programs establish an offset from UTC based on the setting of the system clock.

For more information about customizing a time zone to work with local time, see [Customizing a time zone](#) in *z/OS XL C/C++ Programming Guide*.

Error Code

| Description |
|------------------|
| EOverflow |

EOverflow

The result cannot be represented.

Example

CELEBC33

```
/* CELEBC33

This example polls the system clock by using the library
function &time..
It then prints a message giving the current date and time.
```

```
*/
#include <time.h>
#include <stdio.h>

int main(void)
{
    time_t ltime;

    time(&ltime);
    printf("the time is %s", ctime(&ltime));
}
```

Output

```
the time is Fri Jun 16 16:03:38 2006
```

ctime_r(), ctime64_r() – Convert time value to date and time character string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 Language Environment | both | OS/390 V2R8 |

Format

```
#define _XOPEN_SOURCE 500
#include <time.h>

char *ctime_r(const time_t *clock, char *buf);

#define _LARGE_TIME_API
#include <time.h>
```

```
char *ctime64_r (const time64_t *clock, char *buf);
```

General description

The `ctime_r()` function converts the calendar time pointed to by *clock* to local time in exactly the same form as `ctime()` and puts the string into the array pointed to by *buf*. (which contains at least 26 bytes) and returns *buf*.

Unlike `ctime()`, the thread-safe version `ctime_r()` is not required to set *tzname*.

The function `ctime64_r()` will behave exactly like `ctime_r()` except it will convert a `time64_t` value pointing to a calendar time beyond 03:14:07 UTC on January 19, 2038 with a limit of 23:59:59 UTC on December 31, 9999.

Returned value

If successful, `ctime_r()` returns a pointer to the string pointed to by *buf*.

If unsuccessful, `ctime_r()` returns a NULL pointer.

There are no documented `errno` values.

ctrace() — Request a traceback

Standards

| Standards / Extensions | C or C++ | Dependencies |
|-------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <ctest.h>

int ctrace(char *dumptitle);
```

General description

Requests a traceback. The output is identified with *dumptitle*. ctrace() invokes the CEE3DMP Language Environment callable service with the following options: TRACEBACK, NOFILE, NOBLOCK, NOVARIABLE, NOSTORAGE, STACKFRAME(ALL), NOCOND, NOENTRY. See the CEE3DMP Language Environment callable service in [z/OS Language Environment Programming Guide](#). to determine where the output is written to.

This function can [list stored line numbers](#), along with the traceback.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

Note: The offsets displayed by ctrace() are from the beginning of the functions, whereas by default, compiler listings show offsets from the beginning of the source file. You can override the displayed offsets and [list function relative offset addresses](#).

Returned value

If successful, ctrace() returns 0.
If unsuccessful, ctrace() returns nonzero.

Example

CELEBC34

```
/* CELEBC34

   This example shows how ctrace() is used and the output produced.

*/
#include <ctest.h>
int main(void) {

    int rc;
    rc = ctrace("Sample ctrace output");
}
```

Output for C++:

cuserid() — Return character login of the user

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4 XPG4.2 | both | |

Format

```

#define _XOPEN_SOURCE
#include <stdio.h>

char *cuserid(char *s);

```

General description

The `cuserid()` function generates a character representation of the name associated with the real or effective user ID of the process.

If `s` is a NULL pointer, this representation is generated in an area that may be overwritten by subsequent calls to `cuserid()`. A pointer to the area is returned. If `s` is not a NULL pointer, `s` is assumed to point to an array of at least `{L_cuserid}` bytes; the representation is deposited in this array. The symbolic constant `{L_cuserid}` is defined in `<stdio.h>` and has a value greater than 0.

Note:

This function and constant `L_cuserid` are kept for historical reasons. They were part of the Legacy Feature in Single UNIX Specification, Version 2, but have been withdrawn and are not supported as part of Single UNIX Specification, Version 3. New applications should use `getpwuid()` instead of `cuserid()`.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

If `s` is not a NULL pointer, `cuserid()` returns `s`.

If `s` is not a NULL pointer and the login name cannot be found, the NULL byte `'\0'` will be placed at `*s`.

If `s` is a NULL pointer and the login name cannot be found, `cuserid()` returns a NULL pointer.

If *s* is a NULL pointer and the login name can be found, `cuserid()` returns the address of a buffer local to the calling thread containing the login name.

dbm_clearerr() — Clear database error indicator

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <ndbm.h>

int dbm_clearerr(DBM *db);
```

General description

The `dbm_clearerr()` function clears the error condition of the database. The argument *db* is a handle to a database previously obtained by `dbm_open()`. Note that this does not correct any problems with the database due to previous failures. It simply allows `dbm_` operations to proceed. The database may be in an inconsistent or damaged state.

Special behavior for z/OS UNIX Services: In a multithreaded environment, the database error indicator is global to all threads using the database handle. Thus, clearing the error indicator affects all threads using the database handle.

Returned value

The return value is unspecified by X/Open.

If successful, `dbm_clearerr()` returns 0.

If unsuccessful, `dbm_clearerr()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

Non-valid database descriptor specified.

dbm_close() — Close a database

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <ndbm.h>

void dbm_close(DBM *db);
```

General description

The `dbm_close()` function closes a database. The `db` argument is the database handle returned by a previous call to `dbm_open()`.

Special behavior for z/OS UNIX Services: A `dbm_close()` function call removes access to the specified database handle to all threads within the process.

Returned value

`dbm_close()` returns no values.

Related information

- [“ndbm.h — ndbm database operations” on page 45](#)

dbm_delete() – Delete database record

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <ndbm.h>

int dbm_delete(DBM *db, datum key);
```

General description

The `dbm_delete()` function deletes a record and its key from the database. The `db` argument specifies the database handle returned by a previous call to `dbm_open()`. The `key` argument identifies the record the program is deleting. The `key` datum must contain a `dptr` pointer to the key, and the key length in `dsize`.

After calling `dbm_delete()`, during a pass through the keys by `dbm_firstkey()` and `dbm_nextkey()`, the application positioning must be reset by calling `dbm_firstkey()`. If not, unpredictable results may occur including retrieval of the same key multiple times, or not at all.

File space is not physically reclaimed by a `dbm_delete()` operation. That is, the file size is not reduced. However, the space is available for reuse, subject to hashing.

Special behavior for z/OS UNIX Services: In a multithreaded environment, changes made to the database by a `dbm_delete()` operation affect all threads using the database handle. Thus, all other threads must also reset their positioning by using the `dbm_firstkey()` function before using `dbm_nextkey()`. A previously executed `dbm_fetch()` operation by **another** thread for the same `key` still has correct buffer pointers to the previous data. The `dbm_delete()` operation does not affect this. All other operations on other threads, such as `dbm_fetch()` to this (now) deleted `key` will fail.

Returned value

If successful, `dbm_delete()` returns 0.

If unsuccessful, `dbm_delete()` returns -1 and sets the error value in `errno`. Also, the database error indicator may be set.

dbm_error() – Check database error indicator

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <ndbm.h>

int dbm_error(DBM *db);
```

General description

The `dbm_error()` function returns the error condition of the database. The argument `db` is a handle to a database previously obtained by `dbm_open()`.

Special behavior for z/OS UNIX Services: In a multithreaded environment, the database error indicator is global to all threads using the database handle. Thus, the database error indicator may be set as a result of a database operation by another thread.

Returned value

`dbm_error()` returns 0 if the error condition is not set.

`dbm_error()` returns nonzero if the error condition is set.

Related information

dbm_fetch() – Get database content

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <ndbm.h>

datum dbm_fetch(DBM *db, datum key);
```

General description

The `dbm_fetch()` function reads a record from the database. The argument *db* is a handle to a database previously obtained by `dbm_open()`. The argument *key* is a datum that has been initialized by the application program to the value of the key that matches the key of the record the program is fetching. A datum is a structure that consists of two members, `dptr` and `dsize`. The member `dptr` is a char pointer to an array of data that is `dsize` bytes in length. (The data is arbitrary binary data and is not NULL-terminated.)

The `dptr` is valid only until the next `dbm_` operation by this thread.

Special behavior for z/OS UNIX Services: In a multithreaded environment, the `dbm_fetch()` function returns a `dptr` in the datum structure to a data area that is thread-specific. This data area is not affected by other threads operations on the database, with the exception of a `dbm_close()` operation, which invalidates the *datum*.

Returned value

If successful, `dbm_fetch()` returns the datum containing a pointer to the data content `dptr`, and the data length `dsize`.

If unsuccessful, `dbm_fetch()` returns a NULL pointer in `dptr` and returns the error value in `errno`. Also, the database error indicator may be set.

Related information

dbm_firstkey() – Get first key in database

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <ndbm.h>
```

```
datum dbm_firstkey(DBM *db);
```

General description

The `dbm_firstkey()` function returns the first key in the database. The argument *db* is a handle to a database previously obtained by `dbm_open()`. Since the keys are arbitrary binary data, the order of key return by `dbm_firstkey()` and `dbm_nextkey()` does not reflect any lexical ordering. In addition, the return order does not reflect record insertion ordering. All keys can be retrieved from the database by executing a loop such as:

```
for (key = dbm_firstkey(db); key.dptr != NULL; key = dbm_nextkey(db))
```

That is, establish positioning to the beginning by use of the `dbm_firstkey()` function, then loop doing `dbm_nextkey()` function calls until a NULL `dptr` is returned in the *datum*.

The returned `dptr` is valid only until the next `dbm_` operation by this thread.

Special behavior for z/OS UNIX Services: In a multithreaded environment, the `dbm_firstkey()` function returns a pointer to data that is thread-specific. In addition, each thread maintains its own positioning information for `dbm_nextkey()` operations. However, other threads making modifications to the database, for example using `dbm_store()` or `dbm_delete()` can cause unpredictable results for threads executing `dbm_nextkey()`, including keys retrieved multiple times or not at all. The application must reset positioning to the beginning using `dbm_firstkey()` if another thread has done a modification to the database.

Returned value

If successful, `dbm_firstkey()` returns the *datum* containing a pointer to the key `dptr`, and the key length `dsize`.

If unsuccessful, `dbm_firstkey()` returns a NULL pointer in `dptr` and returns the error value in `errno`. Also, the database error indicator may be set.

dbm_nextkey() — Get next key in database

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <ndbm.h>

datum dbm_nextkey(DBM * db);
```

General description

The `dbm_nextkey()` function returns the next key in the database. The argument *db* is a handle to a database previously obtained by `dbm_open()`. Since the keys are arbitrary binary data, the order of key return by `dbm_firstkey()` and `dbm_nextkey()` does not reflect any lexical ordering. In addition, the return order does not reflect record insertion ordering. All keys can be retrieved from the database by executing a loop such as:

```
for (key = dbm_firstkey(db); key.dptr !=NULL; key = dbm_nextkey(db))
```

That is, establish positioning to the beginning by use of the `dbm_firstkey()` function, then loop doing `dbm_nextkey()` function calls until a NULL `dptr` is returned in *datum*.

The returned `dptr` is valid only until the next `dbm_` operation by this thread.

Special behavior for z/OS UNIX Services: In a multithreaded environment, the `dbm_nextkey()` function returns a pointer to data that is thread-specific. In addition, each thread maintains its own positioning information for `dbm_nextkey()` operations. However, other threads making modifications to the database, for example using `dbm_store()` or `dbm_delete()` can cause unpredictable results for threads executing `dbm_nextkey()`, including keys retrieved multiple times or not at all. The application must reset positioning to the beginning using `dbm_firstkey()` if another thread has done a modification to the database.

Returned value

If successful, `dbm_nextkey()` returns the *datum* containing a pointer to the key `dptr`, and the key length `dsize`.

If unsuccessful, `dbm_nextkey()` returns a NULL pointer in `dptr` and returns the error value in `errno`. Also, the database error indicator may be set.

dbm_open() – Open a database

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <ndbm.h>

DBM *dbm_open(const char *file, int open_flags, mode_t file_mode);
```

General description

The `dbm_open()` function opens a database. The *file* argument is the path name of the database, not including the filename suffix (the part after the `.`). The database is stored in two files. One file is a directory containing a bit map of blocks in use and has `.dir` as its suffix. The second file contains all the data and has `.pag` as its suffix. The *open_flags* argument has the same meaning as the *flags* argument of `open()` except that a database opened for write-only access opens the files for read and write access. The *file_mode* argument has the same meaning as the third argument of `open()`.

The number of records that can be stored in the database is limited by the file space available for the `.dir` and `.pag` files, and by the underlying key hashing. If multiple keys hash to the same 32 bit hash value, the number of keys for that hash value is limited to the amount of data (key sizes plus content sizes plus overhead) that can be stored in a single logical block of 1024 bytes.

Special behavior for z/OS UNIX Services: In a multithreaded environment, the `dbm_` functions have both POSIX process wide and thread-specific characteristics. z/OS UNIX services provide the following multithreaded behavior:

1. A database handle returned by the `dbm_open()` function is a process wide resource. This means that multiple threads within the process can access the database using the same database handle.
2. Each thread using a given database handle has its own positioning information for `dbm_firstkey()` and `dbm_nextkey()` operations. This means that multiple threads can each be executing a `dbm_nextkey()` loop.
3. Each thread using a given database handle has its own buffering for `dbm_fetch()` operations. This means that a pointer to a keys content (as returned by `dbm_fetch()`) remains valid, even if other threads modify the database.
4. Database modifications are automatically reflected to all of the threads using the same database handle. For example, if a thread adds a key/data pair using `dbm_store()`, a `dbm_fetch()` of that key by another thread will be successful.
5. Operations which modify the database, such as `dbm_store()` and `dbm_delete()`, can cause unpredictable results to threads executing `dbm_nextkey()`. If a database modification is done, all threads should reset positioning using a `dbm_firstkey()` call before executing `dbm_nextkey()`.
6. A `dbm_close()` operation removes access to the database for all threads that use the database handle.
7. Multiple `dbm_open()` operations, whether by a single thread, multiple threads within a process, or by multiple processes are permitted, but for read access only. No protection is provided for database modification, and modification can result in unpredictable results, including database destruction.

Returned value

If successful, `dbm_open()` returns a pointer to the database descriptor.

If unsuccessful, dbm_open() returns a NULL pointer and stores the error value in errno.

dbm_store() — Store database record

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <ndbm.h>

int dbm_store(DBM *db, datum key, datum content, int store_mode);
```

General description

The dbm_store() function writes a record to a database. The *db* argument specifies the database handle returned by a previous call to dbm_open(). The *key* argument identifies the record the program is deleting. The *key* datum must contain a dptr pointer to the key, and the key length in dsize. The argument *content* is a datum. that describes the data record being stored. record the program is writing. The *content* datum. contains a dptr pointer to the data, and the data length in dsize.

The argument *store_mode* controls whether dbm_store() replaces a already existing record that has the same key. The *store_mode* argument may be any one of the following set of symbols defined in the <ndbm.h> include file:

DBM_INSERT

Do not add the *key* and *content* pair if the *key* already exists in the database. If the *key* doesn't already exist, add the new *key* and *content* pair.

DBM_REPLACE

Replace the *key* and *content* pair in the database with the new pair if the *key* already exists. If the *key* doesn't already exist, add the new *key* and *content* pair.

After calling dbm_store(), during a pass through the keys by dbm_firstkey() and dbm_nextkey(), the application positioning must be reset by calling dbm_firstkey(). If not, unpredictable results may occur including retrieval of the same key multiple times, or not at all.

The number of records that can be stored in the database is limited by the file space available for the .dir and .pag files, and by the underlying key hashing. If multiple keys hash to the same 32 bit hash value, the number of keys for that hash value is limited to the amount of data (key sizes plus content sizes plus overhead) that can be stored in a single logical block of 1024 bytes.

Special behavior for z/OS UNIX Services: In a multithreaded environment, changes made to the database by a `dbm_store()` operation affect all threads using the database handle. Thus, all other threads must also reset their positioning by using the `dbm_firstkey()` function before using `dbm_nextkey()`. A previously executed `dbm_fetch()` operation by **another** thread for the same *key* still has correct buffer pointers to the previous data. The `dbm_store()` operation does not affect this. All other operations, such as `dbm_fetch()` or `dbm_delete()`, will automatically have access to the new *key* and *content* pair.

Returned value

If successful, `dbm_store()` returns 0. If `DBM_INSERT` is specified, and the *key* already exists, `dbm_store()` returns 1.

If unsuccessful, `dbm_store()` returns -1 and sets `errno` to one of the following values. Also, the database error indicator may be set.

Error Code Description

EFBIG

Seek/Write operation failed attempting to write new block. This `errno` is not part of the `errno` set described by X/Open for this function. You may be able to store other *key* and *content* pairs when the *key* hashes to a different value.

ENOSPC

key plus *content* plus block overhead does not fit into a block. This `errno` is not part of the `errno` set described by X/Open for this function. The *key* plus *content* underlying data lengths need be less or equal to 1012 bytes in length.

decabs() — Decimal absolute value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C Library | C only | |

Format

```
#include <decimal.h>

decimal(n,p) decabs(decimal(n,p) pdec);
```

General description

The built-in function decabs() accepts a decimal type expression as an argument and returns the absolute value of the decimal argument, in the same decimal type as the argument. The function does not change the content of the argument.

The parameter *n* can be any integral value between 1 and DEC_DIG. The parameter *p* can be any integral value between 0 and DEC_PRECISION, although it must be less than or equal to *n*. DEC_DIG and DEC_PRECISION are defined inside decimal.h.

If the content of the given argument is not in native packed decimal format, behavior is undefined.

Example

CELEBD01

```
/* CELEBD01 */
#include <decimal.h>

decimal(10,2) p1, p2;
int main(void) {
    p2 = -1234.56d;
    p1 = decabs(p2);
    printf("p1 = %D(10,2), p2 = %D(10,2)\n", p1, p2);
    return(0);
}
```

Output

```
p1 = 1234.56, p2 = -1234.56
```

Related information

decchk() — Check for valid decimal types

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C Library | C only | |

Format

```
#include <decimal.h>

int decchk(decimal(n,p) pdec);
```

General description

The built-in function `decchk()` accepts a decimal type expression as an argument and returns a status value of type `int`.

The status can be interpreted as follows:

DEC_VALUE_OK

A valid decimal representation value (including the less-preferred but valid sign, A-F).

DEC_BAD_NIBBLE

The leftmost half-byte is not 0 in a decimal type number that has an even number of digits. For example, 123 is stored in `decimal(2,0)`. If such a number is packed, then it is used.

DEC_BAD_DIGIT

Digits not allowed (not 0-9). If such a number is packed, then it is used.

DEC_BAD_SIGN

Sign not allowed (not A-F). If such a number is packed, then it is used.

The function return status can be masked to return multiple status.

The parameter *n* can be any integral value between 1 and `DEC_DIG`. The parameter *p* can be any integral value between 0 and `DEC_PRECISION`, although it must be less than or equal to *n*. `DEC_DIG` and `DEC_PRECISION` are defined inside `decimal.h`.

If the content of the given argument is not in native packed decimal format, the behavior is undefined.

Example

```
#include <decimal.h>

decimal(10,2) p1;
char mem2[3] = { 0x12, 0x34, 0x5c }; /* bad half-byte */
char mem3[3] = { 0x02, 0xa4, 0x5c }; /* bad digit */
char mem4[3] = { 0x02, 0x34, 0x56 }; /* bad sign */
char mem5[3] = { 0x12, 0xa4, 0x56 }; /* bad half-byte, digit and sign */
decimal(4,0) *pp2;
decimal(4,0) *pp3;
decimal(4,0) *pp4;
decimal(4,0) *pp5;
int main(void) {
    p1 = 123456.78d;
    pp2 = (decimal(4,0) *) mem2;
    pp3 = (decimal(4,0) *) mem3;
    pp4 = (decimal(4,0) *) mem4;
    pp5 = (decimal(4,0) *) mem5;

    if (decchk(p1) == DEC_VALUE_OK) {
        printf("p1 is a valid decimal representation value.\n");
    }
    if (decchk(*pp2) == DEC_BAD_NIBBLE) {
        printf("pp2 points to a bad half-byte value!\n");
    }
    if (decchk(*pp3) == DEC_BAD_DIGIT) {
        printf("pp3 points to an illegal digit!\n");
    }
    if (decchk(*pp4) == DEC_BAD_SIGN) {
        printf("pp4 points to an illegal sign!\n");
    }
    /* The wrong way ----- */
    if (decchk(*pp5) == DEC_BAD_SIGN) {
        printf("YOU SHOULD NOT GET THIS!!!!\n");
    }
    /* The right way ----- */
    if ((decchk(*pp5) & DEC_BAD_SIGN) == DEC_BAD_SIGN) {
        printf("pp5 points to an illegal sign!\n");
    }
    return(0);
}
```

Output

```
p1 is a valid decimal representation value.  
pp2 points to a bad half-byte value!  
pp3 points to an illegal digit!  
pp4 points to an illegal sign!  
pp5 points to an illegal sign!
```

decfix() — Fix up a nonpreferred sign variable

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C Library | C only | |

Format

```
#include <decimal.h>  
  
decimal(n,p) decfix(decimal(n,p) pdec);
```

General description

The built-in function `decfix()` accepts a decimal type expression as an argument and returns a decimal value that has the same type and same value as the argument with the correct preferred sign. The function does not change the content of the argument.

The parameter *n* can be any integral value between 1 and `DEC_DIG`. The parameter *p* can be any integral value between 0 and `DEC_PRECISION`, though it must be less than or equal to *n*. `DEC_DIG` and `DEC_PRECISION` are defined inside `decimal.h`.

If the content of the given argument is not in native packed decimal format, behavior is undefined.

Example

```
#include <decimal.h>  
  
char *ptr;  
char mem[3] = { 0x01, 0x23, 0x4A };  
decimal(4,0) *pp;  
decimal(4,0) p;  
int main(void) {  
    pp = (decimal(4,0) *) mem;  
    p = decfix(*pp);  
    ptr = (char *) p;  
    printf("Before decfix : %X%X%X\n", mem[0], mem[1], mem[2]);  
    printf("After decfix : %X%X%X\n", ptr[0], ptr[1], ptr[2]);  
    return(0);  
}
```

Output

```
Before decfix : 1234A  
After decfix : 1234C
```

DeleteWorkUnit() — Delete a WLM work unit

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <sys/_wlm.h>

int DeleteWorkUnit(wlmetok_t *enclavetoken);
```

General description

The DeleteWorkUnit() function provides the ability for an application to delete a WLM work unit.

***enclavetoken**

Points to a work unit enclave token that was returned from a call to CreateWorkUnit() or ContinueWorkUnit().

Returned value

If successful, DeleteWorkUnit() returns 0.

If unsuccessful, DeleteWorkUnit() returns -1 and sets errno to one of the following values:

Error Code

Description

EFAULT

An argument of this function contained an address that was not accessible to the caller.

EINVAL

An argument of this function contained an incorrect value.

EMVSSAF2ERR

An error occurred in the security product.

EMVSWLMERROR

The WLM delete enclave failed. Use __errno2() to obtain the WLM service reason code for the failure.

EPERM

The calling thread's address space is not permitted to the BPX.WLMSEVER Facility class. The caller's address space must be permitted to the BPX.WLMSEVER Facility class if it is defined. If BPX.WLMSEVER is not defined, the calling process is not defined as a superuser (UID=0).

difftime(), difftime64() — Compute time difference

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

Format of the difftime() function:

```
#include <time.h>

double difftime(time64_t time2, time_t time1);
```

Format of the difftime64() function:

```
#define _LARGE_TIME_API
#include <time.h>

double difftime64(time64_t time2, time64_t time1);
```

General description

Computes the difference in seconds between *time2* and *time1*, which are calendar times returned by `time()`.

The `difftime()` function returns the difference between two calendar times as a double. The return value is hexadecimal floating-point or IEEE Binary Floating-Point format depending on the floating-point mode of the thread invoking `difftime()`. The `difftime()` function uses `__isBFP()` to determine which floating-point format (hexadecimal floating-point or IEEE Binary Floating-Point) to return on the invoking thread.

The function `difftime64()` will behave exactly like `difftime()` except it will support calendar times beyond 03:14:07 UTC on January 19, 2038 with a limit of 23:59:59 UTC on December 31, 9999.

Returned value

Returns the elapsed time in seconds from *time1* to *time2* as a double.

Example

CELEBD04

```

/* CELEBD04

   This example shows a timing application using &diff..
   The example calculates how long, on average, it takes a
   user to input some data to the program.

*/
#include <time.h>
#include <stdio.h>

int main(void)
{
    time_t start, finish;
    int i, n, num;
    int answer;

    printf("11 x 55 = ? Enter your answer below\n");
    time(&start);
    scanf("%d",&answer);
    time(&finish);
    printf("You answered %s in %.0f seconds.\n",
           answer == 605 ? "correctly" : "incorrectly",
           difftime(finish,start));
}

```

Output

```

11 x 55 = ? Enter your answer below
605
You answered correctly in 20 seconds

```

dirfd() — Get directory stream file descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| Single UNIX Specification, Version 4 POSIX.1-2008 | both | |

Format

```
#define _POSIX_C_SOURCE 200809L
#include <dirent.h>

int dirfd(DIR *dirp);
```

General description

The `dirfd()` function returns the file descriptor that is associated with the directory stream *dirp*. This file descriptor must be closed by a call to `closedir()`. If any attempt is made to close the file descriptor or to modify the state of the associated description, the behavior is undefined unless `closedir()`, `readdir()`, `readdir_r()`, `rewinddir()`, or `seekdir()` is used.

Returned value

If successful, `dirfd()` returns a file descriptor, which is a non-negative integer. If unsuccessful, `dirfd()` returns -1 and sets `errno` to the following value:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

EINVAL
The *dirp* argument does not refer to a valid directory stream.

dirname() — Report the parent directory of a path name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <libgen.h>

char *dirname(char *path);
```

General description

The `dirname()` function takes a pointer to a character string that contains a path name, and returns a pointer to a string that is a path name of the parent directory of that file. Trailing '/' characters in the path are not counted as part of the path.

If *path* does not contain a '/' then `dirname()` returns a pointer to the string ".". If *path* is a NULL pointer or points to an empty string, `dirname()` returns a pointer to the string ".".

The `dirname()` function may modify the string pointed to by *path*.

Examples:

| Input String | Output String |
|--------------|---------------|
| "/usr/lib" | "/usr" |
| "/usr/" | "/" |
| "usr" | ." |
| "/" | "/" |
| "." | ." |
| ".." | ." |

Returned value

If successful, `dirname()` returns a pointer to a string that is the parent directory of *path*.

If *path* is a NULL pointer or points to an empty string, `dirname()` returns a pointer to a string ".".

There are no `errno` values defined.

__discarddata() — Release pages backing virtual storage

Standards

| Standards / Extensions | C or C++ | Dependencies |
|-------------------------|----------|--------------|
| Language Environment | both | OS/390 V2R10 |

Format

```
#include <stdlib.h>

int __discarddata(void *addr, size_t size);
```

General description

The `__discarddata()` function is used to release segments of real storage backing virtual storage. Segments backing virtual storage are released beginning at location *addr* for a length of *size*. For AMODE 31, the *addr* must begin on a page (4K) boundary and *size* must be a multiple of 4K. For AMODE 64, the *addr* must begin on a segment (1 MB) boundary and *size* must be a multiple of 1 MB.

Returned value

If successful, `__discarddata()` returns 0.

If unsuccessful, because *addr* does not begin on a page (4K) boundary or *size* is not a multiple of 4K, `__discarddata()` returns -1.

There are no `errno` values defined.

Related information

- [“stdlib.h — Standard library functions” on page 65](#)

DisconnectServer() — Disconnect from WLM server

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <sys/__wlm.h>

int DisconnectServer(unsigned long *conn_tkn);
```

AMODE 64

```
#include <sys/__wlm.h>

int DisconnectServer(unsigned int *conn_tkn);
```

General description

The `DisconnectServer` function provides the ability for an application to disconnect from WLM.

***conn_tkn**

Specifies the connect token that represents the WLM connection that is to be disconnected.

Returned value

If successful, `DisconnectServer()` returns 0.

If unsuccessful, `DisconnectServer()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EFAULT

An argument of this function contained an address that was not accessible to the caller.

EINVAL

An argument of this function contained an incorrect value.

EMVSSAF2ERR

An error occurred in the security product.

EMVSWLMERROR

The WLM disconnect failed. Use `__errno2()` to obtain the WLM service reason code for the failure.

EPERM

The calling thread's address space is not permitted to the BPX.WLMSEVER Facility class. The caller's address space must be permitted to the BPX.WLMSEVER Facility class if it is defined. If BPX.WLMSEVER is not defined, the calling process is not defined as a superuser (UID=0).

div() — Calculate quotient and remainder

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#include <stdlib.h>

div_t div(int numerator, int denominator);
div_t div(long numerator, long denominator);    /* C++ only */
```

C++ TR1 C99:

```
#define _TR1_C99
#include <inttypes.h>
imaxdiv_t div(intmax_t numerator, intmax_t denominator);

#define _TR1_C99
#include <stdlib.h>
lldiv_t div(long long numerator, long long denominator);
```

General description

Calculates the quotient and remainder of the division of *numerator* by *denominator*.

Special behavior for C++: For C++ applications, `div()` is also overloaded for the type `long`.

Returned value

Returns a structure of type `div_t`, containing both the quotient `int quot` and the remainder `int rem`. This structure is defined in `stdlib.h`. If the returned value cannot be represented, the behavior of `div()` is

undefined. If *denominator* is 0, the same exception will be raised as if you divided by 0. That is, you get the error CEE3209S (Fixed-point divide exception).

Related information

- [“stdlib.h — Standard library functions” on page 65](#)

dlclose() — Close a dlopen() object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|--------------|
| Single UNIX Specification, Version 3 | both | z/OS V1R6 |

Format

```
#define _UNIX03_SOURCE
#include <dlfcn.h>

int dlclos(void *handle);
```

General description

Inform the system that the dynamic link library (DLL) referenced by a *handle* returned from a previous `dlopen()` invocation is no longer needed by the application. Once a DLL has been closed, an application should assume that its symbols and the symbols of any dependent DLLs are no longer available to `dlsym()`.

Returned value

NULL is returned if the referenced DLL was successfully closed. If the DLL could not be closed, or if *handle* does not refer to an open DLL, a non-zero value will be returned.

Usage notes

1. A conforming application should use a *handle* returned from a `dlopen()` invocation only within a given scope, bracketed by the `dlopen()` and `dlclose()` operations. The value of a *handle* must be treated as an opaque object by the application, used only in calls to `dlsym()` and `dlclose()`.
2. DLLs that are loaded explicitly, that is with `dlopen()`, and are not freed with a corresponding call to `dlclose()`, are freed automatically at enclave termination in LIFO sequence.
3. Non-local C++ static destructors defined in a DLL are executed only once, when the DLL program object is deleted from memory.
4. More detailed diagnostic information is available through `dlerror()`, the `_EDC_DLL_DIAG` environment variable, and the Language Environment DLL Failure control block (CEEDLLF) chain.
5. This function is not available under SPC, MTF and CSP environments.

Example

The following example illustrates use of `dlopen()` and `dlclose()`:

```
...
/* Open a dynamic library and then close it ... */
#include <dlfcn.h>
```

```
void *mylib;
int eret;

mylib = dlopen("mylib.so", RTLD_LOCAL | RTLD_LAZY);
...
eret = dlclose(mylib);
...
```

Related information

- [“dlerror\(\) — Get diagnostic information” on page 387](#)
- [“dlopen\(\) — Gain access to a dynamic link library” on page 388](#)
- [“dlsym\(\) — Obtain the address of a symbol from a dlopen\(\) object” on page 390](#)
- [“dlfcn.h — Define macros for use with dlopen\(\)” on page 18](#)

dlerror() — Get diagnostic information

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|--------------|
| Single UNIX Specification, Version 3 | both | z/OS V1R6 |

Format

```
#define _UNIX03_SOURCE
#include <dlfcn.h>

void dlerror(void);
```

General description

Returns a null-terminated character string (with no trailing <newline>) that describes the last error that occurred while processing a DLL by `dlopen()`, `dlsym()`, or `dlclose()`. NULL is returned if no errors have occurred since the last invocation of `dlerror()`.

Note: `dlerror()` is thread safe, so the information returned describes the last error that occurred on that thread

Returned value

A null-terminated character string is returned if successful, otherwise NULL is returned.

Usage notes

1. Messages returned by `dlerror()` reside in a static buffer that is overwritten on each new call to `dlerror()` on that thread.
2. Application code should not write to this buffer.
3. Programs wishing to preserve an error message should make their own copies of that message.
4. This function is not available under SPC, MTF and CSP environments.

Example

The following example prints out the last dynamic linking error:

```
...
#include <dlfcn.h>
```

```
char *errstr;

errstr = dlerror();
if (errstr != NULL)
    printf ("A dynamic linking error occurred: (%s)\n", errstr);
...
```

Related information

- [“dlclose\(\) — Close a dlopen\(\) object” on page 386](#)
- [“dlopen\(\) — Gain access to a dynamic link library” on page 388](#)
- [“dlsym\(\) — Obtain the address of a symbol from a dlopen\(\) object” on page 390](#)

dlopen() — Gain access to a dynamic link library

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|--------------|
| Single UNIX Specification, Version 3 | both | z/OS V1R6 |

Format

```
#define _UNIX03_SOURCE
#include <dlfcn.h>

void *dlopen(const char *file, int mode);
```

General description

Makes the dynamic link library (DLL) specified by *file* available to the calling program.

If the *file* argument contains a single slash ("/"), it is used as the z/OS UNIX file system path name for the DLL. If the environment variable LIBPATH is set, each directory that is listed is searched for the DLL. Otherwise, the current directory is searched.

Note: Searching for a DLL in the z/OS UNIX file system is case-sensitive.

If the *file* argument begins with two slashes ("//"), then an attempt is made to load the DLL from the caller's MVS load library search order (in order: STEPLIB/JOBLIB, LPA, Link List). The DLL name must be 8 characters or less, and is converted to uppercase.

If the *file* argument doesn't begin with one slash (/) or two slashes (//, and doesn't contain a single slash (/) anywhere in the name, then it is ambiguous as to where the DLL resides.

- If the POSIX(ON) runtime option is specified, then the z/OS UNIX file system is searched first for the DLL, and if not found, the MVS load library is searched.
- If the POSIX(OFF) runtime option is specified, then the MVS load library is searched first for the DLL, and if not found, the z/OS UNIX file system is searched.

Under the CICS environment, the search sequence for DLL load modules is the same as that used for dynamically loaded CICS modules. Loading DLLs from the z/OS UNIX file system is not supported under CICS.

For more information about how DLLs are loaded and how the search sequence is used, see the topic about [loading DLLs in z/OS Language Environment Programming Guide](#).

A successful call returns a handle, which the caller can use on subsequent calls to `dlsym()` and `dlclose()`. The value of this handle should not be interpreted in any way by the caller.

Only a single copy of a DLL is brought into the address space, even if invoked multiple times for the same DLL, and even if different values of the *file* parameter are used to reference the same DLL.

The *mode* parameter describes how dlopen() operates on a file regarding the processing of dependent DLLs and the scope of visibility of the symbols that are provided within *file*. If a *file* is specified in multiple invocations, *mode* is interpreted at each invocation. The *mode* is a bitwise-OR of the values specified.

Mode Values

When a DLL is loaded, it might contain implicit references to symbols in another "dependent" DLL, whose addresses are not known until that DLL is loaded. These implicit references must be relocated before the symbols can be accessed, which means loading the DLL containing the references. The *mode* parameter governs when these relocations (and loads) take place and might have the following values:

Value

Description

RTLD_LAZY

When possible, the loading of dependent DLLs, and resolution of symbols contained therein, might be deferred until the first reference to one of those symbols. This is the default behavior.

Note: After *RTLD_NOW* is specified, all relocations will have been completed causing additional *RTLD_NOW* operations to be redundant and any further *RTLD_LAZY* operations irrelevant.

RTLD_NOW

Load all dependent DLLs for the DLL being loaded and resolve all symbols before returning. This may include zero or more levels of nested dependent DLLs, all of which are loaded at this time.

RTLD_GLOBAL

Allows symbols in the DLL being loaded to be visible when resolving symbols through the global symbol object that was opened with dlopen(NULL,0). All dependent DLLs are always implicitly loaded as if RTLD_GLOBAL had been specified. This is the default behavior.

RTLD_LOCAL

Prevents symbols in the DLL being loaded to be visible when resolving symbols through the global symbol object that was opened with dlopen(NULL,0). All dependent DLLs of this DLL continue to be implicitly loaded as if RTLD_GLOBAL had been specified.

If a subsequent call is made for this same DLL with a *mode* of *RTLD_GLOBAL*, then the DLL will maintain the *RTLD_GLOBAL* status regardless of any previous or future specification of *RTLD_LOCAL*, as long as the DLL remains loaded (see dlclose()).

If the value of *file* is NULL, dlopen() returns a "global symbol object" *handle*. This object provides access (via dlsym()) to the symbols exported from:

- The main application and dependent DLLs for the main application that were loaded at program start-up, and
- The set of DLLs loaded using dlopen() with the *RTLD_GLOBAL* flag. This set of DLLs can change dynamically as other DLLs are opened and closed.

Symbols introduced by the call to dlopen() for a DLL, and available through dlsym(), are those which are exported by the DLL. Typically such symbols will be those identified by a #pragma export in C, or with the EXPORTALL compile option. For details on how to specify exported data and functions, for C/C++ as well as other languages, see the topic about building a simple DLL in [z/OS Language Environment Programming Guide](#).

Returned value

NULL is returned if:

- *file* cannot be found or opened for reading.
- *file* is not in correct DLL executable format.
- an error occurred during the process of loading *file*, or relocating its symbolic references.

Error Code
Description

- 253**
A 64-bit caller tried to load a 31-bit DLL.
- 254**
A 31-bit caller tried to load a 64-bit DLL.

Usage notes

- 1. For details on how to create and use DLLs, see [z/OS Language Environment Programming Guide](#).
- 2. The AMODE of the application must be the same as the AMODE of the DLL.
- 3. Non-local C++ static constructors defined in a DLL are executed only once, when the DLL program object is physically loaded into memory.
- 4. More detailed diagnostic information is available through dlerror(), the _EDC_DLL_DIAG environment variable, and the Language Environment DLL Failure control block (CEEDLLF) chain.
- 5. This function is not available under SPC, MTF and CSP environments.

Example

The following example illustrates use of dlopen() and dlclose():

```
...
/* Open a dynamic library and then close it ... */
#include <dlfcn.h>

void *mylib;
int eret;

mylib = dlopen("mylib.so", RTLD_LOCAL | RTLD_LAZY);
...
eret = dlclose(mylib);
...
```

Related information

- [“dlerror\(\) — Get diagnostic information” on page 387](#)
- [“dlsym\(\) — Obtain the address of a symbol from a dlopen\(\) object” on page 390](#)
- [“dlfcn.h — Define macros for use with dlopen\(\)” on page 18](#)

dlsym() — Obtain the address of a symbol from a dlopen() object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|--------------|
| Single UNIX Specification, Version 3 | both | z/OS V1R6 |

Format

```
#define _UNIX03_SOURCE
#include <dlfcn.h>

void *dlsym(void *__restrict__ handle, const char *__restrict__ name);
```

General description

Obtains the address of a symbol defined within a dynamic link library (DLL) made accessible through a `dlopen()` call. The *handle* argument is the value returned from a call to `dlopen()` (which has not been released by a call to `dlclose()`), and *name* is the symbol's name as a character string.

The DLL that was loaded by `dlopen()` will be searched for the named symbol. If the symbol is not found in that DLL, then the dependent DLLs of that DLL will be searched, followed by any dependents of those, and continuing in a breadth-first manner until the named symbol is found or all dependent DLLs have been searched. This search order determines how duplicate symbols in different DLLs will be found, although the order in which dependent DLLs at the same level are searched is indeterminate.

Also note that a search of dependent DLLs by `dlsym()` will not result in unloaded dependent DLLs being loaded. Only the dependent DLLs loaded as part of the call to `dlopen()` will be searched. If the full set of dependent DLLs need to be available to subsequent calls to `dlsym()`, make sure the DLL is opened with the `RTLD_NOW` load flag. It is indeterminate which dependent DLLs are loaded when `RTLD_LAZY` is specified

The only exception to this is the global symbol object obtained via a `dlopen(NULL,0)` call, in which case all DLLs (excluding those opened with `RTLD_LOCAL`) are searched in the order in which they were loaded.

Returned value

NULL is returned:

- If *handle* does not refer to a valid DLL opened by `dlopen()`,
- or the named symbol (*name*) cannot be found within any of the DLLs associated with *handle*.

Usage notes

1. The named symbol can be either an exported data item or function.
2. DLLs are enclave level resources. See [z/OS XL C/C++ Programming Guide](#) for more information about the use of DLLs in a multi-threaded environment.
3. C++ symbol names should be passed to `dlsym()` in mangled form; `dlsym()` does not perform any name mangling on behalf of the calling application.
4. More detailed diagnostic information is available through `dlerror()`, the `_EDC_DLL_DIAG` environment variable, and the Language Environment DLL Failure control block (CEEDLLF) chain.
5. This function is not available under SPC, MTF and CSP environments.

Example

The following example shows how `dlopen()` and `dlsym()` can be used to access either function or data objects. For simplicity, error checking has been omitted.

```
void    *handle;
int      *iptr, (*fptr)(int);

/* open the needed object */
handle = dlopen("/usr/home/me/libfoo.so", RTLD_LOCAL | RTLD_LAZY);

/* find the address of function and data objects */
fptr = (int (*)(int))dlsym(handle, "my_function");
iptr = (int *)dlsym(handle, "my_object");

/* invoke function, passing value of integer as a parameter */
(*fptr)(*iptr);
```

dllfree() — Free the supplied dynamic link library

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C Library | both | |

Format

```
#include <dll.h>

int dllfree(dllhandle *dllHandle);
```

General description

Frees the supplied dynamic link library (DLL). It also deletes the DLL from memory if the handle was the last handle accessing the DLL.

Returned value

dllfree() returns one of the following values and set errno if the return code is not 0:

Value

Meaning

0

Successful

1

The dllHandle supplied is NULL or dllhandle is inactive.

2

There are no DLLs to be deleted.

3

DLL is not physically deleted because there is another dllHandle for this DLL or there is an implicit reference to the DLL.

4

Delete of DLL failed.

5

No match is found for input dllHandle.

6

Not supported under this environment.

7

C++ destructors are currently running for this DLL. A dllfree() is already in progress.

8

The handle passed to dllfree() was obtained from dlopen().

Usage notes

1. This function is deprecated; use dlclose() instead.
2. This function is not available under SPC, MTF and CSP environments.
3. If a DLL is loaded implicitly, it cannot be deleted with dllfree(). For more information on the implicit use of DLLs, see [z/OS XL C/C++ Programming Guide](#).

4. DLLs that are loaded explicitly, that is with `dllload()`, and are not freed with a corresponding call to `dllfree()`, are freed automatically at enclave termination in LIFO sequence.
5. C++ destructors are executed only once, when the DLL load module is physically deleted.
6. More detailed diagnostic information is available through the `_EDC_DLL_DIAG` environment variable, and the Language Environment DLL Failure control block (CEEDLLF) chain. The default action is to issue an error message to the Language Environment message file.

Example

CELEBDL4

```

/* CELEBDL4

The following example shows how to use dllfree() to free the
dllhandle for the DLL stream.

*/
#include <stdio.h>
#include <dll.h>
#include <stdlib.h>

int main() {
    dllhandle *handle;
    char *name="stream";
    int (*fptr1)(int);
    int (*fptr)(int);
    int *ptr_var1;
    int *ptr_var;
    int rc=0;

    handle = dllload(name); /* call to stream DLL */
    if (handle == NULL) {
        perror("failed on call to stream DLL");
        exit(-1);
    }

    fptr1 = (int (*)(int)) dllqueryfn(handle,"f1");
    /* retrieving f1 function */
    if (fptr == NULL) {
        perror("failed on retrieving f1 function");
        exit(-2);
    }

    ptr_var = dllqueryvar(handle,"var1");
    /* retrieving var1 variable */
    if (ptr_var1 == NULL) {
        perror("failed on retrieving var1 variable");
        exit(-3);
    }

    rc = fptr(*ptr_var1); /* execute DLL function f1 */
    *ptr_var++;           /* increment value of var1 */

    rc = dllfree(handle); /* freeing handle to stream DLL */
    if (rc != 0) {
        perror("failed on dllfree call");
    }
    return (0);
}

```

dllload() – Load the dynamic link library and connect it to the application

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C Library | both | |

Format

```
#include <dll.h>

dllhandle *dllload(const char *dllName);
```

General description

Note: This function is deprecated; use `dlopen()` instead.

Loads the dynamic link library (DLL) into memory (if it has not been previously loaded) and connects it to the application. The function that called the DLL receives a handle that uniquely identifies the requested DLL for subsequent explicit requests for that DLL.

A different handle is returned for each successful call to `dllload()`. A DLL is physically loaded only once, even though there may be many calls to `dllload()`. C++ constructors are run only once.

The `dllName` identifies the DLL load module to be loaded. It must be a character string terminated with the NULL character. The DLL module must be a member of a PDS or an alias to it.

Note: The AMODE of the application must be the same as the AMODE of the DLL load module.

This function is not available under SPC, MTF and CSP environments.

The `dllName` identifies the DLL load to be loaded. It must be a character string, terminated with the NULL character. The DLL module must be a member of a PDS or an alias to it.

If the file argument contains a single slash ('/'), it is used as the z/OS UNIX file system path name for the DLL. If the environment variable LIBPATH is set, each directory listed will be searched for the DLL. Otherwise, the current directory will be searched.

Note: Searching for a DLL in the z/OS UNIX file system is case-sensitive.

If the file argument begins with two slashes ('//'), then an attempt is made to load the DLL from the caller's MVS load library search order (in order: STEPLIB/JOBLIB, LPA, Link List). The DLL name must be eight characters or less, and is converted to uppercase. Note that qualified DLL names are not supported and the MVS load library search order is used (for example, update or use STEPLIB to specify any number of qualifiers to be included in the search).

If the file argument doesn't begin with one or two slashes ('/' or '//'), and doesn't contain a single slash ('/') anywhere in the name, then it is ambiguous as to where the DLL resides.

- If the POSIX(ON) runtime option is specified, then the z/OS UNIX file system is searched first for the DLL, and if not found, the MVS load library is searched.
- If the POSIX(OFF) runtime option is specified, then the MVS load library is searched first for the DLL, and if not found, the z/OS UNIX file system is searched.

Under CICS environment, the search sequence for DLL load modules is the same as that used for dynamically loaded CICS modules. Loading DLLs from the z/OS UNIX file system is not supported under CICS.

For more information about how DLLs are loaded and how the search sequence is used, see the topic about [loading DLLs in z/OS Language Environment Programming Guide](#).

Returned value

If successful, `dllload()` returns a unique handle that identifies the DLL.

If unsuccessful, `dllload()` returns `NULL` and may set `errno` to one of the following values:

Error Code

Description

253

A 64-bit caller tried to load a 31-bit DLL.

254

A 31-bit caller tried to load a 64-bit DLL.

ELEFENCE

The DLL contains a member language that is not supported on this version of the operating system.

ENOEXEC

The new process image file has the appropriate access permission but is not in the proper format.

Note: Reason codes further qualify the `errno`. For most of the reason codes, see [z/OS UNIX System Services Messages and Codes](#).

For `ENOEXEC`, the reason codes are:

| Reason Code | Explanation |
|-------------|---|
| X'xxxx0C27' | The target z/OS UNIX file system file is not in the correct format to be an executable file. |
| X'xxxx0C31' | The target z/OS UNIX file system file is built at a level that is higher than that supported by the running system. |

Usage notes

1. More detailed diagnostic information is available through the `_EDC_DLL_DIAG` environment variable, and the Language Environment DLL Failure control block (CEEDLLF) chain.

Example

CELEBDL1

```
/* CELEBDL1

The following example shows how to invoke dllload() functions
from a simple C application.

*/
#include <stdio.h>
#include <dll.h>

main() {
    dllhandle *handle;
    char *name="stream";

    handle = dllload(name);
    if (handle == NULL) {
        perror("failed on dllload of stream DLL");
        exit(-1);
    }
}
```

dllqueryfn() — Obtain a pointer to a dynamic link library function

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C Library | both | |

Format

```
#include <dll.h>

void (*dllqueryfn(dllhandle *dllHandle, const char *funcName))();
```

General description

Note: This function is deprecated; use `dlsym()` instead.

Obtains a pointer to a dynamic link library (DLL) function (`funcName`). It uses the `dllHandle` returned from a previous successful call to `dllload()` for input. `funcName` represents the name of an exported function from the DLL. It must be a character string terminated with the NULL character.

This function is not available under the SPC, MTF, and CSP environments.

Returned value

If successful, `dllqueryfn()` returns a pointer to a function, `funcName`, that can be used to invoke the desired function in a DLL.

If unsuccessful, `dllqueryfn()` returns NULL and sets `errno`.

Usage notes

1. More detailed diagnostic information is available through the `_EDC_DLL_DIAG` environment variable, and the Language Environment DLL Failure control block (CEEDLLF) chain.

Example

CELEBDL2

```
/* CELEBDL2

The following example shows how to use dllqueryfn() to obtain
a pointer to a function, f1 that is in DLL load module stream.

*/
#include <stdio.h>
#include <dll.h>

main() {
    dllhandle *handle;
    char *name="stream";
    int (*fptr1)();

    handle = dllload(name);
    if (handle == NULL) {
        perror("failed on dllload of stream DLL");
        exit(-1);
    }

    fptr1 = (int (*)( )) dllqueryfn(handle,"f1");
    if (fptr1 == NULL) {
```

```

        perror("failed on retrieving f1 function");
        exit (-2);
    }
}

```

dllqueryvar() – Obtain a pointer to a dynamic link library variable

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C Library | both | |

Format

```

#include <dll.h>

void* dllqueryvar(dllhandle *dllHandle, const char *varName);

```

General description

Obtains a pointer to a dynamic link library (DLL) variable (*varName*). It uses the *dllHandle* returned from a previous successful call to *dllload()* for input. *varName* represents the name of an exported variable from the DLL. It must be a character string terminated with the NULL character.

This function is not available under SPC, MTF and CSP environments.

Returned value

If successful, *dllqueryvar()* returns a pointer to a variable in the storage of the DLL.

If unsuccessful, *dllqueryvar()* returns NULL and sets *errno*.

Usage notes

1. More detailed diagnostic information is available through the `_EDC_DLL_DIAG` environment variable, and the Language Environment DLL Failure control block (CEEDLLF) chain.

Example

CELEBDL3

```

/* CELEBDL3

The following example shows how to use dllqueryvar() to obtain a
pointer to a variable, var1, that is in DLL load module stream.

*/
#include <stdio.h>
#include <dll.h>

int main() {
    dllhandle *handle;
    char *name="stream";
    int (*fptr1)(int);

```

```

int *ptr_var1;
int rc=0;

handle = dlopen(name);
if (handle == NULL) {
    perror("failed on dlopen of stream DLL");
    exit(-1);
}

fptr1 = (int (*)(int)) dlsym(handle,"f1");
/* retrieving f1 function */
if (fptr1 == NULL) {
    perror("failed on retrieving f1 function");
    exit(-2);
}

ptr_var1 = dlsym(handle,"var1");
if (ptr_var1 == NULL) {
    perror("failed on retrieving var1 variable");
    exit(-3);
}
}

```

dn_comp() — Resolver domain name compression

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| BSD 4.3 | both | OS/390 V2R8 |

Format

```

#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
#include <netinet/in.h>
#include <arpa/nameser.h>
#include <resolv.h>

int dn_comp(const char *exp_dn, u_char *comp_dn, int length,
            u_char **dnptrs, u_char **lastdnptr);

```

General description

The `dn_comp()` function compresses the domain name `exp_dn` and stores it in `comp_dn`. The size of the compressed name is returned or -1 if there were errors. The size of the array pointed to by `comp_dn` is given by `length`. The compression uses an array of pointers `dnptrs` to previously-compressed names in the current message. The first pointer points to the beginning of the message and the list ends with NULL. The limit to the array is specified by `lastdnptr`.

A side effect of `dn_comp()` is to update the list of pointers for labels inserted into the message as the name is compressed. If `dnptr` is NULL, names are not compressed. If `lastdnptr` is NULL, the list of labels is not updated.

Note: The `dn_comp()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support” on page 2123](#) for details.

Returned value

If successful, `dn_comp()` returns the size of the compressed name.

If unsuccessful, `dn_comp()` returns -1 to report the error, when the name to be compressed was not found before the end of the buffer was reached.

There are no documented `errno` values.

dn_expand() — Resolver domain name expansion

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| BSD 4.3 | both | OS/390 V2R8 |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
#include <netinet/in.h>
#include <arpa/nameser.h>
#include <resolv.h>

int dn_expand(const u_char *msg, const u_char *eomorig,
              const u_char *comp_dn, char *exp_dn, int length);
```

General description

The `dn_expand()` function expands the compressed domain name *comp_dn* to a full domain name. The compressed name is contained in a query or reply message; *msg* is a pointer to the beginning of the message. The expanded name is placed in the buffer indicated by *exp_dn* which is of size *length*. The size of the expanded name is returned or -1 if there was an error.

Note: The `dn_expand()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support ” on page 2123](#) for details.

Returned value

If successful, dn_expand() returns the size of the expanded name.

If unsuccessful, dn_expand() returns -1 to report the error, when the name to be expanded was not found before the end of the buffer was reached.

There are no documented errno values.

dn_find() — Resolver domain name find

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| BSD 4.3 | both | OS/390 V2R8 |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
#include <netinet/in.h>
#include <arpa/nameser.h>
#include <resolv.h>

int dn_find(u_char *exp_dn, u_char *msg, u_char **dnptrs, u_char **lastdnptr);
```

General description

The dn_find() function will search for the expanded name *exp_dn* in the list of previously compressed names *dnptrs*.

dnptrs is the pointer to the first name in the list, not the pointer to the start of the message. The limit to the array is specified by *lastdnptr*.

Note: The dn_find() function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support ” on page 2123](#) for details.

Returned value

If successful, `dn_find()` returns the offset of the expanded name *exp_dn* found in the message.

If unsuccessful, `dn_find()` returns -1 to report the error, when the name was not found before the end of the list was reached.

There are no documented `errno` values.

dn_skipname() — Resolver domain name skipping

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| BSD 4.3 | both | OS/390 V2R8 |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
#include <netinet/in.h>
#include <arpa/nameser.h>
#include <resolv.h>

int dn_skipname(const u_char *comp_dn, u_char *eom);
```

General description

The `dn_skipname()` function skips the compressed domain name *comp_dn* and returns the position in the answer buffer that follows the *comp_dn* compressed domain name. If the information supplied in *comp_dn* is not a compressed domain name, -1 is returned to report the error.

Note: The `dn_skipname()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support ” on page 2123](#) for details.

Returned value

If successful, `dn_skipname()` returns the position in the answer buffer that follows the *comp_dn* compressed domain name.

If unsuccessful, `dn_skipname()` returns -1 to report the error, when the name to be skipped was not found before the end of the buffer was reached.

There are no documented `errno` values.

dprintf() — Print to a file descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1-2008 Single UNIX Specification, Version 4 | both | |

Format

```
#define _POSIX_C_SOURCE 200809L
#include <stdio.h>

int dprintf(int fd, const char *restrict format, ...);
```

General description

`dprintf()` is exact analogs of `fprintf()` and `vfprintf()`, except that `dprintf()` outputs to a file descriptor *fd* instead of to a `stdio` stream.

Returned value

If successful, `dprintf()` returns the number of characters output. The ending NULL character is not counted.

If unsuccessful, `dprintf()` returns a negative and `errno` is set to indicate the error.

Related information

- “fprintf(), printf(), sprintf() — Format and write data” on page 593

drand48() — Pseudo-random number generator

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <stdlib.h>

double drand48(void);
```

General description

The drand48(), erand48(), jrand48(), lrand48(), mrand48() and nrand48() functions generate uniformly distributed pseudo-random numbers using a linear congruential algorithm and 48-bit integer arithmetic.

The functions drand48() and erand48() return nonnegative, double-precision, floating-point values, uniformly distributed over the interval [0.0,1.0). These functions have been extended so that the returned value will be in the proper floating-point format (hexadecimal or IEEE) based on the floating-point mode of the invoking thread.

The functions lrand48() and nrand48() return nonnegative, long integers, uniformly distributed over the interval [0,2**31).

The functions mrand48() and jrand48() return signed long integers, uniformly distributed over the interval [-2**31,2**31).

The drand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, X(i), according to the linear congruential formula:

$$X(n+1) = (aX(n) + c) \bmod (2^{**}48) \quad n \geq 0$$

The initial values of X, a, and c are:

```
X(0) = 1
a    = 5deece66d (base 16)
c    = b          (base 16)
```

C/370 provides storage to save the most recent 48-bit integer value of the sequence, X(i). This storage is shared by the drand48(), lrand48() and mrand48() functions. The value, X(n), in this storage may be reinitialized by calling the lcong48(), seed48() or srand48() function. Likewise, the values of a and c, may be changed by calling the lcong48() function. Thereafter, whenever the seed48() or srand48() function is called to change X(n), the initial values of a and c are also reestablished.

Special behavior for z/OS UNIX Services: You can make the drand48() function and other functions in the drand48 family thread-specific by setting the environment variable _RAND48 to the value THREAD before calling any function in the drand48 family.

If you do not request thread-specific behavior for the drand48 family, C/370 serializes access to the storage for X(n), a and c by functions in the drand48 family when they are called by a multithreaded application.

If thread-specific behavior is requested, and the drand48() function is called from thread t, the drand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, X(t,i), for the thread t. The sequence of values for a thread is generated according to the linear congruential formula:

$$X(t,n+1) = (a(t)X(t,n) + c(t))\text{mod}(2^{**}48) \qquad n \geq 0$$

The initial values of X(t), a(t) and c(t) for the thread t are:

$$\begin{aligned} X(t,0) &= 1 \\ a(t) &= 5deece66d \quad (\text{base } 16) \\ c(t) &= b \quad (\text{base } 16) \end{aligned}$$

C/370 provides storage which is specific to the thread t to save the most recent 48-bit integer value of the sequence, X(t,i), generated by the drand48(), lrand48() or mrand48() function. The value, X(t,n), in this storage may be reinitialized by calling the lcong48(), seed48() or srand48() function from the thread t. Likewise, the values of a(t) and c(t) for thread t may be changed by calling the lcong48() function from the thread. Thereafter, whenever the seed48() or srand48() function is called from the thread t to change X(t,n), the initial values of a(t) and c(t) are also reestablished.

Returned value

drand48() transforms the generated 48-bit value, X(n+1), to a double-precision, floating-point value on the interval [0.0,1.0) and returns this transformed value.

Special behavior for z/OS UNIX Services: If thread-specific behavior is requested for the drand48 family and rand48() is called on thread t, drand48() transforms the generated 48-bit value, X(t,n+1), to a double-precision, floating-point value on the interval [0.0,1.0) and returns this transformed value.

dup() – Duplicate an open file descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

int dup(int filde);
```

General description

Returns a new file descriptor that is the lowest numbered available descriptor. The new file descriptor refers to the same open file as *filde* and shares any locks that may be associated with *filde*.

The following operations are equivalent:

```
fd = dup(filde);
fd = fcntl(filde, F_DUPFD, 0);
```

For further information, see [“fcntl\(\) — Control open file descriptors”](#) on page 483.

Note: When *filde* is an XTI endpoint, the lowest numbered available file descriptor must not exceed 65535.

Returned value

If successful, `dup()` returns a new file descriptor.

If unsuccessful, `dup()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

filde is not a valid open file descriptor.

EMFILE

The process has already reached its maximum number of open file descriptors.

Example

CELEBD05

```
/* CELEBD05

   This example duplicates an open file descriptor, using dup().

*/
#define _POSIX_SOURCE
#include <errno.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

void print_inode(int fd) {
    struct stat info;
    if (fstat(fd, &info) != 0)
        fprintf(stderr, "fstat() error for fd %d: %s\n", fd, strerror(errno));
    else
        printf("The inode of fd %d is %d\n", fd, (int) info.st_ino);
}

main() {
    int fd;
    if ((fd = dup(0)) < 0)
        perror("&dupf error");
    else {
        print_inode(0);
        print_inode(fd);
        puts("The file descriptors are different but");
        puts("they point to the same file.");
        close(fd);
    }
}
```

```
    }
}
```

Output

```
The inode of fd 0 is 30
The inode of fd 3 is 30
The file descriptors are different but
they point to the same file.
```

dup2() — Duplicate an open file descriptor to another

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

int dup2(int fd1, int fd2);
```

General description

Returns a file descriptor with the value *fd2*. *fd2* now refers to the same file as *fd1*, and the file that was previously referred to by *fd2* is closed. The following conditions apply:

- If *fd2* is less than 0 or greater than OPEN_MAX, dup2() returns -1 and sets errno to EBADF.
- If *fd1* is a valid file descriptor and is equal to *fd2*, dup2() returns *fd2* without closing it; F_CLOEXEC is not cleared.
- If *fd1* is not a valid file descriptor, dup2() fails and does not close *fd2*.
- If a file descriptor does not already exist, dup2() can be used to create one, a duplicate of *fd1*. F_CLOEXEC is cleared in *fd2*.

Note: If *fd1* is an XTI endpoint, *fd2* must not exceed 65535.

Returned value

If successful, dup2() returns *fd2*.

If unsuccessful, `dup2()` returns -1 and sets `errno` to one of the following values:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

| | |
|--------------|---|
| EBADF | <i>fd1</i> is not a valid file descriptor, or <i>fd2</i> is less than 0 or greater than OPEN_MAX . |
| EINTR | <code>dup2()</code> was interrupted by a signal. |

Example

CELEBD06

```
/* CELEBD06

   This example duplicates an open file descriptor, using dup2().

*/

#define _POSIX_SOURCE
#include <errno.h>
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

void print_inode(int fd) {
    struct stat info;
    if (fstat(fd, &info) != 0)
        fprintf(stderr, "fstat() error for fd %d: %s\n", fd, strerror(errno));
    else
        printf("The inode of fd %d is %d\n", fd, (int) info.st_ino);
}

main() {
    int fd;
    char fn[]="dup2.file";

    if ((fd = creat(fn, S_IWUSR)) < 0)
        perror("creat() error");
    else {
        print_inode(fd);
        if ((fd = dup2(0, fd)) < 0)
            perror("dup2() error");
        else {
            puts("After dup2()...");
            print_inode(0);
            print_inode(fd);
            puts("The file descriptors are different but they");
            puts("point to the same file which is different than");
            puts("the file that the second fd originally pointed to.");
            close(fd);
        }
        unlink(fn);
    }
}
```

Output

```
The inode of fd 3 is 3031
After dup2()...
The inode of fd 0 is 30
The inode of fd 3 is 30
The file descriptors are different but they
point to the same file which is different than
the file that the second fd originally pointed to.
```

dup3() — Duplicate an open file descriptor with flag setting

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <unistd.h>

int dup3(int oldfd, int newfd, int flags);
```

General description

The interface of `dup3()` is the same as `dup2()` except that:

- The caller can force the close-on-exec flag to be set for the new file descriptor by specifying `O_CLOEXEC` in `flags`.
- If `oldfd` equals `newfd`, `dup3()` fails with the error `EINVAL`.

Returned value

If successful, `dup3()` returns the new file descriptor.

If unsuccessful, `dup3()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

`oldfd` is not an open file descriptor, or `newfd` is out of the allowed range for file descriptors.

EINTR

`dup3()` is interrupted by a signal, or `flags` contain an invalid value, or `oldfd` is equal to `newfd`.

EMFILE

The per-process limit on the number of open file descriptors is reached.

dynalloc() — Allocate a data set

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C Library | both | |

Format

```
#include <dynit.h>

int dynalloc(__dyn_t *dyn_parms);
```

General description

The `dynalloc()` function dynamically allocates a MVS data set using the MVS SVC 99 service and by building an SVC 99 parameter list based on parameters specified in `dyn_parms`. The `dynalloc()` function corresponds to verb code 1 for SVC 99. To use other SVC 99 verb codes, see [“svc99\(\) — Access supervisor call”](#) on page 1781.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

The request block extension and the error message parameter list can be used to process the messages returned by SVC99 when an error occurs. To use this feature you must allocate and initialize these structures using the processes described in [z/OS MVS Programming: Authorized Assembler Services Guide](#). You must also make them available to the `dynalloc()` function by assigning their addresses to `__rbx` or `__emsgparmlist`.

Because additional fields have been added to the `__dyn_t` structure, you should recompile existing source code with the latest `dynit.h` header file to access the new fields.

Some values, such as `ddname` and `dsname`, will be converted to uppercase internally when they are used by the `dynalloc()` function.

To dynamically allocate an MVS data set, you should:

- Invoke the `dyninit()` function with a variable of type `__dyn_t`.
- Assign values to the appropriate fields in the variable that will satisfy the `svc99()` request.
- Invoke the `dynalloc()` function with this variable.

[Table 21](#) on page 409 describes the elements that are part of the `__dyn_t` structure, organized as defined in the structure.

Note: For more complete information about the `__dyn_t` structure elements, their usage and restrictions, see the description of SVC 99, the SVC 99 extension block, and the text unit keys and values in [z/OS MVS Programming: Authorized Assembler Services Guide](#) and [z/OS MVS JCL Reference](#).

Table 21. Description of `__dyn_t` Structure Elements

| Element | Text Unit Key | Text Unit Value | Type | Description |
|-----------------------|---------------|-----------------|--------|--|
| <code>__ddname</code> | DALDDNAM | 0001 | char * | ddname (maximum length of 8) ¹ . If 8 question marks (???????) are specified, it means that the request expects a system-generated ddname returned. |
| <code>__dsname</code> | DALDSNAM | 0002 | char * | Fully qualified data-set name (maximum length of 44) ¹ . |

Table 21. Description of __dyn_t Structure Elements (continued)

| Element | Text Unit Key | Text Unit Value | Type | Description |
|--------------|----------------|-----------------|--------|---|
| __sysout | DALYSOU | 0018 | char | The class of the system output data set (for example, SYSOUT=A). Values are: alphabetic character, or the macro __DEF_CLASS, to specify the default class. |
| __sysoutname | DALSPGNM | 0019 | char * | Program name for sysout. The __sysout field must be specified with this field (maximum length of 8) ¹ . |
| __member | DALMEMBR | 0003 | char * | Member of a partitioned data set to be allocated (maximum length of 8) ¹ . |
| __status | DALSTATS | 0004 | char | Data set status. Values are: __DISP_OLD, __DISP_NEW, __DISP_MOD, and __DISP_SHR, which are defined in dynit.h. |
| __normdisp | DALNDISP | 0005 | char | Specifies the normal disposition of a data set. Values are: __DISP_CATLG, __DISP_UNCATLG, __DISP_DELETE, and __DISP_KEEP, which are defined in dynit.h. |
| __condisp | DALCDISP | 0006 | char | Specifies the conditional disposition of a data set. Values are: __DISP_CATLG, __DISP_UNCATLG, __DISP_DELETE, and __DISP_KEEP, which are defined in dynit.h. |
| __unit | DALUNIT | 0015 | char * | Unit name of the device that the data set will (or does, if it already exists) reside on (maximum length of 8) ¹ . |
| __volser | DALVLSER | 0010 | char * | Volume serial number of the device a data set will (or does, if it already exists) reside on (maximum length of 6) ¹ . |
| __dsorg | DALDSORG | 003C | char | Data set organization of a data set. Values are: __DSORG_unknown Unknown __DSORG_VSAM VSAM __DSORG_GS Graphics __DSORG_PO Partitioned organization __DSORG_POU Partitioned organization unmovable __DSORG_DA Direct access __DSORG_DAU Direct access unmovable __DSORG_PS Physical sequential __DSORG_PSU Physical sequential unmovable. |
| __alcunit | DALCYL, DALTRK | 0008, 0007 | char | Unit of space allocation for a data set. Values are: __CYL and __TRK. To specify allocation units in blocks, use the field __avgbk. |
| __primary | DALPRIME | 000A | int | Primary space allocation for a data set. |
| __secondary | DALSECND | 000B | int | Secondary space allocation for a data set. |

Table 21. Description of `__dyn_t` Structure Elements (continued)

| Element | Text Unit Key | Text Unit Value | Type | Description |
|---------------------------|---------------|-----------------|----------------|--|
| <code>__dirblk</code> | DALDIR | 000C | int | Number of directory blocks for a partitioned data set. |
| <code>__avgblk</code> | DALBLKLN | 0009 | int | Specifies the unit of space allocation to be blocks and sets the average block length. |
| <code>__recfm</code> | | 0049 | short | <p>Record format of a data set. The following macros in <code>dynit.h</code> can be added together to determine the <code>__recfm</code> value:</p> <p>_M_ Machine-code printer-control characters</p> <p>_A_ ASA printer-control characters</p> <p>_S_ Standard fixed, spanned variable</p> <p>_B_ Blocked</p> <p>_D_ Variable ASCII records</p> <p>_V_ Variable</p> <p>_F_ Fixed</p> <p>_U_ Undefined</p> <p>_FB_ Fixed blocked</p> <p>_VB_ Variable blocked</p> <p>_FBS_ Fixed blocked standard</p> <p>_VBS_ Variable blocked standard.</p> <p>For example, to specify a <code>recfm</code> of FBA, set: <code>_recfm = _FB_ + _A_</code></p> |
| <code>__blksize</code> | DALBLKSZ | 0030 | short | Block size of a data set. |
| <code>__lrecl</code> | DALLRECL | 0042 | unsigned short | Record length of a data set. |
| <code>__volrefds</code> | DALLVLRDS | 0014 | char * | Fully qualified name of a cataloged data set to be used as a model for obtaining volume serial information (maximum length of 44) ¹ . |
| <code>__dcbrefds</code> | DALDCBDS | 002C | char * | Fully qualified name of a cataloged data set to be used as a model for obtaining DCB information (maximum length of 44) ¹ . |
| <code>__dcbrefdd</code> | DALLDCBDD | 002D | char * | ddname of a data set to be used as a model for obtaining DCB information (maximum length of 9) ¹ . For more information, see <i>z/OS MVS Programming: Authorized Assembler Services Guide</i> . |
| <code>__misc_flags</code> | | | unsigned char | Specifies the attributes. See “ Example ” on page 414 for instructions on how to specify the flags shown below using a logical (OR). |
| <code>__CLOSE</code> | DALCLOSE | 001C | unsigned char | (Flag) Deallocate data set when file is closed. |

Table 21. Description of __dyn_t Structure Elements (continued)

| Element | Text Unit Key | Text Unit Value | Type | Description |
|-------------|---------------|-----------------|-----------------------------|---|
| __RELEASE | DALRLSE | 000D | unsigned char | (Flag) Release unused space when file is closed. |
| __CONTIG | DALSPFRM | 000E | unsigned char | (Flag) Allocate space contiguously. |
| __ROUND | DALROUND | 000F | unsigned char | (Flag) Allocate space in whole cylinders when blocks are requested. |
| __TERM | DALTERM | 0028 | unsigned char | (Flag) Time-sharing terminal is to be used as I/O device. |
| __DUMMY_DSN | DALDUMMY | 0024 | unsigned char | (Flag) Dummy data set is to be allocated. |
| __HOLDQ | DALSHOLD | 0059 | unsigned char | (Flag) Hold queue routing for sysout data set. |
| __PERM | DALPERMA | 0052 | unsigned char | (Flag) Set permanent allocation attribute. |
| __password | DALPASSW | 0050 | char * | Password for a password-protected data set. The dsname field must be specified with this field (maximum length of 8) ¹ . |
| __miscitems | | | char * __ptr32 * __ptr32 | For all other text unit keys not available in __dyn_t, this pointer will let you specify an array of text unit strings. If you specify this field, you must turn the high bit on the last item (as in svc99()). Use the bitwise inclusive-OR (I) operand with the last item and the hexadecimal value 0x80000000. |
| __infocode | | | short | Returns the information code returned by the MVS dynamic allocation functions. For more information, see z/OS MVS Programming: Authorized Assembler Services Guide . |
| __errcode | | | short | Returns the error code returned by the MVS dynamic allocation functions. For more information, see z/OS MVS Programming: Authorized Assembler Services Guide . |
| __storclass | DALSTCL | 8004 | char * | Specifies the storage class of system managed storage. |
| __mgntclass | DALMGCL | 8005 | char * | Specifies the management class of a data set. |
| __dataclass | DALDACL | 8006 | char * | Specifies the data class of a data set. |
| __recorg | DALRECO | 800B | char | Specifies the record organization of a VSAM data set. Values are: __KS, __ES, __RR, __LS. |
| __keyoffset | DALKEYO | 800C | short | Specifies the key offset. The position of the first byte of the key in records of the specified VSAM data set. |
| __keylength | DALKYLEN | 0040 | short | Specifies the length in bytes of the keys used in the data set. |
| __refdd | DALREFD | 800D | char * | Specifies the name of the JCL DD statement from which the attributes are to be copied. For more information, see z/OS MVS Programming: Authorized Assembler Services Guide . |
| __like | DALLIKE | 800F | char * | Specifies the name of the model data set from which the attributes are to be copied. |

Table 21. Description of `__dyn_t` Structure Elements (continued)

| Element | Text Unit Key | Text Unit Value | Type | Description |
|-----------------------------|---------------|-----------------|---|--|
| <code>__dsntype</code> | DALDSNT | 8012 | char | Specifies the type attributes of a data set. Valid types include <code>__DSNT_BASIC</code> , <code>__DSNT_EXTREF</code> , <code>__DSNT_EXTREQ</code> , <code>__DSNT_HFS</code> , <code>__DSNT_LARGE</code> , <code>__DSNT_LIBRARY</code> , <code>__DSNT_PDS</code> , and <code>__DSNT_PIPE</code> . |
| <code>__pathname</code> | DALPATH | 8017 | char * | Pathname (maximum length is 255) ¹ . See z/OS UNIX System Services User's Guide for the pathname format. |
| <code>__pathopts</code> | DALPOPT | 8018 | int | Specifies file options for the z/OS UNIX file. Values are: <code>__PATH_OCREAT</code> , <code>__PATH_OAPPEND</code> , <code>__PATH_OEXCL</code> , <code>__PATH_ONOCTTY</code> , <code>__PATH_OTRUNC</code> , <code>__PATH_ONONBLOCK</code> , <code>__PATH_ORDONLY</code> , <code>__PATH_OWONLY</code> , <code>__PATH_ORDWR</code> . For information about the file options, see z/OS MVS JCL Reference . For information about DYNALLOC, see z/OS MVS Programming: Authorized Assembler Services Guide . |
| <code>__pathmode</code> | DALPMDE | 8019 | int | Specifies the file access attributes for the z/OS UNIX file. Values are: <code>__PATH_SIRUSR</code> , <code>__PATH_SIWUSR</code> , <code>__PATH_SIXUSR</code> , <code>__PATH_SIRWXU</code> , <code>__PATH_SIRGRP</code> , <code>__PATH_SIWGRP</code> , <code>__PATH_SIXGRP</code> , <code>__PATH_SIRWXG</code> , <code>__PATH_SIROTH</code> , <code>__PATH_SIWOTH</code> , <code>__PATH_SIXOTH</code> , <code>__PATH_SIRWXO</code> , <code>__PATH_SISUID</code> , <code>__PATH_SISGID</code> . For information on the file attributes, refer to z/OS MVS JCL Reference . For information on DYNALLOC, refer to z/OS MVS Programming: Authorized Assembler Services Guide . |
| <code>__pathndisp</code> | DALPNDS | 801A | char | Specifies the normal z/OS UNIX file disposition desired. It is either <code>__DISP_KEEP</code> or <code>__DISP_DELETE</code> . |
| <code>__pathcdisp</code> | DALPCDS | 801B | char | Specifies the abnormal z/OS UNIX file disposition desired. It is either <code>__DISP_KEEP</code> or <code>__DISP_DELETE</code> . |
| <code>__rbx</code> | | | <code>__S99rbx_t *</code> <code>__ptr32</code> | For users who make use of the Request Block Extension. |
| <code>__emsgparmlist</code> | | | <code>__S99emparms_t *</code> <code>__ptr32</code> | For users who want to process associated messages with the dynamic allocation. |
| <code>__rls</code> | DALRLS | 801C | char | Specifies the type of record level sharing (RLS) being done for a specific data set. The valid values are <code>__RLS_NRI</code> , <code>__RLS_CR</code> and <code>__RLS_CRE</code> . See z/OS XL C/C++ Programming Guide and z/OS DFSMS Using Data Sets for a description of these VSAM RLS/TVS access modes. |

¹ If an element exceeds its maximum allowable length, it is truncated to that length.

Special behavior for POSIX C: For POSIX C programs, allocations established by the `dynalloc()` function persist neither after an `exec` nor in the child process after `fork()`.

Special behavior for enhanced ASCII: When compiled ASCII, there is one input element in the `__dyn_t` structure that must contain EBCDIC text strings and there is a consideration to note with respect to retrieval of error messages related to a dynamic allocation failure. On input, any character data provided in `__miscitems` must be specified in the EBCDIC codeset. The `__dynalloc()` function does not decode

the text units and convert the character data. The text units are passed directly to the system. When `__emsgparmlist` is specified, indicating intent to retrieve error messages using the IEFDB476 service, it should be noted that all error messages returned by the service will be in the EBCDIC codeset.

Note: The `dynamalloc()` function has a dependency on the level of the enhanced ASCII extensions. See “Enhanced ASCII support” on page 2123 for details.

Special behavior for AMODE 64: The definitions in the `__dyn_t` structure are changed to require three of its pointer elements to be 32 bits wide. This is because the system services that work with these control structures require 31-bit addressable storage. The `__miscitems` are additional text units that are not already supported by elements of the `__dyn_t` structure. These are propagated by the `dynamalloc()` function directly to into an SVC 99 call. The `__rbx` is propagated by the `dynamalloc()` function directly into an SVC 99 call. The `__emsgparmlist` address is designed to be passed as a parameter to the IEFDB476 service, which is an AMODE 31 service, to retrieve messages associated with a dynamic allocation failure. The `__dyn_t` structure itself can be in 64-bit addressable storage. The `__dyn_t` structure must be initialized using the `dyninit()` macro defined in `dyninit.h` to ensure the proper "hidden" version indicator is used. Improper initialization of the `__dyn_t` structure will result in undefined behavior.

Returned value

If successful under the MVS environment, the `dynamalloc()` function returns 0.

If SVC 99 is not supported on your system, or if a text string passed to SVC 99 cannot be built from a field in `dyn_parms`, a negative value is returned.

The value -1 is returned if there is not sufficient storage to process all the text units. Otherwise, the return code is the value returned from SVC 99, and the error and information codes are found in those fields in `dyn_parms`.

For example, if you pass NULL to the `dynamalloc()` function, the return code is nonzero.

For more information about return codes, see [z/OS MVS Programming: Authorized Assembler Services Guide](#).

Example

CELEBD07

```
/* CELEBD07

   This example dynamically allocates a data set.

*/
#include <dynit.h>
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define ZERO 0

int main () {
    __dyn_t ip;

    dyninit(&ip);

    ip.__ddname = "mydd";
    ip.__dsname = "PLIXXX.MY.DATASET";
    ip.__status = __DISP_NEW;
    ip.__normdisp = __DISP_CATLG;
    ip.__alcunit = __CYL;
    ip.__primary = 2;
    ip.__secondary = 1;
    ip.__dirblk = 1;
    ip.__misc_flags = __RELEASE & __CONTIG;
    ip.__dsorg = __DSORG_PO;
    ip.__recfm = __F + __B + __A;
    ip.__lrecl = 121;
    ip.__blksize = 12100;

    /* MYDD DD */
    /* DSN='PLIXXX.MY.DATASET' */
    /* DISP=(NEW,CATLG) */
    /* SPACE=(CYL,(2,1)), */
    /* RLSE,CONTIG) */
    /* DCB=(DSORG=PO, */
    /* RECFM=FBA, */
    /* LRECL=121, */
    /* BLKSIZE=12100) */
}
```

```

    if (dynalloc(&ip) != ZERO)
    {
        printf("Dynalloc failed with error code %d, info code %d\n",
               ip.__errcode, ip.__infocode);
    }
}

```

Related information

- [“dynit.h — Dynamic allocation routines” on page 19](#)
- [“dynfree\(\) — Deallocate a data set” on page 415](#)

dynfree() — Deallocate a data set

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C Library | both | |

Format

```

#include <dynit.h>

int dynfree(__dyn_t *dyn_parms);

```

General description

Dynamically deallocates a z/OS data set in accordance with the attributes defined in *dyn_parms*.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

The only fields in `__dyn_t` that are used by `dynfree()` are:

```

char *__ddname
char *__dsname
char *__member
char *__pathname
char __normdisp
char __pathndisp
char **__miscitems

```

If any other fields are specified, they will be ignored. For more information on the `__dyn_t` structure, see [Table 21 on page 409](#)

To dynamically deallocate a data set on z/OS, you should:

- Invoke `dyninit()` with a variable of type `__dyn_t`
- Assign values to the appropriate fields that will satisfy the `svc99()` request
- Invoke `dynfree()` with this variable.

Note: The `dynfree()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support ” on page 2123](#) for details.

Returned value

If successful under z/OS, dynfree() returns 0.

If unsuccessful, dynfree() returns nonzero. dynfree() returns -1 if there is not sufficient storage to process all the text units.

Example

```
/* This example dynamically deallocates a data set.
 */
#include <dynit.h>

int main(void) {
:
:   __dyn_t ip;
:
:   dyninit(ip);
:   ip.__ddname = "mydd";
:
:   dynfree(&ip);
:
: }
```

Related information

- [“dyninit\(\) — Initialize __dyn_t structure” on page 416](#)
- [“svc99\(\) — Access supervisor call” on page 1781](#)

dyninit() — Initialize __dyn_t structure

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C Library | both | |

Format

```
#include <dynit.h>

int dyninit(__dyn_t *dyn_parms);
```

General description

Initializes the __dyn_t structure that is used to build the parameter lists that are passed to the dynalloc() function and the dynfree() function. If you do not initialize the __dyn_t structure using dyninit(), undefined behavior may result.

The __dyn_t structure is defined in the dynit.h header file. A description of the elements is found in [“dynalloc\(\) — Allocate a data set” on page 409](#).

Returned value

If successful under the [MVS environment](#), dyninit() returns 0.

If unsuccessful, dyninit() returns nonzero.

Example

CELEBD09

```
/* CELEBD09

   This example initializes a __dyn_t
   structure, called ip.

   */
#include <stdio.h>
#include <string.h>
#include <dynit.h>

main() {
    char dsn[]="USER.TEST.DATASET";
    __dyn_t ip;
    int ret;

    dyninit(&ip);
    ip.__ddname  = "TEST";
    ip.__dsname  = dsn;
    ip.__status  = __DISP_NEW;
    ip.__normdisp = __DISP_DELETE;
    ip.__alcunit = __TRK;
    ip.__primary  = 1;
    ip.__unit     = "SYSDA  ";

    if ((ret = dynalloc(&ip)) != 0)
        printf("dynalloc() ret=%d, error code %04x, info code %04x\n",
               ret, ip.__errcode, ip.__infocode);

    else {
        dyninit(&ip);
        ip.__ddname  = "TEST";

        if ((ret = dynfree(&ip)) != 0)
            printf("dynfree() ret=%d, error code %04x, info code %04x\n",
                   ret, ip.__errcode, ip.__infocode);

        else puts("success!");
    }
}
```

ecvt() — Convert double to string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

char *ecvt(double x, int ndigit, int *__restrict__ decpt, int *__restrict__ sign);
```

General description

The `ecvt()` function converts double floating-point argument values to floating-point output strings. The `ecvt()` function has been extended to determine the floating-point format (hexadecimal floating-point or IEEE Binary Floating-Point) of double argument values by using `__isBFP()`.

IBM z/OS C++ formatted output functions, including the `ecvt()` function, convert IEEE Binary Floating-Point infinity and NaN argument values to special infinity and NaN floating-point number output sequences. See [“fprintf Family of Formatted Output Functions”](#) on `fprintf()`, `printf()`, `sprintf()` — Format and write data for a description of the special infinity and NaN output sequences.

The `ecvt()` function converts `x` to a NULL-terminated string of `ndigit` digits (where `ndigit` is reduced to an unspecified limit determined by the precision of a double) and returns a pointer to the string. The high-order digit is nonzero, unless the value is 0. The low-order digit is rounded. The position of the radix character relative to the beginning of the string is stored in the integer pointed to by `decpt` (negative means left of the returned digits). The radix character is not included in the returned string. If the sign of the result is negative, the integer pointed to by `sign` is nonzero, otherwise it is 0.

The function returns a pointer to a buffer used only by the calling thread which may be overwritten by subsequent calls to `ecvt()`, [“fcvt\(\) — Convert double to string”](#) on page 493 and [“gcvt\(\) — Convert double to string”](#) on page 684.

If the converted value is out of range or is not representable, the function returns NULL.

Note: This function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The `sprintf()` function is preferred for portability.

Returned value

If successful, `ecvt()` returns the character equivalent of `x` as specified above.

If unable to allocate the return buffer, or the conversion fails, `ecvt()` returns NULL.

encrypt() — Encoding function

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <unistd.h>

void encrypt(char block[64], int edflag);
```

General description

The `encrypt()` function uses an array of 16 48-bit keys produced by the `setkey()` function to encode bytes specified by the *block* argument according to the Data Encryption Standard (DES) encryption algorithm or to decode argument bytes according to the DES decryption algorithm.

The *block* argument of `encrypt()` is an array of length 64 bytes containing only the bytes with numerical value of 0 and 1. The array is modified in place using keys produced by `setkey()`. If *edflag* is 0, the argument is encoded using the DES encryption algorithm. If *edflag* is 1 the argument is decoded using the DES decryption algorithm.

Special behavior for z/OS UNIX Services: The `encrypt()` function is thread-specific. Thus, for each thread from which the `encrypt()` function is called by a threaded application, the `setkey()` function must first be called from the thread to establish a DES key array for the thread.

Returned value

`encrypt()` returns no values.

Special behavior for z/OS UNIX Services: `encrypt()` will set `errno` to one of the following values:

Error Code

Description

EINVAL

64 byte input array contains bytes with values other than 0x00 or 0x01.

ENOMEM

If `setkey()` has not been called or failed to produce a DES key array for the thread from which `encrypt()` is called.

ENOSYS

If DES key array exists for thread from which `encrypt()` is called to decode data.

Note: Because `encrypt()` returns no values, applications wishing to check for errors should set `errno` to 0, call `encrypt()`, then test `errno` and, if it is nonzero, assume an error has occurred.

endgrent() — Group database entry functions

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <grp.h>

void endgrent(void),
struct group *getgrent (void);
void setgrent(void);
```

General description

The `getgrent()` function returns a pointer to the broken-out fields of a line in the group database, mapped by the **group** structure defined in the `<grp.h>` header file. Repeated calls to `getgrent()` return a pointer to the next **group** structure in the database, until End Of File (EOF), at which point a NULL pointer is returned. `setgrent()` interrupts this sequential search and rewinds the user database to the beginning, such that the next `getgrent()` returns a pointer to the first **group** structure. Use of `setgrent()` is optional after an End Of File (EOF), as the next `getgrent()` after end of file again returns a pointer to the first **group** structure. `endgrent()` is optionally used to close the user database when searching is complete.

The `setgrent()` function effectively rewinds the group database to allow repeated searches.
The `endgrent()` function may be called to close the group database when processing is complete.

Returned value

When first called, `getgrent()` returns a pointer to the next group structure in the group database. Upon subsequent calls it returns a pointer to a group structure, or it returns a NULL pointer on either End Of File (EOF) or an error. The return value may point to static data that is overwritten by each call.
There are no documented `errno` values.

endhostent() — Close the host information data set

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

void endhostent(void);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

void endhostent();
```

General description

The `endhostent()` function closes the local host tables, which contains information about known hosts.

You can use the **X_SITE** environment variable to specify different local host tables and override those supplied by the z/OS global resolver during initialization. For more information on these local host tables or the environment variables, see [z/OS Communications Server: IP Configuration Guide](#).

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

endnetent() — Close network information data sets

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format**X/Open:**

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

void endnetent();
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

void endnetent();
```

General description

The `endnetent()` function closes the `tcpip.HOSTS.ADDRINFO` data set. The `tcpip.HOSTS.ADDRINFO` data set contains information about known networks.

You can use the **X_ADDR** environment variable to specify a data set other than `tcpip.HOSTS.ADDRINFO`. For more information on these data sets and environment variables, see [z/OS Communications Server: IP Configuration Guide](#).

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

endpwent() – User database functions

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 z/OS UNIX | Both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <pwd.h>

void endpwent(void),
struct passwd *getpwent(void);
void setpwent(void);

#define _XPLATFORM_SOURCE 1
#include <pwd.h>
int getpwent_r(struct passwd *pwbuf, char *buf, size_t buflen, struct passwd **pwbufp);
```

General description

The `getpwent()` function returns a pointer to the broken-out fields of a line in the user database, which is mapped by the `passwd` structure that is defined in the `<pwd.h>` header file. The `passwd` structure is saved in a thread-specific storage that is reused in each call by the same thread. Repeated calls to `getpwent()` return a pointer to the next `passwd` structure in the database until End Of File (EOF), at which point a NULL pointer is returned.

`setpwent()` interrupts this sequential search and rewinds the user database to the beginning, such that the next `getpwent()` returns a pointer to the first `passwd` structure. Use of `setpwent()` is optional after an End Of File (EOF), as the next `getpwent()` after end of file again returns a pointer to the first `passwd` structure. `endpwent()` is optionally used to close the user database when searching is complete.

The `setpwent()` function effectively rewinds the user database to allow repeated searches.

The `endpwent()` function might be called to close the user database when processing is complete.

The `getpwent_r()` function is the reentrant version of `getpwent()`. The `passwd` structure that is returned as a pointer `pwbufp` is saved in the caller-supplied buffer `pwbuf`. The string fields that are associated with the `passwd` structure are saved in the caller-supplied buffer `buf` of size `buflen`.

Returned value

When first called, `getpwent()` returns a pointer to the next `passwd` structure in the user database. Upon subsequent calls, `getpwent()` returns a pointer to a `passwd` structure, or it returns a NULL pointer on either End Of File (EOF) or an error. The return value might point to static data that is overwritten by each call.

If unsuccessful, `getpwent()` sets `errno` to one of the following values:

Error Code

Description

EMVSSAF2ERR

The system authorization facility (SAF) or RACF Get GMAP service had an error.

EMVSSAFEXTRERR

The SAF or RACF RACROUTE EXTRACT service had an error.

If successful, `getpwent_r()` returns zero with `*pwbufp` set to the pointer of the passwd structure. If unsuccessful, `getpwent_r()` returns a non-zero value with `*pwbufp` set to NULL and sets `errno` to one of the following values:

Error Code
Description

EINVAL
Invalid parameter supplied.

EMVSSAF2ERR
The system authorization facility (SAF) or RACF Get GMAP service had an error.

EMVSSAFEXTRERR
The SAF or RACF RACROUTE EXTRACT service had an error.

ENOENT
No more entries.

ERANGE
Insufficient buffer space supplied. Try again with larger buffer.
`endpwent()` and `setpwent()` do not set `errno`.

endservent() – Close network services information data sets

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

void endservent(void);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

void endservent();
```

General description

The `endservent()` function closes the `/etc/services` or the `tcpip.ETC.SERVICES` data set, which contains information about network services. Example services are name server, File Transfer Protocol (FTP), and telnet.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

endutxent() — Close the utmpx database

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <utmpx.h>

void endutxent(void);
```

General description

The `endutxent()` function closes the utmpx database for the current thread. The database may be opened by `getutxent()/getutxent64()`, `getutxid()/getutxid64()`, `getutxline()/getutxline64()`, or `pututxline()/pututxline64()`.

Because the `endutxent()` function processes thread-specific data the `endutxent()` function can be used safely from a multithreaded application. If multiple threads in the same process open the database, then each thread opens the database with a different file descriptor. The thread's database file descriptor is closed when the calling thread terminates or the `endutxent()` function is called by the calling thread.

Programs must not reference the data passed back by `getutxent()/getutxent64()`, `getutxid()/getutxid64()`, `getutxline()/getutxline64()`, or `pututxline()/pututxline64()` after `endutxent()` has been called (the storage has been freed.)

After `getutxent()/getutxent64()`, `getutxid()/getutxid64()`, `getutxline()/getutxline64()`, or `pututxline()/pututxline64()`, the utmpx database is open. No other process can do `pututxline()` to this utmpx database until this process issues `endutxent()` or

`__utmpxname()` to close the utmpx database, or this process ends. You can cause all z/OS UNIX user logins/logouts to hang if you fail to `exit()` or issue `endutxent()` or `__utmpxname()`, and you have the `main/etc/utmpx` database open in your process. `endutxent()` resets the name of the next utmpx file to open back to the default. If you want to do additional utmpx operations using a nonstandard utmpx file name, you must reissue `__utmpxname()` after closing the utmpx database with `endutxent()`.

Returned value

`endutxent()` returns no values.

epoll_create(), epoll_create1() — Open an epoll file descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <sys/epoll.h>

int epoll_create(int size);
int epoll_create1(int flags);
```

General description

`epoll_create()` creates a new epoll instance and returns a file descriptor referring to that instance. The returned epoll instance can then be used to register interest in particular file descriptors by using the `epoll_ctl()` function.

`epoll_create()` takes a size argument that must be positive to stand for the number of file descriptors that the caller expected to add to the epoll instance.

`epoll_create1()` is similar to `epoll_create()` except that it has a *flags* argument. If *flags* is 0, `epoll_create1()` is the same as `epoll_create()`. The following value can be included in *flags* to obtain different behavior:

EPOLL_CLOEXEC

Set the close-on-exec (FD_CLOEXEC) flag on the new file descriptor.

Returned value

If successful, `epoll_create()` and `epoll_create1()` return a file descriptor (a nonnegative integer).

If unsuccessful, `epoll_create()` and `epoll_create1()` return -1 and sets `errno` to one of the following values:

Error Code Description

EINVAL

Invalid value specified in *flags* when using `epoll_create1()`.

EMFILE

The per-user limit on the number of `epoll` instances has been reached, or the maximum number of file descriptors that can be open is reached.

ENOMEM

Not enough space is available.

Related information

- [“sys/epoll.h — I/O event notification facility functions”](#) on page 68
- [“epoll_ctl\(\) — Control interface for an epoll file descriptor”](#) on page 427

epoll_ctl() — Control interface for an epoll file descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <sys/epoll.h>

int epoll_ctl(int epfd, int op, int fd, struct epoll_event *event);
```

Compile requirement: This function must be used under the [extended language level](#).

General description

`epoll_ctl()` adds, modifies, or removes file descriptor entries in the interest list of the `epoll` instance. The wanted I/O event might be registered for the specified file descriptor. The file descriptor can be for character special files, pipes, or sockets. The ready list can be retrieved by using the `epoll_wait()` function.

Interest list is the set of file descriptors that the process list an interest in monitoring. Ready list is the set of file descriptors that are "ready" for I/O. The ready list is a subset of the file descriptors in the interest list. The ready list is dynamically populated by the kernel as a result of I/O activity on those file descriptors.

Parameter Description

epfd

File descriptor of an `epoll` instance.

op

Wanted action to be performed on the provided `epoll` file descriptor. Valid values are:

EPOLL_CTL_ADD

Add an entry to the interest list of the `epoll` file descriptor, *epfd*. The entry includes the file descriptor *fd*, a reference to the corresponding open file description, and the settings specified in event.

EPOLL_CTL_MOD

Change the settings that are associated with *fd* in the interest list to the new settings that are specified in event.

EPOLL_CTL_DEL

Remove (unregister) the target file descriptor *fd* from the interest list.

fd

File descriptor that corresponds to an open file description.

event

The object that is linked to the file descriptor *fd*. The struct `epoll_event` is defined as:

```
typedef union epoll_data {
    void *ptr;
    int fd;
    uint32_t u32;
    uint64_t u64;
} epoll_data_t;

struct epoll_event {
    uint32_t events; /* Epoll events */
    epoll_data_t data; /* User data variable */
};
```

The data member of the `epoll_event` structure specifies data that the kernel must save and then return when this file descriptor becomes ready.

The events member of the `epoll_event` structure is a bit mask that is composed by ORing together zero or more of the following available event types:

EPOLLIN

The associated file is ready for read.

EPOLLOUT

The associated file is ready for write.

EPOLLPRI

Out-of-band data might be received without blocking.

EPOLLERR

An error occurs.

EPOLLHUP

A hang up occurs.

EPOLLONESHOT

Disable monitoring after event notification.

EPOLLEXCLUSIVE

Sets an exclusive wakeup mode for the `epoll` file descriptor. When a wakeup event occurs and multiple `epoll` file descriptors are attached to the same target file by using `EPOLLEXCLUSIVE`, one or more of the `epoll` file descriptors receive an event with `epoll_wait()`. The default in this scenario is for all `epoll` file descriptors to receive an event.

Returned value

If successful, `epoll_ctl()` returns 0.

If unsuccessful, `epoll_ctl()` returns -1 and sets `errno` to one of the following values:

Error Code**Description****EBADF**

epfd or *fd* is not a valid file descriptor.

EEXIST

op is `EPOLL_CTL_ADD`, and the supplied file descriptor *fd* is registered with the `epoll` instance.

EINVAL

epfd is not an epoll file descriptor, or *fd* is the same as *epfd*, or the requested operation *op* is not supported.

An invalid event type is specified along with EPOLLEXCLUSIVE in *event*.

op is EPOLL_CTL_MOD and events includes EPOLLEXCLUSIVE.

op is EPOLL_CTL_MOD and the EPOLLEXCLUSIVE flag is applied to the *epfd* and *fd* pair.

EPOLLEXCLUSIVE is specified in *event* and *fd* refers to an epoll instance.

ELOOP

fd refers to an epoll instance and this EPOLL_CTL_ADD operation results in a circular loop of epoll instances monitoring one another or a nesting depth of epoll instances greater than 5.

ENOENT

op is EPOLL_CTL_MOD or EPOLL_CTL_DEL, and *fd* is not registered with this epoll instance.

ENOMEM

Not enough memory is available.

ENOSPC

The per-user limit on how many file descriptors can be registered in the interest list is reached.

EPERM

The target file *fd* does not support epoll.

Related information

- [“sys/epoll.h — I/O event notification facility functions”](#) on page 68
- [“epoll_wait\(\), epoll_pwait\(\) — Wait for an I/O event on an epoll file descriptor”](#) on page 429

epoll_wait(), epoll_pwait() — Wait for an I/O event on an epoll file descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <sys/epoll.h>

int epoll_wait(int epfd, struct epoll_event *events, int maxevents, int timeout);
int epoll_pwait(int epfd, struct epoll_event *events, int maxevents, int timeout, const
sigset_t *sigmask);
```

Compile requirement: This function must be used under the [extended language level](#).

General description

`epoll_wait()` waits for the desired I/O events on an interest list that are registered with a provided epoll instance.

`epoll_pwait()` is similar to `epoll_wait()` except that it takes an additional *sigmask* argument that specifies the desired signal mask when `epoll_pwait()` is blocked.

Parameter**Description**

epfd

File descriptor of an `epoll` instance.

events

Buffer that is used to return information from the ready list about file descriptors in the interest list that have some events available.

maxevents

The maximum number of events that might be returned. This value must be greater than zero.

timeout

Timeout value in milliseconds that `epoll_wait()` or `epoll_pwait()` blocks. If the timeout value is 0, `epoll_wait()` or `epoll_pwait()` returns immediately with any file descriptors that are in the ready list, if any. If the timeout value is -1, `epoll_wait()` or `epoll_pwait()` blocks until a file descriptor is in the ready list. If the timeout value is positive, it specifies that the number of milliseconds to wait for a ready list to be populated before returning to the caller.

sigmask

Desired signal mask when `epoll_pwait()` is blocked.

Returned value

If successful, `epoll_wait()` and `epoll_pwait()` return the number of file descriptors that are ready for the requested I/O, or zero if no file descriptor become ready during the requested timeout milliseconds.

If unsuccessful, `epoll_wait()` and `epoll_pwait()` return -1 and set `errno` to one of the following values:

Error Code

Description

EBADF

epfd is not a valid file descriptor.

EFAULT

The memory area pointed to by events is not accessible with write permissions.

EINTR

The call is interrupted by a signal handler before either any of the requested events occurs or the timeout expires.

EINVAL

epfd is not an `epoll` file descriptor, or *maxevents* is less than or equal to zero.

- [“sys/epoll.h — I/O event notification facility functions” on page 68](#)
- [“epoll_ctl\(\) — Control interface for an epoll file descriptor” on page 427](#)

erand48() — Pseudo-random number generator

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <stdlib.h>

double erand48(unsigned short int x16v[3]);
```

General description

The drand48(), erand48(), jrand48(), lrand48(), mrand48() and nrand48() functions generate uniformly distributed pseudo-random numbers using a linear congruential algorithm and 48-bit integer arithmetic.

The functions drand48() and erand48() return nonnegative, double-precision, floating-point values, uniformly distributed over the interval [0.0,1.0). These functions have been extended so that the returned value will be in the proper floating-point format (hexadecimal or IEEE) based on the floating-point mode of the invoking thread.

The functions lrand48() and nrand48() return nonnegative, long integers, uniformly distributed over the interval [0,2**31).

The functions mrand48() and jrand48() return signed long integers, uniformly distributed over the interval [-2**31,2**31).

The erand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, X(i), according to the linear congruential formula:

$$X(n+1) = (aX(n) + c) \bmod (2^{**}48) \quad n \geq 0$$

The erand48() function uses storage provided by the argument array, x16v[3], to save the most recent 48-bit integer value in the sequence, X(i). The erand48() function uses x16v[0] for the low-order (rightmost) 16 bits, x16v[1] for the middle-order 16 bits, and x16v[2] for the high-order 16 bits of this value.

The initial values of a, and c are:

```
a  = 5deece66d (base 16)
c  = b         (base 16)
```

The values a and c, may be changed by calling the lcong48() function. The initial values of a and c are restored if either the seed48() or srand48() function is called.

Special behavior for z/OS UNIX Services: You can make the erand48() function and other functions in the drand48 family thread-specific by setting the environment variable _RAND48 to the value THREAD before calling any function in the drand48 family.

If you do not request thread-specific behavior for the drand48 family, C/370 serializes access to the storage for X(n), a and c by functions in the drand48 family when they are called by a multithreaded application.

If thread-specific behavior is requested and the erand48() function is called from thread t, the erand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, X(t,i), for the thread according to the linear congruential formula:

$$X(t,n+1) = (a(t)X(t,n) + c(t)) \bmod (2^{**}48) \quad n \geq 0$$

The erand48() function uses storage provided by the argument array, x16v[3], to save the most recent 48-bit integer value in the sequence, X(t,i). The erand48() function uses x16v[0] for the low-order (rightmost) 16 bits, x16v[1] for the middle-order 16 bits, and x16v[2] for the high-order 16 bits of this value.

The initial values of a(t) and c(t) on the thread t are:

```
a(t) = 5deece66d (base 16)
c(t) = b         (base 16)
```

The values a(t) and c(t) may be changed by calling the lcong48() function from the thread t. The initial values of a(t) and c(t) are restored if either the seed48() or srand48() function is called from the thread.

Returned value

erand48() saves the generated 48-bit value, X(n+1), in storage provided by the argument array, x16v[3]. erand48() transforms the generated 48-bit value to a double-precision, floating-point value on the interval [0.0,1.0) and returns this transformed value.

Special behavior for z/OS UNIX Services: If thread-specific behavior is requested for the drand48 family and erand48() is called on thread t, erand48() saves the generated 48-bit value, X(t,n+1), in storage provided by the argument array, x16v[3]. erand48() transforms the generated 48-bit value to a double-precision, floating-point value on the interval [0.0,1.0) and returns this transformed value.

erf(), erfc(), erff(), erfl(), erfcf(), erfcl() – Calculate error and complementary error functions

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| SAA XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

SAA:

```
#include <math.h>

double erf(double x);
double erfc(double x);
```

This function must be used with the [runtime library extensions](#) or under the [SAA based language constructs](#).

XPG4:

```
#define _XOPEN_SOURCE
#include <math.h>
```

```
double erf(double x);
double erfc(double x);
```

C99:

```
#define _ISOC99_SOURCE
#include <math.h>

float erff(float x);
long double erfl(long double x);
float erfcf(float x);
long double erfcl(long double x)
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

float erf(float x);
long double erf(long double x);
float erfc(float x);
long double erfc(long double x);
```

General description

Calculates the error and complementary error functions:

$$2\pi^{-1/2} \int_0^x e^{-t^2} dt$$

Because the erfc() function calculates the value of 1.0 - erf(x), it is used in place of erf() for large values of x.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | SPC | Hex | IEEE |
|----------|-----|-----|------|
| erf | X | X | X |
| erff | | X | X |
| erfl | | X | X |
| erfc | X | X | X |
| erfcf | | X | X |
| erfcl | | X | X |

Returned value

Both erf() and erfc() return the calculated value.

If the correct value would cause underflow, 0 is returned and the value of the macro ERANGE is stored in errno. A range error is returned if x is too large.

Special behavior for IEEE: erf() and erfc() are always successful.

Requirements

This function is exposed by enabling the [long long data type support](#) or using the [runtime library extensions](#).

Example

CELEBE01

```
/* CELEBE01

This example uses &erf. and &erfc. to compute the error
function of two numbers.

*/
#include <stdio.h>
#include <math.h>

double smallx, largex, value;

int main(void)
{
    smallx = 0.1;
    largex = 10.0;

    value = erf(smallx);          /* value = 0.112463 */
    printf("Error value for 0.1: %f\n", value);

    value = erfc(largex);         /* value = 2.088488e-45 */
    printf("Error value for 10.0: %e\n", value);
}
```

Output

```
Error value for 0.1: 0.112463
Error value for 10.0: 2.088488e-45
```

erfd32(), erfd64(), erfd128(), erfcd32(), erfcd64(), erfcd128() - Calculate error and complementary error functions

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.10 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  erfd32(_Decimal32 x);
_Decimal64  erfd64(_Decimal64 x);
_Decimal128 erfd128(_Decimal128 x);
_Decimal32  erf(_Decimal32 x);          /* C++ only */
_Decimal64  erf(_Decimal64 x);          /* C++ only */
_Decimal128 erf(_Decimal128 x);         /* C++ only */

_Decimal32  erfcd32(_Decimal32 x);
_Decimal64  erfcd64(_Decimal64 x);
_Decimal128 erfcd128(_Decimal128 x);
_Decimal32  erfc(_Decimal32 x);         /* C++ only */
```

```
_Decimal64 erfc(_Decimal64 x);      /* C++ only */
_Decimal128 erfc(_Decimal128 x);    /* C++ only */
```

General description

Calculates the error and complementary error functions:

$$2\pi^{-1/2} \int_0^x e^{-t^2} dt$$

Because the erfc() function calculates the value of 1.0 - erf(x), it is used in place of erf() for large values of x.

These functions work in IEEE decimal floating-point format. See “IEEE decimal floating-point” on page 97 for more information.

Note: To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

erf() and erfc() are always successful.

Example

CELEBE12

```
/* CELEBE12
   This example illustrates the erfd32() and erfcd32() functions.
*/
#define __STDC_WANT_DEC_FP__
#include <stdio.h>
#include <math.h>

_Decimal32 smallx, largex, value;

int main(void)
{
    smallx = 0.1DF;
    largex = 10.0DF;

    value = erfd32(smallx);
    printf("Error value for 0.1: %Hf\n", value);

    value = erfcd32(largex);
    printf("Error value for 10.0: %He\n", value);
}
```

__err2ad() — Return address of reason code of last failure

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
int *__err2ad(void);
```

General description

The `__err2ad()` function returns the address of the `errno2`. The `errno2` may be set by the z/OS C/C++ runtime library, z/OS UNIX callable services or other callable services.

`__err2ad()` provides assistance in diagnosing problems by allowing an application to reset the `errno2` value prior to calling a function.

Returned value

`__err2ad()` is always successful.

Related information

- “[__errno2\(\) — Return reason code information](#)” on page 436

[__errno2\(\) — Return reason code information](#)

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
int __errno2(void);
```

General description

The `__errno2()` function can be used when diagnosing application problems. This function enables application programs to access additional diagnostic information, `errno2` (`errnoj`), associated with `errno`. The `errno2` may be set by the z/OS C/C++ runtime library, z/OS UNIX callable services or other callable services. The `errno2` is intended for diagnostic display purposes only and it is not a programming interface. The `__errno2()` function is not portable.

Note: Not all functions set `errno2` when `errno` is set. In the cases where `errno2` is not set, the `__errno2()` function may return a residual value. You may use the `__err2ad()` function to clear `errno2` to reduce the possibility of a residual value being returned.

Returned value

The `__errno2()` function is always successful. The returned value is intended for diagnostic display purposes only.

The returned value may input to the BPXMTEXT utility to produce detailed information about the reported error if available.

Example

CELEBE02

```
/* CELEBE02
The following example's output only occurs
```

```

    if the buffer is flushed.

    */
#include <errno.h>
#include <stdio.h>
int main(void) {
    FILE *f;
    f = fopen("notafile", "r");
    if (f==NULL) {
        perror("fopen() failed");
        printf("__errno2 = %08x\n", __errno2());
    }
    return(0);
}

```

Sample output of routine using __errno2(), CELEBE02:

fopen() failed: EDC5129I No such file or directory. __errno2 = 05620062

CELEBE08

```

#pragma runopts(posix(on))
#define _EXT
#include <stdio.h>
#include <errno.h>
#include <stdlib.h>

int main(void){
    FILE *fp;
    /* add errno2 to perror message */
    setenv("_EDC_ADD_ERRNO2", "1", 1);
    fp = fopen("testfile.dat", "r");
    if (fp == NULL)
        perror("fopen() failed");
    return 0;
}

```

Sample output of routine using _EDC_ADD_ERRNO2, CELEBE08:

fopen() failed: EDC5129I No such file or directory. (errno2=0x05620062)

CELEBE09

```

#pragma runopts(posix(on))
#define _EXT
#include <stdio.h>
#include <errno.h>

int main(void){
    FILE *f;
    f = fopen("testfile.dat", "r");
    if (f == NULL){
        perror("fopen() failed");
        printf("__errno2 = %08x\n", __errno2());
    }

    /* reset errno2 to zero */
    *_err2ad() = 0x0;
    printf("__errno2 = %08x\n", __errno2());

    f = fopen("testfile.dat", "r");
    if (f == NULL){
        perror("fopen() failed");
        printf("__errno2 = %08x\n", __errno2());
    }

    return 0;
}

```

__etoa() – EBCDIC to ISO8859-1 string conversion

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <unistd.h>

int __etoa(char *string);
```

General description

The `__etoa()` function converts an EBCDIC character string *string* to its ISO8859-1 equivalent. The conversion is performed using the codeset page associated with the current locale. The input character string up to, but not including, the NULL character is changed from the current locale to an ISO8859-1 representation.

The argument *string* points to the EBCDIC character string to be converted to its ISO8859-1 equivalent.

Returned value

If successful, `__etoa()` converts the input EBCDIC string to its equivalent ISO8859-1 value, and returns the length of the converted string.

If unsuccessful, `__etoa()` returns -1 and sets `errno` to one of the following values. (This function internally may call `iconv_open()` and `iconv()`. The `errno`s returned by these functions are propagated without modification.)

Error Code Description

EINVAL

The current locale does not describe a single-byte character set.

ENOMEM

There is insufficient storage to complete the conversion process.

Related information

- [“sys/msg.h – Message queue structures” on page 69](#)
- [“unistd.h – Implementation-specific functions” on page 77](#)
- [“iconv\(\) – Code conversion” on page 824](#)

__etoa_l() – EBCDIC to ISO8859-1 conversion operation

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <unistd.h>

int __etoa_l(char *bufferptr, int leng);
```

General description

The `__etoa_l()` function converts *leng* EBCDIC bytes in the buffer pointed to by *bufferptr* to their ISO8859-1 equivalent. The conversion is performed using the codeset page associated with the current locale.

The argument *bufferptr* points to a buffer containing the EBCDIC bytes to be converted to their ISO8859-1 equivalent. The input buffer is treated as a sequence of bytes, and all bytes in the input buffer are converted, including any imbedded NULLs.

Returned value

If successful, `__etoa_l()` converts the input EBCDIC bytes to their equivalent ISO8859-1 value, and returns the number of bytes converted.

If unsuccessful, `__etoa_l()` returns -1 and sets `errno` to one of the following values. (This function may internally call `iconv_open()` and `iconv()`. The `errno`s returned by these functions are propagated without modification.)

Error Code

Description

EINVAL

The current locale does not describe a single-byte character set.

ENOMEM

There is insufficient storage to complete the conversion process.

Related information

- [“sys/msg.h – Message queue structures” on page 69](#)
- [“unistd.h – Implementation-specific functions” on page 77](#)
- [“iconv\(\) – Code conversion” on page 824](#)

eventfd() – Create a file descriptor for event notification

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <sys/eventfd.h>

int eventfd(unsigned int initval, int flags);
```

General description

`eventfd()` function creates an `eventfd` object that can be used as an event wait/notify mechanism by user applications, and by the kernel to notify user application of events. The object contains an unsigned 64-bit integer counter that is maintained by the kernel. This counter is initialized with the value that is specified in the argument *initval*.

`eventfd()` returns a new file descriptor that can be used to refer to the `eventfd` object. The following values are used in *flags* to change the behavior of `eventfd()`:

EFD_CLOEXEC

Set the close-on-exec (FD_CLOEXEC) flag on the new file descriptor.

EFD_NONBLOCK

Set the O_NONBLOCK file status flag on the open file description referred to by the new file descriptor. Using this flag saves extra calls to `fcntl()` to achieve the same result.

EFD_SEMAPHORE

Provide semaphore-like semantics for reads from the new file descriptor.

The following operations can be performed on the file descriptor that is returned by `eventfd()`:

read()

Each successful `read()` returns an 8-byte integer from the `eventfd` count. A `read()` fails with the error EINVAL if the size of the supplied buffer is less than 8 bytes.

The value that is returned by `read()` is in host byte order.

If the `eventfd` counter is zero at the time of the call to `read()`, then the call either blocks until the counter becomes nonzero (at which time, the `read()` proceeds as described previously) or fails with the error EAGAIN if the file descriptor has been made nonblocking.

write()

A `write()` call adds the 8-byte integer value that is supplied in its buffer to the counter. The maximum value that can be stored in the counter is the largest unsigned 64-bit value minus 1. If the addition causes the counter's value to exceed the maximum, the `write()` either blocks until a `read()` is performed on the file descriptor, or fails with the error EAGAIN if the file descriptor has been made nonblocking.

A `write()` fails with the error EINVAL if the size of the supplied buffer is less than 8 bytes, or if an attempt is made to write the value 0xffffffffffffffff.

poll(), select()

Waits for one or more of the file descriptors to become ready to perform I/O. The returned file descriptor supports `poll()`, as follows:

- The file descriptor is readable (the `select()` readlist argument; the `poll()` POLLIN flag) if the counter has a value greater than 0.
- The file descriptor is writable (the `select()` writelist argument; the `poll()` POLLOUT flag) if it is possible to write a value of at least "1" without blocking.
- If an overflow of the counter value is detected, `select()` indicates the file descriptor as being both readable and writable, and `poll()` returns a POLLERR event.

The `eventfd` file descriptor also supports the other file-descriptor multiplexing APIs: `pselect()`.

close()

When the file descriptor is no longer required, it must be closed. When all file descriptors that are associated with the same `eventfd` object are closed, the resources for object are freed by the kernel.

A copy of the file descriptor that is created by `eventfd()` is inherited by the child that is produced by `fork()`. The duplicate file descriptor is associated with the same `eventfd` object. File descriptors that are created by `eventfd()` are preserved across `exec` functions, unless the `close-on-exec` flag is set.

Parameter Description

initval

The initialized value for the counter that is maintained by the kernel.

flags

Flag to change the behavior of the `eventfd` object.

Returned value

If successful, `eventfd()` returns a new `eventfd` file descriptor.

If unsuccessful, `eventfd()` returns -1 and sets `errno` to one of the following values:

Error Code Description

EINVAL

An unsupported value is specified in `flags`.

EMFILE

The per-process limit on the number of open file descriptors is reached.

ENFILE

The system-wide limit on the total number of open files is reached.

ENODEV

Unable to mount (internal) anonymous inode device.

ENOMEM

No sufficient memory to create a new `eventfd` file descriptor.

Example

```
#include <sys/eventfd.h>
#include <unistd.h>
#include <inttypes.h>          /* Definition of PRIu64 & PRIx64 */
#include <stdlib.h>
#include <stdio.h>
#include <stdint.h>           /* Definition of uint64_t */

#define handle_error(msg) do { perror(msg); exit(EXIT_FAILURE); } while (0)

int main(int argc, char *argv[]) {
    int efd;
    uint64_t u;
    ssize_t s;

    if (argc < 2) {
        fprintf(stderr, "Usage: %s <num>...\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    efd = eventfd(0, 0);
    if (efd == -1)
        handle_error("eventfd");

    switch (fork()) {
    case 0:
        for (int j = 1; j < argc; j++) {
            printf("Child writing %s to efd\n", argv[j]);
            u = strtoull(argv[j], NULL, 0); /* strtoull() allows various bases */
            s = write(efd, &u, sizeof(uint64_t));
            if (s != sizeof(uint64_t))
                handle_error("write");
        }
        printf("Child completed write loop\n");
        exit(EXIT_SUCCESS);
```

```
        default:
            sleep(2);

            printf("Parent about to read\n");
            s = read(efd, &u, sizeof(uint64_t));
            if (s != sizeof(uint64_t))
                handle_error("read");
            printf("Parent read %"PRIu64" (%#"PRIx64") from efd\n", u, u);
            exit(EXIT_SUCCESS);

        case -1:
            handle_error("fork");
        }
    }
```

exec functions

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>
extern char **environ;

int execl(const char *path, const char *arg, ..., NULL);
int execlp(const char *path, const char *arg, ..., NULL, char *const envp[]);
int execlp(const char *file, const char *arg, ..., NULL);
int execv(const char *path, char *const argv[]);
int execve(const char *path, char *const argv[], char *const envp[]);
int execvp(const char *file, char *const argv[]);
```

Note: Although POSIX.1 does not require that the `unistd.h` include file be included, it is recommended that you include it for portability.

General description

All `exec` functions run a new program by replacing the current process image with a new process image obtained from a file in the z/OS UNIX file system.

For information on specifying names for MVS data sets and z/OS UNIX files, see [z/OS XL C/C++ Programming Guide](#).

A successful `exec` function never returns control because the calling process is overwritten with the new process.

The argument *path* is a string giving the absolute or relative path name of a file. This file contains the image of the process to be run.

file is a string that is used in determining the path name of the file containing the image of the process to be run. If *file* contains a slash character (/), it is assumed to be the absolute or relative path name of the file. If *file* does not contain a slash, the system searches for the given file name under the list of directories given by the PATH environment variable. The system checks under directories in the order they appear in the PATH variable, and executes the first file whose name matches the *file* string. The file must reside in the z/OS UNIX file system.

The exec functions use the following environment variables:

STEPLIB

Supports the creation and propagation of a STEPLIB environment to the new process image. The following are the accepted values for the STEPLIB environment variable and the actions taken for each value:

- STEPLIB=NONE. No Steplib DD is to be created for the new process image.
- STEPLIB=CURRENT. The TASKLIB, STEPLIB or JOBLIB DD data set allocations that are active for the calling task at the time of the call to exec() are propagated to the new process image, if they are found to be cataloged. Uncataloged data sets are not propagated to the new process image.
- STEPLIB=Dsn1:Dsn2;...DsnN. The specified data sets, Dsn1:Dsn2:...DsnN, are built into a STEPLIB DD in the new process image.

Note: The actual name of the DD is not STEPLIB, but is a system-generated name that has the same effect as a STEPLIB DD. The data sets are concatenated in the order specified. The specified data sets must follow standard MVS data set naming conventions. Data sets found to be in violation of this standard are ignored. The data sets are ignored if the data sets do follow the standard, but the following situations exist:

- The caller does not have the proper security access to a data set
- A data set is uncataloged or is not in load library format

The system also ignores the data set and continues allocating other data sets in these situations:

- If the system cannot acquire a shared ENQueue on the data set name because another job has ENQueued it exclusively.
- If the specified data set does not exist, which is similar but not strictly equal to the case of uncataloged data sets.

Because the data sets in error are ignored, the executable file may run without the proper STEPLIB environment. If a data set is in error due to improper security access, a X'913' abend is generated. The dump for this abend can be suppressed by your installation.

The ENQueues on an original STEPLIB DD (from submitting the job) are DEQueued (freed) if this is the last JCL step naming the data set on a STEPLIB or other DD statement. This is standard initiator behavior. The system acquires new ENQueues for the data sets named in the STEPLIB variable each time an exec() type function is called.

If the STEPLIB environment variable is not specified, the exec() default behavior is the same as if STEPLIB=CURRENT were specified.

If the program to be invoked is a set-user-ID or set-group-ID file and the user-ID or group-ID of the file is different from that of the current process image, the data sets to be built into the STEPLIB environment for the new process image must be found in the system sanction list for set-user-id and set-group-id programs. Only those data sets that are found in the sanction list are built into the STEPLIB environment for the new process image. For detailed information regarding the sanction list, and for information on STEPLIB performance considerations, see [z/OS UNIX System Services Planning](#).

_BPX_JOBNAME

Used to change the jobname of the new process image. The jobname change is allowed only if the invoker has appropriate privileges and is running in an address space created by fork. If these

conditions are not met, the environment variable is ignored. Accepted values are strings of 1–8 alphanumeric characters. Incorrect specifications are ignored.

_BPX_ACCT_DATA

Used to change the account data of the new process image. Rules for specifying account data:

- Up to 142 actual account data characters are allowed, including any commas
- Sub-parameters must be separated by commas.
- There is no restriction on the character set.
- If the account data is greater than 142 characters, the data is ignored.

_BPXK_JOBLOG

The `_BPXK_JOBLOG` environment variable can be used to specify that WTO messages are to be written to an open job log file. The following are the allowable values:

Value

Description

nn

Job log messages are to be written to open file descriptor nn.

STDERR

Job log messages are to be written to the standard error file descriptor, 2.

None

Job log messages are not to be written. This is the default.

The file that is used to capture messages can be changed at any time by calling the `oe_env_np` service (BPX1ENV) and specifying `_BPXK_JOBLOG` with a different file descriptor.

Message capturing is turned off if the specified file descriptor is marked for close on a fork or exec.

Message capturing is process-related. All threads under a given process share the same job log file. Message capturing may be initiated by any thread under that process.

Multiple processes in a single address space can each have different files active as the JOBLOG file; some or all of them can share the same file; and some processes can have message capturing active while others do not.

Only files that can be represented by file descriptors may be used as job log files; MVS data sets are not supported.

Message capturing will be propagated on a `fork()` or `spawn()`. In the case where a file descriptor was specified, the physical file must be the same for message capturing to continue in the forked or spawned process. If `STDERR` was specified, the file descriptor may be re-mapped to a different physical file.

Message capturing may be overridden on `exec()` or `spawn()` by specifying the `_BPXK_JOBLOG` environment variable as a parameter to the `exec()` or `spawn()`.

Message capturing will only work in forked (BPXAS) address spaces.

Note: This is not true joblog support, messages that would normally go to the JESYSMSG data set are captured, but messages that go to JESMSGLOG are not captured.

Special behavior for XPG4: If this file is not a valid executable object, the `execlp()` and `execvp()` functions invoke `/bin/sh` with the invoker's path name and the rest of the input arguments. It is similar to invoking:

```
execl("/bin/sh",
      "sh",
      "--",
      fully_expanded_pathname,
      arg1, arg2, ..., argn,
      NULL
      );
```

where `arg1`, `arg2`, ..., `argn` are the caller's arguments to `execlp()` or `execvp()`, and `fully_expanded_pathname` is the path name of the shell script found by searching the directories in the current `PATH`.

`arg`, ..., `NULL` is a series of pointers to NULL-terminated character strings specifying arguments for the process being invoked. If the new process is a `main()`, these strings are stored in an array, and a pointer to the array is passed in the `argv` parameter. The first argument is required, and it should point to a string containing the name of the file that is associated with the process that `exec` is starting. A NULL pointer must follow the last argument string pointer.

`argv[]` is a pointer to an array of pointers to NULL-terminated character strings. There must be a NULL pointer after the last character string to mark the end of the array. These strings are used as arguments for the process being invoked. `argv[0]` should point to a string containing the name of a file associated with the process being started by `exec`. `envp[]` is a pointer to an array of pointers to NULL-terminated character strings. There must be a NULL pointer after the last character string to mark the end of the array. The strings of `envp` provide the environment variables for the new process.

All the forms of `exec` functions provide a way to locate the file containing the new process you want to run and a collection of arguments that should be passed to the new process. Each form of `exec` has its own method for specifying this information.

Some `exec` calls explicitly pass an environment using an `envp` argument. In versions where an environment is not passed explicitly—`execl()`, `execlp()`, `execv()`, and `execvp()`—the system uses the entire environment of the caller. The caller's environment is assumed to be the *environment variables* that the *external variable* `**environ` points to.

The variable **ARG_MAX**, obtained from z/OS UNIX services by an invocation of `sysconf(_SC_ARG_MAX)`, specifies the maximum number of bytes that can be used for arguments and environment variables passed to the process being invoked. The number of bytes includes the NULL terminator on each string.

A process started by an `exec` function has all of the open file descriptors that were present in the caller, except for those files opened with the close-on-exec flag `FD_CLOEXEC`. See [“fcntl\(\) — Control open file descriptors”](#) on page 483 for more information about this flag. In file descriptors that remain open, all attributes remain unchanged (including file locks).

Directory streams that are open in the calling process image are closed in the new process image.

The state of conversion descriptors and message catalog descriptors is undefined.

Signals set to be ignored in the caller, `SIG_IGN`, are set to be ignored in the new process image. Be careful to take care of signals that are being ignored. Although `sigaction()` specifying a handler is not passed by, `SIG_IGN` is. Blocking of signals is also passed by. All other signals are set to the default action, `SIG_DFL`, in the new process image, no matter how the caller handled such signals.

The real user ID (UID), real group ID (GID), and supplementary group IDs of the new process are the same as those of the caller. If the set-user-ID mode bit of the program file is on, the effective user ID of the new process is set to the file's owner. Similarly, if the set-group-ID mode bit of the program file is on, the effective group ID of the new process is set to the file's group. The effective user ID of the new process image is saved as the saved set-user-ID, and the effective group ID of the new process image is saved as the saved set-group-ID.

Any shared memory segments attached to the calling process image will not be attached to the new process image, see [“shmat\(\) — Shared memory attach operation”](#) on page 1593. Any shared memory segments attached to the calling process image will be detached (that is, the value of `shm_nattch` decremented by one). If this is the last thread attached to the shared memory segment and a `shmctl()` `RMID` has been issued, the segment will be removed from the system.

Special behavior for XPG4.2: Interval timers are preserved across an `exec`.

The new process also inherits the following from the caller:

- Controlling terminal (**XPG4.2**)
- Nice value (see [“nice\(\) — Change priority of a process”](#) on page 1150) (**XPG4**)

- `semadj` values (see [“semop\(\) — Semaphore operations”](#) on page 1488) (**XPG4**)
- Process ID
- Parent process ID
- Process group ID
- Resource limits (see [“setrlimit\(\) — Control maximum resource consumption”](#) on page 1568 and [“ulimit\(\) — Get or set process file size limits”](#) on page 1924) (**XPG4.2**)
- Session membership
- Time left until an alarm clock signal
- Working directory
- Root directory
- File mode creation mask
- File size limit (see [“ulimit\(\) — Get or set process file size limits”](#) on page 1924) (**XPG4**)
- Process signal mask
- Pending signals
- `tms_utime`, `tms_stime`, `tms_cstime`, and `tms_cutime`. See [“times\(\) — Get process and child process times”](#) on page 1867 for more about these qualities.

A successful `exec` function automatically opens the specified program file, and updates the access time `st_atime` for that file. The program file is closed automatically after the program has been read from the file. The precise time of this close operation is undefined.

Special behavior for z/OS UNIX Services:

1. A prior loaded copy of an HFS program in the same address space is reused under the same circumstances that apply to the reuse of a prior loaded MVS unauthorized program from an unauthorized library by the MVS XCTL service with the following exceptions:
 - If the calling process is in Ptrace debug mode, a prior loaded copy is not reused.
 - If the calling process is not in Ptrace debug mode, but the only prior loaded usable copy found of the HFS program is in storage modifiable by the caller, the prior copy is not reused.
2. If the specified file name represents an external link or a sticky bit file, the program is loaded from the caller's MVS load library search order. For an external link, the external name is only used if the name is eight characters or less, otherwise the caller receives an error from the `loadhfs` service. For a sticky bit program, the file name is used if it is eight characters or less. Otherwise, the program is loaded from the HFS, and the following restriction exists for sticky bit programs that have the `set-user-ID` or `set-group-ID` attribute:

If the program is found in the MVS program search order, the MVS program name must have a `BPX.STICKYSUG.program_name` resource profile defined in the RACF FACILITY class. See [z/OS UNIX System Services Planning](#) for details on defining the resource profile. Failure to follow this restriction will cause the abend EC6 with code `xxxxE055`.
3. If the calling task is in a WLM enclave, the resulting task in the new process image is joined to the same WLM enclave. This allows WLM to manage the old and new process images as one 'business unit of work' entity for system accounting and management purposes.

Note: If you are expecting this function to take advantage of the z/OS UNIX magic number support, the Language Environment runtime option to `POSIX(ON)` must have been set when the process was initialized. Attempting to use magic number support with a process initialized with `POSIX(OFF)` may produce undesirable effects. See [z/OS UNIX System Services Planning](#) and [z/OS UNIX System Services User's Guide](#) for details and uses of the z/OS UNIX magic number.

Returned value

If successful, an `exec` function never returns control because the calling process is overwritten with the new process.

If unsuccessful, an exec function returns -1 and sets errno to one of the following values:

Error Code Description

E2BIG

The combined argument list and environment list of the new process has more bytes than the system-defined length. See [“sysconf\(\) — Determine system configuration options”](#) on page 1794 for information about the system-defined length.

EACCES

The process did not have appropriate permissions to run the specified file, for one of these reasons:

- The process did not have permission to search a directory named in your *path*.
- The process did not have execute permission for the file to be run.
- The system cannot run files of this type.

EFAULT

A bad address was received as an argument of the call, or the user exit program checked.

Consult Reason Code to determine the exact reason the error occurred. The following reason code can accompany the return code: JRExecParmErr and JRExitRtnError.

EINVAL

The new process image file has the appropriate permission and has a recognized format, but the system does not support execution of a file with this format.

ELOOP

A loop exists in symbolic links. This error is issued if the number of symbolic links detected in the resolution of the *path* or *file* argument is greater than POSIX_SYMLoop (a value defined in the limits.h header file)

ELEMULTITHREAD

The exec function was invoked from a multithreaded AMODE 31 environment.

EMVSSAF2ERR

The executable file is a set-user-ID or set-group-ID file, and the file owner's UID or GID is not defined to RACF.

ENAMETOOLONG

All or part of the file name is too long. This can happen if:

- A *path* or *file* argument exceeds the value of **PATH_MAX**, or an element of your *path* exceeds **PATH_MAX**.
- Any *pathname* component is greater than **NAME_MAX**, and **_POSIX_NO_TRUNC** is in effect.
- The length of a path name string substituted for a symbolic link in the *path* argument exceeds **PATH_MAX**.

The **PATH_MAX** and **NAME_MAX** values are determined with pathconf().

ENOENT

One or more *pathname* components in *path* or *file* does not exist. This error is also issued if *path* or *file* is a NULL string.

ENOEXEC

The new process image file has the appropriate access permission but has an unrecognized format. This errno can be returned from any one of the exec family of functions, except for execlp() and execvp().

Note: Reason codes further qualify the errno. For most of the reason codes, see [z/OS UNIX System Services Messages and Codes](#).

For ENOEXEC, the reason codes are:

| Reason Code | Explanation |
|-------------|--|
| X'xxxx0C27' | The target file is not in the correct format to be an executable file. |

| Reason Code | Explanation |
|-------------|---|
| X'xxxx0C31' | The target file is built at a level that is higher than that supported by the running system. |

ENOMEM

The new process requires more memory than is permitted by the operating system.

ENOTDIR

A directory component of *path* or *file* is not really a directory.

Example**CELEBE03**

```

/* CELEBE03

   This example runs a program, using the execl() function.

   */
#define _POSIX_SOURCE
#include <stdio.h>
#include <sys/wait.h>          /*FIX: used be <wait.h>*/
#include <sys/types.h>
#include <unistd.h>

main() {
    pid_t pid;
    int status;

    if ((pid = fork()) == 0) {
        execl("/bin/false", NULL);
        perror("The execl() call must have failed");
        exit(255);
    }
    else {
        wait(&status);
        if (WIFEXITED(status))
            printf("child exited with status of %d\n", WEXITSTATUS(status));
        else
            puts("child did not exit successfully\n");
    }
}

```

Output

```
child exited with status of 1
```

exit() — End program

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 C11 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdlib.h>

__noreturn__ void exit(int status);
```

General description

The `exit()` function:

1. Calls all functions registered with the `atexit()` function, and destroys C++ objects with static storage duration, all in last-in-first-out (LIFO) order. C++ objects with static storage duration are destroyed in the reverse order of the completion of their constructor. (Automatic objects are not destroyed as a result of calling `exit()`.)

Functions registered with `atexit()` are called in the reverse order of their registration. A function registered with `atexit()`, before an object `obj1` of static storage duration is initialized, will not be called until `obj1`'s destruction has completed. A function registered with `atexit()`, after an object `obj2` of static storage duration is initialized, will be called before `obj2`'s destruction starts.

2. Flushes all buffers, and closes all open files.
3. All files opened with `tmpfile()` are deleted.
4. Returns control to the host environment from the program.

Process termination in `_exit()` is equivalent to program termination in `exit()`.

The argument *status* can have a value from 0 to 255 inclusive or be one of the macros `EXIT_SUCCESS` or `EXIT_FAILURE`. The value of `EXIT_SUCCESS` is defined in `stdlib.h` as 0; the value of `EXIT_FAILURE` is 8.

This function is also available to C applications in a stand-alone Systems Programming C (SPC) Environment.

In a POSIX C program, `exit()` returns control to the kernel with the value of *status*. The kernel then performs normal process termination.

POSIX-level thread cleanup routines are *not* executed. These includes cleanup routines created with `pthread_cleanup_push()` and destructor routines created with `pthread_key_create()`.

Special behavior for C++: If `exit()` is called in a IBM z/OS C++ program, the program terminates without leaving the current block, and therefore destructors are not called for local (automatic) variables. Destructors for initialized static objects will be called in the reverse order of the completion of their constructors.

Functions registered with `atexit()` are called in the reverse order of their registration. A function registered with `atexit()`, before an object `obj1` of static storage duration is initialized, will not be called until `obj1`'s destruction has completed. A function registered with `atexit()`, after an object `obj2` of static storage duration is initialized, will be called before `obj2`'s destruction starts.

Returned value

`exit()` returns no values.

`exit()` returns control to its host environment, with the returned value *status*.

For example, if program A invokes program B using a call to the `system()` function, and program B calls the `exit()` function, then program B returns to its host environment, which is program A.

Example

```
/* This example flushes all buffers, closes any open files, and ends the
   program if it cannot open the file myfile.
*/
#include <stdio.h>
#include <stdlib.h>

FILE *stream;

int main(void)
{
    :
    if ((stream = fopen("myfile.dat", "r")) == NULL)
    {
        printf("Could not open data file\n");
        exit(EXIT_FAILURE);
    }
}
```

`_exit()` — End a process and bypass the cleanup

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

void _exit(int status);
```

General description

Ends the current process and makes an exit status value for the process available to the system.

The argument *status* specifies a return status for the process that is ending. Ending the process has the following results:

- `_exit()` closes all open file descriptors and directory streams in the caller.
- If the caller's parent is currently suspended because of `wait()` or `waitpid()`, the low-order 8 bits of *status* become available to the parent. For a discussion on accessing those 8 bits, refer to [“waitpid\(\) — Wait for a specific child process to end”](#) on page 1981.
- If the caller's parent is not currently suspended because of `wait()` or `waitpid()`, `_exit()` saves the *status* value so that it can be returned to the parent if the parent calls `wait()` or `waitpid()`.
- A SIGCHLD signal is sent to the parent process.
- If the process calling `_exit()` is a controlling process, the SIGHUP signal is sent to each process in the foreground process group of the controlling terminal belonging to the caller.
- If the process calling `_exit()` is a controlling process, `_exit()` disassociates the associated controlling terminal from the session. A new controlling process can then acquire the terminal.
- Exiting from a process does not end its child processes directly. The SIGHUP signal may end children in some cases. Children that survive when a process ends are assigned a new parent process ID. The new parent process ID is always 1, indicating the root ancestor of all processes.
- If a process ends and orphans a process group and if a member of that group is stopped, each member of the group is sent a SIGHUP signal, followed by a SIGCONT signal.
- All threads are ended, and their resources cleaned up. (*Threads* are MVS tasks that call a z/OS UNIX callable service.) POSIX-level thread cleanup routines are *not* executed. These include cleanup routines created with `pthread_cleanup_push()` and destructor routines created with `pthread_key_create()`.

These results occur whenever a process ends. `_exit()` does not cause C runtime library cleanup to be performed; therefore, stream buffers are not necessarily flushed.

Note: If `_exit()` is issued from a TSO/E address space, it ends the calling task and all its subtasks.

Special behavior for C++: If `_exit()` is called in a C++ program, the program terminates without leaving the current block, and destructors are not called for local (automatic) variables. In addition, unlike `exit()`, destructors for global (static) variables are not called.

Returned value

`_exit()` is always successful and returns no values.

No value is stored in `errno` for this function.

Example

CELEBE05

```
/* CELEBE05

   This example ends a process.

*/
#define _POSIX_SOURCE
#include <unistd.h>
#include <stdio.h>

main() {
    puts("Remember that stream buffers are not automatically");
    puts("flushed before _exit()!");
    fflush(NULL);
    _exit(0);
}
```

Output

```
Remember that stream buffers are not automatically
flushed before _exit()!
```

_Exit() — Terminate a process

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| C99 C11 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _ISOC99_SOURCE
#include <stdlib.h>

__noreturn__ void _Exit(int status);
```

General description

When running POSIX(OFF), the `_Exit()` function is equivalent to `exit()` with the exception that it does not run `atexit()` registered routines or signal handlers registered using `signal()`.

When running POSIX(ON), the `_Exit()` function is equivalent to `_exit()`.

Returned value

The `_Exit()` function does not return to its caller.

Related information

exp(), expf(), expl() — Calculate exponential function

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#include <math.h>

double exp(double x);
float expf(float x);           /* C++ only */
long double exp(long double x); /* C++ only */
float expf(float x);
long double expl(long double x);
```

General description

Calculates the exponent of x , defined as e^x , where e equals 2.718281828....

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

Returned value

If successful, the function returns the calculated value.

If an overflow occurs, the function returns HUGE_VAL. If an underflow occurs, it returns 0. Both overflow and underflow set errno to ERANGE.

Example

CELEBE06

```
/* CELEBE06

   This example calculates y as the exponential function of x.

*/
#include <math.h>
#include <stdio.h>

int main(void)
{
    double x, y;

    x = 5.0;
    y = exp(x);

    printf("exp( %f ) = %f\n", x, y);
}
```

Output

```
exp( 5.000000 ) = 148.413159
```

expd32(), expd64(), expd128() — Calculate exponential function

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 expd32(_Decimal32 x);
_Decimal64 expd64(_Decimal64 x);
_Decimal128 expd128(_Decimal128 x);
_Decimal32 exp(_Decimal32 x); /* C++ only */
_Decimal64 exp(_Decimal64 x); /* C++ only */
_Decimal128 exp(_Decimal128 x); /* C++ only */
```

General description

Calculates the exponent of x, defined as e**x, where e equals 2.17128128....

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See [“IEEE binary floating-point” on page 97](#) for more information

Returned value

If successful, the function returns the calculated value.

If an overflow occurs, the function returns HUGE_VAL_D32, HUGE_VAL_D64, or HUGE_VAL_D128. If an underflow occurs, it returns 0. Both overflow and underflow set errno to ERANGE.

Example

```
/* CELEBE11
   This example illustrates the expd64() function.
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal64 x, y;

    x = 5.0DD;
    y = expd64(x);

    printf("expd64(%Df) = %Df\n", x, y);
}
```

expm1(), expm1f(), expm1l() — Exponential minus one

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <math.h>
```

```
double expm1(double x);
```

C99:

```
#define _ISOC99_SOURCE
#include <math.h>

float expm1f(float x);
long double expm1l(long double x);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

float expm1(float x);
long double expm1l(long double x);
```

General description

The expm1() functions calculate the function:
 $e^x - 1.0$

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------|-----|------|
| expm1 | X | X |
| expm1f | X | X |
| expm1l | X | X |

Returned value

If successful, expm1() returns the above function calculated on x.

If unsuccessful, expm1() may fail as follows:

- If x is negative and exceeds an internally defined large value, expm1() functions will return -1.0.
- If the value of the function overflows, expm1() functions will return HUGE_VAL or HUGE_VALF or HUGE_VALL as appropriate, and set errno to ERANGE.

Related information

- [“math.h — Floating-point math functions”](#) on page 40
- [“exp\(\), expf\(\), expl\(\) — Calculate exponential function”](#) on page 453
- [“ilogb\(\), ilogbf\(\), ilogbl\(\) — Integer unbiased exponent”](#) on page 834

[expm1d32\(\), expm1d64\(\), expm1d128\(\) — Exponential minus one](#)

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.11 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 expm1d32(_Decimal32 x);
_Decimal64 expm1d64(_Decimal64 x);
_Decimal128 expm1d128(_Decimal128 x);

_Decimal32 expm1(_Decimal32 x);      /* C++ only */
_Decimal64 expm1(_Decimal64 x);      /* C++ only */
_Decimal128 expm1(_Decimal128 x);    /* C++ only */
```

General description

The `expm1()` functions calculate the function:

$e^x - 1.0$

Notes:

1. These functions work in IEEE decimal floating-point format. See [“IEEE decimal floating-point”](#) on page 97 [IEEE Decimal Floating-Point](#) for more information.
2. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

If successful, `expm1()` returns the above function calculated on `x`.

If unsuccessful, `expm1()` may fail as follows:

- If `x` is negative and exceeds an internally defined large value, `expm1()` functions will return `-1.0`.
- If the value of the function overflows, `expm1()` functions will return `HUGE_VAL_D32` or `HUGE_VAL_D64` or `HUGE_VAL_D128` as appropriate, and set `errno` to `ERANGE`.

Example

```
/* CELEBE13
   This example illustrates the expm1d32() function.
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

void main(void)
{
    _Decimal32 x, y;

    x = 2.5DF;
    y = expm1d32(x);

    printf("expm1d32(%Hf) = %Hf\n", x, y);
}
```

ExportWorkUnit() – WLM export service

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | OS/390 V2R9 |

Format

```
#include <sys/__wlm.h>

int ExportWorkUnit(wlmetok_t *enclavetoken,
                  wlmxtok_t *exporttoken,
                  unsigned long *conntoken);
```

AMODE 64:

```
#include <sys/__wlm.h>

int ExportWorkUnit(wlmetok_t *enclavetoken,
                  wlmxtok_t *exporttoken,
                  unsigned int *conntoken);
```

General description

Exports an enclave to all systems in a parallel sysplex, enabling dispatchable units on other systems to join the enclave.

The ExportWorkUnit() function uses the following parameters:

***enclavetoken**

Points to a work unit enclave token that was returned from a call to CreateWorkUnit() or ContinueWorkUnit().

***exporttoken**

Points to a data field of type wlmxtok_t where the ExportWorkUnit() function is to return the WLM work unit export token.

***conntoken**

Specifies the connect token that represents the connection to WLM.

Returned value

If successful, ExportWorkUnit() returns 0.

If unsuccessful, ExportWorkUnit() returns -1 and sets errno to one of the following values:

Error Code

Description

EFAULT

An argument of this function contained an address that was not accessible to the caller.

EINVAL

An argument of this function contained a value that is not correct.

EMVSSAF2ERR

An error occurred in the security product.

EMVSWLMERROR

A WLM service failed. Use __errno2() to obtain the WLM service reason code for the failure.

EPERM

The calling thread's address space is not permitted to the BPX.WLMSEVER Facility class. The caller's address space must be permitted to the BPX.WLMSEVER Facility class, if the BPX.WLMSEVER

class is defined. If BPX.WLMSEVER is not defined, the calling process is not defined as a superuser (UID=0).

exp2(), exp2f(), exp2l() — Calculate the base-2 exponential

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _ISOC99_SOURCE
#include <math.h>

double exp2(double x);
float exp2f(float x);
long double exp2l(long double x);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

float exp2(float x);
long double exp2(long double x);
```

General description

The exp2 functions compute the base-2 exponential of x .

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------|-----|------|
| exp2 | X | X |
| exp2f | X | X |
| exp2l | X | X |

Returned value

The exp2 functions return 2 to the power x .

Related information

- [“math.h — Floating-point math functions” on page 40](#)

exp2d32(), exp2d64(), exp2d128() – Calculate the base-2 exponential

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.11 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 exp2d32(_Decimal32 x);
_Decimal64 exp2d64(_Decimal64 x);
_Decimal128 exp2d128(_Decimal128 x);

_Decimal32 exp2(_Decimal32 x);      /* C++ only */
_Decimal64 exp2(_Decimal64 x);      /* C++ only */
_Decimal128 exp2(_Decimal128 x);     /* C++ only */
```

General description

The exp2() functions compute the base-2 exponential of x.

Notes:

1. These functions work in IEEE decimal floating-point format. See [“IEEE decimal floating-point” on page 97](#) IEEE Decimal Floating-Point for more information.
2. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

The exp2() functions return 2 to the power x.

Example

```
/* CELEBE14
   This example illustrates the exp2d128() function.
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

void main(void)
{
    _Decimal128 x, y;

    x = 4.785DL;
    y = exp2d128(x);

    printf("exp2d128(%DDf) = %DDf\n", x, y);
}
```

Related information

extlink_np() – Create an external symbolic link

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <unistd.h>

int extlink_np(const char *ename, const char *elink);
```

General description

Creates the external symbolic link file named by *elink* with the object specified by *ename*. The *ename* is not resolved, and refers to an object outside z/OS UNIX. The variable *elink* is the name of the external symbolic link file created, and *ename* is the name of the object contained within that file.

Returned value

If successful, `extlink_np()` returns 0.

If unsuccessful, `extlink_np()` returns -1, does not affect any file it names, and sets `errno` to one of the following values:

Error Code

Description

EACCES

A component of the *elink* path prefix denies search permission.

EEXIST

The file named by *elink* already exists.

EINVAL

elink has a slash as its last component, which indicates that the preceding component will be a directory. An external link cannot be a directory.

ELOOP

A loop exists in symbolic links. This error is issued if the number of symbolic links encountered during resolution of the *elink* argument is greater than `POSIX_SYMLINK_MAX`.

ENAMETOOLONG

pathname is longer than `PATH_MAX` characters, or some component of *pathname* is longer than `NAME_MAX` characters while `_POSIX_NO_TRUNC` is in effect. For symbolic links, the length of the *pathname* string substituted for a symbolic link exceeds `PATH_MAX`. The `PATH_MAX` and `NAME_MAX` values can be determined with `pathconf()`.

ENOTDIR

A component of the path prefix of *elink* is not a directory.

ENOSPC

The new external link cannot be created because there is no space left on the file system to contain it.

EROFS

The file named by *elink* cannot be created on a read-only file system.

Example

CELEBE07

```

/* CELEBE07

   This example creates an external symbolic link.

*/
#include <stdio.h>
#include <fcntl.h>
#include <errno.h>
#include <unistd.h>
#include <stdlib.h>
#include <sys/stat.h>
#include <sys/types.h>

main( argc, argv )
    int  argc ;
    char *argv ;
{
    int  i_rc ;
    int  i_fd ;
    char ac_mvds[] = "SYS1.LINKLIB" ;
    char ac_mvds sextsymlnk[] = "sys1.linklib.extsymlnk" ;

    i_rc = unlink( ac_mvds sextsymlnk ) ;

    if ( ( i_rc == -1 ) && ( errno == ENOENT ) ) {
    }
    else
    {
        perror( "unlink() error" ) ;
        return( -1 ) ;
    }

    printf( "Before extlink_np() call ...\n" ) ;
    system( "ls -il sys1.*" ) ;

    i_rc = extlink_np( ac_mvds, ac_mvds sextsymlnk ) ;

    if ( i_rc == -1 )
    {
        perror( "extlink_np() error" ) ;
        return( -1 ) ;
    }

    printf( "After extlink_np() call ...\n" ) ;
    system( "ls -il sys1.*" ) ;

    i_rc = unlink( ac_mvds sextsymlnk ) ;
}

```

ExtractWorkUnit() – Extract enclave service

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | OS/390 V2R8 |

Format

```
#include <sys/__wlm.h>

int ExtractWorkUnit(wlmetok_t *enclavetoken);
```

General description

The ExtractWorkUnit() function will allow the task to retrieve the enclaves token for the purpose of performance management.

The ExtractWorkUnit() function uses the following parameter:

***enclavetoken**

Points to a data field of type wlmetok_t where the ExtractWorkUnit() function is to return the WLM work unit token to which the current process is joined.

Returned value

If successful, ExtractWorkUnit() returns 0.

If unsuccessful, ExtractWorkUnit() returns -1 and sets errno to one of the following values:

Error Code

Description

EFAULT

An argument of this service contained an address that was not accessible to the caller.

EINVAL

The Functioncode parm contains a value that is not correct or the function parmlist data is incorrect.

EMVSSAF2ERR

An error occurred in the security product. Consult the reason code, which can be retrieved using the __errno2() function.

EMVSWLMERROR

A WLM service failed. Consult the reason code, which can be retrieved using the __errno2() function.

EPERM

Do not have appropriate permissions and privilege.

ESRCH

A WLM_EXTRACT_WORKUNIT request was issued but the WLM enclave token was not returned.

Related information

- [“sys/__wlm.h – WorkLoad Manager functions” on page 73](#)

__e2a_l() – Convert characters from EBCDIC to ASCII

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | z/OS V1R2 |

Format

```
#include <unistd.h>

size_t __e2a_l(char *bufptr, size_t szLen)
```

General description

The `__e2a_l` function converts *szLen* characters in *bufptr* between IBM-1047 and ISO8859-1, returning the number of characters converted if successful or -1 if not. Conversion occurs in place in the buffer. `__e2a_l` is not sensitive to the locale, and only converts between ISO8859-1 and IBM-1047.

Note: This function is valid for applications compiled XPLINK only.

Returned value

If successful, `__e2a_l` returns the number of characters converted.

If unsuccessful, `__e2a_l` returns -1 and sets `errno` to the following value:

Error Code

Description

EINVAL

The pointer to *bufptr* is NULL or *szLen* is a negative value.

Related information

- [“unistd.h – Implementation-specific functions” on page 77](#)
- [“__a2e_l\(\) – Convert characters from ASCII to EBCDIC” on page 208](#)
- [“__a2e_s\(\) – Convert string from ASCII to EBCDIC” on page 209](#)

__e2a_s() – Convert string from EBCDIC to ASCII

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | z/OS V1R2 |

Format

```
#include <unistd.h>

size_t __e2a_s(char *string)
```

General description

The `__e2a_s()` function converts a string between IBM-1047 and ISO8859-1, returning the string length if successful or -1 if not. Conversion occurs in place in the string. `__e2a_s()` is not sensitive to the locale, and only converts between ISO8859-1 and IBM-1047.

Note: This function is valid for applications compiled XPLINK only.

Returned value

If successful, `__e2a_s()` returns the string length.

If unsuccessful, `__e2a_s()` returns -1 and sets `errno` to the following value:

Error Code

Description

EINVAL

The pointer to string is NULL.

Related information

- [“unistd.h — Implementation-specific functions” on page 77](#)
- [“__a2e_l\(\) — Convert characters from ASCII to EBCDIC” on page 208](#)

`fabs()`, `fabsf()`, `fabsl()` — Calculate floating-point absolute value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#include <math.h>

double fabs(double x);
float fabsf(float x);           /* C++ only */
long double fabsl(long double x); /* C++ only */
float fabsf(float x);
long double fabsl(long double x);
```

General description

The `fabs()` functions calculate the absolute value of a floating-point argument.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

Returned value

Returns the absolute value of the float input.

Example

```
/* This example calculates y as the absolute value of x. */
#include <math.h>

int main(void)
{
    double x, y;

    x = -5.6798;
    y = fabs(x);

    printf("fabs( %f ) = %f\n", x, y);
}
```

Output

```
fabs( -5.679800 ) = 5.679800
```

Related information

- [“math.h — Floating-point math functions” on page 40](#)
- [“abs\(\), absf\(\), absl\(\) — Calculate integer absolute value” on page 105](#)
- [“labs\(\) — Calculate long absolute value” on page 934](#)

fabsd32(), fabsd64(), fabsd128() — Calculate floating-point absolute value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 fabsd32(_Decimal32 x);
_Decimal64 fabsd64(_Decimal64 x);
_Decimal128 fabsd128(_Decimal128 x);
_Decimal32 fabs(_Decimal32 x); /* C++ only */
_Decimal64 fabs(_Decimal64 x); /* C++ only */
_Decimal128 fabs(_Decimal128 x); /* C++ only */
```

General description

The fabs() functions calculate the absolute value of a decimal floating-point argument.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See [“IEEE binary floating-point” on page 97](#) for more information

Returned value

Returns the absolute value of the decimal floating-point input.

Example

```
/* CELEBF75

   This example illustrates the fabstd128() function.

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal128 x, y;

    x = -5.6798DL;
    y = fabstd128(x);

    printf("fabstd128(%DDf) = %DDf\n", x, y);
}
```

Related information

faccessat() — Determine accessibility of a file relative to directory file descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1-2008 Single UNIX Specification, Version 4 | both | |

Format

```
#define _POSIX_C_SOURCE 200809L
#include <fcntl.h>          /* Definition of AT_* constants */
#include <unistd.h>

int faccessat(int dirfd, const char *pathname, int mode, int flags);
```

General description

`faccessat()` operates in the same way as `access()` except for the following differences:

- If *pathname* is relative, it is interpreted relative to the directory that is referred to by the file descriptor *dirfd* (rather than relative to the current working directory of the calling process, as is done by `access()` for a relative *pathname*).
- If *pathname* is relative and *dirfd* is the special value `AT_FDCWD`, *pathname* is interpreted relative to the current working directory of the calling process (like `access()`).

If *pathname* is absolute, *dirfd* is ignored.

flags is constructed by ORing together zero or more of the following values:

AT_EACCESS

Perform access checks by using the effective user and group IDs. By default, `faccessat()` uses the real IDs (like `access()`).

AT_SYMLINK_NOFOLLOW

If *pathname* is a symbolic link, do not dereference it but return information about the link itself instead.

Returned value

If successful, `faccessat()` returns 0.

If unsuccessful, `faccessat()` returns -1 and sets `errno` to one of the following values:

Error Code**Description****EACCES**

The process does not have appropriate permissions to access the file in the specified way, or does not have search permission on some component of the *pathname* prefix.

EBADF

The *pathname* argument does not specify an absolute path and the *fd* argument is not `AT_FDCWD` or a valid file descriptor that is open for reading or searching.

EINVAL

mode is incorrectly specified or an invalid flag is specified in *flags*.

ELOOP

A loop exists in symbolic links that are encountered during resolution of the *pathname* argument.

ENAMETOOLONG

pathname is longer than `PATH_MAX` characters. The `PATH_MAX` value is determined by using `pathconf()`.

ENOENT

No file is named *pathname*, or the *pathname* argument is an empty string.

ENOTDIR

Some component of the *pathname* prefix is not a directory.

EROFS

Write access is requested for a file on a read-only file system.

ETXTBSY

Write access is requested to an executable that is being executed.

Related information

- [“fcntl.h — POSIX functions for file operations” on page 23](#)
- [“unistd.h — Implementation-specific functions” on page 77](#)
- [“access\(\) — Determine whether a file can be accessed” on page 115](#)

- [“chown\(\) — Change the owner or group of a file or directory” on page 277](#)

fattach() — Attach a STREAMS-based file descriptor to a file in the file system name space

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stropts.h>

int fattach(int fildev, const char *path);
```

General description

The `fattach()` function attaches a STREAMS-based file descriptor to a file, effectively associating a path name with *fildev*. The *fildev* argument must be a valid open file descriptor associated with a STREAMS file. The *path* argument points to a path name of an existing file. The process must have appropriate privileges, or must be the owner of the file named by *path* and have write permission. A successful call to `fattach()` causes all path names that name the file named by *path* to name the STREAMS file associated with *fildev*, until the STREAMS file is detached from the file. A STREAMS file can be attached to more than one file and can have several path names associated with it.

The attributes of the named STREAMS file are initialized as follows: the permissions, user ID, group ID, and times are set to those of the file named by *path*, the number of links is set to 1, and the size and device identifier are set to those of the STREAMS file associated with *fildev*. If any attributes of the named STREAMS file are subsequently changed (for example, by `chmod()`), neither the attributes of the underlying file nor the attributes of the STREAMS file to which *fildev* refers are affected.

File descriptors referring to the underlying file, opened before an `fattach()` call, continue to refer to the underlying file.

Returned value

If successful, `fattach()` returns 0.

If unsuccessful, `fattach()` returns -1 and sets `errno` to one of the following values.

Note: z/OS UNIX services do not supply any STREAMS devices or pseudodevices. It is impossible for `fattach()` to attach a STREAMS-based file descriptor to a file. It will always return -1 with `errno` set to indicate the failure. See [“open\(\) — Open a file” on page 1157](#) for more information.

Error Code

Description

EACCES

Search permission is denied for a component of the path prefix, or the process is the owner of *path* but does not have write permissions on the file named by *path*.

EBADF

The *fildev* argument is not a valid open file descriptor.

EBUSY

The file named by *path* is currently a mount point or has a STREAMS file attached to it.

EINVAL

The *fildev* argument does not refer to a STREAMS file.

ELOOP

Too many symbolic links were encountered in resolving *path*.

ENAMETOOLONG

The size of *path* exceeds **PATH_MAX**, or a component of *path* is longer than **NAME_MAX**, or path name resolution of a symbolic link produced an intermediate result whose length exceeds **PATH_MAX**.

ENOENT

A component of *path* does not name an existing file or *path* is an empty string.

ENOTDIR

A component of the path prefix is not a directory.

EPERM

The effective user ID of the process is not the owner of the file named by *path* and the process does not have appropriate privilege.

Related information

__fbufsize() — Retrieve the buffer size of an open stream

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <stdio.h>
#include <stdio_ext.h>

size_t __fbufsize(FILE *stream);
```

General description

The `__fbufsize()` function retrieves the buffer size, in bytes, of the specified stream.

Returned value

The `__fbufsize()` function returns the size of the buffer in bytes. Otherwise, the `__fbufsize()` function returns 0. If an error has occurred, `__fbufsize()` returns 0 and sets `errno` to nonzero.

An application wishing to check for error situations should set `errno` to 0, then call `__fbufsize()`, and then check `errno`. If `errno` is nonzero, assume that an error has occurred.

Error Code

Description

EBADF

The stream specified by *stream* is not valid.

Example

CELEBF87

```

/* CELEBF87

   This example determines the size of the I/O buffer
   for an open stream.

*/

#include <stdio.h>
#include <stdio_ext.h>

void main() {
    FILE *f;
    int bufsize = 0;
    char filename[FILENAME_MAX] = "myfile.dat";

    f = fopen(filename,"wb");
    if (f == NULL) {
        perror("fopen failed\n");
        return;
    }

    bufsize = __fbufsize(f);

    printf("The buffer size for %s is %d\n",filename,bufsize);

    return;
}

```

Output

```
The buffer size for myfile.dat is 4096
```

__fchattr(), __fchattr64() — Change the attributes of a file or directory by file descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R2 |

Format

__fchattr:

```

#define _OPEN_SYS_FILE_EXT 1
#include <sys/stat.h>

int __fchattr(int filedес, attrib_t *attributes, int attributes_len);

```

__fchattr64:

```
#define _LARGE_TIME_API
#define _OPEN_SYS_FILE_EXT 1
#include <sys/stat.h>
```

```
int __fchattr64(int filedes, attrib64_t *attributes, int attributes_len);
```

Compile requirement: Use of the `__fchattr64` function requires the `long long` data type. For more information on how to make the `long long` data type available, see [z/OS XL C/C++ Language Reference](#).

General description

The `__fchattr()` function modifies the attributes that are associated with a file. It can be used to change the mode, owner, access time, modification time, change time, reference time, audit flags, general attribute flags, file tag, and file format and size. The file to be impacted is defined by its file descriptor with the *filedes* argument.

The *attributes* argument is the address of an `attrib_t` structure which is used to identify the attributes to be modified and the new values desired. The `attrib_t` type is an `f_attributes` structure as defined in `<sys/stat.h>` for use with the `__fchattr()` function. For proper behavior, the user should ensure that this structure has been initialized to zeros before it is populated. The `f_attributes` structure is defined as indicated in [Table 20 on page 262](#).

The `__fchattr64()` function behaves exactly like `__fchattr()` except `__fchattr64()` uses `struct attrib64_t` instead of `struct attrib_t` to support time beyond 03:14:07 UTC on January 19, 2038.

The `attrib64_t` type is an `f_attributes64` structure as defined in `<sys/stat.h>` for use with the `__fchattr64()` function.

Returned value

If successful, `__fchattr()` returns 0.

If unsuccessful, `__fchattr()` returns -1 and sets `errno` to one of the following values:

Error Code**Description****EACCES**

The calling process did not have appropriate permissions. Possible reasons include:

- The calling process was attempting to set access time or modification time to current time, and the effective UID of the calling process does not match the owner of the file; the process does not have write permission for the file; or the process does not have appropriate privileges.
- The calling process was attempting to truncate the file, and it does not have write permission for the file.

EBADF

The *filedes* parameter is not a valid file descriptor.

ECICS

An attempt was made to change file tag attributes under non-OTE CICS and file tagging is not supported in that environment.

EFBIG

The calling process was attempting to change the size of a file but the specified length is greater than the maximum file size limit for the process.

EINVAL

The attributes structure containing the requested changes is not valid.

EPERM

The operation is not permitted for one of the following reasons:

- The calling process was attempting to change the mode or the file format but the effective UID of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges.
- The calling process was attempting to change the owner but it does not have appropriate privileges.
- The calling process was attempting to change the general attribute bits but it does not have write permission for the file.
- The calling process was attempting to set a time value (not current time) but the effective UID does not match the owner of the file, and it does not have appropriate privileges.
- The calling process was attempting to set the change time or reference time to current time but it does not have write permission for the file.
- The calling process was attempting to change auditing flags but the effective UID of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges.
- The calling process was attempting to change the Security Auditor's auditing flags but the user does not have auditor authority.

EROFS

pathname specifies a file that is on a read-only file system.

fchaudit() — Change audit flags for a file by descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <sys/stat.h>

int fchaudit(int fildes, unsigned int flags, unsigned int option);
```

General description

Changes the audit flags of a file. The parameter *fildes* is the file descriptor for the open file whose audit flags are to be changed. *flags* specifies what the audit flags should be changed to:

AUDTREADFAIL

Audit failing read requests.

AUDTREADSUCC

Audit successful read requests.

AUDTWRITEFAIL

Audit failing write requests.

AUDTWritesucc

Audit successful write requests.

AUDTEXECFAIL

Audit failing execute or search requests.

AUDTEXECSUCC

Audit successful execute or search requests. The bitwise inclusive-OR of any or all of these can be used to set more than one type of auditing.

The parameter *option* specifies whether the user audit flags or the security auditor audit flags should be changed:

AUDT_USER (0)

User audit flags are changed. The user must be the file owner or have appropriate authority to change the user audit flags for a file.

AUDT_AUDITOR (1)

Security-auditor audit flags are changed. The user must have security auditor authority to change the security auditor audit flags for a file.

Returned value

If successful, fchaudit() returns 0.

If unsuccessful, fchaudit() returns -1 and sets errno to one of the following values:

Error Code**Description****EBADF**

fildev is not a valid open file descriptor.

EINVAL

option does not contain a 0 or 1.

EPERM

The effective user ID (UID) of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges.

EROFS

fildev is associated with a file that is on a read-only file system.

Example**CELEBF02**

```
/* CELEBF02

   The following program changes the audit flags of a file.

*/
#define _OPEN_SYS
#include <fcntl.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <unistd.h>
#include <stdio.h>

main() {
    int fd;
    char fn[]="fchaudit.file";

    if ((fd = creat(fn, S_IRUSR|S_IWUSR)) < 0)
        perror("creat() error");
    else {
        if (fchaudit(fd, AUDTREADSUCC, AUDT_USER) != 0)
            perror("fchaudit() error");
        close(fd);
        unlink(fn);
    }
}
```

fchdir() — Change working directory

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int fchdir(int fildevs);
```

General description

The `fchdir()` function has the same effect as `chdir()` except that the directory that is to be new current working directory is specified by the file descriptor *fildevs*.

Returned value

If successful, `fchdir()` changes the working directory and returns 0.

If unsuccessful, `fchdir()` does not change the working directory, returns -1, and sets `errno` to one of the following values:

Error Code

Description

EACCES

Search permission is denied for the directory referenced by *fildevs*.

EBADF

The *fildevs* arguments is not an open file descriptor.

ENOTDIR

The open file descriptor *fildevs* does not refer to a directory.

Related information

- [“unistd.h — Implementation-specific functions” on page 77](#)
- [“chdir\(\) — Change the working directory” on page 270](#)
- [“chroot\(\) — Change root directory” on page 281](#)

fchmod() — Change the mode of a file or directory by descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1a XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX1_SOURCE 2
#include <sys/stat.h>

int fchmod(int fildes, mode_t mode);
```

General description

Sets the S_ISUID, S_ISGID, and file permission bits of the open file identified by *fil*des, its file descriptor.

The *mode* argument is created with one of the symbols defined in the sys/stat.h header file. For more information on these symbols, refer to [“chmod\(\) — Change the mode of a file or directory” on page 274](#).

Returned value

If successful, fchmod() marks for update the st_ctime field of the file and returns 0.

If unsuccessful, fchmod() returns -1 and sets errno to one of the following values:

Error Code

Description

EBADF

*fil*des is not a valid open file descriptor.

EPERM

The effective user ID (UID) does not match the owner of the file, and the calling process does not have appropriate privileges.

EROFS

The file resides on a read-only file system.

Example

CELEBF03

```
/* CELEBF03
   This example changes a file permission.
*/
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
    char fn[]="temp.file";
    int fd;
    struct stat info;

    if ((fd = creat(fn, S_IWUSR)) < 0)
```

```

    perror("creat() error");
else {
    stat(fn, &info);
    printf("original permissions were: %08x\n", info.st_mode);
    if (fchmod(fd, S_IRWXU|S_IRWXG) != 0)
        perror("fchmod() error");
    else {
        stat(fn, &info);
        printf("after fchmod(), permissions are: %08x\n", info.st_mode);
    }
    close(fd);
    unlink(fn);
}
}

```

Output

```

original permissions were: 03000080
after fchmod(), permissions are: 030001f8

```

fchmodat() — Change the mode of a file relative to a directory file descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1-2008 Single UNIX Specification, Version 4 | both | |

Format

```

#define _POSIX_C_SOURCE 200809L
#include <fcntl.h> /* Definition of AT_* constants */
#include <sys/stat.h>

int fchmodat(int fd, const char *path, mode_t mode, int flag);

```

General description

fchmodat() function is equivalent to the chmod() function except for the following differences:

- If *pathname* is relative, it is interpreted relative to the directory referred to by the file descriptor *dirfd* (rather than relative to the current working directory of the calling process, as is done by chmod() for a relative *pathname*).
- If *pathname* is relative and *dirfd* is the special value AT_FDCWD, *pathname* is interpreted relative to the current working directory of the calling process (like chmod()).

- If *pathname* is absolute, then *dirfd* is ignored.

flags can either be 0 or include the following list, which is defined in `<fcntl.h>`:

AT_SYMLINK_NOFOLLOW

If *pathname* is a symbolic link, the mode of the symbolic link is changed.

If `fchmodat()` is passed the special value `AT_FDCWD` in the *fd* parameter, the current working directory must be used. In this case, if *flag* is zero, the behavior must be identical to a call to `chmod()`.

Returned value

If successful, `fchmodat()` returns 0.

If unsuccessful, `fchmodat()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

The calling process does not have permission to search some component of *pathname*.

EBADF

The *pathname* argument does not specify an absolute path and the *fd* argument is not `AT_FDCWD` or a valid file descriptor that is open for reading or searching.

EINVAL

One of the input parameters is not valid.

ELOOP

A loop exists in symbolic links. This error is issued if more than `POSIX_SYMLINK_MAX` symbolic links are encountered during resolution of the symlink argument.

ENAMETOOLONG

pathname is longer than 1023 characters, or a component of *pathname* is longer than 255 characters. (Filename truncation is not supported.)

ENOENT

A component of *pathname* does not name an existing file or *pathname* is an empty string.

ENOTDIR

A component of the *pathname* prefix is not a directory.

EPERM

The effective UID of the calling process does not match the owner of the file, and the calling process does not have appropriate privilege.

EROFS

The file resides on a read-only file system.

Related information

fchown() — Change the owner or group by file descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1a XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX1_SOURCE 2
#include <unistd.h>

int fchown(int fildes, uid_t owner, gid_t group);
```

General description

Changes the owner or group (or both) of a file. *fil*des is the file descriptor for the file. *owner* is the user ID (UID) of the new owner of the file. *group* is the group ID of the new group for the file.

If `_POSIX_CHOWN_RESTRICTED` is defined in the `unistd.h` header file, a process can change the group of a file only if one of the following conditions is true:

1. The process has appropriate privileges.
- Or
2. All of the following are true:
 - a. The effective user ID of the process is equal to the user ID of the file owner.
 - b. The *owner* argument is equal to the user ID of the file owner or `(uid_t)-1`,
 - c. The *group* argument is either the effective group ID or a supplementary group ID of the calling process.

If *fil*des points to a regular file and one or more of the `S_IXUSR`, `S_IXGRP`, or `S_IXOTH` bits of the file mode are set when `fchown()` returns successfully, it clears the set-user-ID (`S_ISUID`) and set-group-ID (`S_ISGID`) bits of the file mode.

If the file referred to by *fil*des is not a regular file and one or more of the `S_IXUSR`, `S_IXGRP`, or `S_IXOTH` bits of the file mode are set, the set-user-ID (`S_ISUID`) and set-group-ID (`S_ISGID`) bits of the file are cleared.

When `fchown()` completes successfully, it marks the `st_ctime` field of the file to be updated.

Returned value

If successful, `fchown()` updates the change time for the file and returns 0.

If unsuccessful, `fchown()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

*fil*des is not a valid open file descriptor.

EPERM

Either the effective user ID does not match the owner of the file, or the calling process does not have appropriate privileges, and `POSIX_CHOWN_RESTRICTED` indicates that such privilege is required.

EROFS

The file resides on a read-only system.

Example**CELEBF04**

```
/* CELEBF04

   This example changes the owner ID and group ID.

*/
#define _POSIX_SOURCE
#include <fcntl.h>
#include <unistd.h>
#include <sys/stat.h>
#include <sys/types.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
    char fn[]="temp.file";
    FILE *stream;
    int fd;
    struct stat info;

    if ((fd = creat(fn, S_IWUSR)) < 0)
        perror("creat() error");
    else {
        stat(fn, &info);
        printf("original owner was %d and group was %d\n", info.st_uid,
               info.st_gid);
        if (fchown(fd, 25, 0) != 0)
            perror("fchown() error");
        else {
            stat(fn, &info);
            printf("after fchown(), owner is %d and group is %d\n",
                   info.st_uid, info.st_gid);
        }
        close(fd);
        unlink(fn);
    }
}
```

Output

```
original owner was 0 and group was 500
after fchown(), owner is 25 and group is 0
```

fchownat() — Change owner and group of a file relative to directory file descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1-2008 Single UNIX Specification, Version 4 | both | |

Format

```
#define _POSIX_C_SOURCE 200809L
#include <unistd.h>
#include <fcntl.h>

int fchownat(int dirfd, const char *path, uid_t owner, gid_t group, int flag);
```

General description

fchownat() operates in the same way as chown() except for the following differences:

- If the *pathname* is relative, it is interpreted relative to the directory referred to by the file descriptor *dirfd* (rather than relative to the current working directory of the calling process, as is done by chown() for a relative *pathname*).
- If *pathname* is relative and *dirfd* is the special value AT_FDCWD, *pathname* is interpreted relative to the current working directory of the calling process (like chown()).
- If *pathname* is absolute, *dirfd* is ignored.
- *flags* can either be 0 or include the following flag:

AT_SYMLINK_NOFOLLOW

- If *pathname* is a symbolic link, do not dereference it but operate on the link itself instead (like chown()). By default, fchownat() dereferences symbolic links, like chown().

Returned value

If successful, fchownat() returns 0.

If unsuccessful, fchownat() returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

dirfd is not a valid open file descriptor.

EPERM

Either the effective user ID does not match the owner of the file, or the calling process does not have appropriate privileges, and POSIX_CHOWN_RESTRICTED indicates that such privilege is required.

EROFS

The file resides on a read-only file system.

EINVAL

An invalid flag is specified in *flags*.

ENOTDIR

pathname is relative and *dirfd* is a file descriptor referring to a file other than a directory.

Related information

- [“fchown\(\) — Change the owner or group by file descriptor” on page 479](#)

fclose() — Close file

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdio.h>

int fclose(FILE *stream);
```

General description

Flushes a stream, and then closes the file associated with that stream. Afterwards, the function releases any buffers associated with the stream. To *flush* means that unwritten buffered data is written to the file, and unread buffered data is discarded.

A pointer to a closed file *cannot* be used as an input value to the `freopen()` function.

Notes:

1. The storage pointed to by the FILE pointer is freed by the `fclose()` function. An attempt to use the FILE pointer to a closed file is not valid. This restriction is true even when `fclose()` fails.
2. If an application has locked a (FILE *) object (with `flockfile()` or `ftrylockfile()`), it is responsible for relinquishing the locked (FILE *) object (with `funlockfile()`) before calling `fclose()`. Failure to relinquish a locked (FILE *) object may cause deadlock (or looping).

Returned value

If successful closing the stream, `fclose()` returns 0.

If a failure occurs in flushing buffers or in outputting data, `fclose()` returns EOF. An attempt will still be made to close the file.

Special behavior for XPG4

`fclose()` sets `errno` to one of the following values:

Error Code

Description

EAGAIN

The `O_NONBLOCK` flag is set and output cannot be written immediately.

EBADF

The underlying file descriptor is not valid.

EFBIG

Writing to the output file would exceed the maximum file size or the process's file size supported by the implementation.

EINTR

The `fclose()` function was interrupted by a signal before it had written any output.

EIO

The process is in a background process group and is attempting to write to its controlling terminal, but `TOSTOP` (defined in the `termio.h` include file) is set, the process is neither ignoring nor blocking `SIGTTOU` signals, and the process group of the process is orphaned.

ENOSPC

There is no free space left on the output device

ENXIO

A request was made of a nonexistent device, or the request was outside the device.

EPIPE

`fclose()` is trying to write to a pipe or FIFO that is not open for reading by any process. This error also generates a `SIGPIPE` signal.

Example

```
/* This example opens a file myfile.dat for reading as a stream and then
   closes the file.
*/
#include <stdio.h>

int main(void)
{
    FILE *stream;

    stream = fopen("myfile.dat", "r");
    :
    if (fclose(stream)) /* Close the stream. */
        printf("fclose error\n");
}
```

fcntl() — Control open file descriptors

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <fcntl.h>

int fcntl(int fil-des, int action, ...);
```

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
#include <unistd.h>
#include <fcntl.h>

int fcntl(int socket, int cmd, ...);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <unistd.h>
#include <fcntl.h>

int fcntl(int socket, int cmd, ...);
```

General description

The `fcntl()` function performs various actions on open file descriptors.

The argument *fil-des* is a file descriptor for the file you want to manipulate. *action* is a symbol indicating the action you want to perform on *fil-des*. These symbols are defined in the `<fcntl.h>` header file. If needed, “...” indicates a third argument. The type of the third argument depends on *action*, and some actions do not need an additional argument.

Behavior for sockets: The operating characteristics of sockets can be controlled with the `fcntl()` call. The operations to be controlled are determined by *cmd*. The *arg* parameter is a variable with a meaning that depends on the value of the *cmd* parameter.

Parameter Description

socket

The socket descriptor.

cmd

The command to perform.

arg

The data associated with *cmd*.

The *action* argument can be one of the following symbols:

F_CLOSF

Closes a range of file descriptors. A third `int` argument must be specified to indicate the upper limit for the range of the file descriptors to be closed, while *fil-des* specifies the lower limit. If -1 is specified for the third argument, all file descriptors greater than or equal to the lower limit are closed.

F_DUPFD

Duplicates the file descriptor. A third `int` argument must be specified. `fcntl()` returns the lowest file descriptor greater than or equal to this third argument that is not already associated with an open file. This file descriptor refers to the same file as *fil-des* and shares any locks. The flags `FD_CLOEXEC` and `FD_CLOFORK` are turned off in the new file descriptor, so that the file is kept open if an `exec` function is called.

Note: If *fil-des* is an XTI endpoint, there must be at least one available file descriptor greater than or equal to the third argument and less than 65536.

F_DUPFD2

Duplicates the file descriptor. A third `int` argument must be specified to indicate which file descriptor to use as the duplicate. This file descriptor is closed if already open and then used as the new file descriptor. The new file descriptor refers to the same file as *fdes* and shares any locks. The flag `FD_CLOEXEC` is turned off in the new file descriptor, so that the file is kept open if an `exec` function is called.

Note:

1. If the third argument refers to the same file descriptor as *fdes*, the file descriptor is not closed and `FD_CLOEXEC` is not turned off.
2. If *fdes* is an XTI endpoint, the third argument must not exceed the limit of 65535.

F_GETFD

Obtains the file descriptor flags for *fdes*. `fcntl()` returns these flags as its result. For a list of supported file descriptor flags, see [“File flags” on page 487](#).

F_SETFD

Sets the file descriptor flags for *fdes*. You must specify a third `int` argument, giving the new file descriptor flag settings. `fcntl()` returns 0 if it successfully sets the flags.

F_GETFL

Obtains the file status flags and file access mode flags for *fdes*. `fcntl()` returns these flags as its result. For a list of supported file status and file access mode flags, see [“File flags” on page 487](#).

Usage of the `F_GETFL` action will return the setting of `O_LARGEFILE` status flag when `fcntl()` has been enabled to operate on large files

Behavior for sockets: This command gets the status flags of socket descriptor *socket*.

With the `_OPEN_SYS` feature test macro you can query the `FNDELAY` flag. With the `_XOPEN_SOURCE_EXTENDED 1` feature test macro you can query the `O_NDELAY` flag. The `FNDELAY` and `O_NDELAY` flags mark *socket* as being in nonblocking mode. If data is not present on calls that can block, such as `read()`, `readv()`, and `recv()`, the call returns with -1, and the error code is set to `EWOULDBLOCK`.

F_SETFL

Sets the file status flags for *fdes*. You must specify a third `int` argument, giving the new file descriptor flag settings. `fcntl()` does not change the file access mode, and file access bits in the third argument are ignored. `fcntl()` returns 0 if it successfully sets the flags.

Behavior for sockets: This command sets the status flags of socket descriptor *socket*. With the `_OPEN_SYS` feature test macro you can set the `FNDELAY` flag. With the `_XOPEN_SOURCE_EXTENDED 1` feature test macro you can set the `O_NDELAY` flag.

F_GETLK

Obtains locking information for a file. See [“File locking” on page 488](#)

F_SETLK

Sets or clears a file segment lock. See [“File locking” on page 488](#)

F_SETLKW

Sets or clears a file segment lock; but if a shared or exclusive lock is blocked by other locks, `fcntl()` waits until the request can be satisfied. See [“File locking” on page 488](#)

F_GETOWN

Behavior for sockets: Obtains the PID for the *filedes* and returns this value. The value returned will be either the process ID or the process group ID that is associated with the socket. If it is a positive integer, it specifies a process ID. If it is a negative integer (other than -1), it specifies a process group ID.

F_SETOWN

Behavior for sockets: Sets either the process ID or the process group ID that is to receive either the `SIGIO` or `SIGURG` signals for the socket associated with *filedes*. The `SIGURG` signal is generated as a result of receiving out-of-band data. Refer to `send()`, `sendto()`, `sendmsg()`, and `recv()`, `recvfrom()` and `recvmsg()` for more information on sending and receiving out-of-band data.

You must specify a third int argument, giving the PID requested. This value can be either a positive integer, specifying a process ID, or a negative integer (other than -1), specifying a process group ID. The difference between specifying a process ID or a process group ID is that in the first case only a single process will receive the signal, while in the second case all processes in the process group will receive the signal.

F_SETTAG

Sets the file tag for the file referred to by file descriptor *fildev*.

The third argument *ftag* is the address of a populated file_tag structure.

If the *ftag* argument supplied to fcntl(F_SETTAG) does not have the ft_deferred bit set ON, fcntl() will immediately set the file's File Tag with the provided *ftag*'s ft_ccsid and ft_txtflag values.

If the *ftag* argument supplied to fcntl(F_SETTAG) has the ft_deferred bit set ON, fcntl() will not set the file's File Tag until first write to the file. The CCSID used to tag the file will be the current Program CCSID at the time of first write, regardless of the *ftag* ft_ccsid value, however the ft_txtflag value will be used.

If the ft_ccsid of the specified file_tag differs from the Program CCSID, automatic file conversion will occur, provided both of the following conditions are met:

- The ft_txtflag is set to ON.
- Environment variable _BPXK_AUTOCVT is ON or ALL; or if _BPXK_AUTOCVT is unset, the BPXPRMxx member AUTOCVT is either ON or ALL.

Restriction: When _BPXK_AUTOCVT is ON, automatic conversion can only take place between IBM-1047 and ISO8859-1 code sets. Other CCSID pairs are not supported for automatic text conversion. To request automatic conversion for any CCSID pairs that Unicode service supports, set _BPXK_AUTOCVT to ALL.

If AUTOCVT(OFF) and _BPXK_AUTOCVT=OFF, the file will be tagged with the specified file_tag's ft_ccsid and ft_txtflag values, but automatic conversion will not occur. See the “Using Environment Variables” chapter in *z/OS XL C/C++ Programming Guide* for more information about the _BPXK_AUTOCVT environment variable.

If the *ftag* argument supplied to fcntl(F_SETTAG) has the ft_deferred bit set ON, pipes and FIFOs are tagged from the write end with the Program CCSID of the first writer.

F_CONTROL_CVT

Controls or queries the conversion status of the open file referred to by file descriptor *fildev*. Conversion control is generally used to provide CCSID information for untagged files or untagged programs.

Character set conversion between a program and a file, pipe or other I/O stream can be enabled or changed with F_CONTROL_CVT. A pair of CCSID's is specified or defaulted, one for the program and one for the data. As the program reads and writes data, the system will convert from one CCSID to the other.

The third f_cnvrt argument is the required address of an f_cnvrt structure. This structure is defined in <fcntl.h> and includes the following members:

Table 22. Struct f_cnvrt Element Descriptions

| Element | Data Type | Description |
|---------|-----------|--|
| pccsid | short | The Program CCSID - This is output from query and input to setting conversion ON. A value of 0 on input indicates to use the previously set value or the current Program CCSID. |
| fccsid | short | The File CCSID - This is output from query and input to setting conversion ON. A value of 0 on input indicates to use the CCSID from the File Tag as stored in the file, specified on mount, or set by a prior call. |

Table 22. Struct `f_cnvrt` Element Descriptions (continued)

| Element | Data Type | Description |
|---------------------|------------------|--|
| <code>cvtcmd</code> | <code>int</code> | <p>Conversion Control Command. The following conversion controls are available:</p> <ul style="list-style-type: none"> • Query Conversion - Returns whether or not conversion is in effect and the Program and File CCSIDs being used. On input, <code>cvtcmd</code> is set to <code>QUERYCVT</code>, and on output, it is changed to either <code>SETCVTON</code>, <code>SETCVTOFF</code>, or <code>SETCVTALL</code> to indicate that conversion is currently ON, OFF, or ALL respectively. The current CCSIDs are also returned in their respective positions in the <code>f_cnvrt</code> structure. • Set Conversion OFF - Turns OFF any conversion that may be in effect. On input, <code>cvtcmd</code> is set to <code>SETCVTOFF</code> and the rest of the <code>f_cnvrt</code> is ignored. There is no output. A program can use this to override an automatic conversion that might be established by the environment within which it is invoked. If conversion is currently in effect, the CCSIDs being used will be remembered while conversion is turned OFF, so that the prior conversion may be resumed without the program having to remember what the prior CCSIDs were. • Set Conversion ON - Turns on enhanced ASCII conversion environment and optionally specifies the CCSIDs to use in place of the Program or File CCSIDs that are currently in effect. On input, <code>cvtcmd</code> is set either to <code>SETCVTON</code> to unconditionally turn on Enhanced ASCII, or to <code>SETAUTOCVTON</code> to turn on it only if <code>_BPXK_AUTOCVT=ON</code> or <code>AUTOCVT(ON)</code> was specified in <code>BPXPRMxx</code>. In this case, automatic conversion can only take place between IBM-1047 and ISO8859-1 code sets. Other CCSID pairs are not supported for automatic text conversion. A value of 0 for the Program CCSID indicates that the current Program CCSID be used. A value of 0 for the file CCSID indicates that no change should be made to the File CCSID. This does not affect the stored File Tag or the current Program CCSID. It only changes the values being used to control conversion on this data stream. • Set Conversion ALL - Turns on Unicode conversion environment and optionally specifies the CCSIDs to use in place of the Program or File CCSIDs that are currently in effect. On input, <code>cvtcmd</code> can be set either to <code>SETCVTALL</code> to unconditionally turn on Unicode conversion, or to <code>SETAUTOCVTALL</code> to turn on it only if <code>_BPXK_AUTOCVT=ALL</code> or <code>AUTOCVT(ALL)</code> was specified in <code>BPXPRMxx</code>. <code>SETCVTALL</code> or <code>SETAUTOCVTALL</code> has no effect after the first read or write of the file. In this case, automatic conversion can take place between any code sets that Unicode service supports. A value of 0 for the Program CCSID indicates that the current Program CCSID be used. A value of 0 for the file CCSID indicates that no change should be made to the File CCSID. This does not affect the stored File Tag or the current Program CCSID. It only changes the values being used to control conversion on this data stream. |

The call fails if a conversion table is not installed for the resulting CCSID pair.

Attention: Flipping the autoconversion mode off and on, or changing the CCSID values when file conversion and/or tagging takes place, or setting the CCSIDs to values that are not compatible with the program or file, can be quite unpredictable.

Large file support for z/OS UNIX files: Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the [long long data type support](#) enabled and define the `_LARGE_FILES` feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the `_LARGE_FILES` feature test macro as well.

File flags

There are several types of flags associated with each open file. Flags for a file are represented by symbols defined in the `<fcntl.h>` header file.

The following *file descriptor* flags can be associated with a file:

FD_CLOEXEC

If this flag is 1, the file descriptor is closed if the process executes one of the exec function calls. If it is 0, the file remains open.

FD_CLOFORK

If this flag is 1 when a fork occurs, the file descriptor will be closed for the child process. If it is 0, the file remains open for the child.

The following *file status* flags can be associated with a file:

O_APPEND

Append mode. If this flag is 1, every write operation on the file begins at the end of the file.

O_ASYNC

If this flag is 1, then asynchronous I/O will be used for the file.

O_CLOEXEC

If this flag is 1, set the `close-on-exec` flag for the new file descriptor. This flag is defined by the `_XPLATFORM_SOURCE` feature test macro.

O_DIRECT

If this flag is 1, try to minimize cache effects of the I/O to and from this file. This flag is defined by the `_XPLATFORM_SOURCE` feature test macro.

O_NONBLOCK

No blocking. If this flag is 1, read and write operations on the file return with an error status if they cannot perform their I/O immediately. If this flag is 0, read and write operations on the file wait (or “block”) until the file is ready for I/O. For more details, see [“read\(\) — Read from a file or socket”](#) on page 1380 and [“write\(\) — Write data on a file or socket”](#) on page 2070.

O_SYNC

Force synchronous update. If the flag is 1, every `write()` operation on the file is written to permanent storage. That is, the file system buffers are forced to permanent storage. (See [“fsync\(\) — Write changes to direct-access storage”](#) on page 655.) If this flag is 0, update operations on the file will not be completed until the data has been written to permanent storage. On return from a function that performs a synchronous update, the program is assured that all data for the file has been written to permanent storage.

The following *file access mode* flags can be associated with a file:

O_RDONLY

The file is opened for reading only.

O_RDWR

The file is opened for reading and writing.

O_WRONLY

The file is opened for writing only.

Two masks can be used to extract flags:

O_ACCMODE

Extracts file access mode flags.

O_GETFL

Extracts file status flags and file access mode flags.

File locking

A process can use `fcntl()` to lock out other processes from a part of a file, so that the process can read or write to that part of the file without interference from others. File locking can ensure data integrity when several processes have a file accessed concurrently. File locking can only be performed on file descriptors

that refer to regular files. Locking is not permitted on file descriptors that refer to directories, FIFOs, pipes, character special files, or any other type of files.

A structure that has the type `struct flock` (defined in the `<fcntl.h>` header file) controls locking operations. This structure has the following members:

short l_type

Indicates the type of lock, using one of the following symbols (defined in the `<fcntl.h>` header file):

F_RDLCK

Indicates a *read lock*, also called a *shared lock*. The process can read the locked part of the file, and other processes cannot obtain write locks for that part of the file in the meantime. More than one process can have a read lock on the same part of a file simultaneously.

To establish a read lock, a process must have the file accessed for reading.

F_WRLCK

Indicates a *write lock*, also called an *exclusive lock*. The process can write on the locked part of the file, and no other process can establish a read lock or write lock on that same part or on an overlapping part of the file. A process cannot put a write lock on part of a file if there is already a read lock on an overlapping part of the file. To establish a write lock, a process must have accessed the file for writing.

F_UNLCK

Unlocks a lock that was set previously. An unlock (`F_UNLCK`) request in which `l_len` is non-zero and the offset of the last byte of the requested segment is the maximum value for an object of type `off_t`, when the process has an existing lock in which `l_len` is 0 and which includes the last byte of the requested segment, is treated as a request to unlock from the start of the requested segment with an `l_len` equal to 0. Otherwise, an unlock (`F_UNLCK`) request attempts to unlock only the requested segment.

short l_whence

One of three symbols used to determine the part of the file that is affected by this lock. These symbols are defined in the `<unistd.h>` header file and are the same as symbols used by `lseek()`:

SEEK_CUR

The current file offset in the file

SEEK_END

The end of the file

SEEK_SET

The start of the file.

off_t l_start

Gives the byte offset used to identify the part of the file that is affected by this lock. The part of the file affected by the lock begins at this offset from the location given by `l_whence`. For example, if `l_whence` is `SEEK_SET` and `l_start` is 10, the locked part of the file begins at an offset of 10 bytes from the beginning of the file.

off_t l_len

Gives the size of the locked part of the file in bytes. If `l_len` is 0, the locked part of the file begins at the position specified by `l_whence` and `l_start`, and extends to the end of the file. If `l_len` is positive, the area affected starts at `l_start` and end at `l_start + l_len - 1`. If `l_len` is negative, the area affected starts at `l_start + l_len` and end at `l_start - 1`. Locks may start and extend beyond the current end of a file, but cannot extend before the beginning of the file. A lock can be set to extend to the largest possible value of the file offset for that file by setting `l_len` to 0. If such a lock also has `l_start` set to 0 and `l_whence` is set to `SEEK_SET`, the whole file is locked.

pid_t l_pid

Specifies the process ID of the process that holds the lock. This is an output field used only with `F_GETLK` actions.

You can set locks by specifying `F_SETLK` as the *action* argument for `fcntl()`. Such a function call requires a third argument pointing to a `struct flock` structure, as in this example:

```
struct flock lock_it;
lock_it.l_type = F_RDLCK;
lock_it.l_whence = SEEK_SET;
lock_it.l_start = 0;
lock_it.l_len = 100;
fcntl(filides, F_SETLK, &lock_it);
```

This example sets up an `flock` structure describing a read lock on the first 100 bytes of a file, and then calls `fcntl()` to establish the lock. You can unlock this lock by setting `l_type` to `F_UNLCK` and making the same call. If an `F_SETLK` operation cannot set a lock, it returns immediately with an error saying that the lock cannot be set.

The `F_SETLKW` operation is similar to `F_SETLK`, except that it waits until the lock can be set. For example, if you want to establish an exclusive lock and some other process already has a lock established on an overlapping part of the file, `fcntl()` waits until the other process has removed its lock. If `fcntl()` is waiting in an `F_SETLKW` operation when a signal is received, `fcntl()` is interrupted. After handling the signal, `fcntl()` returns `-1` and sets `errno` to `EINTR`.

`F_SETLKW` operations can encounter *deadlocks* when process A is waiting for process B to unlock a region, and B is waiting for A to unlock a different region. If the system detects that an `F_SETLKW` might cause a deadlock, `fcntl()` fails with `errno` set to `EDEADLK`.

A process can determine locking information about a file by using `F_GETLK` as the *action* argument for `fcntl()`. In this case, the call to `fcntl()` should specify a third argument pointing to an `flock` structure. The structure should describe the lock operation you want. When `fcntl()` returns, the structure indicated by the `flock` pointer is changed to show the first lock that would prevent the proposed lock operation from taking place. The returned structure shows the type of lock that is set, the part of the file that is locked, and the process ID of the process that holds the lock. In the returned structure:

- `l_whence` is always `SEEK_SET`.
- `l_start` gives the offset of the locked portion from the beginning of the file.
- `l_len` is the length of the locked portion.

If there are no locks that prevent the proposed lock operation, the returned structure has `F_UNLCK` in `l_type`, and is otherwise unchanged.

A process can have several locks on a file simultaneously but only one type of lock set on a given byte. Therefore, if a process puts a new lock on part of a file that it had locked previously, the process has only one lock on that part of the file: the type of the lock is the one specified in the most recent locking operation.

All of a process's locks on a file are removed when the process closes any file descriptor that refers to the locked file. Locks are not inherited by child processes created with `fork()`.

All locks are advisory only. Processes can use locks to inform each other that they want to protect parts of a file, but locks do not prevent I/O on the locked parts. If a process has appropriate permissions on a file, it can perform whatever I/O it chooses, regardless of what locks are set. Therefore, file locking is only a convention, and it works only when all processes respect the convention.

Returned value

If successful, the value `fcntl()` returns will depend on the *action* that was specified.

If unsuccessful, `fcntl()` returns `-1` and sets `errno` to one of the following values:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

| | |
|---------------|---|
| EAGAIN | The process tried to set a lock with <code>F_SETLK</code> , but the lock is in conflict with a lock already set by some other process on an overlapping part of the file. |
|---------------|---|

EBADF

fildes is not a valid open file descriptor; or the process tried to set a read lock on a file descriptor open for writing only; or the process tried to set a write lock on a file descriptor open for reading only; or the *socket* parameter is not a valid socket descriptor.

In an F_DUPFD2 operation, the third argument is negative, or greater than or equal to **OPEN_MAX**, which is the highest file descriptor value allowed for the process.

EDEADLK

The system detected the potential for deadlock in a F_SETLKW operation.

EINTR

fcntl() was interrupted by a signal during a F_SETLKW operation.

EINVAL

In an F_DUPFD operation, the third argument is negative or greater than or equal to **OPEN_MAX**, the highest file descriptor value allowed for the process. The **OPEN_MAX** value can be determined using pathconf().

In a locking operation, *fildes* refers to a file with a type that does not support locking, or the struct flock pointed to by the third argument has an incorrect form.

If an F_CLOSF operation, the third argument, which specifies the upper limit, is less than *filedes* but is not equal to -1.

Behavior for sockets: The *arg* parameter is not a valid flag, or the *cmd* parameter is not a valid command.

EMFILE

In an F_DUPFD operation, the process has already reached its maximum number of file descriptors, or there are no available file descriptors greater than the specified third argument.

ENOLCK

In an F_SETLK or F_SETLKW operation, the specified file has already reached the maximum number of locked regions allowed by the system.

EOVERFLOW

One of the values to be returned cannot be represented correctly.

The *cmd* argument is F_GETLK, F_SETLK or F_SETLKW and the smallest or, if *l_len* is nonzero, the largest offset of any byte in the requested segment cannot be represented correctly in an object of type *off_t*.

EPERM

The operation was F_CLOSF, but all the requested file descriptors were not closed.

Examples

CELEBF06

```
/* CELEBF06

   This example illustrates one use of fcntl().
   The example will compile only with C/MVS.

*/
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <signal.h>
#include <stdio.h>

void catcher(int signum) {
    puts("inside catcher...");
}

main() {
    int p[2], flags;
    struct sigaction sact;
```

```

char c;

if (pipe(p) != 0)
    perror("pipe() error");
else {
    sigemptyset(&sact.sa_mask);
    sact.sa_flags = 0;
    sact.sa_handler = catcher;
    sigaction(SIGALRM, &sact, NULL);

    alarm(10);

    if (read(p[0], &c, 1) == -1)
        perror("first read() failed");

    if ((flags = fcntl(p[0], F_GETFL)) == -1)
        perror("first fcntl() failed");
    else if (fcntl(p[0], F_SETFL, flags | O_NONBLOCK) == -1)
        perror("second fcntl() failed");
    else {
        alarm(10);

        if (read(p[0], &c, 1) == -1)
            perror("second read() failed");

        alarm(0);
    }
    close(p[0]);
    close(p[1]);
}
}

```

Output

```

inside catcher...
first read() failed: Interrupted function call
second read() failed: Resource temporarily unavailable

```

Sockets example:

```

#define _OPEN_SYS
int s;
int rc;
int flags;
:
/* Place the socket into nonblocking mode */
rc = fcntl(s, F_SETFL, FNDELAY);

/* See if asynchronous notification is set */
flags = fcntl(s, F_GETFL, 0);
if (flags & FNDELAY)
    /* it is set */
else
    /* it is not */

```

fcvt() — Convert double to string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

char *fcvt(double x, int ndigit, int *__restrict__ decpt, int *__restrict__ sign);
```

General description

The `fcvt()` function converts double floating-point argument values to floating-point output strings. The `fcvt()` function has been extended to determine the floating-point format (hexadecimal floating-point or IEEE Binary Floating-Point) of double argument values by using `__isBFP()`.

IBM z/OS C/C++ formatted output functions, including the `fcvt()` function, convert IEEE Binary Floating-Point infinity and NaN argument values to special infinity and NaN floating-point number output sequences. See [“fprintf Family of Formatted Output Functions” on fprintf\(\), printf\(\), sprintf\(\) — Format and write data](#) for a description of the special infinity and NaN output sequences.

The `fcvt()` function converts `x` to a NULL-terminated string which has `ndigit` digits to the right of the radix point (where the total number of digits in the output string is restricted by the precision of a double) and returns a pointer to the string. The function behaves identically to [“ecvt\(\) — Convert double to string” on page 417](#) in all respects other than the number of digits in the return value.

Note: This function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The `sprintf()` function is preferred for portability.

Returned value

If successful, `fcvt()` returns the character equivalent of `x` as specified above.

If unable to allocate the return buffer, or the conversion fails, `fcvt()` returns NULL.

fdatasync() — Write changes to direct-access storage

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1-2001 POSIX.1-2008 Single UNIX Specification, Version 2 | both | |

Format

```
#define _XOPEN_SOURCE 500
#include <unistd.h>

int fdatasync(int fildes);
```

General description

The `fdatasync()` function is equivalent to `fsync()`, which doesn't provide performance advantages.

Returned value

If successful, `fdatasync()` returns 0.

If unsuccessful, `fdatasync()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

*fil*des is not a valid open file descriptor.

EINVAL

The file is not a regular file.

Note: If the `fdatasync()` function fails, outstanding I/O operations are not guaranteed to be completed.

fdclosedir() — Closes directory associated with file descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX __XPLAT | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <dirent.h>

int fdclosedir(DIR *dirp);
```

General description

The `fdclosedir()` function is equivalent to the `closedir()` function except that `fdclosedir()` returns a directory file descriptor instead of closing it.

Returned value

If successful, `fdclosedir()` returns a file descriptor.

If unsuccessful, `fdopendir()` returns -1 and sets `errno` to indicate the error.

Error Code

Description

ENOTDIR

Not a directory.

Example

```
#define _POSIX_SOURCE
#define _POSIX_C_SOURCE 200809L
#define _XPLATFORM_SOURCE
#include <dirent.h>
#include <stdio.h>

int main() {
    int fd = 0;

    DIR *dir;
    DIR *newdirp;
    struct dirent *entry;
    dir = opendir("/u/userexample/fdopendir");
    fd = dirfd(dir);
    newdirp = fdopendir(fd);
    while ((entry = readdir(newdirp)) != NULL)
        printf(" %s\n", entry->d_name);
    fd = fdclosedir(newdirp);

    return 0;
}
```

fdelrec() — Delete a VSAM record

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <stdio.h>

int fdelrec(FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int fdelrec_unlocked(FILE *stream);
```

General description

Removes the record previously read by `fread()` from the VSAM file associated with `stream`. The `fdelrec()` function can only be used after an `fread()` call has been performed and before any other operation on that file pointer. For example, if you need to acquire the file position using `ftell()` or `fgetpos()`, you can do it either before the `fread()` or after the `fdelrec()`. An `fread()` after an `fdelrec()` will retrieve the next record.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

The `fdelrec()` function can be used with *key sequenced data sets* (KSDS), KSDS PATHs, and *relative record data set* (RRDS) opened in an update mode (that is, `rb+ / r+b`, `wb+ / w+b`, or `ab+ / a+b`), with `type=record`.

VSAM does not support deletions from ESDSs.

`fdelrec_unlocked()` is functionally equivalent to `fdelrec()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

If successful, `fdelrec()` returns 0.

If unsuccessful, `fdelrec()` returns nonzero.

Example

```
/* This example shows how a VSAM record is deleted using the fdelrec()
   function.
*/
#include <stdio.h>
FILE *stream;
char buf[80];
int num_read;
int rc;
stream = fopen("DD:MYCLUS", "rb+,type=record");
:
num_read = fread(buf, 1, sizeof(buf), stream);
rc = fdelrec(stream);
:
```

fdetach() — Detach a name from a STREAMS-based file descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stropts.h>

int fdetach(const char *path);
```

General description

The `fdetach()` function detaches a STREAMS-based file from the file to which it was attached by a previous call to `fattach()`. The *path* argument points to the path name of the attached STREAMS file. The process must have appropriate privileges or be the owner of the file. A successful call to `fdetach()` causes all path names that named the attached STREAMS file to again name the file to which the STREAMS file was attached. All subsequent operations on *path* will operate on the underlying file and not on the STREAMS file.

All open file descriptions established while the STREAMS file was attached to the file referenced by *path*, will still refer to the STREAMS file after the `fdetach()` has taken effect.

If there are no open file descriptors or other references to the STREAMS file, then a successful call to `fdetach()` has the same effect as performing the last `close()` on the attached file.

Returned value

If successful, `fdetach()` returns 0.

If unsuccessful, `fdetach()` returns -1 and sets `errno` to one of the following values.

Note: z/OS UNIX services do not supply any STREAMS devices or pseudodevices. It is impossible for `fdetach()` to detach a file from a STREAMS-based file descriptor. See [“open\(\) — Open a file”](#) on page 1157 for more information.

Error Code Description

EACCES

Search permission is denied on a component of the path prefix.

EINVAL

The *path* argument names a file that is not currently attached.

ELOOP

Too many symbolic links were encountered in resolving *path*.

ENAMETOOLONG

The size of a path name exceeds **PATH_MAX**, or a path name component is longer than **NAME_MAX**, or path name resolution of a symbolic link produced an intermediate result whose length exceeds **PATH_MAX**.

ENOENT

A component of *path* does not name an existing file or *path* is an empty string.

ENOTDIR

A component of the path prefix is not a directory.

EPERM

The effective user ID is not the owner of *path* and the process does not have appropriate privileges.

fdim(), fdimf(), fdiml() — Calculate the positive difference

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R5 |

Format

```
#define _ISOC99_SOURCE
#include <math.h>

double fdim(double x, double y);
float fdimf(float x, float y);
long double fdiml(long double x, long double y);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

float fdim(float x, float y);
long double fdim(long double x, long double y);
```

General description

The fdim functions compute the positive difference between *x* and *y*.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------|-----|------|
| fdim | X | X |
| fdimf | X | X |
| fdiml | X | X |

Restriction: The `fdimf()` function does not support the `_FP_MODE_VARIABLE` feature test macro.

Returned value

The `fdim` functions return the positive difference between `x` and `y`.

Related information

fdimd32(), fdimd64(), fdimd128() — Calculate the positive difference

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 fdimd32(_Decimal32 x, _Decimal32 y);
_Decimal64 fdimd64(_Decimal64 x, _Decimal64 y);
_Decimal128 fdimd128(_Decimal128 x, _Decimal128 y);
_Decimal32 fdim(_Decimal32 x, _Decimal32 y);      /* C++ only */
_Decimal64 fdim(_Decimal64 x, _Decimal64 y);     /* C++ only */
_Decimal128 fdim(_Decimal128 x, _Decimal128 y);  /* C++ only */
```

General description

The `fdim` functions compute the positive difference between `x` and `y`.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See [“IEEE binary floating-point” on page 97](#) for more information

Returned value

The `fdim` functions return the positive difference between `x` and `y`.

Example

```
/* CELEBF76

   This example illustrates the fdimd32() function.
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal32 x = 56789.70DF, y = 56790.00DF, z;

    z = fdimd32(y, x);
```

```
printf("The result of fdim32(%Hf, %Hf)\n is %Hf\n", y, x, z);
return 0;
}
```

fdopen() — Associate a stream with an open file descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <stdio.h>

FILE *fdopen(int fildes, const char *options);
```

General description

Associates a stream with an open file descriptor. A *stream* is a pointer to a FILE structure that contains information about a file. A stream permits user-controllable buffering and formatted input and output. For a discussion of the z/OS UNIX services implementation of buffering, see [z/OS XL C/C++ Programming Guide](#).

The specified *options* must be permitted by the current mode of the file descriptor. For example, if the file descriptor is open-read-only (O_RDONLY), the corresponding stream cannot be opened write-only (w).

These options are the same as for an fopen() operation.

Special behavior for XPG4.2: The values for options are changed to include binary streams.

Mode

Description

r or rb

Open for reading.

w or wb

Open for writing.

a or ab

Open for appending.

r+ or rb+ or r+b

Open for update (reading and writing).

w+ or wb+ or w+b

Open for update (reading and writing).

a+ or ab+ or a+b

Open for update at End Of File (EOF) (reading and writing).

All these options have the same behavior as the corresponding `fopen()` options, except that `w`, `wb`, `w+`, `wb+` and `w+b` do not truncate the file.

The file position indicator of the new stream is the file offset associated with the file descriptor. The error indicator and end of file (EOF) indicator for the stream are cleared.

Returned value

If successful, `fdopen()` returns a `FILE` pointer to the control block for the new stream.

If unsuccessful, `fdopen()` returns `NULL` and sets `errno` to one of the following values:

Error Code

Description

EBADF

fdes is not a valid open file descriptor.

EINVAL

The specified mode is incorrect or does not match the mode of the open file descriptor.

Example

CELEBF08

```
/* CELEBF08

   This example associates stream with the file descriptor fd which is
   open for the file fdopen.file.
   The association is made in write mode.

*/
#define _POSIX_SOURCE
#include <stdio.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <fcntl.h>
#include <unistd.h>

main() {
    char fn[]="fdopen.file";
    FILE *stream;
    int fd;

    if ((fd = creat(fn, S_IWUSR)) < 0)
        perror("creat() error");
    else {
        if ((stream = fdopen(fd, "w")) == NULL) {
            perror("fdopen() error");
            close(fd);
        }
        else {
            fputs("This is a test", stream);
            fclose(stream);
        }
    }
}
```

Related information

- [“stdio.h — Standard input and output” on page 63](#)
- [“fileno\(\) — Get the file descriptor from an open stream” on page 541](#)

fdopendir() — Opens directory associated with file descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| POSIX.1 | both | |

Format

```
#define _POSIX_C_SOURCE 200809L
#include <dirent.h>

DIR *fdopendir(int fd);
```

General description

The `fdopendir()` function is equivalent to the `opendir()` function except that the directory is specified by a file descriptor rather than by a name. The file offset that is associated with the file descriptor at the time of the call determines which entries are returned.

Upon successful return from `fdopendir()`, the file descriptor is under the control of the system, and if any attempt is made to close the file descriptor, or to modify the state of the associated description, other than by `closedir()`, `readdir()`, `readdir_r()`, `rewinddir()`, or `seekdir()`, the behavior is undefined.

Upon calling `closedir()`, the file descriptor is closed.

Returned value

If successful, `fdopendir()` returns a pointer to an object of type `DIR`.

If unsuccessful, `fdopendir()` returns a null pointer and sets `errno` to indicate the error.

Error Code Description

EBADF
The *fd* argument is not a valid file descriptor open for reading.

ENOTDIR
Not a directory.

ENOMEM
Insufficient memory to complete the operation.

Example

```
#define _POSIX_SOURCE
#define _POSIX_C_SOURCE 200809L
#include <dirent.h>
#include <stdio.h>

int main() {
    int fd = 0;

    DIR *dir;
    DIR *newdirp;
    struct dirent *entry;
    dir = opendir("/u/userexample/fdopendir");
    fd = dirfd(dir);
    newdirp = fdopendir(fd);
    while ((entry = readdir(newdirp)) != NULL)
        printf(" %s\n", entry->d_name);
}
```

```
    return 0;
}
```

feclearexcept() — Clear the floating-point exceptions

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _ISOC99_SOURCE
#include <fenv.h>

int feclearexcept (int excepts);
```

General description

feclearexcept() clears the supported floating-point exceptions represented by *excepts*.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|---------------|-----|------|
| feclearexcept | | X |

Returned value

If successful, feclearexcept() returns 0 if the argument passed is 0 or if all the exceptions are successfully cleared.

Related information

•

fe_dec_getround() – Get the current rounding mode

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <fenv.h>

int fe_dec_getround(void);
```

General description

The `fe_dec_getround` function gets the current rounding mode for decimal floating-point operations.

The following rounding modes are defined for decimal floating-point, and are located in `fenv.h`:

FE_DEC_DOWNWARD

rounds towards minus infinity

FE_DEC_TONEAREST

rounds to nearest

FE_DEC_TOWARDZERO

rounds toward zero

FE_DEC_UPWARD

rounds toward plus infinity

FE_DEC_TONEARESTFROMZERO

rounds to nearest, ties away from zero

_FE_DEC_AWAYFROMZERO

rounds away from zero

_FE_DEC_TONEARESTTOWARDZERO

rounds to nearest, ties toward zero

_FE_DEC_PREPAREFORSHORTER

rounds to prepare for shorter precision

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, returns the value of the current rounding mode for decimal floating-point operations.

If there is no such rounding mode or the current rounding mode can't be determined returns -1.

Example

```
/* CELEBF77

sample program that issues fe_dec_getround()/setround()

This program calls fe_dec_getround() to get the DFP rounding mode.
```

```

Then it will compare the returned value with FE_DEC_TONEAREST
rounding mode. If not the same, it will call fe_dec_setround() to
set the rounding mode to the desired value FE_DEC_TONEAREST.
*/

#define __STDC_WANT_DEC_FP__
#include <fenv.h>
#include <stdlib.h>
#include <stdio.h>

int main(int argc, char *argv[]){
    int r;
    if ((r = fe_dec_getround()) == -1){
        perror("fe_dec_getround");
        exit (-1);
    }
    printf("The Decimal floating point rounding mode is %d\n", r);
    if (r != FE_DEC_TONEAREST){
        printf("The DFP rounding mode is not FE_DEC_TONEAREST.\n");
        if (fe_dec_setround(FE_DEC_TONEAREST) == -1){
            perror("fe_dec_setround");
            exit (-1);
        }
    }
    printf("The DFP rounding mode has been set to FE_DEC_TONEAREST.\n");
    return 0;
}

```

Related information

- [“fenv.h — Floating-point environment” on page 23](#)

fe_dec_setround() — Set the current rounding mode

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```

#define __STDC_WANT_DEC_FP__
#include <fenv.h>

int fe_dec_setround(int round);

```

General description

The `fe_dec_setround` function establishes the rounding mode for decimal floating-point operations represented by its argument *round*. If the argument is not equal to the value of a valid rounding mode, the rounding mode is not changed.

The following rounding modes are defined for decimal floating-point, and are located in `fenv.h`:

FE_DEC_DOWNWARD

rounds towards minus infinity

FE_DEC_TONEAREST

rounds to nearest

FE_DEC_TOWARDZERO

rounds toward zero

FE_DEC_UPWARD

rounds toward plus infinity

FE_DEC_TONEARESTFROMZERO

rounds to nearest, ties away from zero

_FE_DEC_AWAYFROMZERO

rounds away from zero

_FE_DEC_TONEARESTTOWARDZERO

rounds to nearest, ties toward zero

_FE_DEC_PREPAREFORSHORTER

rounds to prepare for shorter precision

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, returns a zero value.

If the argument is not equal to a valid rounding mode, returns -1. The following errnos are defined:

Error Code**Definition****EINVAL**

The rounding mode specified is not a valid Decimal Floating Point rounding mode.

EMVSERR

The function was unable to set the specified rounding mode due to an internal error.

Example

```

/* CELEBF77

sample program that issues fe_dec_getround()/setround()

This program calls fe_dec_getround() to get the DFP rounding mode.
Then it will compare the returned value with FE_DEC_TONEAREST
rounding mode. If not the same, it will call fe_dec_setround() to
set the rounding mode to the desired value FE_DEC_TONEAREST.
*/

#define __STDC_WANT_DEC_FP__
#include <fenv.h>
#include <stdlib.h>
#include <stdio.h>

int main(int argc, char *argv[]){
    int r;
    if ((r = fe_dec_getround()) == -1){
        perror("fe_dec_getround");
        exit (-1);
    }
    printf("The Decimal floating point rounding mode is %d\n", r);
    if (r != FE_DEC_TONEAREST){
        printf("The DFP rounding mode is not FE_DEC_TONEAREST.\n");
        if (fe_dec_setround(FE_DEC_TONEAREST) == -1){
            perror("fe_dec_setround");
            exit (-1);
        }
    }
    printf("The DFP rounding mode has been set to FE_DEC_TONEAREST.\n");
    return 0;
}

```

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| C99 Single UNIX Specification, Version 3 C/C++ DFP C++ TR1 C99 | both | z/OS V1R8 |

Format

```
#define _ISOC99_SOURCE
#include <fenv.h>

int feholdexcept(fenv_t *envp);
```

General description

`feholdexcept()` saves the current floating-point environment in the object pointed to by `envp`, clears the floating-point status flags, and then installs a non-stop (continue on floating-point exceptions) mode, if available, for all floating-point exceptions.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|---------------------------|-----|------|
| <code>feholdexcept</code> | | X |

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. If the hardware has the Decimal Floating-Point Facility installed, this function will save the decimal floating-point rounding mode.
3. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, `feofexcept()` returns 0 when the non-stop floating-point exception handling was successfully installed.

feof() – Test end of file (EOF) indicator

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```
#include <stdio.h>

int feof(FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int feof_unlocked (FILE *stream);
```

General description

Indicates whether the EOF flag is set for the given stream pointed to by *stream*.

The EOF flag is set when the user attempts to read past the EOF. Thus, a read of the last character in the file does not turn the flag on. A subsequent read attempt reaches the EOF.

For z/OS UNIX files, a simultaneous reader cannot see the extensions automatically. Use `clearerr()` is required to reset the EOF flag.

If the file has a simultaneous writer that extends the file, the flag can be turned on by the reader before the file is extended. After the extension becomes visible to the reader, a subsequent read will get the new data and set the flag appropriately (see `fflush()`). For example, if the read does not read past the EOF, the

flag is turned off. If a file does not have a simultaneous writer that is extending the file, it is not possible to read past EOF.

A successful repositioning in a file (with `fsetpos()`, `rewind()`, `fseek()`) or a call to `clearerr()` resets the EOF flag. For a terminal file, when the EOF flag is set, subsequent reads will continue to deliver no data until the EOF flag is cleared. This can be accomplished by calling `clearerr()` or `rewind()`.

The terminal can only read past the EOF after the `rewind()` function or the `clearerr()` function is called. The EOF flag is cleared by calling `rewind()`, `fsetpos()`, `fseek()`, or `clearerr()` for this stream.

`feof_unlocked()` is functionally equivalent to `feof()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

If and only if the EOF flag is set for *stream*, `feof()` returns nonzero.

Otherwise, `feof()` returns 0.

Example

CELEBF09

```
/* CELEBF09
   This example scans the input stream until it reads an EOF character.
*/
#include <stdio.h>
#include <stdlib.h>

main() {
    FILE *stream;
    int rc;
    stream = fopen("myfile.dat", "r");

    /* myfile.dat contains 3 characters "abc" */
    while (1) {
        rc = fgetc(stream);
        if (rc == EOF) {
            if (feof(stream)) {
                printf("at EOF\n");
                break;
            }
            else {
                printf("error\n");
                break;
            }
        }
        else {
            printf("read %c\n", rc);
        }
    }
}
```

Output

```
read a
read b
read c
at EOF
```

feraiseexcept() — Raise the supported floating-point exceptions

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _ISOC99_SOURCE
#include <fenv.h>

int feraiseexcept(int excepts);
```

General description

feraiseexcept() raises the supported floating-point exceptions represented by *excepts*. The order in which these floating-point exceptions are raised is unspecified.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|---------------|-----|------|
| feraiseexcept | | X |

Returned value

If successful, feraiseexcept() returns 0 if the argument passed is 0 or if all the exceptions are successfully raised.

Related information

•

ferror() — Test for read and write errors

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```
#include <stdio.h>

int ferror(FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int ferror_unlocked (FILE *stream);
```

General description

Tests for an error in reading from or writing to the specified *stream*. If an error occurs, the error indicator for the *stream* remains set until you close the *stream*, call `rewind()`, or call `clearerr()`.

If a non-valid parameter is given to an I/O function, the compiler does not turn the error flag on. This case differs from one where parameters are not valid in context with one another.

`ferror_unlocked()` is functionally equivalent to `ferror()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

If successful, `ferror()` returns a nonzero value to indicate an error for the stream pointed to by *stream*.

If unsuccessful, `ferror()` returns 0.

Example

CELEBF10

```
/* CELEBF10

   This example puts data out to a stream and then checks that
   a write error has not occurred.

*/
#include <stdio.h>

int main(void)
{
    FILE *stream;
    char *string = "Important information";
    stream = fopen("myfile.dat", "w");

    fprintf(stream, "%s\n", string);
    if (ferror(stream))
    {
        printf("write error\n");
        clearerr(stream);
    }
    if (fclose(stream))
        printf("fclose error\n");
}
```

Related information

fesetenv() – Set the floating-point environment

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| C99 Single UNIX Specification, Version 3 C/C++ DFP C++ TR1 C99 | both | z/OS V1R8pd |

Format

```
#define _ISOC99_SOURCE
#include <fenv.h>

int fesetenv(const fenv_t *envp);
```

General description

`fesetenv()` establishes the floating-point environment represented by the object pointed to by *envp*. The argument *envp* points to an object set by a call to `fegetenv()` or `feholdexcept()`, or equal to a floating-point environment macro. `fesetenv()` merely installs the state of the floating-point status flags represented through *envp* and does not raise these floating-point exceptions.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|-----------------------|-----|------|
| <code>fesetenv</code> | | X |

Notes:

1. If the hardware has the Decimal Floating-Point Facility installed, this function can be used to set the decimal floating-point rounding mode.
2. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, `fesetenv()` returns 0 if the settings are restored.

If unsuccessful, `fesetenv()` returns -1 and sets one of the following `errno` values:

Error Code

Description

EINVAL

The rounding mode specified is not a valid Decimal Floating Point rounding mode.

EMVSERR

The function was unable to set the specified rounding mode due to an internal error.

fesetexceptflag() — Set the floating-point status flags

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _ISOC99_SOURCE
#include <fenv.h>

int fesetexceptflag(const fexcept_t *flagp, int excepts);
```

General description

`fesetexceptflag()` sets the floating-point status flags indicated by *excepts* to the states stored in the object pointed to by *flagp*. The value of *flagp* should be set by `fegetexceptflag()`, whose second argument represents the floating-point exceptions indicated by the argument *excepts*. This function does not raise floating-point exceptions, but only sets the state of the flags.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|------------------------------|-----|------|
| <code>fesetexceptflag</code> | | X |

Returned value

If successful, `fesetexceptflag()` returns 0 if *excepts* is 0 or if all selected exceptions are successfully set.

Related information

-

fesetround() — Set the current rounding mode

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _ISOC99_SOURCE
#include <fenv.h>
```

```
int fesetround(int round);
```

General description

fesetround() establishes the rounding mode represented by *round*. If the argument is not equal to the value of a rounding mode macro, the rounding mode is not changed.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|------------|-----|------|
| fesetround | | X |

Note: This function will not return or update decimal floating-point rounding mode bits. The *fe_dec_getround()* and *fe_dec_setround()* functions can be used to get and set the current rounding mode for decimal floating-point operations.

Returned value

If successful, fesetround() returns 0 when *round* is set to a rounding mode.

Related information

- [“fe_dec_getround\(\) — Get the current rounding mode” on page 504](#)
- [“fe_dec_setround\(\) — Set the current rounding mode” on page 505](#)

fetch() — Get a load module

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | C | |

Format

```
#include <stdlib.h>

void (*fetch(const char *name))();
```

General description

Dynamically loads the load module specified by *name* into memory. The load module can then be invoked from a C program. The name or the alias by which the fetchable load module is identified in the load module library must appear in a fetch() library function call.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

You cannot fetch a module that contains a main(). If you do, fetch() will not return a usable pointer. Use of the pointer will result in undefined behavior. To call these types of modules, use the system() library function. Alternatively, when creating the module, you can reset the entry point so that the linkage is provided by the compiler.

When non-reentrant modules have been fetched multiple times, you should release them in the reverse order; otherwise the load modules may not be deleted immediately.

You can fetch modules written in C and C++. For C modules, the source of the fetched module must, in general, contain `#pragma linkage(..., fetchable)` (the exception is described below). To fetch a C++ module, the routine must be declared `extern "C"`, and must be declared in a **`#pragma linkage(..., fetchable)`** directive. See also [“fetchep\(\) — Share writable static”](#) on page 526 for more information about the need for `#pragma linkage`.

Note: For C or C++ modules that are compiled with the XPLINK linkage and are to be fetched, `#pragma linkage(..., fetchable)` is required. They cannot use the technique of resetting the entry point. If an application tries to fetch() an XPLINK routine that did not specify `FETCHABLE`, then an error will be returned.

XPLINK programs can fetch non-XPLINK programs, and vice versa. The function descriptor returned by `fetch()` will contain glue code to support a stack swap and parameter list conversion if necessary. Calls to a fetched routine that do not cross an XPLINK linkage boundary will not incur any glue code overhead.

If the fetched module is compiled as a DLL it can import variables and functions from other DLL modules, but it cannot export variables or functions.

Nested fetching is supported. That is, a fetched module can also invoke the `fetch()` library function to dynamically load a separate fetchable module.

Multiple fetching is also supported. Fetching a module more than once will result in separate fetch pointers. If the module is marked “reentrant”, multiple fetches will not reload the module into storage. In the MVS environment, you can place the reentrant module into the Extended Link Pack Area or the Link Pack Area (ELPA/LPA) to save time on the load. Although multiple copies of the reentrant module are not brought into storage, each fetch returns a separate pointer. If a module is not reentrant, multiple fetches cause multiple loads into storage. Be aware that if you fetch() a non-reentrant module multiple times, the module may not get deleted by `release()` until all fetch instances have been released. Also, you should keep in mind that multiple loads of a non-reentrant module can be costly in terms of storage.

Writable statics are, in general, process-scoped. The exception is that, when a thread calls a fetched module, the writable statics are changed for that thread only, that is, thread-scoped.

In the MVS environment, fetchable (or dynamically loaded) modules must be link-edited and accessible using the standard system search. MVS supports fetching of non-reentrant, serially reusable, and reentrant modules.

Under POSIX, however, the fetchable, dynamically loaded modules cannot be in the z/OS UNIX file system. Note also, that the POSIX and XPG4 external variables are propagated. Refer to [z/OS XL C/C++ Programming Guide](#) for more information on external variables.

Unless your program is naturally reentrant, each reentrant module has a different copy of writable static. Follow these steps to allow the fetching of your reentrant module that has writable static:

1. The compiler needs to [generate reentrant code](#) for the module to be fetched.
2. Using the object module created in step 1, generate a fetchable member. You must specify the entry point as the function you are fetching unless you have included a **`#pragma linkage(..., FETCHABLE)`** directive.

See [Figure 2 on page 518](#) for the program flow of a fetchable module. (FECB refers to a Fetch Control Block, which is a C internal control block used by `fetch()`.)

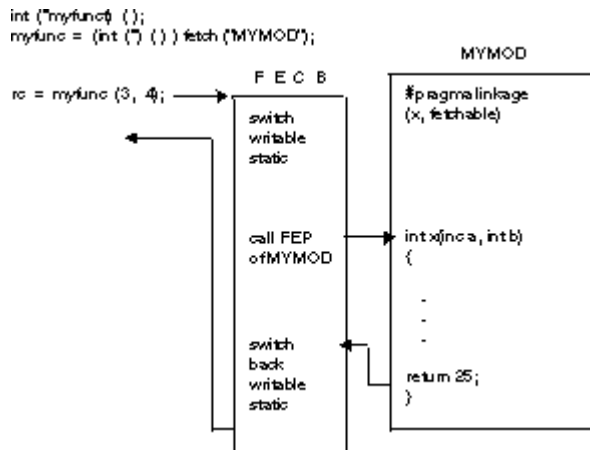

Figure 2. Program Flow of a Fetchable Module

To dynamically fetch a set of functions with shared writable static, you can use the library function `fetchep()`. See “[fetchep\(\) — Share writable static](#)” on page 526 for more details.

Both the module being fetched and the module invoking the `fetch()` library function can be reentrant.

You can fetch modules without specifying the directive, `#pragma linkage(..., FETCHABLE)`, in the fetched module. If you do, then using the fetch pointer will result in calling the entry point for that module. When you link the module, you must reset the entry point. In addition, you cannot have any writable static.

It follows that fetching a reentrant C module containing writable statics requires that you use the `#pragma linkage(..., FETCHABLE)` preprocessor directive in the fetched module.

If the entry point linkage is not a C linkage, you must use a `pragma linkage` with a function pointer defined by a *typedef*. The following sample excerpt would set up a COBOL linkage for a COBOL routine.

```
typedef int COBOL_FUNC ();
#pragma linkage (COBOL_FUNC, COBOL)
:
COBOL_FUNC * fetch_ptr;
fetch_ptr = (COBOL_FUNC *) fetch(module); /* loads fetched module */
fetch_ptr(args); /* sets up the proper linkage for the call */
```

Once the module is fetched, calling the fetched function is similar to making an interlanguage call.

`fetch()` also supports AMODE switching: when the function call is made, AMODE will be switched; upon return, the AMODE will be restored. Beware of calling fetched modules with AMODE=24 that try to access variables or the library above the line.

Notes:

1. You cannot call functions through a function pointer that crosses load module boundaries, except through `fetchep()`. (See “[fetchep\(\) — Share writable static](#)” on page 526 for more information.) For example, you cannot pass the address of a function to a fetched routine and invoke it from the fetched routine because the C writable static will not be swapped.
2. If you need to access code that has to run in a restricted addressing mode (such as a AMODE 24), you can package the code into a module to be fetched. The module can then be linked using the restricted addressing mode, but fetched from a program with an unrestricted addressing mode.
3. A program that invokes `fetch()` many times without releasing all of the load modules may run out of memory.

Link considerations: When linking the function to be fetched, you must link in the necessary libraries and specify the entry point as the function you are fetching unless you have included this directive: `#pragma linkage(..., FETCHABLE)`.

When linking the `main()` C function, you must specify the necessary libraries to use the functions you are fetching. For example, if you are fetching a COBOL function, specify the COBOL library. This requirement does *not* apply to Language Environment.

When running `main()`, specify the runtime libraries you will need for `main()`, as well as the functions you will fetch. This requirement does *not* apply to Language Environment.

Special behavior for C++: a C++ program cannot call `fetch()`. If you attempt to call `fetch()` from a C++ program, the compiler issues an error message. There are three alternatives to `fetch()`:

- You can replace `fetch()` with DLL (dynamic link library) calls.
- You can provide a C DLL module to fetch modules, as shown in examples CELEBF52 and CELEBF53. See [“Examples” on page 519](#).
- C++ programs may statically call a C function that, in turn, fetches another module.

Returned value

If successful, `fetch()` returns a pointer to a stub that will call the entry point to the fetched load module.

If the load fails, `fetch()` returns NULL and may set `errno` to one of the following values:

Error Code

Definition

ELEFENCE

The DLL contains a member language not supported on this version of the operating system.

Examples

Examples of using the `fetch()` function with C: The following example demonstrates how to compile, link, and run a program that fetches a function in another object module that contains the directive: `pragma linkage(..., FETCHABLE)`.

Begin with the main program.

```
#include <stdio.h>
#include <stdlib.h>

typedef int (*funcPtr)(); /* pointer to a function returning an int */

int main(void)
{
    int result;
    funcPtr add;

    printf("fetch module\n");
    add = (funcPtr) fetch("f1a");          /* load module F1A      */

    if (add == NULL) {
        printf("ERROR: fetch failed\n");
    }
    else {
        printf("execute fetched module\n");
        result = (*add)(1,2);             /* execute module F1A    */
        printf("1 + 2 == %d\n", result);
    }
}
```

Then the fetched function:

```
#pragma linkage(func1, fetchable)

int func1(int a, int b)
{
    printf("in fetched module\n");
    return(a+b);
}
```

Next, JCL to compile, link, and run under the MVS environment:

```
>
//F1A      EXEC EDCC,INFILE='userid.TEST.SOURCE(F1A)'
//          OUTFILE='userid.TEST.OBJ(F1A),DISP=SHR',
//          CPARM='NOSEQ,NOMARGIN,RENT'
//F1B      EXEC EDCPL,INFILE='userid.TEST.OBJ(F1A)'
//          OUTFILE='userid.TEST.LOAD(F1A),DISP=SHR'
//F1       EXEC EDCCLG,INFILE='userid.TEST.SOURCE(F1)'
//GO.STEPLIB DD
//          DD DSN=userid.TEST.LOAD,DISP=SHR
```

This example demonstrates the use of `fetch()` with COBOL and how to compile, link, and run the program.

```
/* cob1 */
#include <stdlib.h>
#include <stdio.h>

typedef void funcV();      /* function returning void      */
#pragma linkage(funcV, COBOL) /* establish Cobol linkage */

int main(void)
{
    int var1 = 1;
    int var2 = 2;
    funcV *add;

    printf("fetch module\n");
    add = (funcV *) fetch("cob1a");          /* load module COB1A */

    if (add == NULL)
    {
        printf("ERROR: fetch failed\n");
    }
    else
    {
        printf("execute fetched module\n");
        (*add)(&var1, &var2);              /* execute module COB1A */
        printf("1 + 2 == %d\n", var1);
    }
}
```

Here is the fetched COBOL subroutine COB1A.

```
IDENTIFICATION DIVISION.
PROGRAM-ID. COB1A.
*****
* This subroutine receives 2 integer parameters.      *
* The first is added to the second and the result is stored *
* back into the first.                                  *
*****
ENVIRONMENT DIVISION.

//GO.STEPLIB DD
// DD DSN=userid.TEST.LOAD,DISP=SHR
```

Examples of alternatives to `fetch()` under C++: This example shows how to use DLL as an alternative to `fetch()`. Here, `myfunc()` is the function to be dynamically loaded using DLL, and `main()` invokes DLL.

CELEBF52

```
// CELEBF52-part 1 of 2-other file is CELEBF53.

// This example shows how to use DLL as an alternative to fetch().

// C++ program that invokes myfunc using DLL

#include <stdlib.h>
#include <stdio.h>
#include <dll.h>

extern "C" { // needed to indicate C linkage
    typedef int (*funcPtr)(); // pointer to a function returning an int
}

int main (void)
{
    dllhandle *dllh;
    funcPtr fptr;

    if ((dllh = dllload( "celebf53" )) == NULL) {
```

```

    perror( "failed to load celebf53" );
    exit( -1 );
}
if ((fptr = (funcPtr) dllqueryfn( dllh, "myfunc" )) == NULL) {
    perror( "failed to retrieve myfunc" );
    exit( -2 );
}
if ( fptr() != 0 ) {
    perror( "failed to execute myfunc" );
    exit( -3 );
}
if ( dllfree( dllh ) != 0 ) {
    perror( "failed to free celebf53" );
    exit( -4 );
}
return( 0 );
}

```

CELEBF53

```

/* CELEBF53-part 2 of 2-other file is CELEBF52.

   This example shows how to use DLL as an alternative to fetch().

*/
/*

   C function dynamically loaded using DLL

*/
#include <stdio.h>

int myfunc (void)
{
    printf( "Hello world\n" );
    return( 0 );
}

```

The following example shows how a C++ program can dynamically call a function in a C DLL module, to fetch other C modules.

CELEBF54

```

// CELEBF54-part 1 of 3-other files are CELEBF55, CELEBF56.
// This example shows how a C++ program can dynamically call a function
// in a C DLL module, to fetch other C modules

// C++ program that dynamically calls a function in a C DLL module

#include <stdio.h>
#include <stdlib.h>
#include <dll.h>
#include <iostream>
using namespace std;

extern "C" {
    // needed to indicate C linkage
    typedef int (*funcPtr)(); // pointer to a function returning an int
}

int main (void)
{
    dllhandle *dllh;
    funcPtr fptr;

    if ((dllh = dllload( "mydll" )) == NULL) {
        perror( "failed to load mydll" );
        exit( -1 );
    }
    if ((fptr = (funcPtr) dllqueryfn( dllh, "fwrap" )) == NULL) {
        perror( "failed to retrieve fwrap" );
        exit( -2 );
    }
    if ( fptr() != 0 ) {
        perror( "failed to execute fwrap" );
        exit( -3 );
    }
    if ( dllfree( dllh ) != 0 ) {

```

```

        perror( "failed to free mydll" );
        exit( -4 );
    }
    return( 0 );
}

```

CELEBF55

```

/* CELEBF55-part 2 of 3-other files are CELEBF54, CELEBF56.
   This example shows how a C++ program can dynamically call a function
   in a C DLL module, to fetch other C modules

   fwrap function used in a DLL module-it fetches mymod, which
   contains myfunc
*/
#include <stdio.h>
#include <stdlib.h>

typedef int (*funcPtr)(); /* pointer to a function returning an int */

int fwrap (void)
{
    funcPtr    fptr;

    if ((fptr = (funcPtr) fetch( "mymod" )) == NULL) {
        perror( "failed to fetch mymod" );
        return( -1 );
    }
    else
        return(fptr());
}

```

CELEBF56

```

/* CELEBF56-part 3 of 3-other files are CELEBF54, CELEBF55.
   This example shows how a C++ program can dynamically call a function
   in a C DLL module, to fetch other C modules
*/

/*    C function to be fetched    */

#include <stdio.h>
#pragma linkage(myfunc, fetchable)

int myfunc (void)
{
    printf( "in fetched module\n" );
    return( 0 );
}

```

The following example shows how to statically call a C function that in turn fetches other functions. Here, myfunc() is the function to be fetched, fetcher() is a C function that fetches myfunc(), and main() is a function that statically calls fetcher().

CELEBF57

```

// CELEBF57-part 1 of 3-other files are CELEBF58, CELEBF59.
// This example shows how to statically call a C function that
// fetches other functions.

// C++ statically calling a C program that uses fetch()

#include <iostream>
using namespace std;

extern "C" { /* needed to indicate C linkage */
    int fetcher (void);
}

int main (void)
{
    cout << "The fetcher says: ";
    fetcher();
    cout << "and returns";
    return( 0 );
}

```

CELEBF58

```

/* CELEBF58-part 2 of 3-other files are CELEBF57, CELEBF59.
   This example shows how to statically call a C function that fetches
   other functions.
*/

/*
   C function that fetches mymod which contains myfunc
*/
#include <stdio.h>
#include <stdlib.h>

typedef int (*funcPtr)(); /* pointer to a function returning an int */

int fetcher (void)
{
    funcPtr fptr;

    if ((fptr = (funcPtr) fetch( "mymod" )) == NULL) {
        perror( "failed to fetch mymod" );
        return( -1 );
    }
    else {
        fptr(); /* invoke fetched function */
        return( 0 );
    }
}

```

CELEBF59

```

/* CELEBF59-part 3 of 3-other files are CELEBF57, CELEBF58.
   This example shows how to statically call a C function that fetches
   other functions.
*/

/* C function to be fetched */
#include <stdio.h>
#pragma linkage(myfunc, fetchable)

int myfunc (void)
{
    printf( "Hello world " );
    return( 0 );
}

```

Although fetching and using DLL are functionally comparable, there is one subtle difference. Fresh copies of static and global variables are allocated each time a module is fetched, but not each time a DLL load of the same module is done.

The following example shows that, when a module is fetched multiple times, fresh copies of static and global variables are allocated.

CELEBF60

```

/* CELEBF60-part 1 of 2-other file is CELEBF61.
   This example shows how copies of variables are allocated when multiple
   fetches are done.
*/

/*
   C program fetching mymod multiple times--mymod contains myfunc.
*/
#include <stdio.h>
#include <stdlib.h>

typedef int (*funcPtr)(int); /*pointer to a function returning an int*/

int main (void)
{
    funcPtr fptr1, fptr2;

    if ((fptr1 = (funcPtr) fetch( "mymod" )) == NULL) {
        perror( "failed to fetch mymod" );
        return( -1 );
    }
}

```

```

    if ( fptr1(100) != 0 ) {
        perror( "failed to execute myfunc" );
        exit( -2 );
    }
    if ((fptr2 = (funcPtr) fetch( "mymod" )) == NULL) {
        perror( "failed to fetch mymod" );
        return( -3 );
    }
    if ( fptr2(100) != 0 ) {
        perror( "failed to execute myfunc" );
        exit( -4 );
    }
    return( 0 );
}

```

CELEBF61

```

/* CELEBF61-part 2 of 2-other file is CELEBF60.
   This example shows how copies of variables are allocated when multiple
   fetches are done.
*/

/*      C module mymod      */
#include <stdio.h>
#pragma linkage(myfunc, fetchable)

int globvar = 5;

int myfunc (int x)
{
    globvar += x;
    printf( "%d\n", globvar );
    return( 0 );
}

```

Running this example would produce the following results:

```

105
105

```

The following example shows that fresh copies of static and global variables are not allocated for multiple DLL loads of the same module.

CELEBF62

```

// CELEBF62-part 1 of 2-other file is CELEBF63.
// This example shows how copies of variables are allocated when
// multiple DLL loads are done.

// C++ program doing multiple DLL loads of the same module

#include <stdlib.h>
#include <stdio.h>
#include <dll.h>

extern "C" {
    typedef int (*funcPtr)(int); //needed to indicate C linkage
    //pointer to a function returning an int
}

int main (void)
{
    dllhandle *dllh1, *dllh2;
    funcPtr fptr;

    if ((dllh1 = dllload( "mydll" )) == NULL) {
        perror( "failed to load mydll" );
        exit( -1 );
    }
    if ((fptr = (funcPtr) dllqueryfn( dllh1, "myfunc" )) == NULL) {
        perror( "failed to retrieve myfunc" );
        exit( -2 );
    }
    if ( fptr(100) != 0 ) {
        perror( "failed to execute myfunc" );
        exit( -3 );
    }
    if ((dllh2 = dllload( "mydll" )) == NULL) {
        perror( "failed to load mydll" );
    }
}

```

```
    exit( -4 );
}
if ((fptr = (funcPtr) dllqueryfn( dllh2, "myfunc" )) == NULL) {
    perror( "failed to retrieve myfunc" );
    exit( -5 );
}
if ( fptr(100) != 0 ) {
    perror( "failed to execute myfunc" );
    exit( -6 );
}
if ( dllfree( dllh1 ) != 0 ) {
    perror( "failed to free mydll" );
    exit( -7 );
}
return( 0 );
}
```

CELEBF63

```
/* CELEBF63-part 2 of 2-other file is CELEBF62.
   This example shows how copies of variables are allocated when multiple
   DLL loads are done.
*/

/* C function invoked using DLL */

#include <stdio.h>
#include <stdlib.h>

int globvar = 5;
int myfunc (int);

int myfunc (int x)
{
    globvar += x;
    printf( "%d\n", globvar );
    return( 0 );
}
```

Running this example would produce the following results:

```
105
205
```

fetchep() – Share writable static

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | C only | |

Format

```
#include <stdlib.h>

void ( *fetchep( void ( *entry_point)()))();
```

General description

Dynamically fetches a set of functions with shared writable static variables. `fetchep()` is used to register an entry point. It returns a pointer that may be passed across the fetch boundary and used as if it were the original entry point. Therefore, you can create more than one entry point from a fetched module. A call to the new entry point will use the same writable static as the original fetch pointer uses on each invocation.

`fetchep()` is called within a fetched module but not from the same level as the `fetch()` call. If `fetchep()` is called in the root program that is not a fetched module, `fetchep()` returns a fetch pointer that will use the root program's writable static (if any exists).

If the *entry_point* given as input to `fetchep()` is a function address external to the current module or is an non-valid function address, use of the resulting pointer returned from the call will result in undefined behavior.

If writable static is required, then this directive must be used:

```
#pragma linkage(entry_point, FETCHABLE)
```

In addition, the steps for fetching a reentrant module must be followed as described in “[fetch\(\) — Get a load module](#)” on page 516. If writable static is *not* required, the C module using `fetchep()` need not contain the directive: `#pragma linkage(..., FETCHABLE)`.

You can release the new fetch pointer without any effect on the original or any other fetch pointer created from the original fetch pointer. If the original fetched function is released, however, all the fetch pointers created using the `fetchep()` function will also be released. Trying to use a fetch pointer once it has been released or its origin has been released will result in undefined behavior.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

Note: The external entry point name for `fetchep()` is `__ftchep()`, **NOT** `__fetchep()`.

Examples

These examples and diagram demonstrate the program flow of a call to `fetch()` and subsequent calls to `fetchep()`.

```
/* The module that calls fetch()    */
#include <stdlib.h>
typedef int (*FUNC_T)();

int main(void) {
    FUNC_T (*myfunc)();
    FUNC_T myfunc1;
    FUNC_T myfunc2;
    FUNC_T myfunc3;

    myfunc = (FUNC_T (*)())fetch("MYMOD");
    myfunc1 = myfunc(0);
    myfunc2 = myfunc(1);
    myfunc3 = myfunc(2);
}
```

```
/*
   The following code is the fetched module.
   Please see fetch() for information on how to compile and link the
   above.
*/

/* inside MYMOD */
#include <stdlib.h>
typedef int (*FUNC_T)();
int k; /* global variable to share within MYMOD */
#pragma linkage(x, fetchable)
FUNC_T x(int a)
{
```

```

switch(a)
{
  case 0:
    return (FUNC_T)fetchep((void(*)())func1);
  case 1:
    return (FUNC_T)fetchep((void(*)())func2);
  case 2:
    return (FUNC_T)fetchep((void(*)())func3);
}
}

int func1(int a, int b)
{
  k = 6;
  ...
}

int func2(int a, int b)
{
  k = 4;
  ...
}

int func3(int a, int b)
{
  k = 5;
  ...
}

```

fetetestexcept() – Test the floating-point status flags

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _ISOC99_SOURCE
#include <fenv.h>

int fetetestexcept(int excepts);
```

General description

fetetestexcept() determines which of a specified subset of floating-point exception flags are currently set. *excepts* specifies the floating-point status flags to be queried.

Note: The following table shows the viable formats for these functions. See “IEEE binary floating-point” on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------------|-----|------|
| fetetestexcept | | X |

Returned value

If successful, fetetestexcept() returns the value of the bitwise OR for the floating-point exception macros corresponding to the currently set floating-point exceptions included in *excepts*.

feupdateenv() – Save the currently raised floating-point exceptions

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| C99 Single UNIX Specification, Version 3 C/C++ DFP C++ TR1 C99 | both | z/OS V1R8 |

Format

```
#define _ISOC99_SOURCE
#include <fenv.h>

int feupdateenv(const fenv_t *envp);
```

General description

feupdateenv() saves the currently raised floating-point exceptions in its automatic storage, installs the floating-point environment represented by the object pointed to by *envp*, and then raises the saved floating-point exceptions. *envp* should point to an object set by feholdexcept() or fegetenv(), or equal a floating-point environment macro.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|-------------|-----|------|
| feupdateenv | | X |

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. If the hardware has the Decimal Floating-Point Facility installed, this function can update the decimal floating-point rounding mode.
3. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, feupdateenv() returns 0 if the settings have been restored.

If unsuccessful, feupdateenv() returns -1 and sets one of the following errno values:

Error Code

Description

EINVAL

The rounding mode specified is not a valid Decimal Floating Point rounding mode.

EMVSERR

The function was unable to set the specified rounding mode due to an internal error.

fflush() – Write buffer to file

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```
#include <stdio.h>

int fflush(FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int fflush_unlocked(FILE *stream);
```

General description

Flushes the stream pointed to by *stream*. If *stream* is NULL, it flushes all open streams.

The `fflush()` function is affected by the `ungetc()` and `ungetwc()` functions. Calling these functions causes `fflush()` to back up the file position when characters are pushed back. For details, see the `ungetc()` and `ungetwc()` functions respectively. If desired, the `_EDC_COMPAT` environment variable can be set at open time such that `fflush()` discards any pushed-back characters and leaves the file position where it was when the first `ungetc()` or `ungetwc()` function call was issued.

If `fflush()` is used after `ungetwc()` has pushed a wide char on a text stream, the position will be backed up by one wide character from the position the file was at when the `ungetwc()` was issued. For a wide-oriented binary stream, the position will be backed up based on the number of bytes used to represent the wide char in the `ungetc` buffer. For this reason, attempting to use `ungetwc()` on a character when the destination is a binary wide-oriented stream that was never read in the first place results in undefined behavior for `fflush()`. Note that the `_EDC_COMPAT` environment variable also changes the behavior of `fflush()` after `ungetwc()`, and will cause any wide char pushed-back to be discarded and the position left at the point where the `ungetwc()` was issued. For details on the `_EDC_COMPAT` environment variable, see the “Environment Variables” in [z/OS XL C/C++ Programming Guide](#).

If `fflush()` fails, the position is left at the point in the file where the first `ungetc()` or `ungetwc()` function call was issued. All pushed-back characters are discarded.

Note: The system automatically flushes buffers when you close the stream or when a program ends normally without closing the stream.

The buffering mode and the file type can have an effect on when output data is flushed. For more information, see “Buffering of C Streams” in [z/OS XL C/C++ Programming Guide](#).

stream remains open after the `fflush()` call. Because a read operation cannot immediately follow or precede a write operation, the `fflush()` function can be used to allow exchange between these two modes. The `fflush()` function can also be used to refresh the buffer when working with a reader and a simultaneous writer/updater.

`fflush_unlocked()` is functionally equivalent to `fflush()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

The `fflush()` function has no effect for files opened with `type=blocked`.

Returned value

If successful in flushing the buffer, `fflush()` returns 0.

If unsuccessful, `fflush()` returns EOF. When flushing all open files, a failure to flush any of the files causes EOF to be returned. However, flushing will continue on any other open files that can be flushed successfully.

Example

CELEBF15

```
/* CELEBF15

   This example flushes a stream buffer.
   It tests for the returned value of 0 to see if the flushing was
   successful.

   */
#include <stdio.h>

int retval;
int main(void)
{
    FILE *stream;
    stream = fopen("myfile.dat", "w");

    retval=fflush(stream);
    printf("return value=%i",retval);
}
```

ffs() — Find first set bit in an integer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <strings.h>

int ffs(int i);
```

General description

The `ffs()` function finds the first bit set (beginning with the least significant bit) and returns the index of that bit. Bits are numbered starting at one (the least significant bit).

Returned value

If successful, `ffs()` returns the index of the first bit set.

If *i* is 0, `ffs()` returns 0.

There are no `errno` values defined.

Related information

- [“strings.h — String operations” on page 67](#)

fgetc() — Read a character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```
#include <stdio.h>

int fgetc(FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int fgetc_unlocked(FILE *stream);
```

General description

Reads a single-byte unsigned character from the input stream pointed to by *stream* at the current position, and increases the associated file pointer so that it points to the next character.

The `fgetc()` function is not supported for files opened with `type=record` or `type=blocked`.

`fgetc()` has the same restriction as any read operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

`fgetc_unlocked()` is functionally equivalent to `fgetc()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

If successful, `fgetc()` returns the character read as an integer.

If unsuccessful, `fgetc()` returns EOF to indicate an error or an EOF condition. Use `feof()` or `ferror()` to determine whether the EOF value indicates an error or the end of the file.

Note: EOF is only reached when an attempt is made to read “past” the last byte of data. Reading up to and including the last byte of data does *not* turn on the EOF indicator.

Example

CELEBF16

```
/* CELEBF16
```

```
This example gathers a line of input from a stream.
It tests to see if the file can be opened.
If the file cannot be opened &error. is called.

*/
#include <stdio.h>
#define MAX_LEN 80

int main(void)
{
    FILE *stream;
    char buffer[MAX_LEN + 1];
    int i, ch;

    if ((stream = fopen("myfile.dat","r")) != NULL) {
        for (i = 0; (i < (sizeof(buffer)-1) &&
            ((ch = fgetc(stream)) != EOF) && (ch != '\n')); i++)
            printf("character is %d\n",ch);
            buffer[i] = ch;

        buffer[i] = '\0';

        if (fclose(stream))
            perror("fclose error");
    }
    else
        perror("fopen error");
}
```

fgetpos() — Get file position

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```
#include <stdio.h>

int fgetpos(FILE * __restrict__stream, fpos_t * __restrict__pos);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int fgetpos_unlocked(FILE * __restrict__stream, fpos_t * __restrict__pos);
```

General description

The `fgetpos()` function stores the current value of the file pointer associated with *stream* into the object pointed to by *pos*. The value pointed to by *pos* can be used later in a call to `fsetpos()` to reposition the stream pointed to by *stream*.

Both the `fgetpos()` and `fsetpos()` function save state information for wide-oriented files. The value stored in *pos* is unspecified, and it is usable only by `fsetpos()`.

The position returned by the `fgetpos()` function is affected by the `ungetc()` and `ungetwc()` functions. Each call to these functions causes the file position indicator to be backed up from the position where the `ungetc()` or `ungetwc()` function was issued. For details on how the `ungetc()` function affects the `fgetpos()` function behavior, see [“ungetc\(\) — Push character onto input stream” on page 1941](#). For details on how the `ungetwc()` function affects the `fgetpos()` function behavior for a wide-oriented stream, see [“ungetwc\(\) — Push a wide character onto a stream” on page 1943](#).

Multivolume data sets performance: Using the `fgetpos()` and `fsetpos()` functions generally results in better repositioning performance compared to the `ftell()` and `fseek()` functions when working with multivolume data sets.

Large file support for MVS data sets, VSAM data sets, and z/OS UNIX files: The `fgetpos()` function implicitly supports operating on large files. Defining the `_LARGE_FILES` feature test macro is not required to use this function on large files.

Usage notes

1. The `_EDC_COMPAT` environment variable can be set at open time such that the `fgetpos()` function will ignore any pushed-back characters. For further details on `_EDC_COMPAT`, see the environment variables topic in [z/OS XL C/C++ Programming Guide](#).
2. The `fgetpos_unlocked()` function is functionally equivalent to the `fgetpos()` function with the exception that it is not threadsafe. The `fgetpos()` function can safely be used in a multithreaded application if, and only if, it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` functions.

Returned value

If successful, the `fgetpos()` function returns 0.

If unsuccessful, the `fgetpos()` function returns nonzero and sets `errno` to nonzero.

Special behavior for XPG4.2: The `fgetpos()` function returns -1 and sets `errno` to `ESPIPE` if the underlying file type for the stream is a PIPE or a socket.

Example

CELEBF17

```
/* CELEBF17

   This example opens the file myfile.dat for reading.
   The current file pointer position is stored into the variable pos.

*/
#include <stdio.h>

int main(void)
{
    FILE *stream;
    int retcode;
    fpos_t pos;

    stream = fopen("myfile.dat", "rb");

    /* The value returned by fgetpos can be used by fsetpos()
       to set the file pointer if 'retcode' is 0 */
    if ((retcode = fgetpos(stream, &pos)) == 0)
```

```

    printf("Current position of file pointer found\n");
    fclose(stream);
}

```

fgets() — Read a string from a stream

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```

#include <stdio.h>

char *fgets(char * __restrict__string, int n, FILE * __restrict__stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

char *fgets_unlocked(char * __restrict__string, int n, FILE * __restrict__stream);

```

General description

Reads bytes from a stream pointed to by *stream* into an array pointed to by *string*, starting at the position indicated by the file position indicator. Reading continues until the number of characters read is equal to *n*-1, or until a newline character (`\n`), or until the end of the stream, whichever comes first. The `fgets()` function stores the result in *string* and adds a NULL character (`\0`) to the end of the string. The *string* includes the newline character, if read.

The `fgets()` function is not supported for files opened with `type=record` or `type=blocked`.

`fgets()` has the same restriction as any read operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

`fgets_unlocked()` is functionally equivalent to `fgets()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

If successful, `fgets()` returns a pointer to the *string* buffer.

If unsuccessful, `fgets()` returns NULL to indicate failure.

Note: When the `O_NONBLOCK` flag is set for the file descriptor’s underlying stream and the thread would be delayed in the `fgets()` operation, then `fgets()` will set `errno` to `EAGAIN`. In the case of a FIFO stream, if some data has been read into the string buffer, `fgets()` will return a pointer to the string buffer to indicate the partial read.

If *n* is less than or equal to 0, it indicates a domain error; `errno` is set to `EDOM` to indicate the cause of the failure.

When *n* equals 1, it indicates a valid result. It means that the string buffer has only room for the NULL terminator; nothing is physically read from the file. (Such an operation is still considered a read operation, so it cannot immediately follow a write operation unless there is an intervening flush or reposition operation first.)

If *n* is greater than 1, `fgets()` will only fail if an I/O error occurs or if EOF is reached, and no data is read from the file.

The `ferror()` and `feof()` functions are used to distinguish between a read error and an EOF. Note that EOF is only reached when an attempt is made to read “past” the last byte of data. Reading up to and including the last byte of data does *not* turn on the EOF indicator.

If EOF is reached after data has already been read into the string buffer, `fgets()` returns a pointer to the string buffer to indicate success. A subsequent call would result in NULL being returned since EOF would be reached without any data being read.

Example

CELEBF18

```
/* CELEBF18

   This example gets a line of input from a data stream.
   It reads no more than MAX_LEN - 1 characters, or up
   to a new-line character, from the stream.

*/
#include <stdio.h>
#define MAX_LEN 100

int main(void)
{
    FILE *stream;
    char line[MAX_LEN], *result;

    stream = fopen("myfile.dat", "r");

    if ((result = fgets(line, MAX_LEN, stream)) != NULL)
        printf("The string is %s\n", result);

    if (fclose(stream))
        printf("fclose error\n");
}
```

fgetwc() — Get next wide character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C Amendment XPG4 XPG4.2C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```
#include <wchar.h>

wint_t fgetwc(FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

wint_t fgetwc_unlocked(FILE *stream);
```

General description

Obtains the next multibyte character from the input stream pointed to by *stream*, converts it to a wide character, and advances the associated file position indicator for the stream (if defined).

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Using non-wide-character functions with `fgetwc()` results in undefined behavior. This happens because `fgetwc()` processes a whole multibyte character and does not expect to be “within” such a character. In addition, `fgetwc()` expects state information to be set already. Because functions like `fgetc()` and `fputc()` do not obey such rules, their results fail to meet the assumptions made by `fgetwc()`.

`fgetwc()` has the same restriction as any read operation for read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

`fgetwc_unlocked()` is functionally equivalent to `fgetwc()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

If successful, `fgetwc()` returns the next wide character that corresponds to the multibyte character from the input stream pointed to by *stream*.

If the stream is at EOF, the EOF indicator for the stream is set and `fgetwc()` returns WEOF.

If a *read* error occurs, the error indicator for the stream is set and `fgetwc()` returns WEOF. If an *encoding* error occurs (an error converting the multibyte character into a wide character), the value of the macro EILSEQ (illegal sequence) is stored in `errno` and WEOF is returned.

The `ferror()` and `feof()` functions are used to distinguish between a read error and an EOF. Note that EOF is only reached when an attempt is made to read “past” the last byte of data. Reading up to and including the last byte of data does *not* turn on the EOF indicator.

Example

CELEBF19

```
/* CELEBF19
*/

#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>
#include <errno.h>

int main(void)
{
    FILE    *stream;
    wint_t   wc;

    if ((stream = fopen("myfile.dat", "r")) == NULL) {
        printf("Unable to open file\n");
        exit(1);
    }

    errno = 0;
    while ((wc = fgetwc(stream)) != WEOF)
        printf("wc=0x%X\n", wc);

    if (errno == EILSEQ) {
        printf("An invalid wide character was encountered.\n");
        exit(1);
    }

    fclose(stream);
}
```

fgetws() — Get a wide-character string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```
#include <wchar.h>

wchar_t *fgetws(wchar_t * __restrict__ wcs, int n, FILE * __restrict__ stream);
```

```
#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

wchar_t *fgetws_unlocked(wchar_t * __restrict __wcs,
                        int n, FILE * __restrict __stream);
```

General description

Reads at most one less than the number of the wide characters specified by *n*, from the stream pointed to by *stream*, into the array pointed to by *wcs*. No additional wide characters are read after a newline wide character (which is retained) or after the EOF. A NULL wide character is written immediately after the last wide character read into the array.

The `fgetws()` function advances the file position unless there is an error, when the file position is undefined.

The behavior of this wide-character function is affected by the `LC_CTYPE` category of the current locale. If you change the category, undefined results can occur.

Using non-wide-character functions with `fgetws()` results in undefined behavior. This happens because `fgetws()` processes a whole multibyte character and does not expect to be “within” such a character. In addition, `fgetws()` expects state information to be set already. Because functions like `fgetc()` and `fputc()` do not obey such rules, their results fail to meet the assumptions made by `fgetws()`.

`fgetws()` has the same restriction as any read operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

`fgetws_unlocked()` is functionally equivalent to `fgetws()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

If successful, `fgetws()` returns the new value of *wcs*.

If EOF is encountered and no wide characters have been read into the array, the contents of the array remain unchanged and `fgetws()` returns a NULL pointer.

If a read error or an encoding error occurs during the operation, the array contents are indeterminate and `fgetws()` returns a NULL pointer. An *encoding* error is one that occurs when a wide character is converted to a multibyte character. If it occurs, `errno` is set to `EILSEQ` and `fgetws()` returns NULL.

If *n* is less than or equal to 0, it indicates a domain error; `errno` is set to `EDOM` to indicate the cause of the failure.

When *n* equals 1, it indicates a valid result. It means that the string buffer has only room for the NULL terminator; nothing is physically read from the file. (Such an operation is still considered a read operation, so it cannot immediately follow a write operation unless there is an intervening flush or reposition operation first.)

If *n* is greater than 1, `fgetws()` will only fail if an I/O error occurs or if EOF is reached, and no data is read from the file. To find out which error has occurred, use either the `feof()` or the `ferror()` function. If EOF is reached after data has already been read into the string buffer, `fgetws()` returns a pointer to the string buffer to indicate success. A subsequent call would result in NULL being returned because EOF would be reached without any data being read.

The `ferror()` and `feof()` functions are used to distinguish between a read error and an EOF. Note that EOF is only reached when an attempt is made to read “past” the last byte of data. Reading up to and including the last byte of data does *not* turn on the EOF indicator.

Example

CELEBF20

```

/* CELEBF20
*/

#include <errno.h>
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>

int main(void)
{
    FILE    *stream;
    wchar_t  wcs[100];
    wchar_t  *ptr;

    if ((stream = fopen("myfile.dat", "r")) == NULL) {
        printf("Unable to open file\n");
        exit(1);
    }

    errno = 0;
    ptr = fgetws(wcs, 100, stream);

    if (ptr == NULL) {
        if (errno == EILSEQ) {
            printf("An invalid wide character was encountered.\n");
            exit(1);
        }
        else if (feof(stream))
            printf("end of file reached\n");
        else
            perror("read error");
    }

    printf("wcs=\"%ls\"\n", wcs);

    fclose(stream);
}

```

fileno() — Get the file descriptor from an open stream

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1a XPG4 XPG4.2 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```

#define _POSIX_SOURCE
#include <stdio.h>

```

```
int fileno(const FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int fileno_unlocked(const FILE *stream);
```

General description

Returns the file descriptor number associated with a specified IBM z/OS C++ I/O stream. The argument *stream* points to a FILE structure controlling a IBM z/OS C++ I/O stream.

The unistd.h header file defines the following macros, which are constants that map to the file descriptors of the standard streams:

STDIN_FILENO

Standard input, `stdin` (value 0)

STDOUT_FILENO

Standard output, `stdout` (value 1)

STDERR_FILENO

Standard error, `stderr` (value 2)

Note that `stdin`, `stdout`, and `stderr` are macros, not constants.

`fileno_unlocked()` is functionally equivalent to `fileno()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

If successful, `fileno()` returns the file descriptor number associated with an open HFS stream (that is, one opened with `fopen()` or `freopen()`). MVS data sets are not supported, so `fileno()` of an MVS data set returns -1.

If unsuccessful, `fileno()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

One of the following error conditions exists:

- *stream* points to a closed stream
- *stream* is an incorrect *stream* pointer
- *stream* points to a stream associated with an MVS data set.

Example

CELEBF21

```
/* CELEBF21

   This example illustrates one use of fileno().

*/
#define _POSIX_SOURCE
#include <errno.h>
#include <stdio.h>

main() {
    FILE *stream;
    char hfs_file[] = ".hfs_file", mvs_ds[] = "//mvs.ds";

    printf("fileno(stdin) = %d\n", fileno(stdin));

    if ((stream = fopen(hfs_file, "w")) == NULL)
```

```

    perror("fopen() error for HFS file");
else {
    printf("fileno() of the HFS file is %d\n", fileno(stream));
    fclose(stream);
    remove(hfs_file);
}

if ((stream = fopen(mvs_ds, "w")) == NULL)
    perror("fopen() error for MVS data set");
else {
    errno = 0;
    printf("fileno() returned %d for MVS data set,\n",fileno(stream));
    printf("  errno=%s\n", strerror(errno));
    fclose(stream);
    remove(mvs_ds);
}
}

```

Output

```

fileno(stdin) = 0
fileno() of the HFS file is 3
fileno() returned -1 for the MVS data set,
errno=Bad file descriptor

```

finite() — Determine the infinity classification of a floating-point number

Standards

| Standards / Extensions | C or C++ | Dependencies |
|-------------------------|----------|--------------|
| Language Environment | both | OS/390 V2R6 |

Format

```

#define _AIX_COMPATIBILITY
#include <math.h>

int finite(x)
double x;

```

General description

The `finite()` function determines the infinity classification of floating-point number `x`.

Note: This function works in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See “[IEEE binary floating-point](#)” on page 97 for more information about IEEE Binary Floating-Point.

Returned value

finite() returns nonzero if the x parameter is a finite number, that is, if x is not +-, INF, NaNQ, or NaNS.

finite() does not return errors or set bits in the floating-point exception status, even if a parameter is a NaNs.

Special behavior for hex: finite() always returns 1 when it is called from HFP mode.

Related information

__flbf() — Determine if a stream is line buffered

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | None |

Format

```
#include <stdio.h>
#include <stdio_ext.h>

int __flbf(FILE *stream);
```

General description

The __flbf() function determines if the specified stream is line buffered.

Returned value

The __flbf() function returns nonzero if the stream is line buffered. Otherwise, the __flbf() function returns 0. If an error has occurred, __flbf() returns 0 and sets errno to nonzero.

An application wishing to check for error situations should set errno to 0, then call __flbf(), and then check errno. If errno is nonzero, assume that an error has occurred.

Error Code
Description

EBADF
The stream specified by *stream* is not valid.

Example

CELEBF84

```
/* CELEBF84
   This example flushes all the line-buffered files.
*/

#include <stdio.h>
#include <stdio_ext.h>
#include <string.h>

#define BUF_SIZE 128

int main(void)
```

```

{
    char lbuf[BUF_SIZE]; /* line buffer */
    char fbuf[BUF_SIZE]; /* full buffer */
    char *tagstr = "This file was modified!";
    FILE *lfp;
    FILE *ffp;

    lfp = fopen("newlfile.dat", "a+");
    if(lfp == NULL){
        perror("Open file failed!\n");
        return -1;
    }
    if(setvbuf(lfp, lbuf, _IOLBF, sizeof(lbuf)) != 0){ /* set lbuf to line-buffered */
        perror("Format line-buffered failed!\n");
        fclose(lfp);
        return -1;
    }

    if (__flbf(lfp)) printf("newlfile.dat is line-buffered\n");
    else printf("newlfile.dat is not line-buffered\n");

    if(fwrite(lfp, strlen(tagstr), 1, lfp) != 1){ /* write tag string to line buffer*/
        perror("Write line buffer failed!\n");
        fclose(lfp);
        return -1;
    }
    printf("Write to the line buffered file succeeded\n");

    ffp = fopen("newffile.dat", "a+");
    if(ffp == NULL){
        perror("Open file failed!\n");
        fclose(lfp);
        return -1;
    }
    if(setvbuf(ffp, fbuf, _IOFBF, sizeof(fbuf)) != 0){ /* set fbuf to full-buffered */
        perror("Format full-buffered failed!\n");
        fclose(ffp);
        return -1;
    }

    if (__flbf(ffp)) printf("newffile.dat is line-buffered\n");
    else printf("newffile.dat is not line-buffered\n");

    if(fwrite(tagstr, strlen(tagstr), 1, ffp) != 1){ /* write tag string to full buffer */
        perror("Write full buffer failed!\n");
        fclose(lfp);
        fclose(ffp);
        return -1;
    }
    printf("Write to the full buffered file succeeded\n");
    _flushlbf(); /* flush line buffered files */
    printf("Only line buffered files are flushed...\n");
    fclose(lfp);
    fclose(ffp);
    return 0;
}

```

Output

```

newlfile.dat is line-buffered
Write to the line buffered file succeeded
newffile.dat is not line-buffered
Write to the full buffered file succeeded
Only line buffered files are flushed...

```

fldata() – Retrieve file information

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <stdio.h>

int fldata(FILE *file, char *filename, fldata_t *info);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int fldata_unlocked(FILE *file, char *filename, fldata_t *info);
```

General description

Retrieves information about an open stream pointed to by *file*. It returns the file name in the buffer that is pointed by *filename* and other information in the structure that is pointed by *info*. The file name buffer and other information structure are user provided. The file name returned in *filename* is the name specified in `fopen()` or `freopen()`. If the file is opened with a *ddname* (for example, `fopen("DD:A", "w")`), then the *filename* field will contain the *ddname* used to open the file, prefixed with `dd:`. If the file is a DASD data set or a memory file, the field `__dsname` contains the *dsname*. If the file is a z/OS UNIX file, the field `__dsname` contains the path name. For all other files, it is NULL.

After a failure, the contents of the information structure are indeterminate.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

For full details about *filename* considerations, see one of the “Opening Files” sections in [z/OS XL C/C++ Programming Guide](#).

If *fldata* is the first reference to a standard stream, a call to the `fldata()` function opens the stream.

See [Table 23 on page 547](#).

Notes:

- A file name of NULL indicates that no file name will be returned.
- `FILENAME_MAX` is recommended for the size of the file name buffer.

The table "Elements Returned in `fldata_t` Data Structure" describes the fields in the `fldata_t` data structure. For further details, see [z/OS XL C/C++ Programming Guide](#).

`fldata_unlocked()` is functionally equivalent to `fldata()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Special behavior for POSIX C: Under z/OS UNIX services, if there had been an exec to an application that invokes `fldata()`, the standard streams are opened at the time of the exec. Thus `fldata()` does not attempt to open them again.

Returned value

If successful, `fldata()` returns 0.

If unsuccessful, `fldata()` returns nonzero.

Table 23. Elements Returned in `fldata_t` Data Structure

| Element | Data Type | General Description |
|------------------------------|----------------|---|
| <code>__recfmF:1</code> | unsigned int | Indicates whether it has fixed-length records. |
| <code>__recfmV:1</code> | unsigned int | Indicates whether it has variable-length records. |
| <code>__recfmU:1</code> | unsigned int | Indicates whether it has undefined-length records. |
| <code>__recfmS:1</code> | unsigned int | Indicates whether it has either standard (if fixed-length) or spanned (if variable-length) records. |
| <code>__recfmBlk:1</code> | unsigned int | Indicates whether it has blocked records. |
| <code>__recfmASA:1</code> | unsigned int | Indicates whether it has ASA print-control characters. |
| <code>__recfmM:1</code> | unsigned int | Indicates whether it has machine print-control codes. |
| <code>__dsorgPO:1</code> | unsigned int | Indicates whether it is a partitioned data set. |
| <code>__dsorgPDSmem:1</code> | unsigned int | Indicates whether a file is a member. |
| <code>__dsorgPDSdir:1</code> | unsigned int | Indicates whether a file is a PDS or PDSE directory. |
| <code>__dsorgPS:1</code> | unsigned int | Indicates whether it is a sequential data set. |
| <code>__dsorgConcat:1</code> | unsigned int | Indicates whether it is a sequentially concatenated file. |
| <code>__dsorgMem:1</code> | unsigned int | Indicates whether it is a memory file. |
| <code>__dsorgHiper:1</code> | unsigned int | Indicates whether it is a memory file in hiperspace. |
| <code>__dsorgTemp:1</code> | unsigned int | Indicates whether it is a temporary file created by <code>tmpfile()</code> . |
| <code>__dsorgVSAM:1</code> | unsigned int | Indicates whether it is a VSAM file. |
| <code>__dsorgHFS:</code> | unsigned int | Indicates whether it is a z/OS UNIX file. |
| <code>__openmode:2</code> | unsigned int | Values are <code>__TEXT</code> , <code>__BINARY</code> , <code>__RECORD</code> , <code>__BLOCKED</code> . |
| <code>__modeflag:4</code> | unsigned int | Values are <code>__APPEND</code> , <code>__READ</code> , <code>__UPDATE</code> , <code>__WRITE</code> . These macros can be added together to determine the value; for example, a file opened with mode <code>a+</code> will have the value <code>__APPEND + __UPDATE</code> . |
| <code>__dsorgPDSE:1</code> | unsigned int | Indicates whether a file is a PDSE. |
| <code>__vsamRLS:3</code> | unsigned int | Returned values are <code>__NORLS</code> , <code>__RLS</code> , <code>__TVS</code> . |
| <code>__recfmB:1</code> | unsigned int | Indicates whether it was allocated with blocked records |
| <code>__reserve2:3</code> | unsigned int | Reserved bits. |
| <code>__device</code> | char | Returned values are <code>__DISK</code> , <code>__TERMINAL</code> , <code>__PRINTER</code> , <code>__TAPE</code> , <code>__TDQ</code> , <code>__DUMMY</code> , <code>__OTHER</code> , <code>__MEMORY</code> , <code>__MSGFILE</code> , <code>__HFS</code> , <code>__HIPERSPACE</code> , <code>__MSGRTN</code> . |
| <code>__blksize</code> | unsigned long | Total block size of the file, including all control information needed in the block. |
| <code>__maxreclen</code> | unsigned long | Maximum length of the data in the record, including ASA control characters, if present. |
| <code>__vsamtype</code> | unsigned short | Returned values are <code>__NOTVSAM</code> , <code>__ESDS</code> , <code>__KSDS</code> , <code>__RRDS</code> , <code>__ESDS_PATH</code> , <code>__KSDS_PATH</code> . Note: Valid only if <code>__dsorgVSAM</code> is set. |

Table 23. Elements Returned in `fldata_t` Data Structure (continued)

| Element | Data Type | General Description |
|-------------------------------|---------------|--|
| <code>__vsamkeylen</code> | unsigned long | Length of VSAM key (if any). Note: Valid only if <code>__dsorgVSAM</code> is set. |
| <code>__vsamRKP</code> | unsigned long | Key position. Note: Valid only if <code>__dsorgVSAM</code> is set. |
| <code>__access_method</code> | uint8_t | Identifies the access method used for the data set. Values include: <code>__AM_UNSPEC</code> <code>__AM_BSAM</code> <code>__AM_QSAM</code> Note: Valid only if <code>__dsorgPS</code> or <code>__dsorgPO</code> is set. |
| <code>__noseek_to_seek</code> | uint8_t | Identifies the reason noseek was changed to seek. Values include: <code>__AM_BSAM_NOSWITCH</code> <code>__AM_BSAM_UPDATE</code> <code>__AM_BSAM_BSAMWRITE</code> <code>__AM_BSAM_FBS_APPEND</code> <code>__AM_BSAM_LRECLX</code> <code>__AM_BSAM_PARTITIONED_DIRECTORY</code> <code>__AM_BSAM_PARTITIONED_INDIRECT</code> Note: Valid only if <code>__dsorgPS</code> or <code>__dsorgPO</code> is set. |
| <code>__dsname</code> | char * | The contents of this field is determined by the following: <ul style="list-style-type: none"> • If the file is a DASD data set, memory file, or a z/OS UNIX file, then <code>__dsname</code> contains the real file name of file opened by <code>ddname</code> • If you open by <code>ddname</code>, and the <code>ddname</code> is a concatenation of PDS or PDSE data sets, then <code>__dsname</code> contains the data set name of the first PDS or PDSE. This is because you are only opening the directory of the first PDS or PDSE. • If you open by <code>ddname(member)</code> and the <code>ddname</code> is a concatenation of PDS or PDSE data sets, then <code>__dsname</code> contains the data set name of the first PDS or PDSE containing the member. Otherwise this field is NULL. The char * <code>__dsname</code> field is allocated internally by the library functions and must be saved before the next call to the <code>fldata()</code> function. |
| <code>__reserve4</code> | unsigned long | Reserved. |

Note: The numeric values for the macro names can be found in `stdio.h`. The meaning of the `__noseek_to_seek` values are described in topic about using the `__amrc` structure in [z/OS XL C/C++ Programming Guide](#).

Example

```
#include <stdio.h>

int main(void)
{
    FILE *stream;
    char filename[100];
    fldata_t fileinfo;
    int rc;

    stream = fopen("myfile.dat","rb+");
    :
    rc = fldata(stream, filename, &fileinfo);
    if (rc != 0)
        printf("fldata failed\n");
    else
        printf("filename is %s\n",filename);
}
```

Related information

flocate() — Locate a VSAM record

Standards

| Standards / Extensions | C or C++ | Dependencies |
|-------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <stdio.h>

int flocate(FILE *stream, const void *key, size_t key_len, int options);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int flocate_unlocked(FILE *stream, const void *key, size_t key_len, int options);
```

General description

Moves the VSAM file position indicator associated with the stream pointed to by *stream*, according to the rest of the arguments specified.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

key points to a key used for positioning.

key_len specifies the length of the search key. The *key_len* argument value must always be nonzero, except for `__KEY_FIRST` and `__KEY_LAST`.

KSDS, KSDS PATH, and ESDS PATH

The *key* can point to a field of any storage type except `register`. Typically it points to a character string whose length is *key_len*. The *key_len* must be less than or equal to the key length of the data

set. If *key_len* is the same as the file's key length, a full key search is automatically used; otherwise, a generic search is used. A generic key search is one in which the search key is a leading portion of the key field. The record positioned to is the first of the records having the same generic key.

ESDS

The *key* points to a relative byte address that may be stored as 4 or 8 byte value. *key_len* is either 4 or 8.

RRDS

The *key* points to a relative record number stored as an unsigned `long int`. *key_len* is either 4 or 8.

options specifies the position options described in [Table 24 on page 550](#).

Table 24. Position Options Parameter for flocate()

| | |
|---------------------|--|
| __KEY_FIRST | Positions to the first record in the file. Subsequent reads are in the forward direction. <i>key</i> and <i>key_len</i> are ignored. |
| __KEY_LAST | Positions to the last record in the file. Subsequent reads are in backward order. <i>key</i> and <i>key_len</i> are ignored. Only applies to VSAM files opened in record mode. |
| __KEY_EQ | Positions to the first record with the specified key. Subsequent reads are in the forward direction. |
| __KEY_EQ_BWD | Positions to the first record with the specified key. Subsequent reads are in backward order. Using this option requires a full key search. <i>key_len</i> must be equal to the key length as defined for the data set. Only applies to VSAM files opened in record mode. |
| __KEY_GE | Positions to the first record with a key greater than or equal to the specified key. |
| __RBA_EQ | Positions to the record with the specified RBA. Subsequent reads are in the forward direction. You cannot use <code>__RBA_EQ</code> with an alternative index path. Using this option with RRDS is <i>not</i> recommended. The underlying VSAM utilities do not support seeking to an RBA in an RRDS file. The <code>flocate()</code> function attempts to convert the RBA to a Relative Record Number by dividing the value by the LRECL of the file and using the equivalent <code>__KEY_EQ</code> . Using this option with KSDS is <i>not</i> recommended because the RBA of a given record may change over time, because of inserts, deletions, or updates of other records. |
| __RBA_EQ_BWD | Positions to the record with the specified RBA. Subsequent reads are in backward order. You cannot use <code>__RBA_EQ_BWD</code> with an alternative index path. Using this option with RRDS is not recommended. The underlying VSAM utilities do not support seeking to an RBA in an RRDS file. The <code>flocate()</code> function attempts to convert the RBA to a Relative Record Number by dividing the value by the LRECL of the file and using the equivalent <code>__KEY_EQ_BWD</code> . Using this option with KSDS is <i>not</i> recommended because the RBA of a given record may change over time, because of inserts, deletions, or updates of other records. Only applies to VSAM files opened in record mode. |

Table 24. Position Options Parameter for *flocate()* (continued)

| | |
|--------------------|---|
| _KEY_EQ_BWD | Positions to the first record with the specified key. Subsequent reads are in backward order. Using this option requires a full key search. <i>key_len</i> must be set equal to the key length as defined for the data set. Only applies to VSAM files opened in record mode. |
|--------------------|---|

Notes:

1. When you are trying to use *flocate()* in a path to a nonunique key, the resulting position will be at the first physical record of the duplicate key set.
2. *flocate()* releases all record locking.
3. Writes to VSAM data sets are not affected by preceding calls to *flocate()*.
4. If a record was not found, you must successfully relocate to another position before reading or writing (using the *flocate()* function). The exception to this is that a write that follows a failed *flocate()* will succeed if the file was opened for initial loading, but no records have been written to it yet.

flocate_unlocked() is functionally equivalent to *flocate()* with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the *flockfile()* or *ftrylockfile()* function.

Considerations for VSAM extended addressability data sets: *flocate()* accepts key lengths of 4 or 8 when relative byte address (RBA) values are used for positioning. A key length of 8 is required only when the working with a VSAM extended addressability data set, because when the address grows past the 4GB boundary, the key needs to be large enough to hold the value.

When using the value 4GB-1 as the key to *flocate()*, the key length must be 8 and the data type used must be 8 bytes in size (for example, X' 00000000FFFFFFFF') . If the key length is 4, *flocate()* treats the key as -1(EOF).

Returned value

If successful, *flocate()* returns 0.

If a record was not found or the position is beyond the EOF, *flocate()* returns EOF.

Example

```
#include <stdio.h>

int main(void)
{
    FILE *stream;
    int    vsam_rc;
    char *key = "RECORD 27";

    stream = fopen("DD:MYCLUS", "rb+", type=record);
    vsam_rc = flocate(stream, key, 9, _KEY_EQ);
    ...
}
```

flock()— Apply or remove an advisory lock on an open file

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| BSD 4.4 | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <sys/file.h>

int flock(int fd, int operation);
```

General description

`flock()` applies or removes an advisory lock on the open file specified by `fd`. The argument `operation` is one of the following:

- `LOCK_SH` Place a shared lock. More than one process might hold a shared lock for a given file at a given time.
- `LOCK_EX` Place an exclusive lock. Only one process might hold an exclusive lock for a given file at a given time.
- `LOCK_UN` Remove an existing lock that is held by this process.

A call to `flock()` might block if an incompatible lock is held by another process. To make a nonblocking request, include `LOCK_NB` (by ORing) with any of the previous operations.

A single file might not simultaneously have both shared and exclusive locks.

Locks that are created by `flock()` are associated with an open file description. This means that duplicate file descriptors (created by, for example, `fork()` or `dup()`) refer to the same lock, and this lock might be modified or released by using any of these file descriptors. Furthermore, the lock is released either by an explicit `LOCK_UN` operation on any of these duplicate file descriptors, or when all such file descriptors are closed.

If a process uses `open()` (or similar) to obtain more than one file descriptor for the same file, these file descriptors are treated independently by `flock()`. An attempt to lock the file by using one of these file descriptors might be denied by a lock that the calling process places via another file descriptor.

A process might hold only one type of lock (shared or exclusive) on a file. Subsequent `flock()` calls on an locked file convert an existing lock to the new lock mode.

Locks that are created by `flock()` are preserved across an `execve()` call.

A shared or exclusive lock can be placed on a file regardless of the mode in which the file is opened.

Returned value

If successful, `flock()` returns 0.

If unsuccessful, `flock()` returns -1 and sets `errno` to one of the following values:

Error Code Description

EBADF

fd is not an open file descriptor.

EINTR

While waiting to acquire a lock, the call is interrupted by delivery of a signal that is caught by a handler.

EINVAL

operation is invalid.

ENOLCK

The kernel runs out of memory for allocating lock records.

EWOULDBLOCK

The file is locked and the LOCK_NB flag is selected.

flockfile()— stdio locking

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|--------------|
| Single UNIX Specification, Version 3 | both | z/OS V1R8 |

Format

```
#define _UNIX03_SOURCE
#include <stdio.h>

void flockfile(FILE *file);
```

General description

This function provides explicit application-level locking of stdio (FILE*) objects. The flockfile() family of the functions can be used by a thread to delineate a sequence of I/O statements that are executed as a unit.

The flockfile() function acquires ownership of a (FILE*) object for the thread, waiting if necessary, and increases the internal lock count. If the thread has previously been granted ownership, the internal lock count is increased.

The internal lock count allows matching calls to flockfile() (or successful calls to ftrylockfile()) and funlockfile() to be nested.

z/OS Consideration: The flockfile() family of functions acts upon FILE * objects. It is possible to have the same physical file represented by multiple FILE * objects that are not recognized as being equivalent. For

example, `fopen()` opens a file and `open()` opens the same file, and then `fdopen()` creates a `FILE *` object. In this case, locking the first `FILE *` does not prevent the second `FILE *` from also being locked and used.

Returned value

None.

Notes:

1. Because the `flockfile()` function returns void, no error information can be returned.
2. It is the application's responsibility to prevent deadlock (or looping). For example, deadlock (or looping) may occur if a (`FILE *`) object is closed, or a thread is terminated, before relinquishing all locked (`FILE *`) objects.

floor(), floorf(), floorl() — Round down to integral value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#include <math.h>

double floor(double x);
float floor(float x);           /* C++ only */
long double floor(long double x); /* C++ only */
float floorf(float x);
long double floorl(long double x);
```

General description

Calculates the largest integer that is less than or equal to x .

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

Returned value

Returns the calculated integral value expressed as a double, float, or long double value. The result cannot have a range error.

Example

CELEBF24

```

/* CELEBF24

   This example assigns y the value of the largest integer that is less
   than or equal to 2.8, and it assigns z the value of the largest integer
   that is less than or equal to -2.8.

*/
#include <math.h>
#include <stdio.h>

int main(void)
{
    double y, z;

    y = floor(2.8);
    z = floor(-2.8);

    printf("floor( 2.8 ) = %f\n", y);
    printf("floor( -2.8 ) = %f\n", z);
}

```

Output

```

floor( 2.8 ) = 2.000000
floor( -2.8 ) = -3.000000

```

floor32(), floor64(), floor128() — Round down to integral value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```

#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 floor32(_Decimal32 x);
_Decimal64 floor64(_Decimal64 x);
_Decimal128 floor128(_Decimal128 x);
_Decimal32 floor(_Decimal32 x); /* C++ only */
_Decimal64 floor(_Decimal64 x); /* C++ only */
_Decimal128 floor(_Decimal128 x); /* C++ only */

```

General description

Calculates the largest integer that is less than or equal to *x*.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

Returns the calculated integral value expressed as a _Decimal32, _Decimal64, or _Decimal128 value. The result cannot have a range error.

Example

```
/* CELEBF78

This example illustrates the floord64() function.

This example assigns y the value of the largest integer that is less
than or equal to 2.8, and it assigns z the value of the largest
integer that is less than or equal to -2.8.

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal64 y, z;

    y = floord64(+2.8DD);
    z = floord64(-2.8DD);

    printf("floord64(+2.8) = %Df\n", y);
    printf("floord64(-2.8) = %Df\n", z);
}
```

_flushlbf() — Flush all open line-buffered files

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | None |

Format

```
#include <stdio.h>
#include <stdio_ext.h>

void _flushlbf(void);

#define _OPEN_SYS_UNLOCKED 1
#include <stdio.h>
#include <stdio_ext.h>

void _flushlbf_unlocked(void);
```

General description

The `_flushlbf()` function flushes all open line-buffered streams.

The `_flushlbf()` function is affected by the `ungetc()` and `ungetwc()` functions. Calling this function causes `_flushlbf()` to back up the file position when characters are pushed back. For details, see [“ungetc\(\) — Push character onto input stream” on page 1941](#) and [“ungetwc\(\) — Push a wide character onto a stream” on page 1943](#). If needed, the `_EDC_COMPAT` environment variable can be set at open time such that `_flushlbf()` discards any pushed-back characters and leaves the file position where it was when the first `ungetc()` or `ungetwc()` function call was issued.

If the `_flushlbf()` function is used after the `ungetwc()` function pushed a wide char on a text stream, the position will be backed up by one wide character from the position of the file when the `ungetwc()` function was issued. For a wide-oriented binary stream, the position will be backed up based on the number of bytes that are used to represent the wide char in the `ungetc` buffer. For this reason, attempting to use `ungetwc()` on a character when the destination is a binary wide-oriented stream that was never read in the first place results in undefined behavior for `_flushlbf()`. Note that the `_EDC_COMPAT` environment variable also changes the behavior of `_flushlbf()` after `ungetwc()`, and will cause any wide char pushed-back to be discarded and the position left at the point where the `ungetwc()` was issued. For details about the `_EDC_COMPAT` environment variable, see *Environment Variables in z/OS XL C/C++ Programming Guide*.

If `_flushlbf()` fails, the position is left at the point in the file where the first `ungetc()` or `ungetwc()` function call was issued. All pushed-back characters are discarded.

Note:

1. The system automatically flushes buffers when you close the stream or when a program ends normally without closing the stream.
2. The `_flushlbf()` function has no effect on line-buffered text files, because the compiler writes all records to the system as they are completed. All incomplete new records remain in the buffer.

The buffering mode and the file type can have an effect on when output data is flushed. For more information, see *Buffering of C Streams in z/OS XL C/C++ Programming Guide*.

All streams remain open after the `_flushlbf()` call. Because a read operation cannot immediately follow or precede a write operation, the `_flushlbf()` function can be used to allow exchange between these two modes. The `_flushlbf()` function can also be used to refresh the buffer when working with a reader and a simultaneous writer or updater.

The `_flushlbf_unlocked()` function is equivalent to the `_flushlbf()` function with the exception that it is not thread-safe. This function can be safely used in a multithreaded application whether the user has locked all open line-buffered files or not.

When flushing all open line-buffered files, a failure to flush any of the files will leave it unchanged. However, flushing will continue on any other open line-buffered files that can be flushed successfully.

Returned value

The `_flushlbf()` function returns no values.

Example

CELEBF84

```
/* CELEBF84
   This example flushes all the line-buffered files.
*/

#include <stdio.h>
#include <stdio_ext.h>
#include <string.h>

#define BUF_SIZE 128
```

```

int main(void)
{
    char lbuf[BUF_SIZE]; /* line buffer */
    char fbuf[BUF_SIZE]; /* full buffer */
    char *tagstr = "This file was modified!";
    FILE *lfp;
    FILE *ffp;

    lfp = fopen("newlfile.dat", "a+");
    if(lfp == NULL){
        perror("Open file failed!\n");
        return -1;
    }
    if(setvbuf(lfp, lbuf, _IOLBF, sizeof(lbuf)) != 0){ /* set lbuf to line-buffered */
        perror("Format line-buffered failed!\n");
        fclose(lfp);
        return -1;
    }

    if (__flbf(lfp)) printf("newlfile.dat is line-buffered\n");
    else printf("newlfile.dat is not line-buffered\n");

    if(fwrite(lfp, strlen(tagstr), 1, lfp) != 1){ /* write tag string to line buffer*/
        perror("Write line buffer failed!\n");
        fclose(lfp);
        return -1;
    }
    printf("Write to the line buffered file succeeded\n");

    ffp = fopen("newffile.dat", "a+");
    if(ffp == NULL){
        perror("Open file failed!\n");
        fclose(lfp);
        return -1;
    }
    if(setvbuf(ffp, fbuf, _IOFBF, sizeof(fbuf)) != 0){ /* set fbuf to full-buffered */
        perror("Format full-buffered failed!\n");
        fclose(ffp);
        return -1;
    }

    if (__flbf(ffp)) printf("newffile.dat is line-buffered\n");
    else printf("newffile.dat is not line-buffered\n");

    if(fwrite(tagstr, strlen(tagstr), 1, ffp) != 1){ /* write tag string to full buffer */
        perror("Write full buffer failed!\n");
        fclose(lfp);
        fclose(ffp);
        return -1;
    }
    printf("Write to the full buffered file succeeded\n");
    _flushlbf(); /* flush line buffered files */
    printf("Only line buffered files are flushed...\n");
    fclose(lfp);
    fclose(ffp);
    return 0;
}

```

Output

```

newlfile.dat is line-buffered
Write to the line buffered file succeeded
newffile.dat is not line-buffered
Write to the full buffered file succeeded
Only line buffered files are flushed...

```

fma(), fmaf(), fmal() – Multiply then add

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _ISOC99_SOURCE
#include <math.h>

double fma(double x, double y, double z);
float fmaf(float x, float y, float z);
long double fmal(long double x, long double y, long double z);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

float fma(float x, float y, float z);
long double fma(long double x, long double y, long double z);
```

General description

The fma() family of functions compute $(x * y) + z$, rounded as one ternary operation: they compute the value to infinite precision and round once to the resulting format according to the rounding mode characterized by the value of FLT_ROUNDS.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------|-----|------|
| fma | X | X |
| fmaf | X | X |
| fmal | X | X |

Restriction: The fmaf() function does not support the _FP_MODE_VARIABLE feature test macro.

Returned value

If successful, they return the rounded value of $(x * y) + z$ as one ternary operation.

Related information

- [“math.h — Floating-point math functions”](#) on page 40

fmad32(), fmad64(), fmad128() – Multiply then add

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.11 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 fmad32(_Decimal32 x, _Decimal32 y, _Decimal32 z);
_Decimal64 fmad64(_Decimal64 x, _Decimal64 y, _Decimal64 z);
_Decimal128 fmad128(_Decimal128 x, _Decimal128 y, _Decimal128 z);

_Decimal32 fma(_Decimal32 x, _Decimal32 y, _Decimal32 z);    /* C++ only */
_Decimal64 fma(_Decimal64 x, _Decimal64 y, _Decimal64 z);    /* C++ only */
_Decimal128 fma(_Decimal128 x, _Decimal128 y, _Decimal128 z); /* C++ only */
```

General description

The fma() family of functions compute $(x * y) + z$ rounded as one ternary operation: they compute the value to infinite precision and round once to the resulting format according to the current rounding mode.

Notes:

1. These functions work in IEEE decimal floating-point format. See [“IEEE decimal floating-point” on page 97](#) IEEE Decimal Floating-Point for more information.
2. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

If successful, they return the rounded value of $(x * y) + z$ as one ternary operation.

Example

```
/* CELEBF82

   This example illustrates the fmad64() function.

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

void main(void)
{
    _Decimal64 w, x, y, z;

    x = 2.5DD;
    y = 6.7DD;
    z = 1.0DD;
    w = fmad64(x,y,z);

    printf("fmad64( %Df, %Df, %Df ) = %Df\n", x, y, z, w);
}
```

fmax(), fmaxf(), fmaxl() – Calculate the maximum numeric value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _ISOC99_SOURCE
#include <math.h>

double fmax(double x, double y);
float fmaxf(float x, float y);
long double fmaxl(long double x, long double y);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

float fmax(float x, float y);
long double fmax(long double x, long double y);
```

General description

The fmax() family of functions determine the maximum numeric value of their arguments. NaN arguments are treated as missing data. If one argument is a NaN and the other numeric, then the numeric value will be chosen.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------|-----|------|
| fmax | X | X |
| fmaxf | X | X |
| fmaxl | X | X |

Restriction: The fmaxf() function does not support the _FP_MODE_VARIABLE feature test macro.

Returned value

If successful, they return the maximum numeric value of their arguments.

fmod(), fmodf(), fmodl() – Calculate floating-point remainder

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#include <math.h>

double fmod(double x, double y);
float fmodf(float x, float y);      /* C++ only */
long double fmod(long double x, long double y); /* C++ only */
float fmodf(float x, float y);
long double fmodl(long double x, long double y);
```

General description

Calculates the floating-point remainder of x/y . The absolute value of the result is always less than the absolute value of y . The result will have the same sign as x .

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

Restriction: The `fmodf()` function does not support the `_FP_MODE_VARIABLE` feature test macro.

Returned value

If y is 0, or the result would overflow, then the function returns 0. `Errno` remains unchanged.

Special behavior for IEEE

If successful, the function returns the floating-point remainder of x/y .

If y is 0, the function sets `errno` to `EDOM` and returns `NaNQ`. No other errors will occur.

Example

CELEBF25

```
/* CELEBF25

   This example computes z as the remainder of x/y; here x/y is -3 with a
   remainder of -1.

*/
#include <math.h>
#include <stdio.h>

int main(void)
{
    double x, y, z;

    x = -10.0;
    y = 3.0;
    z = fmod(x,y);      /* z = -1.0 */
```

```
printf("fmod( %f, %f) = %lf\n", x, y, z);
}
```

Output

```
fmod( -10.000000, 3.000000) = -1.000000
```

fmtmsg() — Display a message in the specified format

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <fmtmsg.h>

int fmtmsg(long classification, const char *label, int severity,
           const char *text, const char *action, const char *tag);
```

General description

The `fmtmsg()` function can be used to display messages in a specified format instead of the traditional `printf()` function.

Based on a message's classification component, `fmtmsg()` writes a formatted message either to standard error, to the console, or to both.

A formatted message consists of up to five components as defined below. The component classification is not part of a message displayed to the user, but defines the source of the message and directs the display of the formatted message.

classification

Contains identifiers from the following groups of major classifications and subclassifications. Any one identifier from a subclass may be used in combination with a single identifier from a different subclass. Two or more identifiers from the same subclass should not be used together, with the exception of identifiers from the display subclass. (Both display subclass identifiers may be used so that messages can be displayed to both standard error and the system console).

Major Classifications

Identifies the source of the condition. Identifiers are: **MM_HARD** (hardware), **MM_SOFT** (software), and **MM_FIRM** (firmware).

Message Source Subclassifications

Identifies the type of software in which the problem is detected. Identifiers are: **MM_APPL** (application), **MM_UTIL** (utility), and **MM_OPSYS** (operating system).

Display Subclassifications

Indicates where the message is to be displayed. Identifiers are: **MM_PRINT** to display the message on the standard error stream, **MM_CONSOLE** to display the message on the system console. One or both identifiers may be used.

Status Subclassifications

Indicates whether the application will recover from the condition. Identifiers are: **MM_RECOVER** (recoverable) and **MM_NRECOV** (non-recoverable).

An additional identifier, **MM_NULLMC**, indicates that no classification component is supplied for the message.

label

Identifies the source of the message. The format is two fields separated by a colon. The first field is up to 10 bytes, the second is up to 14 bytes. The constant **__MM_MXLABELLN** defines the maximum length of *label*.

severity

Indicates the seriousness of the condition. Identifiers for the levels of severity are:

MM_HALT

indicates that the application has encountered a severe fault and is halting. Produces the string "HALT".

MM_ERROR

indicates that the application has detected a fault. Produces the string "ERROR".

MM_WARNING

indicates a condition that is out of the ordinary, that might be a problem, and should be watched. Produces the string "WARNING".

MM_INFO

provides information about a condition that is not in error. Produces the string "INFO".

MM_NOSEV

indicates that no severity level is supplied for the message.

Other

provides an unknown severity. Produce the string "SV=n", where n is the *severity* value specified.

text

Describes the error condition that produced the message. The character string is not limited to a specific size. If the character string is empty, then the text produced is unspecified.

action

Describes the first step to be taken in the error-recovery process. The `fmtmsg()` function precedes the action string with the prefix: "TO FIX:". The action string is not limited to a specific size.

tag

An identifier that references on-line documentation for the message. Suggested usage is that tag includes the label and a unique identifying number. A sample tag is "XSI:cat:146". The constant **__MM_MXTAGLN** defines the maximum length of *tag*.

The MSGVERB environment variable (for message verbosity) tells `fmtmsg()` which message components it is to select when writing messages to standard error. The value of MSGVERB is a colon-separated list of optional keywords. Valid keywords are: label, severity, text, action, and tag. If MSGVERB contains a keyword for a component and the component's value is not the component's NULL value, `fmtmsg()` includes that component in the message when writing the message to standard error. If MSGVERB does not include a keyword for a message component, that component is not included in the display of the message. The keywords may appear in any order. If MSGVERB is not defined, if its value is the NULL string, if its value is not of the correct format, or if it contains keywords other than the valid ones listed above, `fmtmsg()` selects all components.

MSGVERB affects only which components are selected for display to standard error. All message components are included in console messages.

Returned value

fmtmsg() returns one of the following values:

Value

Description

MM_OK

The function succeeded.

MM_NOCON

The function was unable to generate a console message, but otherwise succeeded.

MM_NOMSG

The function was unable to generate a message on standard error, but otherwise succeeded.

MM_NOTOK

The function failed completely.

Examples

The following is an example of fmtmsg():

```
fmtmsg(MM_PRINT, "XSI:cat", MM_ERROR, "illegal option",
"refer to cat in user's reference manual", "XSI:cat:001")

    produces a complete message in the specified message format:

XSI:cat: ERROR: illegal option
TO FIX: refer to cat in user's reference manual XSI:cat:001
```

The following is another example when the environment variable MSGVERB is set.

```
export MSGVERB=severity:text:action

fmtmsg(MM_PRINT, "XSI:cat", MM_ERROR, "illegal option",
"refer to cat in user's reference manual", "XSI:cat:001")

    produces a complete message in the specified message format:

ERROR: illegal option
TO FIX: refer to cat in user's reference manual
```

fnmatch() — Match file name or path name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <fnmatch.h>

int fnmatch(const char *pattern, const char *string, int flags);
```

General description

The `fnmatch()` function matches patterns as described in the **XCU** specification, **Section 2.13.1, Patterns Matching a Single Character**, and **Section 2.13.2, Patterns Matching Multiple Characters**. It checks the string specified by the *string* argument to see if it matches the pattern specified by the *pattern* argument.

The *flags* argument modifies the interpretation of *pattern* and *string*. It is the bitwise inclusive-OR of zero or more of the flags defined in the header `<fnmatch.h>`. If the `FNM_PATHNAME` flag is set in *flags*, then a slash character in *string* will be explicitly matched by a slash in *pattern*; it will not be matched by either the asterisk or question-mark special characters, nor by a bracket expression. If `FNM_PATHNAME` is set and either of these characters would match a slash, the function returns `FNM_ESLASH`. If the `FNM_PATHNAME` flag is not set, the slash character is treated as an ordinary character.

If `FNM_NOESCAPE` is not set in *flags*, a backslash character (`\`) in *pattern* followed by any other character will match that second character in *string*. In particular, `\\` will match a backslash in *string*. If `FNM_NOESCAPE` is set, a backslash character will be treated as an ordinary character.

If `FNM_PERIOD` is set in *flags*, then a leading period in *string* will match a period in *pattern*; as described by rule 2 in the **XCU** specification, **Section 2.13.3, Patterns Used for Filename Expansion**, where the location of “leading” is indicated by the value of `FNM_PATHNAME`:

- If `FNM_PATHNAME` is set, a period is “leading” if it is the first character in *string* or if it immediately follows a slash.
- If `FNM_PATHNAME` is not set, a period is “leading” only if it is the first character of *string*.

If `FNM_PERIOD` is not set, then no special restrictions are placed on matching a period. If `FNM_PERIOD` is set, and a pattern wildcard would match a leading period as defined by the above rules, then the function returns `FNM_EPERIOD`.

Returned value

If *string* matches the pattern specified by *pattern*, `fnmatch()` returns 0.

If there is no match, `fnmatch()` returns `FNM_NOMATCH`, which is defined in the header `<fnmatch.h>`.

If an error occurs, `fnmatch()` returns another nonzero value. See the discussion above for the various possible nonzero returns.

Related information

- [“fnmatch.h — Filename matching types” on page 27](#)

fopen() — Open a file

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdio.h>

FILE *fopen(const char *__restrict__filename, const char *__restrict__mode);
```

General description

The `fopen()` function opens the file specified by *filename* and associates a stream with it. The *mode* variable is a character string specifying the type of access requested for the file. The *mode* variable contains one positional parameter followed by optional keyword parameters. The positional parameters are described in [Table 25 on page 572](#) and [Table 27 on page 573](#).

The positional parameters must be passed as lowercase characters.

The keyword parameters can be passed in mixed case. They must be separated by commas. Only one instance of a keyword can be specified.

The file name passed to `fopen()` often determines the type of file that is opened. A set of file-naming rules exist, which allow you to create an application that references both MVS and z/OS UNIX files specifically. For details on how `fopen()` determines the type of file from the *filename* and *mode* strings, see the topics about opening files in [z/OS XL C/C++ Programming Guide](#).

Large file support for z/OS UNIX files: Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the [long long data type support](#) enabled and define the `_LARGE_FILES` feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the `_LARGE_FILES` feature test macro as well.

Named pipes in multithreaded environment: Do not use `fopen()` to open named pipes in multithreaded environment. If used, a deadlock will occur. See [z/OS XL C/C++ Programming Guide](#) for a detailed explanation.

File mode

Restriction: When running with `POSIX(OFF)` and specifying a mode parameter that includes `t`, for example, `rt`, `rt+`, `r+t`, `wt`, `wt+`, `w+t`, `at`, `at+` or `a+t`, the `fopen()` request will fail with a message indicating a non-valid mode was specified.

Positional parameter points to a string that begins with one of the following sequences. To support extended file modes, additional characters can be included either as a last character or as a character between the characters in any of the two-character strings.

Table 25. Values for positional parameter under file mode

| File mode | General description |
|------------|---|
| r | Open a text file for reading. (The file must exist.) |
| w | Open a text file for writing. If the w mode is specified for a ddname that has DISP=MOD, the behavior is the same as if a had been specified. Otherwise, if the file already exists, its contents are destroyed. |
| a | Open a text file in append mode for writing at the end of the file. fopen() creates the file if it does not exist. |
| r+ | Open a text file for both reading and writing. (The file must exist.) |
| w+ | Open a text file for both reading and writing. If the w+ mode is specified for a ddname that has DISP=MOD, the behavior is the same as if a+ had been specified. Otherwise, if the file already exists, its contents are destroyed. |
| a+ | Open a text file in append mode for reading or updating at the end of the file. fopen() creates the file if it does not exist. |
| rb | Open a binary file for reading. (The file must exist.) |
| wb | Open an empty binary file for writing. If the wb mode is specified for a ddname that has DISP=MOD, the behavior is the same as if ab had been specified. Otherwise, if the file already exists, its contents are destroyed. |
| ab | Open a binary file in append mode for writing at the end of the file. fopen() creates the file if it does not exist. |
| rt | Open a text file for reading. (The file must exist.) |
| wt | Open a text file for writing. If the file already exists, its contents are destroyed. |
| at | Open a text file in append mode for writing at the end of the file. fopen() creates the file if it does not exist. |
| r+b or rb+ | Open a binary file for both reading and writing. (The file must exist.) |
| w+b or wb+ | Open an empty binary file for both reading and writing. If the w+b (or wb+) mode is specified for a ddname that has DISP=MOD, the behavior is the same as if ab+ had been specified. Otherwise, if the file already exists, its contents are destroyed. |
| a+b or ab+ | Open a binary file in append mode for reading or updating at the end of the file. fopen() creates the file if it does not exist. |
| r+t or rt+ | Open a text file for both reading and writing. (The file must exist.) |
| w+t or wt+ | Open a text file for both reading and writing. If the file already exists, its contents are destroyed. |
| a+t or at+ | Open a text file in append mode for reading or updating at the end of the file. fopen() creates the file if it does not exist. |

Table 26. Values for positional parameter under extended file mode

| Extended file mode | General description |
|--------------------|--|
| e | Open the z/OS UNIX system file with the O_CLOEXEC flag. This flag is ignored for fdopen(). This flag is ignored if the file not a z/OS UNIX system file. |
| x | Open the z/OS UNIX system file exclusively. If the file already exists, fopen() fails, and sets errno to EEXIST. This flag is ignored for fdopen(). This flag is ignored if the file is not a z/OS UNIX system file. |

Attention: Use the `w`, `w+`, `wb`, `w+b`, and `wb+` parameters with care; data in existing files of the same name will be lost.

Text files contain printable characters and control characters organized into lines. Each line ends with a newline character. The system may insert or convert control characters in an output text stream. For example, `\r` written to an MVS DASD text file will be treated as if `\n` (newline) was written.

Note: When compared, data output to a text stream may not be equal to data input from the same text stream.

Binary files contain a series of characters. For binary files, the system does not translate control characters on input or output. Under IBM z/OS C/C++, some types of files are always treated as binary files, even when opened in text mode.

In such cases, a control character is written to the file as binary data. On input, the control character will be read back as it was written. See the topic about the byte stream model in [z/OS XL C/C++ Programming Guide](#) for more information.

IBM z/OS C/C++ has *Record I/O* and *Blocked I/O* file extensions. These files are binary in nature—no data interpretation—and require additional qualifiers: `type=record` and `type=blocked`. See the topics about writing to record I/O files and writing to blocked I/O files in [z/OS XL C/C++ Programming Guide](#) for more information.

When you open a file with `a`, `a+`, `ab`, `a+b`, or `ab+` mode, all write operations take place at the end of the file. Although you can reposition the file pointer using `fseek()`, `fsetpos()`, or `rewind()`, the write functions move the file pointer back to the end of the file before they carry out any output operation. This action prevents you from overwriting existing data.

When you specify the update mode (using `+` in the second or third position), you can both read from and write to the file. However, when switching between reading and writing, you must include an intervening positioning function such as `fseek()`, `fsetpos()`, `rewind()`, or `fflush()`. Output may immediately follow input if the EOF was detected.

Table 27. Keyword Parameters for File Mode

| Parameter | Description |
|----------------------------|--|
| <code>abend=value</code> | Controls whether the runtime library should attempt to recover from an abend issued during OS I/O operations against the stream being opened. The <i>value</i> can be abend or recover . See z/OS XL C/C++ Programming Guide for more information. |
| <code>acc=value</code> | Indicator of the direction of the access of the VSAM data set. The <i>value</i> can be fwd or bwd . |
| <code>acc=bwd</code> | Sets the file position indicator to the last record. The access direction may be changed by a call to <code>flocate()</code> . |
| <code>asis</code> | Indicates that the file name is not to be converted to uppercase but used as is. This option is the default under POSIX. It is also the default for z/OS UNIX file names (see z/OS XL C/C++ Programming Guide for more information). |
| <code>blksize=value</code> | Specifies the maximum length, in bytes, of a physical block of records. To check whether your <code>blksize</code> parameter is valid and is within its limits, see the appropriate topic in z/OS XL C/C++ Programming Guide for the type of file you are opening. |
| <code>byteseek</code> | Indicator to allow byte seeks for a binary file. For more information, see the <code>ftell()</code> and <code>fseek()</code> functions. |

Table 27. Keyword Parameters for File Mode (continued)

| Parameter | Description |
|------------------|---|
| lrec1=value | Specifies the length, in bytes, for fixed-length records and the maximum length for variable-length records. To check whether your lrec1 parameter is valid and is within its limits, see the appropriate topic in <i>z/OS XL C/C++ Programming Guide</i> for the type of file you are opening. |
| noseek | Indicates that the stream may not use any of the reposition functions. This may improve performance. |
| password=xxxxxxx | Specifies the password for a VSAM data set. |
| recfm=A | ASA print-control characters |
| recfm=F | Fixed-length, unblocked |
| recfm=FA | Fixed-length, ASA print-control characters |
| recfm=FB | Fixed-length, blocked |
| recfm=FM | Fixed-length, machine print-control codes |
| recfm=FS | Fixed-length, unblocked, standard |
| recfm=FBA | Fixed-length, blocked, ASA print-control characters |
| recfm=FBM | Fixed-length, blocked, machine print-control codes |
| recfm=FBS | Fixed-length, unblocked, standard ASA print-control characters |
| recfm=FSA | Fixed-length, unblocked, standard, ASA print-control characters |
| recfm=FSM | Fixed-length, unblocked, standard, machine print-control codes |
| recfm=FBSA | Fixed-length, blocked, standard, ASA print-control characters |
| recfm=FBSM | Fixed-length, blocked, standard, machine print-control codes |
| recfm=U | Undefined-length |
| recfm=UA | Undefined-length, ASA print control characters |
| recfm=UM | Undefined-length, machine print control codes |
| recfm=V | Variable, unblocked |
| recfm=VA | Variable, ASA print-control characters |
| recfm=VB | Variable, blocked |
| recfm=VM | Variable, machine print-control codes |
| recfm=VS | Variable, unblocked, spanned |
| recfm=VBA | Variable, blocked, ASA print-control characters |
| recfm=VBM | Variable, blocked, machine print-control codes |
| recfm=VBS | Variable, blocked, spanned |
| recfm=VSA | Variable, unblocked, spanned, ASA print-control characters |
| recfm=VSM | Variable, unblocked, spanned, machine print-control codes |
| recfm=VBSA | Variable, blocked, spanned, ASA print-control characters |
| recfm=VBSM | Variable, blocked, spanned, machine print-control codes |

Table 27. Keyword Parameters for File Mode (continued)

| Parameter | Description |
|-------------------------|---|
| recfm=* | Existing file attributes are used if file is opened in write mode. Note: Using recfm=* is only valid for existing DASD data sets. It is ignored in all other cases. |
| recfm=+ | Identical to recfm=* with the following exceptions: <ul style="list-style-type: none"> • If there is no record format for the existing DASD data set, defaults are assigned as if the data set did not exist. • When append mode is used, the fopen() fails. See z/OS XL C/C++ Programming Guide for more information about fopen() default attributes. |
| samethread | This parameter specifies that I/O operations against the stream are restricted to the thread in which the stream was opened. The library will not lock the stream in a multithread environment. Use of this keyword can improve performance when the stream does not need to be accessed on different threads. |
| space | Space attributes for MVS data sets. Within the parameter, you cannot have any imbedded blanks. Where: <ul style="list-style-type: none"> u unit type of space requested p primary amount of space requested s secondary amount of space requested d number of directory space requested See the topic about fopen() and freopen() parameters in z/OS XL C/C++ Programming Guide for more information about the syntax of this parameter. |
| type=blocked | This parameter specifies that the file is to be opened for sequential blocked I/O. The file must be opened as a binary file; otherwise, fopen() fails. Read and write operations are done with the fread() and fwrite() functions. |
| type=memory | This parameter identifies this file as a memory file that is accessible only from C programs. |
| type=memory(hiperspace) | If you are using MVS/ESA, you can specify the HIPERSPACE suboption to open a hiperspace memory file. Restriction: For AMODE 64 applications, type=memory(hiperspace) is treated as type=memory. |
| type=record | This parameter specifies that the file is to be opened for sequential record I/O. The file must be opened as a binary file; otherwise, fopen() fails. Read and write operations are done with the fread() and fwrite() functions. This is the default fopen() mode for accessing VSAM clusters. |

Returned value

If successful, `fopen()` returns a pointer to the object controlling the associated stream.

If unsuccessful, `fopen()` returns a NULL pointer.

`fopen()` generally fails if parameters are mismatched.

Special behavior for large files: The following is a possible value of `errno`:

Error Code

Description

EEXIST

The named file refers to a symbolic link, or a file or directory already exists with the mentioned pathname.

EOVERFLOW

The named file is a regular file and the size of the file cannot be represented correctly in an object of type `off_t`.

Example

CELEBF26

```
/* CELEBF26

   This example attempts to open two files for reading, myfile.dat
   and myfile2.dat.

*/
#include <stdio.h>

int main(void)
{
    FILE *stream;

    /* The following call opens a text file for reading */
    if ((stream = fopen("myfile.dat", "r")) == NULL)
        printf("Could not open data file for reading\n");

    /* The following call opens:
       the file myfile2.dat,
       a binary file for reading and writing,
       whose record length is 80 bytes,
       and maximum length of a physical block is 240 bytes,
       fixed-length, blocked record format
       for sequential record I/O.
    */

    if ( (stream = fopen("myfile2.dat", "rb+", lrecl=80,\
        blksize=240, recfm=fb, type=record)) == NULL )
        printf("Could not open data file for read update\n");
}
```

fork() — Create a new process

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <sys/types.h>
#include <unistd.h>

pid_t fork(void);
```

Note: Although POSIX.1 does not require that the `<sys/types.h>` include file be included, XPG4 has it as an optional header. Therefore, it is recommended that you include it for portability.

General description

Creates a new process. The new process (the *child process*) is an exact duplicate of the process that calls `fork()` (the *parent process*), except for the following:

- The child process has a unique process ID (PID) that does not match any active process group ID.
- The child has a different parent process ID, that is, the process ID of the process that called `fork()`.
- The child has its own copy of the parent's file descriptors. Each file descriptor in the child refers to the same open file description as the corresponding file descriptor in the parent.
- The child has its own copy of the parent's open directory streams. Each child's open directory stream can share directory stream positioning with the corresponding parent's directory stream.
- The following elements in the `tms` structure are set to 0 in the child:

```
tms_utime
tms_stime
tms_cutime
tms_cstime
```

For more information about these elements, see [“times\(\) — Get process and child process times” on page 1867](#).

- The child does not inherit any file locks previously set by the parent.
- The child process has no alarms set (similar to the results of a call to `alarm()` with an argument value of 0).
- The child has no pending signals.
- The child process has only a single thread. That thread is a copy of the thread in the parent that called `fork()`. The child process has a different thread ID. If the parent process was multithreaded (invoked `pthread_create()` at least once), the child process can only safely invoke async-signal-safe functions before it invokes an `exec()` family function. (This restriction also applies to any process created as the result of the child invoking `fork()` before it invokes an `exec()` family function because the child process is still considered multithreaded.) The child process does not inherit pthread attributes or pthread security environment. See [Table 28 on page 578](#) for a list of async-signal-safe functions.

In all other respects, the child is identical to the parent. Because the child is a duplicate, it contains the same call to `fork()` that was in the parent. Execution begins with this `fork()` call, which returns a value of 0; the child then proceeds with normal execution.

The child address space inherits the following address space attributes of the parent address space:

- Region size
- Time limit

If the parent process is multithreaded, it is the responsibility of the application to ensure that the application data is in a consistent state when the `fork()` occurs. For example, mutexes that are used to serialize updates to application data may need to be locked before the `fork()` and unlocked afterwards.

For more information on `fork()`, refer to [z/OS UNIX System Services Programming: Assembler Callable Services Reference](#).

You can use MVS memory files from a z/OS UNIX program. However, use of the `fork()` function from the program removes access from a hiperspace memory file for the child process. Use of an `exec` function from the program clears a memory file when the process address space is cleared.

The child process that results from a `fork()` in a multithreaded environment can only invoke async-signal-safe functions.

An async-signal-safe function is defined as a function that may be invoked, without restriction, from signal-catching functions. All supported async-signal-safe functions are listed in [Table 28 on page 578](#).

Table 28. Async-signal-safe library functions

| | | | |
|----------------------|----------------------------|----------------------------|----------------------------|
| abort() | <code>fpathconf()</code> | <code>raise()</code> | <code>sigpending()</code> |
| accept() | <code>fstat()</code> | <code>read()</code> | <code>sigprocmask()</code> |
| access() | <code>fsync()</code> | <code>readlink()</code> | <code>sigqueue()</code> |
| aio_error() | <code>ftruncate()</code> | <code>recv()</code> | <code>sigset()</code> |
| aio_return() | <code>getegid()</code> | <code>recvfrom()</code> | <code>sigsuspend()</code> |
| aio_suspend() | <code>geteuid()</code> | <code>recvmsg()</code> | <code>socket()</code> |
| alarm() | <code>getgid()</code> | <code>rename()</code> | <code>socketpair()</code> |
| bind() | <code>getgroups()</code> | <code>rmdir()</code> | <code>stat()</code> |
| cfgetispeed() | <code>getpeername()</code> | <code>select()</code> | <code>symlink()</code> |
| cfgetospeed() | <code>getpgrp()</code> | <code>send()</code> | <code>sysconf()</code> |
| cfsetispeed() | <code>getpid()</code> | <code>sendmsg()</code> | <code>tcdrain()</code> |
| cfsetospeed() | <code>getppid()</code> | <code>sendto()</code> | <code>tcflow()</code> |
| chdir() | <code>getsockname()</code> | <code>setgid()</code> | <code>tcflush()</code> |
| chmod() | <code>getsockopt()</code> | <code>setpgid()</code> | <code>tcgetattr()</code> |
| chown() | <code>getuid()</code> | <code>setsid()</code> | <code>tcgetpgrp()</code> |
| close() | <code>kill()</code> | <code>setsockopt()</code> | <code>tcsendbreak()</code> |
| connect() | <code>link()</code> | <code>setuid()</code> | <code>tcsetattr()</code> |
| creat() | <code>listen()</code> | <code>shutdown()</code> | <code>tcsetpgrp()</code> |
| dup() | <code>lseek()</code> | <code>sigaction()</code> | <code>time()</code> |
| dup2() | <code>lstat()</code> | <code>sigaddset()</code> | <code>times()</code> |
| execle() | <code>mkdir()</code> | <code>sigdelset()</code> | <code>umask()</code> |
| execve() | <code>mkfifo()</code> | <code>sigemptyset()</code> | <code>uname()</code> |

Table 28. Async-signal-safe library functions (continued)

| | | | |
|-----------------|------------|---------------|-----------|
| _Exit() | open() | sigfillset() | unlink() |
| _exit() | pathconf() | sigismember() | utime() |
| fchmod() | pause() | sleep() | wait() |
| fchown() | pipe() | signal() | waitpid() |
| fcntl() | poll() | sigpause() | write() |
| fork() | | | |

Interoperability restriction: For POSIX resources, fork() behaves as just described. But in general, MVS resources that existed in the parent do *not* exist in the child. This is true for open streams in MVS data sets and assembler-accessed MVS facilities, such as STIMERS. In addition, MVS allocations (through JCL, SVC99, or ALLOCATE) are not passed to the child process.

Special behavior for z/OS UNIX Services:

1. A prior loaded copy of an HFS program in the same address space is reused under the same circumstances that apply to the reuse of a prior loaded MVS unauthorized program from an unauthorized library by the MVS XCTL service with the following exceptions:
 - If the calling process is in Ptrace debug mode, a prior loaded copy is not reused.
 - If the calling process is not in Ptrace debug mode, but the only prior loaded usable copy found of the HFS program is in storage modifiable by the caller, the prior copy is not reused.
2. If the specified file name represents an external link or a sticky bit file, the program is loaded from the caller's MVS load library search order. For an external link, the external name is only used if the name is eight characters or less, otherwise the caller receives an error from the loadhfs service. For a sticky bit program, the file name is used if it is eight characters or less. Otherwise, the program is loaded from the HFS.
3. If the calling task is in a WLM enclave, the resulting task in the new process image is joined to the same WLM enclave. This allows WLM to manage the old and new process images as one 'business unit of work' entity for system accounting and management purposes.

Returned value

If successful, fork() returns 0 to the child process and the process ID of the newly created child to the parent process.

If unsuccessful, fork() fails to create a child process, returns -1 to the parent, and sets errno to one of the following values:

Error Code Description

EAGAIN

There are insufficient resources to create another process, or the process has already reached the maximum number of processes you can run.

ELEMSGERR

Language Environment message file not available.

ELEMULTITHREAD

Application contains a language that does not support fork() in a multithreaded environment, or the multithreaded fork() is being attempted while running in a Language Environment preinitialization (CEEPIPI) environment.

ELENOFORK

Application contains a language that does not support fork().

ENOMEM

The process requires more space than is available.

Example

CELEBF27

```

/* CELEBF27

   This example creates a new child process.

*/
#define _POSIX_SOURCE
#include <sys/types.h>
#include <stdio.h>
#include <unistd.h>
#include <stdlib.h>
#include <sys/wait.h>

main() {
    pid_t pid;
    int status;

    if ((pid = fork()) < 0)
        perror("fork() error");
    else if (pid == 0) {
        puts("This is the child.");
        printf("Child's pid is %d and my parent's is %d\n",
            (int) getpid(), (int) getppid());
        exit(42);
    }
    else {
        puts("This is the parent.");
        printf("Parent's pid is %d and my child's is %d\n",
            (int) getpid(), (int) pid);
        puts("I'm waiting for my child to complete.");
        if (wait(&status) == -1)
            perror("wait() error");
        else if (WIFEXITED(status))
            printf("The child exited with status of %d\n",
                WEXITSTATUS(status));
        else
            puts("The child did not exit successfully");
    }
}

```

Output

```

This is the parent.
This is the child.
Child's pid is 1114120 and my parent's is 2293766
Parent's pid is 2293766 and my child's is 1114120
I'm waiting for my child to complete.
The child exited with status of 42

```

fortrc() — Return FORTRAN return code

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C Library | both | |

Format

```
#include <stdlib.h>

int fortrc(void);
```

External entry point: @@FORTRC, __fortrc

General description

Restriction: This function is not supported in AMODE 64.

The `fortrc()` function returns the value specified on the FORTRAN RETURN statement issued by the last FORTRAN routine called from the C program.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

The FORTRAN routine called must be identified to C as a FORTRAN routine using the following preprocessor directive:

```
#pragma linkage(identifier,FORTRAN,RETURNCODE)
```

The function `fortrc()` should be called immediately after a call to the FORTRAN routine *identifier* or else results are unpredictable.

fp_clr_flag() — Reset floating-point exception status flag

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | OS/390 V2R6 |

Format

```
#include <float.h>
#include <fpxcp.h>

void fp_clr_flag(mask)
fpflag_t mask;
```

General description

The fp_clr_flag() function resets the exception status flags defined by the mask parameter to 0 (false). The remaining flags in the exception status remain unchanged.

Note: This function works only in IEEE Binary Floating-Point. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

The **fpxcp.h** file defines the following names for the flags indicating floating-point exception status:

- FP_INVALID**
Invalid operation summary
- FP_OVERFLOW**
Overflow
- FP_UNDERFLOW**
Underflow
- FP_DIV_BY_ZERO**
Division by 0
- FP_INEXACT**
Inexact result

Users can reset multiple exception flags using the fp_clr_flag() function by OR-ing the names of individual flags. For example, the following resets both the overflow and inexact flags.

```
fp_clr_flag(FP_OVERFLOW | FP_INEXACT)
```

Returned value

fp_clr_flag() returns no values.

Related information

- [“float.h — ISO C/C++ constants for floating-point data types”](#) on page 24
- [“fpxcp.h — Floating-point exception interfaces”](#) on page 27
- [“fp_raise_xcp\(\) — Raise a floating-point exception”](#) on page 582
- [“fp_read_flag\(\) — Return the current floating-point exception status”](#) on page 584
- [“__isBFP\(\) — Determine application floating-point format”](#) on page 905

fp_raise_xcp() — Raise a floating-point exception

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | OS/390 V2R6 |

Format

```
#include <fpxcp.h>

int fp_raise_xcp(mask)
fpflag_t mask;
```

General description

The `fp_raise_xcp()` function causes floating-point exceptions defined by the *mask* parameter to be raised immediately.

If the exceptions defined by the *mask* parameter are enabled and the program is running in serial mode, the signal for floating-point exceptions, SIGFPE, is raised.

Note: This function works only in IEEE Binary Floating-Point. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

The **fpxcp.h** file defines the following names for the flags indicating floating-point exception status:

FP_INVALID

Invalid operation summary

FP_OVERFLOW

Overflow

FP_UNDERFLOW

Underflow

FP_DIV_BY_ZERO

Division by 0

FP_INEXACT

Inexact result

Users can cause multiple exceptions using `fp_raise_xcp()` by OR-ing the names of individual flags. For example, the following causes both overflow and division by 0 exceptions to occur.

```
fp_raise_xcp(FP_OVERFLOW | FP_DIV_BY_ZERO)
```

If more than one exception is included in the mask variable, the exceptions are raised in the following order:

1. Non-valid operation
2. Division by zero
3. Underflow
4. Overflow
5. Inexact result

Thus, if the user exception handler does not disable further exceptions, one call to the `fp_raise_xcp()` function can cause the exception handler to be entered many times.

Returned value

If successful, `fp_raise_xcp()` returns 0.

If unsuccessful, `fp_raise_xcp()` returns nonzero.

Related information

- [“fp_xcp.h — Floating-point exception interfaces”](#) on page 27
- [“fp_clr_flag\(\) — Reset floating-point exception status flag”](#) on page 581
- [“fp_read_flag\(\) — Return the current floating-point exception status”](#) on page 584
- [“__isBFP\(\) — Determine application floating-point format”](#) on page 905

fp_read_flag() — Return the current floating-point exception status

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | OS/390 V2R6 |

Format

```
#include <float.h>
#include <fpxcp.h>

fpflag_t fp_read_flag()
```

General description

The `fp_read_flag()` function returns the current floating-point exception status.

These functions aid in determining both when an exception has occurred and the exception type. These functions can be called explicitly around blocks of code that may cause a floating-point exception.

According to the IEEE Standard for Binary Floating-Point Arithmetic, the following types of floating-point operations must be signaled when detected in a floating-point operation:

- Non-valid operation
- Division by zero
- Overflow
- Underflow
- Inexact

A non-valid operation occurs when the result cannot be represented (for example, a square root operation on a number less than 0).

The IEEE Standard for Binary Floating-Point Arithmetic states: “For each type of exception, the implementation shall provide a status flag that shall be set on any occurrence of the corresponding exception when no corresponding trap occurs. It shall be reset only at the user's request. The user shall be able to test and to alter the status flags individually, and should further be able to save and restore all five at one time.”

Floating-point operations can set flags in the floating-point exception status but cannot clear them. Users can clear a flag in the floating-point exception status using an explicit software action such as the `fp_clr_flag (0)` subroutine.

Note: This function works only in IEEE Binary Floating-Point. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

The **fpxcp.h** file defines the following names for the flags indicating floating-point exception status:

FP_INVALID

non-valid operation summary

FP_OVERFLOW

Overflow

FP_UNDERFLOW

Underflow

FP_DIV_BY_ZERO

Division by 0

FP_INEXACT

Inexact result

Returned value

fp_read_flag() returns the current floating-point exception status. The flags in the returned exception status can be tested using the flag definitions above. You can test individual flags or sets of flags.

fp_read_rnd() — Determine rounding mode

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | OS/390 V2R6 |

Format

```
#define _AIX_COMPATIBILITY 1
#include <float.h>

fprnd_t fp_read_rnd(void);
```

General description

For an application running in binary floating-point mode, the fp_read_rnd() function returns the current rounding mode indicated by the rounding mode field of the floating-point control (FPC) register. For an application running in hexadecimal floating-point mode, fp_read_rnd() returns 0.

Note: This function will not return or update decimal floating-point rounding mode bits.

Returned value

For an application running in IEEE Binary Floating-Point mode, fp_read_rnd() returns the following:

Value**Rounding Mode****_FP_RND_RZ**

Round toward 0

_FP_RND_RN

Round to nearest

_FP_RND_RP

Round toward +infinity

_FP_RND_RM

Round toward -infinity

For an application running in hexadecimal floating-point mode, fp_read_rnd() returns 0.

Related information

- [“float.h — ISO C/C++ constants for floating-point data types” on page 24](#)
- [“fp_swap_rnd\(\) — Swap rounding mode” on page 586](#)
- [“__isBFP\(\) — Determine application floating-point format” on page 905](#)

fp_swap_rnd() — Swap rounding mode

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | OS/390 V2R6 |

Format

```
#define _AIX_COMPATIBILITY 1
#include <float.h>

fpnd_t fp_swap_rnd(RoundMode)
fpnd_t RoundMode
```

General description

For an application running in IEEE Binary Floating-Point mode, the fp_swap_rnd() function returns the current rounding mode specified by the rounding mode field of the floating-point control (FPC) register and sets the rounding mode field in the FPC register based on the value of *RoundMode* as follows:

Value

Rounding Mode

_FP_RND_RZ

Round toward 0

_FP_RND_RN

Round to nearest

_FP_RND_RP

Round toward +infinity

_FP_RND_RM

Round toward -infinity

Notes:

1. When processing IEEE Binary Floating-Point values, the z/OS C/C++ runtime library math functions require IEEE rounding mode of round to nearest. The z/OS C/C++ runtime library takes care of setting round to nearest rounding mode while executing math functions and restoring application rounding mode before returning to the caller.
2. This function will not return or update decimal floating-point rounding mode bits.

Returned value

For an application running in hexadecimal floating-point mode, fp_swap_rnd() returns 0.

For an application running in IEEE Binary Floating-Point mode, fp_swap_rnd() returns the previous (changed from) rounding mode as follows:

Value**Rounding Mode****_FP_RND_RZ**

Round toward 0

_FP_RND_RN

Round to nearest

_FP_RND_RP

Round toward +infinity

_FP_RND_RM

Round toward -infinity

fpathconf() — Determine configurable path name variables

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

long fpathconf(int fildes, int varcode);
```

General description

Determines the value of a configuration variable (*varcode*) associated with a particular file descriptor (*fildes*).

fpathconf() works exactly like pathconf(), except that it takes a file descriptor as an argument rather than taking a path name.

The *varcode* argument can be any one of a set of symbols defined in the unistd.h header file. Each symbol stands for a configuration variable. These are the possible symbols:

_PC_LINK_MAX

Represents **LINK_MAX**, the maximum number of links the file can have. If *pathname* is a directory, fpathconf() returns the maximum number of links that can be established to the directory itself.

_PC_MAX_CANON

Represents **MAX_CANON**, the maximum number of bytes in a terminal canonical input line. *pathname* must refer to a character special file for a terminal.

_PC_MAX_INPUT

Represents **MAX_INPUT**, the minimum number of bytes for which space will be available in a terminal input queue. This input space is the maximum number of bytes that a portable application will

allow an end user to enter before the application actually reads the input. *pathname* must refer to a character special file for a terminal.

_PC_NAME_MAX

Represents **NAME_MAX**, the maximum number of characters in a file name (not including any terminating NULL character if the file name is stored as a string). This limit refers only to the file name itself, that is, the last component of the file's path name. `fpathconf()` returns the maximum length of file names.

_PC_PATH_MAX

Represents **PATH_MAX**, the maximum number of characters in a complete path name (not including any terminating NULL if the path name is stored as a string). `fpathconf()` returns the maximum length of a relative path name.

_PC_PIPE_BUF

Represents **PIPE_BUF**, the maximum number of bytes that can be written to a pipe as one unit. If more than this number of bytes is written to a pipe, the operation can take more than one physical write operation and can require more than one physical read operation to read the data on the other end of the pipe. If *pathname* is a FIFO special file, `fpathconf()` returns the value for the file itself. If *pathname* is a directory, `fpathconf()` returns the value for any FIFOs that exist or can be created under the directory. If *pathname* is any other kind of file, an `errno` of `EINVAL` (see description below) will be returned.

_PC_CHOWN_RESTRICTED

Represents `_POSIX_CHOWN_RESTRICTED` defined in the `unistd.h` header file. This symbol indicates that the use of `chown()` is restricted; see the callable service `chown()` for more details. If *pathname* is a directory, `fpathconf()` returns the value for any kind of file under the directory, but not for subdirectories of the directory.

_PC_NO_TRUNC

Represents `_POSIX_NO_TRUNC` defined in the `unistd.h` header file. This symbol indicates that an error should be generated if a file name is longer than **NAME_MAX**. If *pathname* refers to a directory, the value returned by `fpathconf()` applies to all files under that directory.

_PC_VDISABLE

Represents `_POSIX_VDISABLE` defined in the `unistd.h` header file. This symbol indicates that terminal special characters can be disabled using this character value, if it is defined. See the callable service `tcsetattr()` for details. *pathname* must refer to a character special file for a terminal.

_PC_ACL

Returns 1 if an access control mechanism is supported by the security product for the file identified by the file descriptor.

_PC_ACL_ENTRIES_MAX

Returns the maximum number of ACL entries in an ACL for the file or directory identified by the file descriptor.

Returned value

If a particular variable has no limit, `fpathconf()` returns -1 but does not change `errno`.

If successful, `fpathconf()` returns the value of the variable requested in *varcode*.

If unsuccessful, `fpathconf()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

fd is not a valid open file descriptor.

EINVAL

varcode is not a valid variable code, or the given variable cannot be associated with the specified file.

- If *varcode* refers to **MAX_CANON**, **MAX_INPUT**, or `_POSIX_VDISABLE`, and *pathname* does not refer to a character special file, `fpathconf()` returns -1 and sets `errno` to `EINVAL`.

- If *varcode* refers to **NAME_MAX**, **PATH_MAX**, or **POSIX_NO_TRUNC**, and *pathname* does not refer to a directory, `fpathconf()` returns the requested information.
- If *varcode* refers to **PC_PIPE_BUF** and *pathname* refers to a pipe or a FIFO, the value returned applies to the referenced object itself. If *pathname* refers to a directory, the value returned applies to any FIFOs that exist or can be created within the directory. If *pathname* refers to any other type of file, the function sets `errno` to `EINVAL`.

Example

CELEBF29

```

/* CELEBF29

   This example uses fpathconf() with __PC_NAME_MAX to determine the value
   of the NAME_MAX configuration variable.

*/
#define _POSIX_SOURCE
#include <errno.h>
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
    long result;
    char fn[]="temp.file";
    int fd;

    if ((fd = creat(fn, S_IRUSR)) < 0)
        perror("creat() error");
    else {
        errno = 0;
        puts("examining NAME_MAX limit for current working directory's");
        puts("filesystem:");
        if ((result = fpathconf(fd, _PC_NAME_MAX)) == -1)
            if (errno == 0)
                puts("There is no limit to NAME_MAX.");
            else
                perror("fpathconf() error");
        else
            printf("NAME_MAX is %ld\n", result);
        close(fd);
        unlink(fn);
    }
}

```

Output

```

examining NAME_MAX limit for current working directory's
file system:
NAME_MAX is 255

```

fpclassify() – Classifies an argument value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| C99 Single UNIX Specification, Version 3 C/C++ DFP C++ TR1 C99 | both | z/OS V1R8 |

Format

```
#define _ISOC99_SOURCE
#include <math.h>

int fpclassify (real-floating x);

#define __STDC_WANT_DEC_FP__
#include <math.h>

int fpclassify([real-floating|decimal-floating] x);

#define _TR1_C99
#include <math.h>

int fpclassify(real-floating x);
```

General description

This macro or function template classifies its argument value as NaN, infinite, normal, subnormal or zero based on the type of its argument. If the argument is represented in a format wider than its semantic type, then it is converted to its semantic type and then it is classified.

| Function | Hex | IEEE |
|------------|-----|------|
| fpclassify | X | X |

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

fpclassify() returns:

- FP_NAN if the argument is Not-a-Number.
- FP_INFINITE if the argument is plus or minus infinity.
- FP_ZERO if the argument is of value zero.
- FP_SUBNORMAL if the argument is too small to be represented in the normal format.
- FP_NORMAL if none of the above.

Special behavior in hex:

- FP_ZERO if the argument is of value zero.
- FP_NORMAL if the argument is a normalized number.

- FP_SUBNORMAL if the argument is an unnormalized number.

__fpending() — Retrieve number of bytes pending for write

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <stdio.h>
#include <stdio_ext.h>

size_t __fpending(FILE *stream);

#define _OPEN_SYS_UNLOCKED 1
#include <stdio.h>
#include <stdio_ext.h>

size_t __fpending_unlocked(FILE *stream);
```

General description

The `__fpending()` function retrieves the number of bytes pending to be written in the output buffer associated with the specified binary stream. When the stream is opened for text processing, the `__fpending()` function retrieves the number of characters pending to be written.

The `__fpending_unlocked()` function is equivalent to the `__fpending()` function with the exception that it is not thread-safe. This function can be safely used in a multithreaded application if it is called while the invoking thread owns the (FILE *) object, such as after a successful call to either the `flockfile()` or `ftrylockfile()` function.

The `__fpending()` function cannot be used on buffers in read mode or opened read-only.

Usage notes

1. If `__fpending()` is called when the stream is currently reading, `__fpending()` returns 0 and sets `errno` to a nonzero value.
2. If `__fpending()` is called on a data set opened `type=record`, `__fpending()` returns 0 and sets `errno` to a nonzero value.
3. For text data sets, any newline characters representing record boundaries written to the buffer will be included in the returned value.

Returned value

The `__fpending()` functions return the number of bytes or characters pending to be written in the current buffer, depending on the type of stream. Otherwise, the `__fpending()` functions return 0. If an error has occurred, `__fpending()` functions return 0 and set `errno` to nonzero.

When the stream is wide-oriented text, the `__fpending()` functions return a value measured in wide characters.

An application wishing to check for error situations should set `errno` to 0, then call `__fpending()`, and then check `errno`. If `errno` is nonzero, assume that an error has occurred.

Error Code

Description

EBADF

The stream specified by *stream* is not valid.

Example

CELEBF89

```
/* CELEBF89

   This example writes and reads data to a file while querying the
   stream for information about data in the I/O buffer.

*/

#include <stdio.h>
#include <stdio_ext.h>

void main() {
    FILE *f;
    char filename[FILENAME_MAX] = "myfile.dat";
    char data[128] = "There are 34 bytes in this buffer\n";
    int datalen = strlen(data);
    size_t n = 0;

    f = fopen(filename, "wb+");
    if (f == NULL) {
        perror("fopen() failed\n");
        return;
    }

    if (__fwritable(f)) printf("Writing is allowed on the open stream\n");
    if (__freadable(f)) printf("Reading is allowed on the open stream\n");

    n = fputs(data, f);
    if (n == EOF) {
        perror("fputs() failed\n");
        return;
    }

    n = __fpending(f);
    printf("There are %d bytes in the buffer pending to be written\n", n);

    if (__fwriting(f)) printf("The last operation on the stream was a write\n");

    rewind(f);

    n = fgetc(f);

    n = __freadahead(f);
    printf("There are %d bytes remaining to be read from the buffer\n", n);

    if (__freading(f)) printf("The last operation on the stream was a read\n");

    return;
}
```

Output

```
Writing is allowed on the open stream
Reading is allowed on the open stream
There are 34 bytes in the buffer pending to be written
The last operation on the stream was a write
There are 33 bytes remaining to be read from the buffer
The last operation on the stream was a read
```

fprintf(), printf(), sprintf() – Format and write data

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| C/C++ DFP ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | z/OS V1.8 |

Format

```
#include <stdio.h>

int fprintf(FILE *__restrict__stream, const char *__restrict__format-string, ...);
int printf(const char *__restrict__format-string, ...);
int sprintf(char *__restrict__buffer, const char *__restrict__format-string, ...);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int fprintf_unlocked(FILE *__restrict__stream,
                    const char *__restrict__format-string, ...);
int printf_unlocked(const char *__restrict__format-string, ...);
```

General description

These three related functions are referred to as the fprintf family.

The fprintf() function formats and writes output to a *stream*. It converts each entry in the *argument list*, if any, and writes to the stream according to the corresponding format specification in the *format-string*. The fprintf() function cannot be used with a file that is opened using type=record or type=blocked.

The printf() function formats and writes output to the standard output stream stdout. printf() cannot be used if stdout has been reopened using type=record or type=blocked.

The sprintf() function formats and stores a series of characters and values in the array pointed to by *buffer*. Any *argument-list* is converted and put out according to the corresponding format specification in the *format-string*. If the strings pointed to by *buffer* and *format* overlap, behavior is undefined.

fprintf() and printf() have the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

The *format-string* consists of ordinary characters, escape sequences, and conversion specifications. The ordinary characters are copied in order of their appearance. Conversion specifications, beginning with a percent sign (%) or the sequence (%n\$) where n is a decimal integer in the range [1,NL_ARGMAX], determine the output format for any *argument-list* following the *format-string*. The *format-string* can contain multibyte characters beginning and ending in the initial shift state. When the *format-string* includes the use of the optional prefix *ll* to indicate the size expected is a long long datatype then the corresponding value in the argument list should be a long long datatype if correct output is expected.

fprintf_unlocked() is functionally equivalent to fprintf() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking

thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

printf_unlocked() is functionally equivalent to printf() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

The *format-string* is read from left to right. When the first format specification is found, the value of the first *argument* after the *format-string* is converted and output according to the format specification. The second format specification causes the second *argument* after the *format-string* to be converted and output, and so on through the end of the *format-string*. If there are more arguments than there are format specifications, the extra arguments are evaluated and ignored. The results are undefined if there are not enough arguments for all the format specifications. The format specification is illustrated below.

Format Specification for fprintf(), printf(), and sprintf()

Each field of the format specification is a single character or number signifying a particular format option. The *type* character, which appears after the last optional format field, determines whether the associated argument is interpreted as a character, a string, a number, or pointer. The simplest format specification contains only the percent sign and a *type* character (for example, `%s`).

Percent sign: If a percent sign (`%`) is followed by a character that has no meaning as a format field, the character is simply copied to stdout. For example, to print a percent sign character, use `%%`.

Flag characters: The *flag* characters in Table 29 on page 595 are used for the justification of output and printing of thousands' grouping characters, signs, blanks, decimal-points, octal and hexadecimal prefixes, the semantics for `wchar_t` precision unit and the separator for vector data type output

conversion. Notice that more than one *flag* can appear in a format specification. This is an optional field.

Table 29. Flag Characters for fprintf Family

| Flag | Meaning | Default |
|--------------------|---|---|
| ' | Added for XPG4: The integer portion of the result of a decimal conversion(%i,%d,%u,%f,%g or %G) will be formatted with the thousands' grouping characters. | No grouping. |
| - | Left-justify the result within the field width. | Right-justify. |
| + | Prefix the output value with a sign (+ or -) if the output value is of a signed type. | Sign appears only for negative signed values (-). |
| <i>blank</i> (' ') | Prefix the output value with a blank if the output value is signed and positive. The + flag overrides the <i>blank</i> flag if both appear, and a positive signed value will be output with a sign. | No blank. |
| # | When used with the o, x, or X formats, the # flag prefixes any nonzero output value with 0, 0x, or 0X, respectively. For o conversion, it increases the precision, if and only if necessary, to force the first digit of the result to be a zero (if the value and precision are both 0, a single 0 will be printed) | No prefix. |
| | When used with the f, e, or E formats, the # flag forces the output value to contain a decimal-point in all cases. The decimal-point is sensitive to the LC_NUMERIC category of the same current locale. | Decimal-point appears only if digits follow it. |
| | When used with the g or G formats, the # flag forces the output value to contain a decimal-point in all cases and prevents the truncation of trailing zeros. | Decimal-point appears only if digits follow it; trailing zeros are truncated. |
| | When used with the lS or S format, the # flag causes precision to be measured in wide characters. | Precision indicates the maximum number of bytes to be output. |
| 0 | When used with the d, i, o, u, x, X, e, E, f, g, or G formats, the 0 flag causes leading 0's to pad the output to the field width. The 0 flag is ignored if <i>precision</i> is specified for an integer or if the - flag is specified. | Space padding. |
| , ; : _ | Indicates the separator character between each two components in the vector data type conversion. Only one separator character can be specified. | The default value for the separator character is a space (' '), unless the c format is being used. For the c format, there is no separator at all if no separator character is specified. |

The code point for the # character varies between the EBCDIC encoded character sets. The definition of the # character is based on the current LC_SYNTAX category. The default C locale expects the # character to use the code point for encoded character set IBM-1047.

When the LC_SYNTAX category is set using setlocale(), the format strings passed to the printf() functions must use the same encoded character set as is specified for the LC_SYNTAX category.

The # flag should not be used with c, lc, C, d, i, u, s, or p conversion specifier.

Output width: The *width* argument is a nonnegative decimal integer controlling the minimum number of characters printed. If the number of characters in the output value is less than the specified *width*, blanks are added on the left or the right (depending on whether the – flag is specified) until the minimum width is reached.

The width never causes a value to be truncated; if the number of characters in the output value is greater than the specified *width*, or *width* is not given, all characters of the value are output (subject to the *precision* specification).

The *width* specification can be an asterisk (*); if it is, an argument from the argument list supplies the value. The *width* argument must precede the value being formatted in the argument list. This is an optional field.

If *format-string* contains the %n\$ form of conversion specification, *width* can be indicated by the sequence *m\$, where m is a decimal integer in the range [1,NL_ARGMAX] giving the position of an integer argument in the argument list containing the field width.

Output precision: The *precision* argument is a nonnegative decimal integer preceded by a period. It specifies the number of characters to be output, or the number of decimal places. Unlike the *width* specification, the *precision* can cause truncation of the output value or rounding of a floating-point value.

Be aware that the rounding of floating-point values may not always occur as expected based on the decimal value of the number. This is because the internal binary representation cannot always be an exact representation of the decimal value, so the rounding may occur on an inexact value. This is true of both OS/390 hexadecimal and IEEE 754 binary floating-point formats.

The *precision* argument can be an asterisk (*); if it is, an argument from the argument list supplies the value. The *precision* argument must precede the value being formatted in the argument list. The *precision* field is optional.

If *format-string* contains the %n\$ form of conversion specification, *precision* can be indicated by the sequence *m\$, where m is a decimal integer in the range [1,NL_ARGMAX] giving the position of an integer argument in the argument list containing the field precision.

The interpretation of the *precision* value and the default when the *precision* is omitted depend upon the *type*, as shown in Table 30 on page 596.

Table 30. Precision Argument in fprintf Family

| Type | Meaning | Default |
|----------------------------|--|---|
| d i o u x X | <i>precision</i> specifies the minimum number of digits to be output. If the number of digits in the argument is less than <i>precision</i> , the output value is padded on the left with zeros. The value is not truncated when the number of digits exceeds <i>precision</i> . | Default <i>precision</i> is 1. If <i>precision</i> is 0, or if the period (.) appears without a number following it, the <i>precision</i> is set to 0. When <i>precision</i> is 0, conversion of the value zero results in no characters. |
| e E f F | <i>precision</i> specifies the number of digits to be output after the decimal-point. The last digit output is rounded. The decimal-point is sensitive to the LC_NUMERIC category of the current locale. | Default <i>precision</i> is 6. If <i>precision</i> is 0 or the period appears without a number following it, no decimal-point is output. |

Table 30. Precision Argument in fprintf Family (continued)

| Type | Meaning | Default |
|---------|---|--|
| a A | For non decimal floating-point numbers, <i>precision</i> specifies the number of hexadecimal digits to be output after the decimal-point character. For decimal floating-point numbers, precision determines the style of formatting to be used. | For non decimal floating-point numbers, default <i>precision</i> is 6. If <i>precision</i> is 0, no decimal-point is output. For decimal floating-point numbers, precision is determined by the quantum of the decimal floating-point number. Refer to Table 31 on page 598 for more details. |
| g G | <i>precision</i> specifies the maximum number of significant digits output. | All significant digits are output. |
| c | No effect. | The character is output. |
| C lc | No effect. | The wide character is output. |
| s | <i>precision</i> specifies the maximum number of characters to be output. Characters in excess of <i>precision</i> are not output. | Characters are output until a NULL character is encountered. |
| S ls | <i>precision</i> specifies the maximum number of bytes to be output. Bytes in excess of <i>precision</i> are not output; however, multibyte integrity is always preserved. | wchar_t characters are output until a NULL character is encountered. |
| m lm | <i>precision</i> specifies the maximum number of characters to be output. Characters in excess of precision are not output. | Characters are output until a NULL character is encountered. |

Optional prefix: The optional prefix characters used to indicate the size of the argument expected or size of a single component in a vector data type output conversion are explained:

Prefix

Meaning

h

Specifies that the d, i, o, u, x, or X conversion specifier applies to a short or unsigned short argument (the argument will have been promoted according to the integer promotions, but its value shall be converted to short or unsigned short before printing); or that a following n conversion specifier applies to a pointer to a short argument.

hh

Specifies that the d, i, o, u, x, or X conversion specifier applies to a signed char or unsigned char argument (the argument will have been promoted according to the integer promotions, but its value shall be converted to signed char or unsigned char before printing); or that a following n conversion specifier applies to a pointer to a signed char argument.

l

(ell) Specifies that the d, i, o, u, x, or X conversion specifier applies to a long or unsigned long argument; that a following n conversion specifier applies to a pointer to a long argument; that the c conversion specifier applies to a wint_t argument; that the s conversion specifier applies to a pointer to a wchar_t argument. It has no effect on the a, A, e, E, f, F, g, G, or m conversion specifier.

- ll**
(ell-ell) Specifies that the d, i, o, u, x, or X conversion specifier applies to a long long or unsigned long long argument; or that the n conversion specifier applies to a pointer to a long long argument.
- j**
Specifies that the d, i, o, u, x, or X conversion specifier applies to an intmax_t or uintmax_t argument; or that the n conversion specifier applies to a pointer to an intmax_t argument.
- t**
Specifies that the d, i, o, u, x, or X conversion specifier applies to a ptrdiff_t or the corresponding unsigned type argument; or that the n conversion specifier applies to a pointer to a ptrdiff_t argument.
- z**
Specifies that the d, i, o, u, x, or X conversion specifier applies to a size_t or the corresponding signed integer type argument; or that the n conversion specifier applies to a pointer to a signed integer type corresponding to a size_t argument.
- D**
Specifies that the a, A, e, E, f, F, g, or G conversion specifier applies to an _Decimal64 argument.
- DD**
Specifies that the a, A, e, E, f, F, g, or G conversion specifier applies to an _Decimal128 argument.
- H**
Specifies that the a, A, e, E, f, F, g, or G conversion specifier applies to an _Decimal32 argument.
- L**
Specifies that the a, A, e, E, f, F, g, or G conversion specifier applies to a long double argument.
- v**
Specifies that a following c, d, i, u, o, x, or X conversion specifier applies to a vector signed char, vector unsigned char, or vector bool char parameter. It consumes one argument and interprets the data as a series of sixteen 1-byte components.
- vh, hv**
Specifies that a following d, i, u, o, x, or X conversion specifier applies to a vector signed short, vector unsigned short, or vector bool short parameter. It consumes one argument and interprets the data as a series of eight 2-byte integer components.
- vl, lv**
Specifies that a following d, i, u, o, x, or X conversion specifier applies to a vector signed int, vector unsigned int, or vector bool int parameter. It consumes one argument and interprets the data as a series of four 4-byte integer components.
- vll, llv**
Specifies that a following d, i, u, o, x, or X conversion specifier applies to a vector signed long long, vector unsigned long long, or vector bool long long parameter. It consumes one argument and interprets the data as a series of two 8-byte integer components.
- vL, Lv**
specifies that a following a, A, e, E, f, F, g, or G conversion specifier applies to a vector double parameter. It consumes one argument and interprets the data as a series of two 8-byte floating point components.

Conversion specifier: [Table 31 on page 598](#) explains the meaning of the type characters used in the precision argument.

Table 31. Type Characters and their Meanings

| Conversion specifier | Argument | Output Format |
|----------------------|----------|---|
| d, i | Integer | Signed decimal integer. |
| u | Integer | Unsigned decimal integer. |
| o | Integer | Unsigned octal integer. |
| x | Integer | Unsigned hexadecimal integer, using abcdef. |
| X | Integer | Unsigned hexadecimal integer, using ABCDEF. |

Table 31. Type Characters and their Meanings (continued)

| Conversion specifier | Argument | Output Format |
|----------------------|-----------------------------|---|
| f, F | Double | Signed value having the form [-]ddd.dddd, where dddd is one or more decimal digits. The number of digits before the decimal-point depends on the magnitude of the number. The number of digits after the decimal-point is equal to the requested precision. The decimal-point is sensitive to the LC_NUMERIC category of the current locale. |
| e | Double | Signed value having the form [-]d.dddd[sign]ddd, where d is a single-decimal digit, dddd is one or more decimal digits, ddd is 2 or more decimal digits, and sign is + or -. A double argument representing an infinity or NaN is converted in the style of an f or F conversion specifier. |
| E | Double | Identical to the e format, except that E introduces the exponent, not e. |
| g | Double | Signed value output in f or e format. The e format is used only when the exponent of the value is less than -4 or greater than or equal to precision. Trailing zeros are truncated, and the decimal-point appears only if one or more digits follow it. A double argument representing an infinity or NaN is converted in the style of an f or F conversion specifier. |
| G | Double | Identical to the g format, except that E introduces the exponent (where appropriate), not e. |
| D(n,p) | Decimal type argument. | Fixed-point value consisting of a series of one or more decimal digits possibly containing a decimal-point. |
| c C or lc | Character Wide Character | Single character. The argument of wchar_t type is converted to an array of bytes representing a multibyte character as if by call to wctomb(). |
| s S or ls | String Wide String | Characters output up to the first NULL character (\0) or until precision is reached. The argument is a pointer to an array of wchar_t type. Wide characters from the array are converted to multibyte characters up to and including a terminating NULL wide character. Conversion takes place as if by a call to wcstombs(), with the conversion state described by the mbstate_t object initialized to 0. The result written out will not include the terminating NULL character. If precision is not specified, the array contains a NULL wide character. If precision is specified, it sets the maximum number of characters written, including shift sequences. A partial multibyte character cannot be written. |
| n | Pointer to integer | Number of characters successfully output so far to the stream or buffer; this value is stored in the integer whose address is given as the argument. |
| p | Pointer | Pointer to void converted to a sequence of printable characters. Refer to the individual system reference guides for the specific format. |

Table 31. Type Characters and their Meanings (continued)

| Conversion specifier | Argument | Output Format |
|----------------------|---|---|
| a, A | Double _Decimal32 _Decimal64 _Decimal128 | <p>A double argument representing a floating-point number is converted to the "[<i>-</i>]0x.hhhhp±d" format, where there is one hexadecimal digit (non-zero when the argument is a normalized floating-point number; otherwise unspecified) before the decimal-point character and the number of hexadecimal digits after it is equal to <i>precision</i>. If <i>precision</i> is missing and FLT_RADIX is a power of 2, then the precision will be sufficient for an exact representation of the value. If <i>precision</i> is missing and FLT_RADIX is not a power of 2, then the precision will be sufficient to distinguish values of type double, except that trailing zeros may be omitted. If <i>precision</i> is zero and the "#" flag is not specified, no decimal-point will appear. The letters "abcdef" are used for the a conversion and the letters "ABCDEF" for the A conversion. The A conversion specifier produces a number with letters "X" and "P" instead of letters "x" and "p". The exponent always contains at least one digit, and only as many more digits as necessary to represent the decimal exponent of 2. If the value is zero, the exponent is zero.</p> <p>A double argument representing an infinity or NaN is converted in the style of an f or F conversion specifier.</p> <p>If <i>precision</i> is zero, results can be different for Hexadecimal floating point format and IEEE floating point format. For Hexadecimal floating point, a decimal point will not appear in the output. For IEEE floating point, a decimal point will appear.</p> <p>If an H, D, or DD modifier is present and <i>precision</i> is missing, then for a decimal floating type argument, either the f or e style formatting is used based on the following criteria:</p> <ul style="list-style-type: none"> f style formatting is used when the quantum is less than or equal to 0 but greater than or equal to $-(n+5)$. The quantum of a number can be determined by calling the quantexp() functions. The number of digits (n) in the digit-sequence includes trailing zeros only and ignores the decimal point. For example: <ul style="list-style-type: none"> 0.000005 contains 1 digit in the digit sequence, n = 1. 0.0000050 contains 2 digits in the digit sequence, n = 2. 12.30 contains 4 digits in the digit sequence, n = 4. <i>precision</i> is equal to -quantum. e style formatting is used when the quantum does not satisfy the f style criteria. <i>precision</i> is equal to n-1, except if the argument is equal to 0 then the digit-sequence in the exponent-part is equal to the quantum. For example: <ul style="list-style-type: none"> 0.0000000 produces 0e-07. -1870 produces -1.87e+03. <p>If <i>precision</i> is present and at least as large as the precision of the decimal floating type, the conversion is as if the precision were missing. If the precision is present and less than the precision of the decimal floating type, the input is first rounded according to the current rounding direction to the number of digits specified by the precision. The result is then converted as if <i>precision</i> were missing.</p> <p>The "quantum" when referring to a finite decimal floating-point number is defined as the "magnitude of a value of one in the rightmost digit position of the significand". For example, pennies and dollars can be represented respectively as $1 * 10$ with a quantum of -2 and 0, or, $1 * 10^{-2}$ and $1 * 10^0$. For more information on the term quantum, see <i>z/Architecture Principles of Operation</i>.</p> |
| m | No argument is required. | Characters of <code>strerror</code> (<code>errno</code>) output up to the NULL character (<code>\0</code>) or until <i>precision</i> is reached. If <i>precision</i> is specified, it sets the maximum number of characters written. |

Special behavior for XPG4:

- If the `%n$` conversion specification is found, the value of the *nth argument* after the *format-string* is converted and output according to the conversion specification. Numbered arguments in the argument list can be referenced from *format-string* as many times as required.
- The *format-string* can contain either form of the conversion specification, that is, % or `%n$` but the two forms cannot be mixed within a single *format-string* except that %% can be mixed with the `%n$` form. When numbered conversion specifications are used, specifying the 'nth' argument requires that the first to (n-1)th arguments are specified in the *format-string*.

Floating-point and the fprintf family of formatted output functions: The fprintf family functions match a, A, e, E, f, F, g, or G conversion specifiers to floating-point arguments for which they produce floating-point number substrings in the output stream. The fprintf family functions have been extended to determine the floating-point format, hexadecimal floating-point or IEEE Binary Floating-Point, of types a, A, e, E, f, F, g, or G by using `__isBFP()`.

The fprintf family functions convert IEEE Binary Floating-Point infinity and NaN argument values to special infinity and NaN floating-point number output sequences.

- The special output sequence for infinity values is a plus or minus sign, then the character sequence INF followed by a white space character (space, tab, or newline), a NULL character (`\0`) or EOF.

- The special output sequence for NaN values is a plus or minus sign, then the character sequence NANS for a signalling NaN or NANQ for a quiet NaN, then a NaN ordinal sequence, and then a white space character (space, tab, or newline), a NULL character (`\0`) or EOF.

For binary floating point NaNs: A NaN ordinal sequence is a left-parenthesis character, "(", followed by a digit sequence representing an integer n , where $1 \leq n \leq \text{INT_MAX}-1$, followed by a right-parenthesis character, ")". The integer value, n , is determined by the fraction bits of the NaN argument value as follows:

1. For a signalling NaN value, NaN fraction bits are reversed (left to right) to produce bits (right to left) of an even integer value, $2*n$. Then formatted output functions produce a (signalling) NaN ordinal sequence corresponding to the integer value n .
2. For a quiet NaN value, NaN fraction bits are reversed (left to right) to produce bits (right to left) of an odd integer value, $2*n-1$. Then formatted output functions produce a (quiet) NaN ordinal sequence corresponding to the integer value n .

For decimal floating point NaNs: A NaN ordinal sequence is a left parenthesis character, "(", followed by a decimal digit sequence of up to 6 digits for a `_Decimal32` output number, up to 15 digits for a `_Decimal64` output value, or up to 33 digits for a `_Decimal128` output value, followed by a right parenthesis, ")". If the NaN ordinal sequence is omitted, NaN ordinal sequence "(0)" is assumed. If the NaN ordinal sequence is shorter than 6, 15, or 33 digits, it will be padded on the left with "0" digits so that the length becomes 6, 15, or 33 digits for `_Decimal32`, `_Decimal64`, and `_Decimal128` values respectively.

For decimal floating point numbers, the digits are not reversed, and both odd or even NaN ordinal sequences can be specified for either a Quiet NaN or Signalling NaN.

The C99 standard does not distinguish between the quiet NaN and signaling NaN values. An argument representing a NaN (Not a Number) is to be displayed as `[-]nan` or `[-]nan(n-char-sequence)`; where the implementation decides the representation. For the A, E, F, and G conversion specifiers, NaN values are displayed as the uppercase versions of the aforementioned character string representations. To get this behavior set the environment variable `_EDC_C99_NAN` to YES.

Some compatibility with NaN sequences output by AIX® formatted output functions can be achieved by setting a new environment variable, `_AIX_NAN_COMPATIBILITY`, which z/OS formatted output functions recognize, to one of the following (string) values:

Value

Output function

1

Formatted output functions which produce special NaN output sequences omit the NaN ordinal output sequence (1). This results in output NaN sequences of plus or minus sign followed by NANS or NANQ instead of plus or minus sign followed by NANS(1) or NANQ(1). All other NaN ordinal sequences are explicitly output.

ALL

Formatted output functions which produce special NaN output sequences omit the NaN ordinal output sequence for all NaN values. This results in output NaN sequences of plus or minus sign followed by NANS or NANQ instead of plus or minus sign followed by NANS(n) or NANQ(n) for all NaN values.

Note: `_AIX_NAN_COMPATIBILITY` does not affect the formatting of DFP NAN values. It affects only the formatting of BFP NAN values.

Vector types and the fprintf family of formatted output functions: The fprintf family functions support character, integer, and floating-point vector data types in the output conversion specification. The vector value is displayed in the following general form:

```
Value1Cvalue2C...CValueN
```

where C is a separator character optionally defined in flag characters, and there can be 2, 4, 8, or 16 output values depending on the optional prefix v, vh, hv, vl, lv, vll, llv, vL, or Lv. Each value is formatted according to the conversion specifier.

The sprintf() function is available to C applications in a stand-alone System Programming C (SPC) Environment.

Usage notes

1. [Hexadecimal floating point representation](#) normalizes differently than [IEEE floating point representation](#). [Hexadecimal floating point representation](#) produces output in 0x0.hhhhhp+/-dd format, not in the 0x1.hhhhhp+/-dd format.
2. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

If successful, fprintf(), printf(), and sprintf() return the number of characters output. The ending NULL character is not counted.

If unsuccessful, they return a negative value.

Example

CELEBF30

```
/* CELEBF30

   This example prints data using &printf. in a variety of
   formats.

*/
#include <stdio.h>

int main(void)
{
    char ch = 'h', *string = "computer";
    int count = 234, hex = 0x10, oct = 010, dec = 10;
    double fp = 251.7366;
    unsigned int a = 12;
    float b = 123.45;
    int c;
    void *d = "a";

    printf("the unsigned int is %u\n\n",a);

    printf("the float number is %g, and %G\n\n",b,b);

    printf("RAY%\n\n",&c);

    printf("last line prints %d characters\n\n",c);

    printf("Address of d is %p\n\n",d);

    printf("%d  %d  %06d  %X  %x  %o\n\n",
        count, count, count, count, count, count);

    printf("1234567890123\n4567890123456789\n\n", &count);

    printf("Value of count should be 13; count = %d\n\n", count);

    printf("%10c%5c\n\n", ch, ch);

    printf("%25s\n%25.4s\n\n", string, string);

    printf("%f  %.2f  %e  %E\n\n", fp, fp, fp, fp);

    printf("%i  %i  %i\n\n", hex, oct, dec);
}
```

Output

```

the unsigned int is 12
the float number is 123.45 and 123.45
RAY
last line prints 3 characters
Address of d is DD72F9
234  +234  000234  EA  ea  352
12345678901234567890123456789
Value of count should be 13; count = 13
      h      h
      computer
      comp
251.736600    251.74    2.517366e+02    2.517366E+02
16    8    10

```

CELEBF31

```

/* CELEBF31
   The following example illustrates the use of printf() to print
   fixed-point decimal data types.
   This example works under C only, not C++.
*/
#include <stdio.h>
#include <decimal.h>

decimal(10,2) pd01 = -12.34d;
decimal(12,4) pd02 = 12345678.9876d;
decimal(31,10) pd03 = 123456789013579246801.9876543210d;

int main(void) {
    printf("pd01 %D(10,2)      = %D(10,2)\n", pd01);
    printf("pd02 %D( 12 , 4 ) = %D( 12 , 4 )\n", pd02);

    printf("pd01 %%010.2D(10,2) = %%010.2D(10,2)\n", pd01);
    printf("pd02 %%20.2D(12,4)  = %%20.2D(12,4)\n", pd02);
    printf("\n Give strange result if the specified size is wrong!\n");
    printf("pd03 %D(15,3)       = %D(15,3)\n\n", pd03);
}

```

Output

```

pd01 %D(10,2)      = -12.34
pd02 %D( 12 , 4 ) = 12345678.9876
pd01 %%010.2D(10,2) = -000012.34
pd02 %%20.2D(12,4)  =          12345678.98

Give strange result if the specified size is wrong!
pd03 %D(15,3)       = -123456789013.579

```

CELEBF32

```

/* CELEBF32
   This example illustrates the use of sprintf() to format and print
   various data.
*/
#include <stdio.h>

char buffer[200];
int i, j;
double fp;
char *s = "baltimore";
char c;

int main(void)
{
    c = 'l';

```

```

i = 35;
fp = 1.7320508;

/* Format and print various data */
j = sprintf(buffer, "%s\n", s);
j += sprintf(buffer+j, "%c\n", c);
j += sprintf(buffer+j, "%d\n", i);
j += sprintf(buffer+j, "%f\n", fp);
printf("string:\n%s\ncharacter count = %d\n", buffer, j);
}

```

Output

```

string:
Baltimore
1
35
1.732051

character count = 24

```

CELEBF90

```

/* CELEBF90
   The following example illustrates the use of printf() to print
   vector data types.
*/
#include <stdio.h>

vector signed char s8 =
    {'a','b',' ','d','e','f','g','h',
     'i','j','k','l','m','!','o','p'};
vector unsigned short u16 = {1,2,3,4,5,6,7,8};
vector signed int s32 = {1, 2, 3, 99};
vector unsigned long long u64 = {1, 2};
vector double d64 = {0.1, 1.2};

int main(void)
{
    printf("s8 = %vc\n", s8);
    printf("s8 = %,vc\n", s8);
    printf("u16 = %vhu\n", u16);
    printf("s32 = %,2lvd\n", s32);
    printf("u64 = %vllu\n", u64);
    printf("d64 = %vLf\n", d64);
}

```

Output

```

s8 = ab defghijklm!op
s8 = a,b, ,d,e,f,g,h,i,j,k,l,m,!,o,p
u16 = 1 2 3 4 5 6 7 8
s32 = 1, 2, 3,99
u64 = 1 2
d64 = 0.100000 1.200000

```

__fpurge() — Discard pending data in a stream

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | None |

Format

```
#include <stdio.h>
#include <stdio_ext.h>

void __fpurge(FILE *stream);

#define _OPEN_SYS_UNLOCKED 1
#include <stdio.h>
#include <stdio_ext.h>

void __fpurge_unlocked(FILE *stream);
```

General description

The `_fpurge()` function requests that any pending data in the stream be discarded.

After a call to `__fpurge()`, if stream is currently reading, any data that has been read from the system but not yet presented to the application will be discarded. Similarly, any data that has been pushed back into the stream with `ungetc()` will also be discarded.

After a call to `__fpurge()`, if stream is currently writing, any data that the application has requested to be written, but has not yet been flushed to an output device will be discarded. Any data that is written to the buffer after a call to `__fpurge()` is destined to be written out, to the block where the discarded data was originally intended to be placed, either explicitly via `fflush()` or implicitly once the buffer is full.

The `__fpurge_unlocked()` function is equivalent to the `__fpurge()` function with the exception that it is not thread-safe. This function can be safely used in a multithreaded application if it is called while the invoking thread owns the (FILE *) object, such as after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Usage note

The `__fpurge()` function is allowed to be called on UNIX files only. Calling this function on any other type of file will not cause pending data in the buffer to be discarded. The function will return and result in `errno` being set to a nonzero value.

Returned value

The `_fpurge()` function returns no values.

An application wishing to check for error situations should set `errno` to 0, then call `__fpurge()`, and then check `errno`. If `errno` is nonzero, assume that an error has occurred.

Error Code

Description

EBADF

The stream specified by *stream* is not valid.

Example

CELEBF86

```
/* CELEBF86

   This example purges pending data in the I/O buffer.
*/

#include <stdio.h>
#include <errno.h>
#include <stdio_ext.h>

void main(int argc, char** argv){
    char *bufflush="data will be written into file";
    char *bufpurge="data will be not written into file";
    FILE *fp=fopen("./myfile", "a");
    if(NULL==fp){
        perror("failed to open file\n");
        exit(0);
    }
    fwrite(bufflush, strlen(bufflush), 1, fp);
    fflush(fp);
    fwrite(bufpurge, strlen(bufpurge), 1, fp);
    errno=0;
    __fpurge(fp);
    if(errno!=0)
        perror("call __fpurge() failed\n");
    fclose(fp);
}
```

Output

The file "myfile" contains the text - data will be written into file

fputc() — Write a character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language environment | both | |

Format

```
#include <stdio.h>
```

```
int fputc(int c, FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int fputc_unlocked(int c, FILE *stream);
```

General description

Converts *c* to an unsigned `char` and then writes *c* to the output stream pointed to by *stream* at the current position and advances the file position appropriately. The `fputc()` function is identical to *putc* but is always a function, because it is not available as a macro.

If the stream is opened with one of the append modes, the character is appended to the end of the stream regardless of the current file position.

The `fputc()` function is not supported for files opened with `type=record` or `type=blocked`.

`fputc()` has the same restriction as any write operation for a read immediately following a write, or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

`fputc_unlocked()` is functionally equivalent to `fputc()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

If successful, `fputc()` returns the character written.

If unsuccessful, `fputc()` returns EOF.

Example

CELEBF34

```
/* CELEBF34

   This example writes the contents of buffer to a file called
   myfile.dat.
   Because the output occurs as a side effect within the second
   expression of the for statement, the statement body is null.

*/
#include <stdio.h>
#define NUM_ALPHA 26

int main(void)
{
    FILE * stream;
    int i;
    int ch;

    char buffer[NUM_ALPHA + 1] = "abcdefghijklmnopqrstuvwxyz";

    if (( stream = fopen("myfile.dat", "w")) != NULL )
    {
        /* Put buffer into file */
        for ( i = 0; ( i < sizeof(buffer) ) &&
              ((ch = fputc( buffer[i], stream)) != EOF ); ++i );
        fclose( stream );
    }
    else
        printf( "Error opening myfile.dat\n" );
}
```

fputs() — Write a string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language environment | both | |

Format

```
#include <stdio.h>

int fputs(const char * __restrict__string, FILE * __restrict__stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int fputs_unlocked(const char * __restrict__string, FILE * __restrict__stream);
```

General description

Writes the string pointed to by *string* to the output stream pointed to by *stream*. It does not write the terminating `\0` at the end of the string.

For a text file, truncation may occur if the record is too long. *Truncation* means that excess characters are discarded after the record is full, up to a control character that ends the line (`\n`). Characters after the `\n` start at the next record. For more information, see the section on “Truncation” in [z/OS XL C/C++ Programming Guide](#).

`fputs()` is not supported for files opened with `type=record` or `type=blocked`.

`fputs()` has the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

`fputs_unlocked()` is functionally equivalent to `fputs()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

If successful, `fputs()` returns the number of bytes written.

If unsuccessful, `fputs()` returns EOF.

Example

CELEBF35

```

/* CELEBF35

   This example writes a string to a stream.

   */
#include <stdio.h>
#define NUM_ALPHA 26

int main(void)
{
    FILE * stream;
    int num;

    /* Do not forget that the '\0' char occupies one character */
    static char buffer[NUM_ALPHA + 1] = "abcdefghijklmnopqrstuvwxyz";

    if ((stream = fopen("myfile.dat", "w")) != NULL )
    {
        /* Put buffer into file */
        if ( (num = fputs( buffer, stream )) != EOF )
        {
            /* Note that fputs() does not copy the \0 character */
            printf( "Total number of characters written to file = %i\n", num );
            fclose( stream );
        }
        else /* fputs failed */
            printf( "fputs failed" );
    }
    else
        printf( "Error opening myfile.dat" );
}

```

fputwc() — Output a wide-character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 Language Environment | both | |

Format

Non-XPG4:

```

#include <stdio.h>
#include <wchar.h>

wint_t fputwc(wchar_t wc, FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

wint_t fputwc_unlocked(wchar_t wc, FILE *stream);

```

XPG4:

```
#define _XOPEN_SOURCE
#include <stdio.h>
#include <wchar.h>

wint_t fputwc(wint_t wc, FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

wint_t fputwc_unlocked(wchar_t wc, FILE *stream);
```

XPG4 and MSE:

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <stdio.h>
#include <wchar.h>

wint_t fputwc(wchar_t wc, FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

wint_t fputwc_unlocked(wchar_t wc, FILE *stream);
```

General description

Converts the wide character specified by *wc* to a multibyte character and writes it to the output stream pointed to by *stream*, at the position indicated by the associated file position indicator for the stream (if defined), and advances the indicator appropriately. If the file cannot support positioning requests or if the stream was opened with append mode, the character is appended to the output stream.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. Using non-wide-character functions with `fputwc()` results in undefined behavior.

`fputwc()` has the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

`fputwc_unlocked()` is functionally equivalent to `fputwc()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Special behavior for XPG4: If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the `wchar` header, then the compiler assumes that your program is using the XPG4 variety of the `fputwc()` function, unless you also define the `_MSE_PROTOS` feature test macro. Please see [Table 2 on page 4](#) for a list of XPG4 and other feature test macros.

The prototype for the XPG4 variety of the `fputwc()` function is:

```
wint_t fputwc(wint_t wc, FILE *stream);
```

The difference between this variety and the MSE variety of the `fputwc()` function is that the first parameter has type `wint_t` rather than type `wchar_t`.

Returned value

If successful, `fputwc()` returns the wide character written.

If a write error occurs, the error indicator for the stream is set and WEOF is returned. If an encoding error occurs during conversion from wide character to a multibyte character, the value of the macro `EILSEQ` is stored in `errno` and WEOF is returned.

Example

CELEBF36

```

/* CELEBF36
*/

#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>
#include <errno.h>

int main(void)
{
    FILE    *stream;
    wchar_t *wcs = L"This test string should not cause a WEOF condition";
    int      i;
    int      rc;

    if ((stream = fopen("myfile.dat", "w")) == NULL) {
        printf("Unable to open file.\n");
        exit(1);
    }

    for (i=0; wcs[i] != L'\0'; i++) {
        errno = 0;
        if ((rc = fputwc(wcs[i], stream)) == WEOF) {
            printf("Unable to fputwc() the wide character.\n");
            printf("wcs[%d] = 0x%lx\n", i, wcs[i]);
            if (errno == EILSEQ)
                printf("An invalid wide character was encountered.\n");
            exit(1);
        }
    }

    fclose(stream);
}

```

fputws() — Output a wide-character string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```

#include <wchar.h>

int fputws(const wchar_t * __restrict__wcs, FILE * __restrict__stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

int fputws_unlocked(const wchar_t * __restrict__wcs, FILE * __restrict__stream);

```

General description

Converts the wide-character string pointed to by *wcs* to a multibyte character string and writes it to the stream pointed to by *stream*, as a multibyte character string. The terminating NULL byte is not written.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. Using non-wide-character functions with `fputws()` results in undefined behavior.

`fputws()` has the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

`fputws_unlocked()` is functionally equivalent to `fputws()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

If successful, `fputws()` returns a nonnegative value.

If a *stream* error occurs, `fputws()` returns -1 and the error indicator for the stream is set.

If an *encoding* error occurs, `fputws()` returns -1 and the value of the macro `EILSEQ` is stored in `errno`. An encoding error is one that occurs when converting a wide character to a multibyte character.

Example

CELEBF37

```
/* CELEBF37 */
#include <errno.h>
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>

int main(void)
{
    FILE    *stream;
    wchar_t *wcs = L"This test string should not return -1";
    int      rc;

    if ((stream = fopen("myfile.dat", "w")) == NULL) {
        printf("Unable to open file.\n");
        exit(1);
    }

    errno = 0;
    rc = fputws(wcs, stream);

    if (rc == EOF) {
        printf("Unable to complete fputws() function.\n");
        if (errno == EILSEQ)
            printf("An invalid wide character was encountered.\n");
        exit(1);
    }

    fclose(stream);
}
```

fread() – Read items

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language environment | both | |

Format

```
#include <stdio.h>

size_t fread(void * __restrict__buffer, size_t size, size_t count, FILE * __restrict__stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

size_t fread_unlocked(void * __restrict__buffer, size_t size,
                      size_t count, FILE * __restrict__stream);
```

General description

Reads up to *count* items of *size* length from the input stream pointed to by *stream* and stores them in the given *buffer*. The file position indicator advances by the number of bytes read.

If there is an error during the read operation, the file position indicator is undefined. If a partial element is read, the element's value is undefined.

When you are using `fread()` for record I/O, set *size* to 1 and *count* to the maximum expected length of the record, to obtain the number of bytes. Only one record is read, regardless of *count*, when using record I/O.

When you are using `fread()` for blocked I/O, set *size* to 1 and *count* to the maximum expected length of the block, to obtain the number of bytes. Only one block is read, regardless of *count*, when using blocked I/O.

`fread()` has the same restriction as any read operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

`fread_unlocked()` is functionally equivalent to `fread()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftwlockfile()` function.

Returned value

`fread()` returns the number of complete items successfully read.

If *size* or *count* is 0, `fread()` returns 0, and the contents of the array and the state of the stream remain unchanged. For record I/O and blocked I/O, it is possible that the number of complete items can be less than *count*. However, this result does not necessarily indicate that an error has occurred.

If the Physical File System does not support simple reads from directories, `fread()` will return 0 if it is used for a directory. Users should use `Opendir()` and `readdir()` instead.

The `ferror()` and `feof()` functions are used to distinguish between a read error and an EOF. Note that EOF is only reached when an attempt is made to read “past” the last byte of data. Reading up to and including the last byte of data does *not* turn on the EOF indicator.

Example

CELEBF38

```
/* CELEBF38

This example attempts to read NUM_ALPHA characters from the
file myfile.dat.
If there are any errors with either &fread. or &fopen., a
message is printed.

*/
#include <stdio.h>
#define NUM_ALPHA 26

int main(void)
{
    FILE * stream;
    int num;          /* number of characters read from stream */

    /* Do not forget that the '\0' char occupies one character too! */
    char buffer[NUM_ALPHA + 1];
    buffer[NUM_ALPHA] = '\0';

    if (( stream = fopen("myfile.dat", "r")) != NULL )
    {
        num = fread( buffer, sizeof( char ), NUM_ALPHA, stream );
        if (num == NUM_ALPHA) { /* fread success */
            printf( "Number of characters read = %i\n", num );
            printf( "buffer = %s\n", buffer );
            fclose( stream );
        }
        else { /* fread failed */
            if ( ferror(stream) ) /* possibility 1 */
                printf( "Error reading myfile.dat" );
            else if ( feof(stream) ) /* possibility 2 */
                printf( "EOF found\n" );
            printf( "Number of characters read %d\n", num );
            printf( "buffer = %.*s\n", num, buffer );
        }
    }
    else
        printf( "Error opening myfile.dat" );
}
```

__freadable() — Determine if a stream is open for reading

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <stdio.h>
#include <stdio_ext.h>

int __freadable(FILE *stream);
```

General description

The `__freadable()` function determines if the specified stream has been opened for reading.

Returned value

The `__freadable()` function returns nonzero if the stream is opened for reading. Otherwise, the `__freadable()` function returns 0. If an error has occurred, `__freadable()` function returns 0 and sets `errno` to nonzero.

An application wishing to check for error situations should set `errno` to 0, then call `__freadable()`, and then check `errno`. If `errno` is nonzero, assume that an error has occurred.

Error Code Description

EBADF

The stream specified by *stream* is not valid.

Example

CELEBF89

```
/* CELEBF89

   This example writes and reads data to a file while querying the
   stream for information about data in the I/O buffer.

*/

#include <stdio.h>
#include <stdio_ext.h>

void main() {
    FILE *f;
    char filename[FILENAME_MAX] = "myfile.dat";
    char data[128] = "There are 34 bytes in this buffer\n";
    int datalen = strlen(data);
    size_t n = 0;

    f = fopen(filename, "wb+");
    if (f == NULL) {
        perror("fopen() failed\n");
        return;
    }

    if (__fwritable(f)) printf("Writing is allowed on the open stream\n");
    if (__freadable(f)) printf("Reading is allowed on the open stream\n");

    n = fputs(data, f);
    if (n == EOF) {
        perror("fputs() failed\n");
        return;
    }

    n = __fpending(f);
    printf("There are %d bytes in the buffer pending to be written\n", n);

    if (__fwriting(f)) printf("The last operation on the stream was a write\n");

    rewind(f);

    n = fgetc(f);

    n = __freadahead(f);
    printf("There are %d bytes remaining to be read from the buffer\n", n);
```

```
    if (__freading(f)) printf("The last operation on the stream was a read\n");
    return;
}
```

Output

```
Writing is allowed on the open stream
Reading is allowed on the open stream
There are 34 bytes in the buffer pending to be written
The last operation on the stream was a write
There are 33 bytes remaining to be read from the buffer
The last operation on the stream was a read
```

__freadahead() — Retrieve number of bytes remaining in input buffer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <stdio.h>
#include <stdio_ext.h>

size_t __freadahead(FILE *stream);

#define _OPEN_SYS_UNLOCKED 1
#include <stdio.h>
#include <stdio_ext.h>

size_t __freadahead_unlocked(FILE *stream);
```

General description

The `__freadahead()` function retrieves the number of bytes remaining to be read in the input buffer that is associated with the specified binary stream. When the stream is opened for text processing, `__fpending` retrieves the number of characters pending to be written.

The `__freadahead_unlocked()` function is equivalent to the `__freadahead()` function with the exception that it is not thread-safe. This function can be safely used in a multithreaded application if it is called while the invoking thread owns the (FILE *) object, such as after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Usage notes

1. If `__freadahead()` is called when the stream is currently writing, `__freadahead()` returns 0 and sets `errno` to a nonzero value.
2. If `__freadahead()` is called on a data set opened `type=record`, `__freadahead()` returns 0 and sets `errno` to a nonzero value.
3. For text data sets, any newline characters representing record boundaries will be included in the returned value.

Returned value

The `__freadahead()` functions return the number of bytes or characters remaining to be read in the current buffer, depending on the type of stream. Otherwise, the `__freadahead()` functions return 0. If an error has occurred, `__freadahead()` functions return 0 and set `errno` to nonzero.

When the stream is wide-oriented text, the `__freadahead()` function returns a value measured in wide characters.

An application wishing to check for error situations should set `errno` to 0, then call `__freadahead()`, and then check `errno`. If `errno` is nonzero, assume that an error has occurred.

Error Code

Description

EBADF

The stream specified by *stream* is not valid.

Example

CELEBF89

```
/* CELEBF89

   This example writes and reads data to a file while querying the
   stream for information about data in the I/O buffer.

*/

#include <stdio.h>
#include <stdio_ext.h>

void main() {
    FILE *f;
    char filename[FILENAME_MAX] = "myfile.dat";
    char data[128] = "There are 34 bytes in this buffer\n";
    int datalen = strlen(data);
    size_t n = 0;

    f = fopen(filename, "wb+");
    if (f == NULL) {
        perror("fopen() failed\n");
        return;
    }

    if (__fwritable(f)) printf("Writing is allowed on the open stream\n");
    if (__freadable(f)) printf("Reading is allowed on the open stream\n");

    n = fputs(data, f);
    if (n == EOF) {
        perror("fputs() failed\n");
        return;
    }

    n = __fpending(f);
    printf("There are %d bytes in the buffer pending to be written\n", n);

    if (__fwriting(f)) printf("The last operation on the stream was a write\n");

    rewind(f);

    n = fgetc(f);
```

```
n = __freadahead(f);
printf("There are %d bytes remaining to be read from the buffer\n", n);

if (__freading(f)) printf("The last operation on the stream was a read\n");

return;
}
```

Output

```
Writing is allowed on the open stream
Reading is allowed on the open stream
There are 34 bytes in the buffer pending to be written
The last operation on the stream was a write
There are 33 bytes remaining to be read from the buffer
The last operation on the stream was a read
```

__freading() — Determine if last operation on stream is a read operation

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <stdio.h>
#include <stdio_ext.h>

int __freading(FILE *stream);

#define _OPEN_SYS_UNLOCKED 1
#include <stdio.h>
#include <stdio_ext.h>

int __freading_unlocked(FILE *stream);
```

General description

The `__freading()` function determines if the last operation on the specified stream is a read operation or if the specified stream is open for read-only.

The `__freading_unlocked()` function is equivalent to the `__freading()` function with the exception that it is not thread-safe. This function can be safely used in a multithreaded application if it is called while the invoking thread owns the (FILE *) object, such as after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

The `__freading()` functions return nonzero when the last operation is a read operation or the stream is open for read-only. Otherwise, the `__freading()` functions return 0. If an error has occurred, `__freading()` functions return 0 and set `errno` to nonzero.

An application wishing to check for error situations should set `errno` to 0, then call `__freading()`, and then check `errno`. If `errno` is nonzero, assume that an error has occurred.

Error Code Description

EBADF

The stream specified by *stream* is not valid.

Example

CELEBF89

```
/* CELEBF89

   This example writes and reads data to a file while querying the
   stream for information about data in the I/O buffer.

*/

#include <stdio.h>
#include <stdio_ext.h>

void main() {
    FILE *f;
    char filename[FILENAME_MAX] = "myfile.dat";
    char data[128] = "There are 34 bytes in this buffer\n";
    int datalen = strlen(data);
    size_t n = 0;

    f = fopen(filename, "wb+");
    if (f == NULL) {
        perror("fopen() failed\n");
        return;
    }

    if (__fwritable(f)) printf("Writing is allowed on the open stream\n");
    if (__freadable(f)) printf("Reading is allowed on the open stream\n");

    n = fputs(data, f);
    if (n == EOF) {
        perror("fputs() failed\n");
        return;
    }

    n = __fpending(f);
    printf("There are %d bytes in the buffer pending to be written\n", n);

    if (__fwriting(f)) printf("The last operation on the stream was a write\n");

    rewind(f);

    n = fgetc(f);

    n = __freadahead(f);
    printf("There are %d bytes remaining to be read from the buffer\n", n);

    if (__freading(f)) printf("The last operation on the stream was a read\n");

    return;
}
```

Output

```
Writing is allowed on the open stream
Reading is allowed on the open stream
There are 34 bytes in the buffer pending to be written
The last operation on the stream was a write
There are 33 bytes remaining to be read from the buffer
The last operation on the stream was a read
```

free() — Free a block of storage

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdlib.h>

void free(void *ptr);
```

General description

Frees a block of storage pointed to by *ptr*. The *ptr* variable points to a block previously reserved with a call to `aligned_alloc()`, `calloc()`, `malloc()`, `posix_memalign()`, `realloc()`, or `strdup()`. The number of bytes freed is the number of bytes specified when you reserved (or reallocated, in the case of `realloc()`), the block of storage. If *ptr* is NULL, `free()` simply returns without freeing anything. Since *ptr* is passed by value `free()` will not set *ptr* to NULL after freeing the memory to which it points.

This function is also available to C applications in a stand-alone System Programming C (SPC) Environment.

Note: Attempting to free a block of storage not allocated with `aligned_alloc()`, `calloc()`, `malloc()`, `posix_memalign()`, `realloc()`, `strdup()`, or previously freed storage, can affect the subsequent reserving of storage and lead to an abend.

Special behavior for C++: Under C++, you cannot use `free()` with an item that was allocated using the C++ `new` keyword.

Returned value

`free()` returns no values.

Example

```
/* This example illustrates the use of calloc() to allocate storage for x
   array elements and then calls free() to free them.
   */
#include <stdio.h>
#include <stdlib.h>
```

```

int main(void)
{
    long * array;      /* start of the array */
    long * index;      /* index variable */
    int i;             /* index variable */
    int num;           /* number of entries of the array */

    printf( "Enter the size of the array\n" );
    scanf( "%i", &num );

    /* allocate num entries */
    if ( (index = array = (long *)calloc( num, sizeof( long ))) != NULL )
    {
        : /* do something with the array */
        free( array ); /* deallocates array */
    }
    else
    { /* Out of storage */
        printf( "Error: out of storage\n" );
        abort();
    }
}

```

freeaddrinfo() — Free addrinfo storage

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| RFC2553 Single UNIX Specification, Version 3 | both | z/OS V1R4 |

Format

```

#define _OPEN_SYS_SOCKET_IPV6
#include <sys/socket.h>
#include <netdb.h>

void *freeaddrinfo(struct addrinfo *ai);

```

SUSV3

```

#define _POSIX_C_SOURCE 200112L
#include <sys/socket.h>
#include <netdb.h>

void *freeaddrinfo(struct addrinfo *ai);

```

General description

The `freeaddrinfo()` function frees one or more `addrinfo` structures returned by `getaddrinfo()`, along with any additional storage associated with those structures. If the `ai_next` field of the structure is not null, the entire list of structures is freed.

Returned value

No return value is defined.

freopen() — Redirect an open file

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdio.h>

FILE *freopen(const char *__restrict__ filename, const char *__restrict__ mode,
              FILE *__restrict__ stream);
```

General description

Closes the file currently associated with *stream* and pointed to by *stream*, opens the file specified by the *filename*, and then associates the stream with it.

The `freopen()` function opens the new file with the type of access requested by the *mode* argument. The *mode* argument is used as in the `fopen()` function. See [“fopen\(\) — Open a file” on page 571](#) for a description of the *mode* parameter.

You can also use the `freopen()` function to redirect the standard stream files `stdin`, `stdout`, and `stderr` to files that you specify. The file pointer input to the `freopen()` function must point to a valid open file. If the file pointer has been closed, the behavior is undefined.

You could use the following `freopen()` call to redirect `stdout` to a memory file `a.b`:

```
freopen("a.b", "wb, type=memory", stdout);
```

If *filename* is an empty string, `freopen()` closes the file and reuses the original file name. For details on how the file name and open mode is interpreted, see [z/OS XL C/C++ Programming Guide](#).

A standard stream can be opened by default to a type of file not available to a general `fopen()`. This is true for standard streams under CICS, and also true for the default `stderr`, when running a non-POSIX Language Environment application.

The following statement uses `freopen()` to have `stdin` use binary mode instead of text mode:

```
fp = freopen("", "rb", stdin);
```

You can use the same empty string method to change the mode from binary back to text. This method is not allowed for:

- The default CICS data queues used by the standard streams under CICS
- The Language Environment Message File (MSGFILE), which is the default for `stderr`
- z/OS UNIX files.
- -CELQPIPI MSGRTN file, which is the default for `stderr` if MSGRTN service routine is specified.

Note: Using the empty string method is included in the SAA C definition, but not in the ISO C standard.

Large file support for z/OS UNIX files: Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the [long long data type support](#) enabled and define the `_LARGE_FILES` feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the `_LARGE_FILES` feature test macro as well.

Returned value

If successful, `freopen()` returns the value of *stream*, the same value that was passed to it, and clears both the error and EOF indicators associated with the stream.

A failed attempt to close the original file is ignored.

If an error occurs in reopening the requested file, `freopen()` closes the original file, and returns a NULL pointer value.

Special behavior for large z/OS UNIX files: The following is the possible value of `errno`:

Error Code

Description

EOVERFLOW

The named file is a regular file and the size of the file cannot be represented correctly in an object of type `off_t`.

Example

This example illustrates the IBM z/OS C extension that allows you to change characteristics of a file by reopening it.

```
#include <stdio.h>

int main(void)
{
    FILE *stream, *stream2;

    stream = fopen("myfile.dat", "r");
    stream2 = freopen("", "w+", stream);
}
```

This example closes the `stream` data stream and reassigns its stream pointer:

```
#include <stdio.h>
```

frexp, frexpf, frexpl

```
int main(void)
{
    FILE *stream, *stream2;

    stream = fopen("myfile.dat", "r");
    stream2 = freopen("myfile2.dat", "w+", stream);
}
```

Note: stream and stream2 will have the same value.

frexp(), frexpf(), frexpl() — Extract mantissa and exponent of the floating-point value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#include <math.h>

double frexp(double x, int *expptr);
float frexp(float x, int *expptr);          /* C++ only */
long double frexp(long double x, int *expptr); /* C++ only */
float frexpf(float x, int *expptr);
long double frexpl(long double x, int *expptr);
```

General description

Breaks down the floating-point value *x* into a component *m* for the normalized fraction component and another term *n* for the exponent, such that the absolute value of *m* is greater than or equal to 0.5 and less than 1.0 or equal to 0, and $x = m * 2^n$. The function stores the integer exponent *n* at the location to which *exp ptr* points.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

Restriction: The frexpf() and frexpl() functions do not support the _FP_MODE_VARIABLE feature test macro.

Returned value

Returns the normalized fraction *m*. If *x* is 0, the function returns 0 for both the fraction and exponent. The fraction has the same sign as the argument *x*. The result of the function cannot have a range error.

Example

CELEBF41

```

/* CELEBF41

   This example decomposes the floating-point value of x, 16.4, into its
   normalized fraction 0.5125, and its exponent 5.
   It stores the mantissa in y and the exponent in n.

*/

#include <math.h>
#include <stdio.h>

int main(void)
{
    double x, m;
    int n;

    x = 16.4;
    m = frexp(x, &n);

    printf("The fraction is %lf and the exponent is %d\n", m, n);
}

```

Output

```
The mantissa is 0.512500 and the exponent is 5
```

frexpd32(), frexpd64(), frexpd128() — Extract mantissa and exponent of the decimal floating-point value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```

#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 frexpd32(_Decimal32 x, int *expptr);
_Decimal64 frexpd64(_Decimal64 x, int *expptr);
_Decimal128 frexpd128(_Decimal128 x, int *expptr);

_Decimal32 frexp(_Decimal32 x, int *expptr); /* C++ only */
_Decimal64 frexp(_Decimal64 x, int *expptr); /* C++ only */
_Decimal128 frexp(_Decimal128 x, int *expptr); /* C++ only */

```

General description

Breaks down the decimal floating-point value x into a component m for the normalized fraction component and another term n for the exponent, such that the absolute value of m is greater than or

equal to 0.1 and less than 1.0 or equal to 0, and $x = m * 10^n$. The function stores the integer exponent n at the location to which *exp_ptr* points.

Notes:

- 1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- 2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

Returns the normalized fraction m . If x is 0, the function returns 0 for both the fraction and exponent. The fraction has the same sign as the argument x . The result of the function cannot have a range error.

Example

```
/* CELEBF81
   This example illustrates the frexpd64() function.
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal64 x, m;
    int n;

    x = 164.5DD;
    m = frexpd64(x, &n);

    printf("The fraction of %Df is %Df and the exponent is %d\n",
           x, m, n);
}
```

fscanf(), scanf(), sscanf() — Read and format data

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 C/C++ DFP Language environment | both | z/OS V1R8 |

Format

```
#include <stdio.h>

int fscanf(FILE *__restrict__stream, const char *__restrict__format-string, ...);
int scanf(const char *__restrict__format-string, ...);
int sscanf(const char *__restrict__buffer, const char *__restrict__format, ...);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int fscanf_unlocked(FILE *__restrict__stream,
                    const char *__restrict__format-string, ...);
int scanf_unlocked(const char *__restrict__format-string, ...);
```

General description

These three related functions are referred to as the `fscanf` family.

Reads data from the current position of the specified *stream* into the locations given by the entries in the argument list, if any. The argument list, if it exists, follows the format string. The `fscanf()` function cannot be used for a file opened with `type=record` or `type=blocked`.

The `scanf()` function reads data from the standard input stream `stdin` into the locations given by each entry in the argument list. The argument list, if it exists, follows the format string. *scanf()* cannot be used if `stdin` has been reopened as a `type=record` or `type=blocked` file.

The `sscanf()` function reads data from *buffer* into the locations given by *argument-list*. Reaching the end of the string pointed to by *buffer* is equivalent to `fscanf()` reaching EOF. If the strings pointed to by *buffer* and *format* overlap, behavior is undefined.

`fscanf()` and `scanf()` have the same restriction as any read operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

For all three functions, each entry in the argument list must be a pointer to a variable of a type that matches the corresponding conversion specification in *format-string*. If the types do not match, the results are undefined.

For all three functions, the *format-string* controls the interpretation of the argument list. The *format-string* can contain multibyte characters beginning and ending in the initial shift state.

The format string pointed to by *format-string* can contain one or more of the following:

- White space characters, as specified by `isspace()`, such as blanks and newline characters. A white space character causes `fscanf()`, `scanf()`, and `sscanf()` to read, but not to store, all consecutive white space characters in the input up to the next character that is not white space. One white space character in *format-string* matches any combination of white space characters in the input.
- Characters that are not white space, except for the percent sign character (%). A non-white space character causes `fscanf()`, `scanf()`, and `sscanf()` to read, but not to store, a matching non-white space character. If the next character in the input stream does not match, the function ends.
- Conversion specifications which are introduced by the percent sign (%) or the sequence (%n\$) where *n* is a decimal integer in the range [1, `NL_ARGMAX`]. A conversion specification causes `fscanf()`, `scanf()`, and `sscanf()` to read and convert characters in the input into values of a conversion specifier. The value is assigned to an argument in the argument list.

All three functions read *format-string* from left to right. Characters outside of conversion specifications are expected to match the sequence of characters in the input stream; the matched characters in the input stream are scanned but not stored. If a character in the input stream conflicts with *format-string*, the function ends, terminating with a “matching” failure. The conflicting character is left in the input stream as if it had not been read.

When the first conversion specification is found, the value of the first *input field* is converted according to the conversion specification and stored in the location specified by the first entry in the argument list. The

second conversion specification converts the second input field and stores it in the second entry in the argument list, and so on through the end of *format-string*.

fscanf_unlocked() is functionally equivalent to fscanf() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

scanf_unlocked() is functionally equivalent to scanf() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

An *input field* is defined as:

- All characters until a white space character (space, tab, or newline) is encountered
- All characters until a character is encountered that cannot be converted according to the conversion specification
- All characters until the field *width* is reached.

If there are too many arguments for the conversion specifications, the extra arguments are evaluated but otherwise ignored. The results are undefined if there are not enough arguments for the conversion specifications.

Syntax of Conversion Specification for fscanf(), scanf(), and sscanf()

Each field of the conversion specification is a single character or a number signifying a particular format option. The *conversion specifier*, which appears after the last optional format field, determines whether the input field is interpreted as a character, a string, or a number. The simplest conversion specification contains only the percent sign and a *conversion specifier* (for example, %s).

Each field of the format specification is discussed in detail below.

Other than conversion specifiers, you should avoid using the percent sign (%), except to specify the percent sign: %%. Currently, the percent sign is treated as the start of a conversion specifier. Any unrecognized specifier is treated as an ordinary sequence of characters. If, in the future, the compiler permits a new conversion specifier, it could match a section of your format string, be interpreted incorrectly, and result in undefined behavior. See [Table 33 on page 630](#) for a list of conversion specifiers.

Flag characters: The *flag* characters in [Table 32 on page 629](#) are used for assignment-suppressing and separator for vector type input conversion. Notice that more than one *flag* can appear in a format specification. This is an optional field.

Table 32. Flag Characters for fscanf Family

| Flag | Meaning | Default |
|---------|--|---|
| * | Suppresses assignment of the next input field, which is interpreted as a field of the specified conversion specifier. The field is scanned but not stored. | |
| , ; : _ | Indicates the separator character between each two components in the vector data type conversion. Only one separator character can be specified. | The default value for the separator character is a space (' '), unless the c format is being used. For the c format, there is no separator at all if no separator character is specified. |

width is a positive decimal integer controlling the maximum number of characters to be read. No more than *width* characters are converted and stored at the corresponding *argument*.

Fewer than *width* characters are read if a white space character (space, tab, or newline), or a character that cannot be converted according to the given format occurs before *width* is reached.

Optional prefix: The optional prefix characters used to indicate the size of the argument expected or size of a single value in a vector data type input conversion are explained:

Prefix

Meaning

h

Specifies that the d, i, o, u, x, X, or n conversion specifier applies to an argument with type pointer to short or unsigned short.

hh

Specifies that the d, i, o, u, x, X, or n conversion specifier applies to an argument with type pointer to signed char or unsigned char.

l

(ell) Specifies that the d, i, o, u, x, X, or n conversion specifier applies to an argument with type pointer to long or unsigned long; the following a, A, e, E, f, F, g, or G conversion specifier applies to an argument with type pointer to double; and the following c, s, or [conversion specifier applies to an argument with type pointer to wchar_t.

ll

(ell-ell) Specifies that the d, i, o, u, x, X, or n conversion specifier applies to an argument with type pointer to long long or unsigned long long.

j

Specifies that the d, i, o, u, x, X, or n conversion specifier applies to an argument with type pointer to intmax_t or uintmax_t.

- t**
Specifies that the d, i, o, u, x, X, or n conversion specifier applies to an argument with type pointer to ptrdiff_t or the corresponding unsigned type.
- z**
Specifies that the d, i, o, u, x, X, or n conversion specifier applies to an argument with type pointer to size_t or the corresponding signed integer type.
- D**
Specifies that the e, E, f, F, g, or G conversion specifier applies to an argument with type pointer to _Decimal64 float.
- DD**
Specifies that the e, E, f, F, g, or G conversion specifier applies to an argument with type pointer to _Decimal128 float.
- H**
Specifies that the e, E, f, F, g, or G conversion specifier applies to an argument with type pointer to _Decimal32 float.
- L**
Specifies that the a, A, e, E, f, F, g, or G conversion specifier applies to an argument with type pointer to long double.
- v**
Specifies that a following c, d, i, u, o, x, or X conversion specifier applies to an argument with type pointer to vector signed char, vector unsigned char, or vector bool char.
- vh, hv**
Specifies that a following d, i, u, o, x, or X conversion specifier applies to an argument with type pointer to vector signed short, vector unsigned short, or vector bool short.
- vl, lv**
Specifies that a following d, i, u, o, x, or X conversion specifier applies to an argument with type pointer to vector signed int, vector unsigned int, or vector bool int.
- vll, llv**
Specifies that a following d, i, u, o, x, or X conversion specifier applies to an argument with type pointer to vector signed long long, vector unsigned long long, or vector bool long long.
- vL, Lv**
Specifies that a following a, A, e, E, f, F, g, or G conversion specifier applies to an argument with type pointer to vector double.

Conversion specifier: [Table 33 on page 630](#) explains the valid conversion specifiers and their meanings are in.

| Table 33. Conversion Specifiers in fscanf Family | | |
|--|--|-------------------------|
| Conversion Specifier | Type of Input Expected | Type of Argument |
| d | Decimal integer | Pointer to int |
| o | Octal integer | Pointer to unsigned int |
| x X | Hexadecimal integer | Pointer to unsigned int |
| i | Decimal, hexadecimal, or octal integer | Pointer to int |
| u | Unsigned decimal integer | Pointer to unsigned int |

Table 33. Conversion Specifiers in fscanf Family (continued)

| Conversion Specifier | Type of Input Expected | Type of Argument |
|----------------------------|--|--|
| e E f F g G | Floating-point value consisting of an optional sign (+ or -); a series of one or more decimal digits possibly containing a decimal-point; and an optional exponent (e or E) followed by a possibly signed integer value | Pointer to <code>float</code> |
| a A | Matches an optionally signed floating-point number, infinity, or NaN, whose format is the same as expected for the subject sequence of <code>strtod()</code> . In the absence of a size modifier, the application shall ensure that the corresponding argument is a pointer to <code>float</code> . | Pointer to <code>float</code> |
| D(n,p) | Fixed-point value consisting of an optional sign (+ or -); a series of one or more decimal digits possibly containing a decimal-point. | Pointer to decimal |
| c | Sequence of one or more characters as specified by field width; white space characters that are ordinarily skipped are read when <code>%c</code> is specified. No terminating null is added. | Pointer to <code>char</code> large enough for input field. |
| C or lc | <p>The input is a sequence of one or more multibyte characters as specified by the field width, beginning in the initial shift state. Each multibyte character in the sequence is converted to a wide character as if by a call to the <code>mbrtowc()</code> function. The conversion state described by the <code>mbstate_t</code> object is initialized to zero before the first multibyte character is converted.</p> <p>The corresponding argument is a pointer to the initial element of an array of <code>wchar_t</code> large enough to accept the resulting sequence of wide characters. No NULL wide character is added.</p> | C or lc uses a pointer to <code>wchar_t</code> . |
| s | Like c, a sequence of bytes of type <code>char</code> (signed or unsigned), except that white space characters are not allowed, and a terminating null is always added. | Pointer to character array large enough for input field, plus a terminating NULL character (<code>\0</code>) that is automatically appended. |
| S or ls | <p>A sequence of multibyte characters that begins and ends in the initial shift state. Each multibyte character in the sequence is converted to a wide character as if by a call to the <code>mbrtowc()</code> function, with the conversion state described by the <code>mbstate_t</code> object initialized to zero before the first multibyte character is converted.</p> <p>The corresponding argument is a pointer to the initial array of <code>wchar_t</code> large enough to accept the sequence and the terminating NULL wide character, which is added automatically.</p> | S or ls uses a pointer to <code>wchar_t</code> string. |

Table 33. Conversion Specifiers in fscanf Family (continued)

| Conversion Specifier | Type of Input Expected | Type of Argument |
|----------------------|---|--|
| n | No input read from <i>stream</i> or buffer. | Pointer to <code>int</code> , into which is stored the number of characters successfully read from the <i>stream</i> or buffer up to that point in the call to either <code>fscanf()</code> or to <code>scanf()</code> . |
| p | Pointer to void converted to series of characters. For the specific format of the input, see the individual system reference guides. | Pointer to void. |
| [| <p>A non-empty sequence of bytes to be matched against a set of expected bytes (the <i>scanset</i>), which form the conversion specification. White space characters that are ordinarily skipped are read when <code>%[</code> is specified.</p> <p>Consider the following situations:</p> <p><code>[^bytes]</code>. In this case, the <i>scanset</i> contains all bytes that do not appear between the circumflex and the right square bracket.</p> <p><code>[]abc] or [^]abc.]</code> In both these cases the right square bracket is included in the <i>scanset</i> (in the first case: <code>]abc</code> and in the second case, <i>not</i> <code>]abc</code>)</p> <p><code>[a–z]</code> In EBCDIC The – is in the <i>scanset</i>, the characters <code>b</code> through <code>y</code> are <i>not</i> in the <i>scanset</i>; in ASCII The – is <i>not</i> in the <i>scanset</i>, the characters <code>b</code> through <code>y</code> are.</p> <p>The code point for the square brackets (<code>[</code> and <code>]</code>) and the caret (<code>^</code>) vary among the EBCDIC encoded character sets. The default C locale expects these characters to use the code points for encoded character set Latin-1 / Open Systems 1047. Conversion proceeds one byte at a time: there is no conversion to wide characters.</p> | Pointer to the initial byte of an array of <code>char</code> , signed <code>char</code> , or unsigned <code>char</code> large enough to accept the sequence and a terminating byte, which will be added automatically. |
| l[| If an <code>l</code> length modifier is present, input is a sequence of multibyte characters that begins and ends in the initial shift state. Each multibyte character in the sequence is converted to a wide character as if by a call to the <code>mbrtowc()</code> function, with the conversion state described by the <code>mbstate_t</code> object initialized to zero before the first multibyte character is converted. The corresponding argument is a pointer to the initial array of <code>wchar_t</code> large enough to accept the sequence and the terminating NULL wide character, which is added automatically. | <code>l[</code> uses a pointer to <code>wchar_t</code> string |

When the `LC_SYNTAX` category is set using `setlocale()`, the format strings passed to the `fscanf()`, `scanf()`, or `sscanf()` functions must use the same encoded character set as is specified for the `LC_SYNTAX` category.

To read strings not delimited by space characters, substitute a set of characters in square brackets (`[]`) for the `s` (string) conversion specifier. The corresponding input field is read up to the first character that does

not appear in the bracketed character set. If the first character in the set is a logical not (\neg), the effect is reversed: the input field is read up to the first character that does appear in the rest of the character set.

To store a string without storing an ending NULL character ($\backslash 0$), use the specification $\%ac$, where a is a decimal integer. In this instance, the c conversion specifier means that the argument is a pointer to a character array. The next a characters are read from the input stream into the specified location, and no NULL character is added.

The input for a $\%x$ conversion specifier is interpreted as a hexadecimal number.

All three functions, `fscanf()`, `scanf()`, and `sscanf()` scan each input field character by character. It might stop reading a particular input field either before it reaches a space character, when the specified *width* is reached, or when the next character cannot be converted as specified. When a conflict occurs between the specification and the input character, the next input field begins at the first unread character. The conflicting character, if there is one, is considered unread and is the first character of the next input field or the first character in subsequent read operations on the input stream.

Special behavior for XPG4.2:

- When the $\%n\$$ conversion specification is found, the value of the *input field* is converted according to the conversion specification and stored in the location specified by the n th argument in the argument list. Numbered arguments in the argument list can only be referenced once from *format-string*.
- The *format-string* can contain either form of the conversion specification, that is, $\%$ or $\%n\$$ but the two forms cannot be mixed within a single *format-string* except that $\%\%$ or $\%\%$ can be mixed with the $\%n\$$ form.

Floating-point and the fscanf family of formatted input functions: The `fscanf` family functions match e , E , f , F , g or G conversion specifiers to floating-point number substrings in the input stream. The `fscanf` family functions convert each input substring matched by an e , E , f , F , g or G conversion specifier to a float, double or long double value depending on a size modifier preceding the e , E , f , F , g or G conversion specifier.

The floating-point value produced is hexadecimal floating-point or IEEE Binary Floating-Point format depending on the floating-point mode of the thread invoking the `fscanf` family function. The `fscanf` family functions use `__isBFP()` to determine the floating-point mode of invoking threads.

Many IBM z/OS C/C++ formatted input functions, including the `fscanf` family, recognize special infinity and NaN floating-point number input sequences when the invoking thread is in IEEE Binary Floating-Point mode as determined by `__isBFP()`.

- The special sequence for infinity input is an optional plus or minus sign, then the character sequence INF, where the individual characters may be uppercase or lowercase, and then a white space character (space, tab, or newline), a NULL character ($\backslash 0$) or EOF.
- The special sequence for NaN input is an optional plus or minus sign, then the character sequence NANS for a signalling NaN or NANQ for a quiet NaN, where the individual characters may be uppercase or lowercase, then an optional NaN ordinal sequence, and then a white space character (space, tab, or newline), a NULL character ($\backslash 0$) or EOF.

For binary floating point NaNs: A NaN ordinal sequence is a left-parenthesis character, "(", followed by a digit sequence representing an integer n , where $1 \leq n \leq \text{INT_MAX}-1$, followed by a right-parenthesis character, ")". If the NaN ordinal sequence is omitted, NaN ordinal sequence (1) is assumed. The integer value, n , corresponding to a NaN ordinal sequence determines what IEEE Binary Floating-Point NaN fraction bits are produced by formatted input functions.

For a signalling NaN, these functions produce NaN fraction bits (left to right) by reversing the bits (right to left) of the even integer value $2*n$.

For a quiet NaN they produce NaN fraction bits (left to right) by reversing the bits (right to left) of the odd integer value $2*n-1$.

For decimal floating point NaNs: A NaN ordinal sequence is a left parenthesis character, "(", followed by a decimal digit sequence of up to 6 digits for a `_Decimal32` output number, up to 15 digits for a `_Decimal64` output value, or up to 33 digits for a `_Decimal128` output value, followed by a right

parenthesis, ")". If the NaN ordinal sequence is omitted, NaN ordinal sequence "(0)" is assumed. If the NaN ordinal sequence is shorter than 6, 15, or 33 digits, it will be padded on the left with "0" digits so that the length becomes 6, 15, or, 33 digits for `_Decimal32`, `_Decimal64`, and `_Decimal128` values respectively.

For decimal floating point numbers, the digits are not reversed, and both odd or even NaN ordinal sequences can be specified for either a Quiet NAN or Signalling NAN.

Vector types and the fscanf family of formatted input functions: The fscanf family functions support character, integer, and floating-point vector data types in the input conversion specification. The vector value to be scanned is in the following general form:

```
Value1Cvalue2C...CValueN
```

where C is a separator character optionally defined in flag characters, and there can be 2, 4, 8, or 16 components depending on the optional prefix v, vh, hv, vl, lv, vll, llv, vL, or Lv. Each value is scanned according to the conversion specifier. If the conversion fails in the middle of a vector value, the successful elements will be saved to the vector argument and the other elements in the vector argument will remain unchanged.

Usage note

To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

All three functions, `fscanf()`, `scanf()`, and `sscanf()` return the number of input items that were successfully matched and assigned. The returned value does not include conversions that were performed but not assigned (for example, suppressed assignments). The functions return EOF if there is an input failure before any conversion, or if EOF is reached before any conversion. Thus a returned value of 0 means that no fields were assigned: there was a matching failure before any conversion. Also, if there is an input failure, then the file error indicator is set, which is not the case for a matching failure.

The `ferror()` and `feof()` functions are used to distinguish between a read error and an EOF. Note that EOF is only reached when an attempt is made to read “past” the last byte of data. Reading up to and including the last byte of data does *not* turn on the EOF indicator.

Examples

CELEBF42

```
/* CELEBF42

   This example scans various types of data
*/
#include <stdio.h>

int main(void)
{
    int i;
    float fp;
    char c, s[81];

    printf("Enter an integer, a real number, a character "
           "and a string : \n");
    if (scanf("%d %f %c %s", &i, &fp, &c, s) != 4)
        printf("Not all of the fields were assigned\n");
    else
    {
        printf("integer = %d\n", i);
        printf("real number = %f\n", fp);
        printf("character = %c\n", c);
        printf("string = %s\n", s);
    }
}
```

Output

If input is: 12 2.5 a yes, then output would be:

```
Enter an integer, a real number, a character and a string:
integer = 12
real number = 2.500000
character = a
string = yes
```

CELEBF43

```
/* CELEBF43
   This example converts a hexadecimal integer to a decimal integer.
   The while loop ends if the input value is not a hexadecimal integer.
*/
#include <stdio.h>

int main(void)
{
    int number;

    printf("Enter a hexadecimal number or anything else to quit:\n");
    while (scanf("%x",&number))
    {
        printf("Hexadecimal Number = %x\n",number);
        printf("Decimal Number      = %d\n",number);
    }
}
```

Output

If input is: 0x231 0xf5e 0x1 q, then output would be:

```
Enter a hexadecimal number or anything else to quit:
Hexadecimal Number = 231
Decimal Number     = 561
Hexadecimal Number = f5e
Decimal Number     = 3934
Hexadecimal Number = 1
Decimal Number     = 1
```

CELEBF44

```
/* CELEBF44
   The next example illustrates the use of scanf() to input fixed-point
   decimal data types. This example works under C only, not C++.
*/
#include <stdio.h>
#include <decimal.h>

decimal(15,4) pd01;
decimal(10,2) pd02;
decimal(5,5) pd03;

int main(void) {
    printf("\nFirst time :-----\n");
    printf("Enter three fixed-point decimal number\n");
    printf("  (15,4) (10,2) (5,5)\n");
    if (scanf("%D(15,4) %D(10,2) %D(5,5)", &pd01, &pd02, &pd03) != 3) {
        printf("Error found in scanf\n");
    } else {
        printf("pd01 = %D(15,4)\n", pd01);
        printf("pd02 = %D(10,2)\n", pd02);
        printf("pd03 = %D(5,5)\n", pd03);
    }
    printf("\nSecond time :-----\n");
    printf("Enter three fixed-point decimal number\n");
    printf("  (15,4) (10,2) (5,5)\n");
    if (scanf("%D(15,4) %D(10,2) %D(5,5)", &pd01, &pd02, &pd03) != 3) {
        printf("Error found in scanf\n");
    } else {
        printf("pd01 = %D(15,4)\n", pd01);
        printf("pd02 = %D(10,2)\n", pd02);
        printf("pd03 = %D(5,5)\n", pd03);
    }
}
```

```
    return(0);
}
```

Output

```
First time :-----
Enter three fixed-point decimal number
(15,4) (10,2) (5,5)
12345678901.2345 -987.6 .24680
pd01 = 12345678901.2345
pd02 = -987.60
pd03 = 0.24680

Second time :-----
Enter three fixed-point decimal number
(15,4) (10,2) (5,5)
123456789013579.24680 123.4567890 987
pd01 = 12345678901.3579
pd02 = 123.45
pd03 = 0.98700
```

CELEBF46

```
/* CELEBF46
   The next example opens the file myfile.dat for reading and then scans
   this file for a string, a long integer value, a character, and a
   floating-point value.
*/
#include <stdio.h>
#define MAX_LEN 80

int main(void)
{
    FILE *stream;
    long l;
    float fp;
    char s[MAX_LEN + 1];
    char c;

    stream = fopen("myfile.dat", "r");

    /* Put in various data. */
    fscanf(stream, "%s", &s[0]);
    fscanf(stream, "%ld", &l);
    fscanf(stream, "%c", &c);
    fscanf(stream, "%f", &fp);

    printf("string = %s\n", s);
    printf("long double = %ld\n", l);
    printf("char = %c\n", c);
    printf("float = %f\n", fp);
}
```

Output

If myfile.dat contains abcdefghijklmnopqrstuvwxyz 343.2, then the expected output is:

```
string = abcdefghijklmnopqrstuvwxyz
long double = 343
char = .
float = 2.000000
```

CELEBS32

```
/* CELEBS32
   This example uses sscanf() to read various data from the string
   tokenstring, and then displays the data.
*/
#include <stdio.h>
#define SIZE 81

int main(void)
{
    char *tokenstring = "15 12 14";
    int i;
    float fp;
    char s[SIZE];
```

```

char c;

/* Input various data */
printf("No. of conversions=%d\n",
       sscanf(tokenstring, "%s %c%d%f", s, &c, &i, &fp));

/* If there were no space between %s and %c,
/* sscanf would read the first character following */
/* the string, which is a blank space. */

/* Display the data */
printf("string = %s\n", s);
printf("character = %c\n", c);
printf("integer = %d\n", i);
printf("floating-point number = %f\n", fp);
}

```

Output

You would see this output from example CELEBS32.

```

No. of conversions = 4
string = 15
character = 1
integer = 2
floating-point number = 14.000000

```

CELEBF91

```

/* CELEBF91
The following example illustrates the use of sscanf()
to input vector data types.
*/
#include <stdio.h>

int main (void)
{
    vector signed char s8;
    vector unsigned short u16;
    vector signed int s32;
    vector unsigned long long u64;
    vector double d64;

    sscanf("ab defghijklm,op", "%vc", &s8);
    printf("s8 = %vc\n", s8);

    sscanf("a,b, ,d,e,f,g,h,i,j,k,l,m,! ,o,p", "%,vc", &s8);
    printf("s8 = %,vc\n", s8);

    sscanf("1 2 3 4 5 6 7 8", "%vhu", &u16);
    printf("u16 = %vhu\n", u16);

    Sscanf(" 1, 2, 3,99", "%,2lvd", &s32);
    printf("s32 = %,2lvd\n", s32);

    sscanf("1 2", "%vllu", &u64);
    printf("u64 = %vllu\n", u64);

    sscanf("0.1 1.2", "%vLf\n", &d64);
    printf("d64 = %vLf\n", d64);
}

```

Output

```

s8 = ab defghijklm!op
s8 = a,b, ,d,e,f,g,h,i,j,k,l,m,! ,o,p
u16 = 1 2 3 4 5 6 7 8
s32 = 1, 2, 3,99
u64 = 1 2
d64 = 0.100000 1.200000

```

fseek() — Change file position

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```
#include <stdio.h>

int fseek(FILE *stream, long int offset, int origin);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int fseek_unlocked(FILE *stream, long int offset, int origin);
```

General description

The `fseek()` function changes the current file position associated with *stream* to a new location within the file. The next operation on the stream takes place at the new location. On a stream opened for update, the next operation can be either a reading or a writing operation.

The *origin* must be one of the following constants defined in `stdio.h`:

Origin

Definition

SEEK_SET

Beginning of file

SEEK_CUR

Current position of file pointer

SEEK_END

End of file

If successful, the `fseek()` function clears the EOF indicator, even when *origin* is `SEEK_END`, and cancels the effect of any preceding `ungetc()` or `ungetwc()` function on the same stream.

If the call to the `fseek()` function or the `fsetpos()` function is not valid, the call is treated as a flush and the `ungetc` characters are discarded.

Behavior for binary streams: ISO C/C++ states that binary streams use relative byte offsets for both the `ftell()` and `fseek()` functions. Under IBM z/OS C/C++, this is true except for record-oriented files that have

variable length records. For these types of files, the default behavior is to use encoded offsets for the `ftell()` function and the `fseek()` function using an origin of `SEEK_SET`.

Encoded offsets restrict you to seeking only to those positions that are recorded by a previous `ftell()` function call or to position 0. If you want to use relative-byte offsets for these types of files, you can either open the file with the `BYTESEEK` `fopen()` function option or set the `_EDC_BYTE_SEEK` environment variable before opening.

With relative-byte offsets, you can calculate your own offsets. If the offset exceeds the EOF, your file is extended with NULLs, except for z/OS UNIX files, for which the file is only extended with NULLs if you subsequently write new data. This is true also under POSIX, using z/OS UNIX files, where the file is only extended with NULLs if you subsequently write new data.

Attempting to reposition to before the start of the file causes the `fseek()` function to fail.

Regardless of whether encoded or relative offsets are returned by the `ftell()` function, you can specify relative offsets when using `SEEK_CUR` and `SEEK_END`.

If the new position is before the start of the file, the `fseek()` function fails. If the relative offset is positioned beyond the EOF, the file is padded with NULLs, except in the case of POSIX, using z/OS UNIX files, where padding does not occur until a subsequent write of new data.

Behavior for text streams: For text streams, the `ftell()` function returns an encoded offset. When seeking with an origin of `SEEK_SET`, you are restricted to seeking only to 0 or to positions returned by a previous `ftell()` function call.

Attempting to calculate your own position is not supported, and might result in a non-valid position and the failure of the `fseek()` function.

When you are using `SEEK_CUR` or `SEEK_END`, the offset is a relative byte offset. Attempting to seek to before the start of the file or past the EOF results in failure.

Behavior for record I/O: For files opened for record I/O using the `type=record` open mode parameter, the `ftell()` function returns the relative record number. For the origins of `SEEK_SET`, `SEEK_CUR`, and `SEEK_END`, the offset is a relative record number.

Attempting to seek to before the first record or past the EOF results in failure.

Behavior for blocked I/O: For files opened for blocked I/O using the `type=blocked` open mode parameter, the `ftell()` function returns the relative block number. For the origins of `SEEK_SET`, `SEEK_CUR`, and `SEEK_END`, the offset is a relative block number.

Attempting to seek to before the first block or past the EOF results in failure.

Behavior for wide-oriented streams: All of the above restrictions apply for wide-oriented streams of any type.

Multivolume data sets performance: Using the `fgetpos()` and `fsetpos()` functions generally results in better repositioning performance compared to the `ftell()` and `fseek()` functions when working with multivolume data sets.

Large file support for MVS data sets, VSAM data sets, and z/OS UNIX files: For AMODE 31 C/C++ applications, the `fseek()` function accepts a signed 4-byte offset and therefore cannot be used to directly or relatively position to offsets beyond 2 GB - 1. To avoid repositioning limitations, AMODE 31 C/C++ applications should define the `_LARGE_FILES` feature test macro before any headers are included and replace the `fseek()` function with the `fseeko()` function. For AMODE 64 C/C++ applications, there are no restrictions on using the `fseek()` function with large files. The AMODE 64 version automatically accepts a signed 8-byte offset.

Usage notes

1. Repositioning within a wide-oriented file and performing updates is strongly discouraged because it is not possible to predict if your update will overwrite part of a multibyte string or character, thereby invalidating subsequent data. For example, you could inadvertently add data that overwrites a

shift-out. The following data expects the shift-out to be there, so is not valid if it is treated as if in the initial shift state. Repositioning to the end of the file and adding new data is safe.

2. If you specify SEEK_CUR, any characters pushed back by the `ungetc()` or `ungetwc()` functions will have backed up the current position of the file pointer—which is the starting point of the seek. The seek will discard any pushed-back characters before repositioning, but the starting point will still be affected. For more information about calling the `fseek()` function after an `ungetc()` or `ungetwc()` function call, see [“ungetc\(\) — Push character onto input stream” on page 1941](#) and [“ungetwc\(\) — Push a wide character onto a stream” on page 1943](#).
3. The `_EDC_COMPAT` environment variable causes `fseek()` to ignore the effects of the `ungetc()` or `ungetwc()` functions. For more details, see the topic about environment variables in [z/OS XL C/C++ Programming Guide](#).
4. The `fseek_unlocked()` function is functionally equivalent to the `fseek()` function with the exception that it is not threadsafe. The `fseek()` function can safely be used in a multithreaded application if, and only if, it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

If successful in moving the pointer, the `fseek()` function returns 0.

If unsuccessful, or on devices that cannot seek, such as terminals and printers, the `fseek()` function returns nonzero.

Special behavior for XPG4.2: If unsuccessful, the `fseek()` function returns -1 and sets `errno` to one of the following values:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

EOVERFLOW

The resulting file offset would be a value which cannot be represented correctly in an object of type `long`.

Note: Environment variable `_EDC_EOVERFLOW` can be used to control behavior of the `fseek()` function with respect to detecting an EOVERFLOW condition for z/OS UNIX files. By default, the `fseek()` function will continue to be able to position beyond a location that the `ftell()` function can return. When `_EDC_EOVERFLOW` is set to YES, the `fseek()` function will check if the new position can be returned by the `ftell()` function.

ESPIPE

The underlying file type for the stream is a PIPE or a socket.

Example

```
/* This example opens a file myfile.dat for reading.
   After performing input operations (not shown), it moves the file
   pointer to the beginning of the file.
*/
#include <stdio.h>

int main(void)
{
    FILE *stream;
    int result;

    if (stream = fopen("myfile.dat", "r"))
    { /* successful */

        if (fseek(stream, 0L, SEEK_SET)); /* moves pointer to */
                                         /* the beginning of the file */
        { /* if not equal to 0
            then error ... */
        }
        else {
            /* fseek() successful */
        }
    }
}
```

```
}
}
```

fseeko() — Change file position

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 Language Environment | both | OS/390 V2R10 |

Format

```
#define _XOPEN_SOURCE 500
#include <stdio.h>

int fseeko(FILE *stream, off_t offset, int origin);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int fseeko_unlocked(FILE *stream, off_t offset, int origin);
```

General description

The fseeko() function changes the current file position associated with *stream* to a new location within the file. The next operation on the stream takes place at the new location. On a stream opened for update, the next operation can be either a reading or a writing operation.

The *origin* must be one of the following constants defined in stdio.h:

Origin

Definition

SEEK_SET

Beginning of file

SEEK_CUR

Current position of file pointer

SEEK_END

End of file

If successful, the fseeko() function clears the EOF indicator, even when the origin is SEEK_END, and cancels the effect of any preceding ungetc() or ungetwc() function on the same stream.

If the call to the `fseeko()` function or the `fsetpos()` function is not valid, the call is treated as a flush and the ungetc characters are discarded.

Behavior for binary streams: ISO C/C++ states that binary streams use relative byte offsets for both the `ftello()` and `fseeko()` functions. Under IBM z/OS C/C++, this is true except for record-oriented files that have variable length records. For these types of files, the default behavior is to use encoded offsets for the `ftello()` function and the `fseeko()` function using an origin of `SEEK_SET`.

Encoded offsets restrict you to seeking only to those positions that are recorded by a previous `ftello()` function call or to position 0. If you want to use relative-byte offsets for these types of files, you can either open the file with the `BYTESEEK` `fopen()` function option or set the `_EDC_BYTE_SEEK` environment variable before opening.

With relative-byte offsets, you can calculate your own offsets. If the offset exceeds the EOF, your file is extended with NULLs, except for z/OS UNIX files, for which the file is only extended with NULLs if you subsequently write new data. This is true also under POSIX, using z/OS UNIX files, where the file is only extended with NULLs if you subsequently write new data.

Attempting to reposition to before the start of the file causes the `fseeko()` function to fail.

Regardless of whether encoded or relative offsets are returned by the `ftello()` function, you can specify relative offsets when using `SEEK_CUR` and `SEEK_END`.

If the new position is before the start of the file, the `fseeko()` function fails. If the relative offset is positioned beyond the EOF, the file is padded with NULLs, except in the case of POSIX, using z/OS UNIX files, where padding does not occur until a subsequent write of new data.

Behavior for text streams: For text streams, the `ftello()` function returns an encoded offset. When seeking with an origin of `SEEK_SET`, you are restricted to seeking only to 0 or to positions returned by a previous `ftello()` function call.

Attempting to calculate your own position is not supported, and might result in a non-valid position and the failure of the `fseeko()` function.

When you are using `SEEK_CUR` or `SEEK_END`, the offset is a relative byte offset. Attempting to seek to before the start of the file or past the EOF results in failure.

Behavior for record I/O: For files opened for record I/O using the `type=record` open mode parameter, the `ftello()` function returns the relative record number. For the origins of `SEEK_SET`, `SEEK_CUR`, and `SEEK_END`, the offset is a relative record number.

Attempting to seek to before the first record or past the EOF results in failure.

Behavior for blocked I/O: For files opened for blocked I/O using the `type=blocked` open mode parameter, the `ftello()` function returns the relative block number. For the origins of `SEEK_SET`, `SEEK_CUR`, and `SEEK_END`, the offset is a relative block number.

Attempting to seek to before the first block or past the EOF results in failure.

Behavior for wide-oriented streams: All of the above restrictions apply for wide-oriented streams of any type.

Multivolume data sets performance: Using the `fgetpos()` and `fsetpos()` functions generally results in better repositioning performance compared to the `ftello()` and `fseeko()` functions when working with multivolume data sets.

Large file support for MVS data sets, VSAM data sets, and z/OS UNIX files: For AMODE 31 C/C++ applications, the `fseeko()` function accepts a signed 4-byte offset and therefore cannot be used to directly or relatively position to offsets beyond 2 GB - 1. To avoid repositioning limitations, AMODE 31 C/C++ applications should define the `_LARGE_FILES` feature test macro before any headers are included. For AMODE 64 C/C++ applications, there are no restrictions on using the `fseeko()` function with large files. The AMODE 64 version automatically accepts a signed 8-byte offset.

Usage notes

1. Repositioning within a wide-oriented file and performing updates is strongly discouraged because it is not possible to predict if your update will overwrite part of a multibyte string or character, thereby invalidating subsequent data. For example, you could inadvertently add data that overwrites a shift-out. The following data expects the shift-out to be there, so is not valid if it is treated as if in the initial shift state. Repositioning to the end of the file and adding new data is safe.
2. If you specify `SEEK_CUR`, any characters pushed back by the `ungetc()` or `ungetwc()` functions will have backed up the current position of the file pointer—which is the starting point of the seek. The seek will discard any pushed-back characters before repositioning, but the starting point will still be affected. For more information about calling the `fseeko()` function after an `ungetc()` or `ungetwc()` function call, see [“ungetc\(\) — Push character onto input stream” on page 1941](#) and [“ungetwc\(\) — Push a wide character onto a stream” on page 1943](#).
3. The `_EDC_COMPAT` environment variable causes `fseeko()` to ignore the effects of the `ungetc()` or `ungetwc()` functions. For more details, see the topic about environment variables in [z/OS XL C/C++ Programming Guide](#).
4. The `fseeko_unlocked()` function is functionally equivalent to the `fseeko()` function with the exception that it is not threadsafe. The `fseek()` function can safely be used in a multithreaded application if, and only if, it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

If successful, `fseeko()` returns 0, which means it successfully moved the pointer.

If unsuccessful, `fseeko()` returns nonzero and sets `errno` to one of the following values.

On devices that cannot seek, such as terminals and printers, the `fseeko()` function returns nonzero.

Error Code

Description

EBADF

The file descriptor underlying stream is not an open file descriptor.

EOVERFLOW

The current file offset cannot be represented correctly in an object of type `off_t`.

ESPIPE

The file descriptor underlying stream is associated with a pipe or FIFO.

Example

```
/* This example opens a file myfile.dat for reading.
   After performing input operations (not shown), it moves the file
   pointer to the beginning of the file.
*/
#define _XOPEN_SOURCE 500
#define _LARGE_FILES 1
#include <stdio.h>

int main(void)
{
    FILE *stream;
    int result;

    if (stream = fopen("/myfile.dat", "r"))
    { /* successful */

        if (fseeko(stream, 0LL, SEEK_SET)); /* moves pointer to */
                                           /* the beginning of the file */
        { /* if not equal to 0
            then error ... */
        }
    }
    else {
        /* fseeko() successful */
    }
}
```

```
}  
}
```

__fseterr() — Set stream in error

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <stdio.h>  
#include <stdio_ext.h>  
  
void __fseterr(FILE *stream);
```

General description

The __fseterr() function sets the specified stream in error.

Returned value

The __fseterr() function returns no values.

An application wishing to check for error situations should set errno to 0, then call __fseterr(), and then check errno. If errno is nonzero, assume that an error has occurred.

Error Code

Description

EBADF

The stream specified by *stream* is not valid.

Example

CELEBF88

```
/* CELEBF88  
  
   This example sets a stream in error.  
  
*/  
  
#include <stdio.h>
```

```
#include <stdio_ext.h>

void main() {
    FILE *f;
    char filename[FILENAME_MAX] = "myfile.dat";

    f = fopen(filename, "wb");
    if (f == NULL) {
        perror("fopen failed\n");
        return;
    }

    if (ferror(f)) printf("The error indicator is set for the open stream\n");
    else printf("The error indicator is not set for the open stream\n");

    __fseterr(f);

    if (ferror(f)) printf("The error indicator is set for the open stream\n");
    else printf("The error indicator is not set for the open stream\n");

    return;
}
```

Output

```
The error indicator is not set for the open stream
The error indicator is set for the open stream
```

__fsetlocking() — Set locking type

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | None |

Format

```
#include <stdio.h>
#include <stdio_ext.h>

int __fsetlocking(FILE *stream, int type);
```

General description

The `__fsetlocking()` function allows the type of locking on an open stream to be controlled or queried by the application.

If `type` is `FSETLOCKING_INTERNAL`, subsequent stdio functions perform implicit locking around every operation on the given stream. This is the default system behavior.

If `type` is `FSETLOCKING_BYCALLER`, subsequent stdio functions assume that the caller is responsible for maintaining the integrity of the stream in the face of access by multiple threads. If only one thread is accessing the stream, nothing further needs to be done. If multiple threads are accessing the stream, you can use the `flockfile()`, `funlockfile()`, and `ftrylockfile()` functions to provide the appropriate serialization.

If *type* is FSETLOCKING_QUERY, the __fsetlocking() function returns the current locking type of the stream without changing it.

Usage notes

1. The _fsetlocking() function acts upon FILE* objects. It is possible to have the same physical file represented by multiple FILE* objects that are not recognized as being equivalent. For example, fopen() opens a file in thread A and sets the locking type as FSETLOCKING_INTERNAL. Then fopen() opens the same file in another thread B and sets the locking type as FSETLOCKING_BYCALLER. If both threads begin to write to their FILE* objects, the results are unpredictable.
2. The __fsetlocking() function impacts the behavior of all other stream operation functions. Using __fsetlocking() to modify the locking type while any of these stream operation functions are executing might produce undesirable behaviors, including hang conditions. You must make sure that __fsetlocking() is used only when no other functions are acting upon the stream.

Returned value

The __fsetlocking() function returns the locking type in effect before the call to __fsetlocking().

The __fsetlocking() function returns -1 if the stream or the locking type is not valid and sets errno to nonzero.

Error Code

Description

EBADF

The stream specified by *stream* is not valid.

EINVAL

The locking type is not valid.

Example

CELEBF85

```
/* CELEBF85

   This example sets LOCKING_TYPE as locking type to a stream.

   It checks that the fopen() function is successful and that
   locking type is setted to the stream and queried from the stream.

*/

#include <stdio.h>
#include <stdio_ext.h>

int main(void)
{
    FILE *stream;
    int locktype;
    int nwrite;
    int buflen;
    char buf[5]="1234";

    if((stream = fopen("myfile.dat", "w+b")) != NULL )
    {
        locktype = __fsetlocking(stream,FSETLOCKING_BYCALLER);
        locktype = __fsetlocking(stream,FSETLOCKING_QUERY);
        if(locktype == FSETLOCKING_BYCALLER){
            printf("__fsetlocking succeeds! \n\
            Lock type is FSETLOCKING_BYCALLER\n");
        }
        buflen = strlen(buf);
        flockfile(stream);
        nwrite = fwrite(buf, 1, buflen, stream);
        if(nwrite < buflen){
            printf("fwrite did not return expected number of bytes\n");
        }
        funlockfile(stream);
    }
}
```

```

    }
    return(0);
}

```

Output

```
__fsetlocking succeeds! Lock type is FSETLOCKING_BYCALLER
```

fsetpos() — Set file position

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```

#include <stdio.h>

int fsetpos(FILE *stream, const fpos_t *pos);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int fsetpos_unlocked(FILE *stream, const fpos_t *pos);

```

General description

The `fsetpos()` function moves the file position associated with *stream* to a new location within the file according to the value of the object pointed to by *pos*. The value of *pos* must be obtained by a call to the `fgetpos()` function. If successful, the `fsetpos()` function clears the EOF indicator, and cancels the effect of any previous `ungetc()` or `ungetwc()` function on the same stream.

If the call to the `fsetpos()` function is not valid, the call is treated as a flush, and the `ungetc` characters are discarded.

The `fsetpos()` function handles the double-byte character set (DBCS) state information for wide-oriented files. An `fsetpos()` function call to a position that no longer exists results in an error.

For text streams, the DBCS shift state is recalculated from the start of the record, which has a performance implication. The `fsetpos()` function repositions to the start of a multibyte character.

For binary streams, the DBCS shift state is set to the state saved by the `fsetpos()` function. If the record has been updated in the meantime, the shift state might be incorrect.

After the `fsetpos()` function call, the next operation on a stream in update mode can be an input or output operation.

Multivolume data sets performance: Using the `fgetpos()` and `fsetpos()` functions generally results in better repositioning performance compared to the `ftell()` and `fseek()` functions when working with multivolume data sets.

Large file support for MVS data sets, VSAM data sets, and z/OS UNIX files: The `fsetpos()` function implicitly supports operating on large files. Defining the `_LARGE_FILES` feature test macro is not required to use this function on large files.

Usage notes

1. Repositioning within a wide-oriented file and performing updates is strongly discouraged because it is not possible to predict if the update will overwrite part of a multibyte string or character, thereby invalidating subsequent data. For example, you could inadvertently add data that overwrites a shift-out. The following data expects the shift-out to be there, so is not valid if it is treated as if in the initial shift state. Repositioning to the end of the file and adding new data is safe. For information about wide-oriented streams, see *z/OS XL C/C++ Programming Guide*.
2. The `fsetpos_unlocked()` function is functionally equivalent to the `fsetpos()` function with the exception that it is not threadsafe. The `fsetpos()` function can safely be used in a multithreaded application if, and only if, it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

If successful in changing the current position of the file, the `fsetpos()` function returns 0.

If unsuccessful, the `fsetpos()` function returns nonzero and sets `errno`.

Special behavior for XPG4.2: If unsuccessful, the `fsetpos()` function returns -1 and sets `errno` to one of the following values:

Error Code

Description

ESPIPE

The underlying file type for the stream is a PIPE or a socket.

Example

```
/* This example opens a file called myfile.dat for reading.
   After performing input operations (not shown), it moves the file
   pointer to the beginning of the file and rereads the first byte.
*/
#include <stdio.h>

int main(void)
{
    FILE *stream;
    int retcode;
    fpos_t pos, pos1, pos2, pos3;
    char ptr[20]; /* existing file 'myfile.dat' has 20 byte records */

    /* Open file, get position of file pointer, and read first record */

    stream = fopen("myfile.dat", "rb");
    fgetpos(stream, &pos);
    pos1 = pos;
    if (!fread(ptr, sizeof(ptr), 1, stream))
        printf("fread error\n");

    /* Perform a number of read operations. The value of 'pos'
       changes if 'pos' is passed to fgetpos() */

    :

    /* Re-set pointer to start of file and re-read first record */
```

```
fsetpos(stream,&pos1);
if (!fread(ptr,sizeof(ptr),1,stream))
    printf("fread error\n");

fclose(stream);
}
```

fstat(), fstat64() — Get status information about a file

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

fstat:

```
#define _POSIX_SOURCE
#include <sys/stat.h>

int fstat(int fildes, struct stat *info);
```

fstat64:

```
#define _LARGE_TIME_API
#define _POSIX_SOURCE
#include <sys/stat.h>

int fstat64 (int fildes, struct stat64 *info);
```

Compile requirement: Use of the fstat64() function requires the long long data type. For more information on how to make the long long data type available, see [z/OS XL C/C++ Language Reference](#).

General description

Gets status information about the file specified by the open file descriptor *fil*des and stores it in the area of memory indicated by the *info* argument. The status information is returned in a stat or stat64 structure, as defined in the sys/stat.h header file. The elements of this structure are described in [“stat\(\), stat64\(\) — Get file information” on page 1706](#).

The fstat64() function behaves exactly like fstat() except fstat64() uses structure stat64 instead of struct stat to support time beyond 03:14:07 UTC on January 19, 2038.

Note: Environment variable _EDC_EOVERFLOW can be used to control behavior of fstat() with respect to detecting an EOVERFLOW condition for z/OS UNIX files. By default, fstat() does not set

EOVERFLOW when the file size cannot be represented correctly in structure pointed to by info. When `_EDC_EOVERFLOW` is set to YES, `fstat()` will check for an overflow condition.

Large file support for z/OS UNIX files: Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the [long long data type support](#) enabled and define the `_LARGE_FILES` feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the `_LARGE_FILES` feature test macro as well.

Returned value

If successful, `fstat()` returns 0.

If unsuccessful, `fstat()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

fildev is not a valid open file descriptor.

EINVAL

info contains a NULL.

EIO

Added for XPG4.2: An I/O error occurred while reading from the file system.

EOVERFLOW

The file size in bytes or the number of blocks allocated to the file or the file serial number cannot be represented correctly in the structure pointed to by info.

Note: The `fstat()` function might fail with error code EOVERFLOW if large file support is not enabled. The environment variable `_EDC_EOVERFLOW` controls this behavior. If `_EDC_EOVERFLOW` is set to YES the new behavior will take place. The default for `_EDC_EOVERFLOW` is NO.

Example

CELEBF47 This example gets status information for the file called `temp.file`.

```
/* CELEBF47 */
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>
#include <time.h>

main() {
    char fn[]="temp.file";
    struct stat info;
    int fd;

    if ((fd = creat(fn, S_IWUSR)) < 0)
        perror("creat() error");
    else {
        if (fstat(fd, &info) != 0)
            perror("fstat() error");
        else {
            puts("fstat() returned:");
            printf("  inode:   %d\n", (int) info.st_ino);
            printf(" dev id:  %d\n", (int) info.st_dev);
            printf("   mode:  %08x\n", info.st_mode);
            printf("  links:  %d\n", info.st_nlink);
            printf("   uid:   %d\n", (int) info.st_uid);
            printf("   gid:   %d\n", (int) info.st_gid);
            printf("created:  %s", ctime(&info.st_createtime));
        }
        close(fd);
    }
}
```

```
        unlink(fn);
    }
}
```

Output

fstat() returned the following output:

```
inode:    3057
dev id:   1
mode:    03000080
links:    1
uid:     25
gid:     500
created:  Fri Jun 16 16:03:16 2006
```

fstatat(), fstatat64() – Get file status information relative to a directory file descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1-2008 Single UNIX Specification, Version 4 | both | |

Format

fstatat:

```
#define _POSIX_C_SOURCE 200809L
#include <fcntl.h>
#include <sys/stat.h>

int fstatat(int dirfd, const char *pathname, struct stat *statbuf, int flags);
```

fstatat64:

```
#define _LARGE_TIME_API
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/stat.h>

int fstatat64(int dirfd, const char *pathname, struct stat64 *statbuf, int flags);
```

Compile requirement: Use of the fstatat64() function requires the long long data type. For more information on how to make the long long data type available, see [z/OS XL C/C++ Language Reference](#).

General description

fstatat() is equivalent to stat() except for the following differences.

- If the *pathname* is relative, it is interpreted relative to the directory referred to by the file descriptor *dirfd* (rather than relative to the current working directory of the calling process, as is done by *stat()* for a relative *pathname*).
- If *pathname* is relative and *dirfd* is the special value *AT_FDCWD*, *pathname* is interpreted relative to the current working directory of the calling process.

If *pathname* is absolute, *dirfd* is ignored.

The *flags* argument is a bit mask consisting of zero or the following flag:

AT_SYMLINK_NOFOLLOW

If *pathname* is a symbolic link, the status of the symbolic link is returned.

Note: Environment variable *_EDC_EOVERFLOW* can be used to control behavior of *fstatat()* regarding detecting an *EOverflow* condition for z/OS UNIX files. By default, *fstatat()* does not set *EOverflow* when the file size cannot be represented correctly in the structure that is pointed to by *statbuf*. When *_EDC_EOVERFLOW* is set to YES, *fstatat()* checks for an overflow condition.

Large file support for z/OS UNIX files: *fstatat64()* automatically supports large z/OS UNIX files for both *AMODE 31* and *AMODE 64 C/C++* applications, which means the *_LARGE_FILES* feature test macro does not need to be defined. However, *fstatat()* automatically supports large z/OS UNIX files for *AMODE 64 C/C++* applications only. *AMODE 31 C/C++* applications must be compiled with the [long long data type support](#) enabled and define the *_LARGE_FILES* feature test macro before any headers are included to enable *fstatat()* to operate on z/OS UNIX files that are larger than 2 GB. File size and offset fields are enlarged to 63 bits. Therefore, any other function operating on the file is required to define the *_LARGE_FILES* feature test macro.

Returned value

If successful, *fstatat()* and *fstatat64()* return 0.

If unsuccessful, *fstatat()* and *fstatat64()* return -1 and sets *errno* to one of the following values:

Error Code

Description

EACCES

The process does not have search permission on some component of the *pathname* prefix.

EBADF

The file descriptor that is specified for *dirfd* is incorrect.

EINVAL

pathname is a NULL pointer, *statbuf* is a NULL pointer, an invalid flag was specified in *flags*, or *dot(.)* or *dot-dot(. .)* is specified in the *pathname*.

ELOOP

A loop exists in symbolic links that are encountered during resolution of the *pathname* argument. This error is returned if more than *POSIX_SYMLINK_LOOP* (defined in the *limits.h* header file) symbolic links are encountered during resolution of the *pathname* argument.

ENAMETOOLONG

pathname is longer than *PATH_MAX* characters, or some component of *pathname* is longer than *NAME_MAX* characters while *_POSIX_NO_TRUNC* is in effect. For symbolic links, the length of the path name string that is substituted for a symbolic link exceeds *PATH_MAX*. The *PATH_MAX* and *NAME_MAX* values can be determined with *pathconf()*.

ENOENT

There is no file that is named *pathname*, or *pathname* is an empty string.

ENOTDIR

A component of the *pathname* prefix names an existing file that is not a directory or a symbolic link to a directory, or the *pathname* argument contains at least one non-*<slash>* character and ends with one or more trailing *<slash>* characters and the last *pathname* component names an existing file that is not a directory or a symbolic link to a directory.

EOVERFLOW

The file size in bytes or the number of blocks that are allocated to the file or the file serial number cannot be represented correctly in the structure that is pointed to by *statbuf*.

Note: The `fstatat()` function might fail with error code `EOVERFLOW` if large file support is not enabled. The environment variable `_EDC_EOVERFLOW` controls this behavior. If `_EDC_EOVERFLOW` is set to `YES`, the new behavior takes place. The default for `_EDC_EOVERFLOW` is `NO`.

fstatfs() — Get file system statistics

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <sys/statfs.h>

int fstatfs(int fd, struct statfs *buf);
```

General description

The `fstatfs()` system call returns information about a mounted file system. *fd* is a descriptor refer to an open file. *buf* is a pointer to a structure of `statfs` as defined in the `sys/statfs.h` header file.

Returned value

If successful, `fstatfs()` returns 0.

If unsuccessful, `fstatfs()` returns -1 and sets `errno` to one of the following values:

Error Code**Description****EBADF**

The *fd* argument is not a valid file descriptor.

EINTR

A signal is caught during the function execution.

EIO

An I/O error occurs while reading the file system.

EINVAL

A parameter is specified incorrectly.

ERANGE

The result is too large to fit in the available buffer space.

Related information

- [“sys/statvfs.h — File system status” on page 71](#)

fstatvfs() — Get file system information

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/statvfs.h>

int fstatvfs(int fildev, struct statvfs *fsinfo);
```

General description

The `fstatvfs()` function obtains information about the file system containing the file referenced by *fildev* and stores it in the area of memory pointed to by the *fsinfo* argument.

The information is returned in a `statvfs` structure, as defined in the `sys/statvfs.h` header file. The elements of this structure are described in [“statvfs\(\) — Get file system information” on page 1712](#). If `fstatvfs()` successfully determines this information, it stores it in the area indicated by the *fsinfo* argument. The size of the buffer determines how much information is stored; data that exceeds the size of the buffer is truncated.

Returned value

If successful, `fstatvfs()` returns 0.

If unsuccessful, `fstatvfs()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

fildev is not a valid open file descriptor.

EINTR

A signal was caught during the execution of the function.

EIO

An I/O error has occurred while reading the file system.

Example

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/statvfs.h>
#include <stdio.h>

main()
{
    char fn[]="temp.file";
    int fd;
    struct statvfs buf;

    if ((fd = creat(fn,S_IWUSR)) < 0)
        perror("creat() error");
```

```

else {
    if (fstatvfs(fd, &buf) == -1)
        perror("fstatvfs() error");
    else {
        printf("each block is %d bytes big\n", buf.f_frsize);
        printf("there are %d blocks available\n", buf.f_bavail);
        printf("out of a total of %d in bytes,\n", buf.f_blocks);
        printf("that's %.0f bytes free out of a total of %.0f\n",
            ((double)buf.f_bavail * buf.f_frsize),
            ((double)buf.f_blocks * buf.f_frsize));
    }
    close(fd);
    unlink(fn);
}
}

```

Output

```

each block is 4096 bytes big
there are 2089 blocks available
out of a total of 2400 in bytes,
that's 8556544 bytes free out of a total of 9830400

```

fsync() — Write changes to direct-access storage

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX1_SOURCE 2
#include <unistd.h>

int fsync(int fildes);
```

General description

Transfers all data for the file indicated by the open file descriptor *fil*des to the storage device associated with *fil*des. fsync() does not return until the transfer has completed, or until an error is detected.

Returned value

If successful, fsync() returns 0.

If unsuccessful, fsync() returns -1 and sets errno to one of the following values:

Error Code

Description

EBADF

*fil*des is not a valid open file descriptor.

EINVAL

The file is not a regular file.

Example

CELEBF48

```
/* CELEBF48 */
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>
#include <stdlib.h>

#define mega_string_len 250000

main() {
    char *mega_string;
    int fd, ret;
    char fn[]="fsync.file";

    if ((mega_string = (char*) malloc(mega_string_len)) == NULL)
        perror("malloc() error");
    else if ((fd = creat(fn, S_IWUSR)) < 0)
        perror("creat() error");
    else {
        memset(mega_string, 's', mega_string_len);
        if ((ret = write(fd, mega_string, mega_string_len)) == -1)
            perror("write() error");
        else {
            printf("write() wrote %d bytes\n", ret);
            if (fsync(fd) != 0)
                perror("fsync() error");
            else if ((ret = write(fd, mega_string, mega_string_len)) == -1)
                perror("write() error");
            else
                printf("write() wrote %d bytes\n", ret);
        }
        close(fd);
        unlink(fn);
    }
}
```

Output

```
write() wrote 250000 bytes
write() wrote 250000 bytes
```

ftell() — Get current file position

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```
#include <stdio.h>

long int ftell(FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

long int ftell_unlocked(FILE *stream);
```

General description

The `ftell()` function obtains the current value of the file position indicator for the stream pointed to by *stream*.

Behavior for binary streams: ISO C/C++ states that the `ftell()` function returns relative byte offsets from the beginning of the file for binary files. Under IBM z/OS C/C++, this is true except for record-oriented files that have variable length records. For these types of files, the `ftell()` function returns an encoded offset.

If you want to use relative-byte offsets for these types of files, you can either open the file with the `BYTESEEK` `fopen()` function option or set the `_EDC_BYTE_SEEK` environment variable before opening.

Behavior for text streams: The `ftell()` function returns an encoded offset for text streams.

Behavior for record I/O: For files opened for record I/O using the `type=record` open mode parameter, the `ftell()` function returns the relative record offset of the current file position from the beginning of the file. All offset values are given in terms of records.

Behavior for blocked I/O: For files opened for blocked I/O using the `type=blocked` open mode parameter, the `ftell()` function returns the relative block offset of the current file position from the beginning of the file. All offset values are given in terms of blocks.

Multivolume data sets performance: Using the `fgetpos()` and `fsetpos()` functions generally results in better repositioning performance compared to the `ftell()` and `fseek()` functions when working with multivolume data sets.

Large file support for MVS data sets, VSAM data sets, and z/OS UNIX files: For AMODE 31 C/C++ applications, the `ftell()` function accepts a signed 4-byte offset and therefore cannot be used to directly or relatively position to offsets beyond 2 GB - 1. To avoid repositioning limitations, AMODE 31 C/C++ applications should define the `_LARGE_FILES` feature test macro before any headers are included and replace the `ftell()` function with the `ftello()` function. For AMODE 64 C/C++ applications, there are no restrictions on using the `ftell()` function with large files. The AMODE 64 version automatically accepts a signed 8-byte offset.

Usage note

The `ftell_unlocked()` function is functionally equivalent to the `ftell()` function with the exception that it is not threadsafe. The `ftell()` function can safely be used in a multithreaded application if, and only if, it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

If successful, the `ftell()` function returns the calculated value.

If unsuccessful, the `ftell()` function returns -1 and sets `errno` to a positive value.

Special behavior for XPG4.2: If unsuccessful, the `ftell()` function returns -1 and sets `errno` to one of the following values:

Error Code

Description

EOverflow

For `ftell()`, the current file offset cannot be represented correctly in an object of type `long`.

Note: Environment variable `_EDC_EOverflow` can be used to control behavior of the `ftell()` function with respect to detecting an `EOverflow` condition for z/OS UNIX files. By default, the `ftell()` function will not set `EOverflow` when the file offset cannot be represented correctly. When `_EDC_EOverflow` is set to YES, the `ftell()` function will check for an overflow condition.

ESPIPE

The underlying file type for the stream is a PIPE or a socket.

Example

```
/* This example opens the file myfile.dat for reading.
   The current file pointer position is stored in the variable pos.
*/
#include <stdio.h>

int main(void)
{
    FILE *stream;
    long int pos;

    stream = fopen("myfile.dat", "rb");

    /* The value returned by ftell can be used by fseek()
       to set the file pointer if 'pos' is not -1          */

    if ((pos = ftell(stream)) != EOF)
        printf("Current position of file pointer found\n");
    fclose(stream);
}
```

ftello() — Get current file position

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 Language Environment | both | OS/390 V2R10 |

Format

```
#define _XOPEN_SOURCE 500
#include <stdio.h>

off_t ftello(FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

off_t ftello_unlocked(FILE *stream);
```

General description

The `ftello()` function obtains the current value of the file position indicator for the stream pointed to by *stream*.

Behavior for binary streams: ISO C/C++ states that the `ftello()` function returns relative byte offsets from the beginning of the file for binary files. Under IBM z/OS C/C++, this is true except for record-oriented files that have variable length records. For these types of files, the `ftello()` function returns an encoded offset.

If you want to use relative-byte offsets for these types of files, you can either open the file with the `BYTESEEK` `fopen()` function option or set the `_EDC_BYTE_SEEK` environment variable before opening.

Behavior for text streams: The `ftello()` function returns an encoded offset for text streams.

Behavior for record I/O: For files opened for record I/O using the `type=record` open mode parameter, the `ftello()` function returns the relative record offset of the current file position from the beginning of the file. All offset values are given in terms of records.

Behavior for blocked I/O: For files opened for blocked I/O using the type=blocked open mode parameter, the ftello() function returns the relative block offset of the current file position from the beginning of the file. All offset values are given in terms of blocks.

Multivolume data sets performance: Using the fgetpos() and fsetpos() functions generally results in better repositioning performance compared to the ftello() and fseeko() functions when working with multivolume data sets.

Large file support for MVS data sets, VSAM data sets, and z/OS UNIX files: For AMODE 31 C/C++ applications, the ftello() function accepts a signed 4-byte offset and therefore cannot be used to directly or relatively position to offsets beyond 2 GB - 1. To avoid repositioning limitations, AMODE 31 C/C++ applications should define the _LARGE_FILES feature test macro before any headers are included. For AMODE 64 C/C++ applications, there are no restrictions on using the ftello() function with large files. The AMODE 64 version automatically accepts a signed 8-byte offset.

Usage notes

1. The ftello_unlocked() function is functionally equivalent to the ftello() function with the exception that it is not threadsafe. The ftello() function can safely be used in a multithreaded application if, and only if, it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

If successful, the ftello() function returns the calculated value.

If unsuccessful, the ftello() function returns (off_t)-1 and sets errno to one of the following values:

Error Code

Description

EBADF

The file descriptor underlying stream is not an open file descriptor.

E_OVERFLOW

The current file offset cannot be represented correctly in an object of type off_t.

ESPIPE

The file descriptor underlying stream is associated with a pipe or FIFO.

Example

```
/* This example opens the file myfile.dat for reading.
   The current file pointer position is stored in the variable
   pos.
*/
#define _XOPEN_SOURCE 500
#define _LARGE_FILES 1
#include <stdio.h>

int main(void)
{
    FILE *stream;
    off_t pos;

    stream = fopen("/myfile.dat", "rb");

    /* The value returned by ftello() can be used by fseeko()
       to set the file pointer if 'pos' is not -1 */

    if ((pos = ftello(stream)) != -1LL)
        printf("Current position of file pointer found\n");
    fclose(stream);
}
```

ftime(), ftime64() — Set the date and time

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

ftime:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/timeb.h>

int ftime(struct timeb *tp);
```

ftime64:

```
#define _LARGE_TIME_API
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/timeb.h>

int ftime64(struct timeb64 *tp);
```

Compile requirement: Use of the `ftime64()` function requires the `long long` data type. For more information on how to make the `long long` data type available, see [z/OS XL C/C++ Language Reference](#).

General description

The `ftime()` function sets the `time` and `millitm` members of the `timeb` structure pointed to by `tp` to contain seconds and milliseconds, respectively, of the current time in seconds since 00:00:00 Coordinated Universal Time (UTC), January 1, 1970.

Note: The `ftime()` function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The `time()` function is preferred for portability.

The `ftime64()` function behaves exactly like `ftime()` except `ftime64()` supports time beyond 03:14:07 UTC on January 19, 2038.

Returned value

If successful, `ftime()` returns 0.

If overflow occurs¹, `ftime()` returns -1.

Related information

ftok() — Generate an interprocess communication (IPC) key

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/ipc.h>

key_t ftok(const char *path, int id);
```

General description

The `ftok()` function returns a key based on *path* and *id* that is usable in subsequent calls to `msgget()`, `semget()`, and `shmget()`. The *path* argument must be the path name of an existing file that the process is able to `stat()`.

The `ftok()` function returns the same key value for all paths that name the same file, when called with the same *id* value. If a different *id* value is given, or a different file is given, a different key is returned. Only the low-order 8-bits of *id* are significant, and must be nonzero.

Note: The `ftok()` function does not guarantee unique key generation. The key is created by combining the given *id* byte, the lower 16 bits of the inode number, and the lower 8 bits of the device number into a 32-bit result. The occurrence of key duplication is very rare.

Returned value

If successful, `ftok()` returns a key.

If unsuccessful, `ftok()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

Search permission is denied for a component of the path prefix.

¹ Overflow occurs when the current time in seconds since 00:00:00 UTC, January 1, 1970 exceeds the capacity of the *time* member of the `timeb` structure pointed to by *tp*. The *time* member is type `time_t`.

EINVAL

The low-order 8-bits of *id* are zero.

ELOOP

Too many symbolic links were encountered in resolving path.

ENAMETOOLONG

One of the following error conditions exists:

- The length of the *path* argument exceeds **PATH_MAX** or a path name component is longer than **NAME_MAX**.
- The path name resolution of a symbolic link produced an intermediate result whose length exceeds **PATH_MAX**.

ENOENT

A component of *path* does not name an existing file or *path* is an empty string.

ENOTDIR

A component of the path prefix is not a directory.

Related information

ftruncate() — Truncate a file

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1a XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX1_SOURCE 2
#include <unistd.h>

int ftruncate(int fil-des, off_t length);
```

General description

The `ftruncate()` function truncates the file indicated by the open file descriptor *fil-des* to the indicated *length*. *fil-des* must be a regular file that is open for writing. If the file size exceeds *length*, any extra data is discarded. If the file size is smaller than *length*, bytes between the old and new lengths are read as zeros. A change to the size of the file has no impact on the file offset.

Special behavior for XPG4.2: If the `ftruncate()` function would cause the file size to exceed the soft file size limit for the process, `ftruncate()` will fail and a SIGXFSZ signal will be generated for the process.

If successful, the `ftruncate()` function marks the `st_ctime` and `st_mtime` fields of the file.

If unsuccessful, the `ftruncate()` function leaves the file unchanged.

Large file support for z/OS UNIX files: Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the [long long data type support](#) enabled and define the `_LARGE_FILES` feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the `_LARGE_FILES` feature test macro as well.

Returned value

If successful, the `ftruncate()` function returns 0.

If unsuccessful, the `ftruncate()` function returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

filides is not a valid open file descriptor.

EFBIG

The length argument was greater than the maximum file size.

EINTR

Added for XPG4.2: A signal was caught during execution.

EINVAL

filides does not refer to a regular file, it is opened read-only, or the length specified is incorrect.

EIO

Added for XPG4.2: An I/O error occurred while reading from or writing to a file system.

EROFS

The file resides on a read-only file system.

Example

CELEBF49

```
/* CELEBF49 */
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>
#include <stdlib.h>

#define string_len 1000

main() {
    char *mega_string;
    int fd, ret;
    char fn[]="write.file";
    struct stat st;

    if ((mega_string = (char*) malloc(string_len)) == NULL)
        perror("malloc() error");
    else if ((fd = creat(fn, S_IWUSR)) < 0)
        perror("creat() error");
    else {
        memset(mega_string, '0', string_len);
        if ((ret = write(fd, mega_string, string_len)) == -1)
            perror("write() error");
        else {
            printf("write() wrote %d bytes\n", ret);
            fstat(fd, &st);
            printf("the file has %ld bytes\n", (long) st.st_size);
            if (ftruncate(fd, 1) != 0)
                perror("ftruncate() error");
            else {
                fstat(fd, &st);
                printf("the file has %ld bytes\n", (long) st.st_size);
            }
        }
    }
}
```

```

    }
    }
    close(fd);
    unlink(fn);
}

```

Output

```

write() wrote 1000 bytes
the file has 1000 bytes
the file has 1 bytes

```

ftrylockfile() — stdio locking

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|--------------|
| Single UNIX Specification, Version 3 | both | z/OS V1R8 |

Format

```

#define _UNIX03_SOURCE
#include <stdio.h>

int ftrylockfile(FILE *file);

```

General description

This function provides explicit application-level locking of stdio (FILE*) objects. The flockfile() family of functions can be used by a thread to delineate a sequence of I/O statements that are executed as a unit.

If the (**FILE***) object specified by the ftrylockfile() function is available, ownership is granted to the thread for the (FILE*) object and the internal lock count is increased. If the thread has previously been granted ownership, the internal lock count is increased. If another thread has been granted ownership, ftrylockfile() does not grant ownership to the calling thread and returns a non-zero value. ftrylockfile() is a non-blocking version of flockfile().

The internal lock count allows matching calls to flockfile() (or successful calls to ftrylockfile()) and funlockfile() to be nested.

z/OS consideration: The flockfile() family of functions acts upon FILE * objects. It is possible to have the same physical file represented by multiple FILE * objects that are not recognized as being equivalent. For example, fopen() opens a file and open() opens the same file, and then fdopen() creates a FILE * object. In this case, locking the first FILE * does not prevent the second FILE * from also being locked and used.

Returned value

The ftrylockfile() function returns zero for success and non-zero to indicate that the lock cannot be acquired.

Error Code
Definition

EBADF

The input (**FILE ***) object is not valid.

EBUSY

The input (**FILE ***) object is locked by another thread.

Note: It is the application’s responsibility to prevent deadlock (or looping). For example, deadlock (or looping) may occur if a (FILE *) object is closed, or a thread is terminated, before relinquishing all locked (FILE *) objects.

ftw(), ftw64() – Traverse a file tree

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

ftw:

```
#define _XOPEN_SOURCE
#include <ftw.h>

int ftw(const char *path,
        int (*fn)(const char *, const struct stat *, int),
        int ndirs);
```

ftw64:

```
#define _LARGE_TIME_API
#define _XOPEN_SOURCE
#include <ftw.h>

int ftw64(const char *path,
           int (*fn)(const char *, const struct stat64 *, int),
           int ndirs);
```

Compile requirement: Use of the ftw64() function requires the long long data type. For more information on how to make the long long data type available, see [z/OS XL C/C++ Language Reference](#).

General description

The ftw() function recursively descends the directory hierarchy rooted in *path*. For each object in the hierarchy, ftw() calls the function pointed to by *fn*, passing it a pointer to a NULL-terminated string containing the name of the object, a pointer to a *stat* structure containing information about the object, and an integer. Possible values of the integer, defined in the <ftw.h> header, are:

FTW_D
for a directory

FTW_DNR

for a directory that cannot be read

FTW_F

for a file

FTW_SL

for a symbolic link

FTW_NS

for an object other than a symbolic link on which `stat()` could not be successfully executed. If the object is a symbolic link, and `stat()` failed, it is unspecified whether `ftw()` passes `FTW_SL` or `FTW_NS` to the user-supplied function.

If the integer is `FTW_DNR`, descendants of that directory will not be processed. If the integer is `FTW_NS`, the `stat` structure will contain undefined values. An example of an object that would cause `FTW_NS` to be passed to the function pointed to by *fn* would be a file in a directory with read but without execute (search) permission.

The `ftw()` function visits a directory before visiting any of its descendants.

The `ftw()` function uses at most one file descriptor for each level in the tree.

The argument *ndirs* should be in the range of 1 to `OPEN_MAX`.

The tree traversal continues until the tree is exhausted, an invocation of *fn* returns a nonzero value, or some other error, other than `[EACCES]`, is detected within `ftw()`.

The *ndirs* argument specifies the maximum number of directory streams or file descriptors or both available for use by `ftw()` while traversing the tree. When `ftw()` returns it closes any directory streams and file descriptors it uses not counting any opened by the application-supplied *fn* function.

The `ftw64()` function behaves exactly like `ftw()` except `ftw64()` uses structure `stat64` instead of struct `stat` to support time beyond 03:14:07 UTC on January 19, 2038.

Large file support for z/OS UNIX files: `ftw64()` automatically supports large z/OS UNIX files for both `AMODE 31` and `AMODE 64` C/C++ applications, which means there is no need for `_LARGE_FILES` feature test macro to be defined. As for `ftw()`, the automatic support is only for `AMODE 64` C/C++ applications. `AMODE 31` C/C++ applications must be compiled with the [long long data type support](#) enabled and define the `_LARGE_FILES` feature test macro before any headers are included to enable `ftw()` to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the `_LARGE_FILES` feature test macro as well.

Returned value

If the tree is exhausted, `ftw()` returns 0. If the function pointed to by *fn* returns a nonzero value, `ftw()` stops its tree traversal and returns whatever value was returned by the function pointed to by *fn()*.

If `ftw()` detects an error, it returns -1 and sets `errno` to one of the following values. All other `errno`s returned by `ftw()` are unchanged.

Error Code**Description****EACCES**

Search permission is denied for any component of *path* or read permission is denied for *path*.

EINVAL

The value of the *ndirs* argument is not valid.

ELOOP

Too many symbolic links were encountered.

ENAMETOOLONG

One of the following error conditions exists:

- Path name resolution of a symbolic link produced an intermediate result whose length exceeds PATH_MAX.
- The length of *path* exceeds PATH_MAX, or a path name component is longer than PATH_MAX.

ENOENT

A component of *path* does not name an existing file or *path* is an empty string.

ENOTDIR

A component of *path* is not a directory.

funlockfile() — stdio unlocking

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|--------------|
| Single UNIX Specification, Version 3 | both | z/OS V1R8 |

Format

```
#define _UNIX03_SOURCE
#include <stdio.h>

void funlockfile(FILE *file);
```

General description

This function provides explicit application-level unlocking of stdio (FILE*) objects. The flockfile() family of functions can be used by a thread to delineate a sequence of I/O statements that are executed as a unit.

The funlockfile() function reduces the internal lock count. When the count is reduced to zero, the funlockfile() function relinquishes the ownership granted to the thread, of a (FILE *) object. If a call to funlockfile() is made by a thread which has not been granted ownership of a (FILE *) object, the call is ignored and the lock count is not reduced.

The internal lock count allows matching calls to flockfile() (or successful calls to ftrylockfile()) and funlockfile() to be nested.

z/OS consideration: The flockfile() family of functions acts upon FILE * objects. It is possible to have the same physical file represented by multiple FILE * objects that are not recognized as being equivalent. For example, fopen() opens a file and open() opens the same file, and then fdopen() creates a FILE * object. In this case, locking the first FILE * does not prevent the second FILE * from also being locked and used.

Returned value

None.

Notes:

1. Because the `funlockfile()` function returns void, no error information can be returned. If an invalid (FILE *) object is input, it will be ignored.
2. It is the application's responsibility to prevent deadlock (or looping). For example, deadlock (or looping) may occur if a (FILE *) object is closed, or a thread is terminated, before relinquishing all locked (FILE *) objects.

Related information

fupdate() — Update a VSAM record

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <stdio.h>

size_t fupdate(const void *buffer, size_t size, FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

size_t fupdate_unlocked(const void *buffer, size_t size, FILE *stream);
```

General description

Replaces the last record read from the VSAM cluster pointed to by *stream*, with the contents of *buffer* for a length of *size*. See “Performing VSAM I/O Operations” in [z/OS XL C/C++ Programming Guide](#) for details.

The `fupdate()` function can be used *only* with a VSAM data set opened in update mode (`rb+ / r+b`, `ab+ / a+b`, or `wb+ / w+b`) with the `type=record` option.

The `fupdate()` function can only be used after an `fread()` call has been performed and before any other operation on that file pointer. For example, if you need to acquire the file position using `ftell()` or `fgetpos()`, you can do it either before the `fread()` or after the `fupdate()`. An `fread()` after an `fupdate()` retrieves the next updated record.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

`fupdate_unlocked()` is functionally equivalent to `fupdate()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

KSDS or KSDS PATH: The size of the record can be changed by a call to `fupdate()`. If the size is greater than the existing record size but less than or equal to the maximum record length of the file, a call to `fupdate()` will lengthen the record up to the maximum record length of the file. If the size is greater than the maximum record length of the file, the record is truncated and `errno` is set. If the size is less than or

equal to the existing record length, all size bytes of the record are written, and no padding or overlaying occurs. The records will be shortened and not partially updated.

ESDS, ESDS PATH, or RRDS: The size of a record cannot be changed by a call to `fupdate()`. If you call `fupdate()` with *size* smaller than the size of the existing record, *size* bytes of the record are updated; the remaining bytes are unchanged, and the record length remains unchanged.

The key of reference (the prime key if opened as a cluster, the alternative index key if opened as a path) cannot be changed by an update. If a data set is opened as a path, the prime key cannot be changed by an update. For RRDS files, the `buffer` must be an RRDS record structure, which includes an `rrds_key`.

Returned value

If successful, `fupdate()` returns the size of the updated record.

If the update operation is not successful, `fupdate()` returns 0.

Example

CELEBF50

```
/* CELEBF50 */
#include <stdio.h>

int main(void)
{
    FILE *stream;
    struct record { char name[20];
                   char address[40];
                   int age;
                   } buffer;
    int vsam_rc, numread;

    stream = fopen("DD:MYCLUS", "rb+", type=record");
    numread = fread(&buffer, 1, sizeof(buffer), stream);
    /* ... Update fields in the record ... */
    vsam_rc = fupdate(&buffer, sizeof(buffer), stream);
}
```

futimes() — Change file access and modification times

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE 1

#include <sys/time.h>

int futimes(int fd, const struct timeval times[2]);
```

General description

The `futimes()` function changes the access and modification times of a file that is pointed to by the `fd` argument to the value of the `times` argument. `futimes()` behaves the same as `utimes()`, except that `futimes()` uses a file descriptor `fd` to specify the file whose timestamps are to be changed while `utimes()` uses a path name to specify the file.

The `times` argument is an array of two `timeval` structures. The first array member represents the date and time of the last access, and the second member represents the date and time of the last modification. The times in the `timeval` structure are measured in seconds and microseconds since the Epoch, but the actual times that are stored with the file are rounded to the nearest second. The `timeval` members are:

tv_sec

Seconds since 1 January 1970 (Coordinated Universal Time)

tv_usec

Microseconds

If the `times` argument is a NULL pointer, the access and modification times of the file are set to the current time.

Returned value

If successful, `futimes()` returns 0.

If unsuccessful, `futimes()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

The process does not have search permission on some components of the `path` prefix; or all of the following are true:

- `times` is NULL.
- The effective user ID of the process does not match the owner of the file.
- The process does not have write permission on the file.

EBADF

The `fd` argument is not a valid file descriptor.

EPERM

`times` is not NULL. The effective user ID of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges.

EROFS

The file is on a read-only file system.

Related information

- [“sys/time.h — Time types” on page 71](#)
- [“utime\(\), utime64\(\) — Set file access and modification times” on page 1952](#)

- [“lutimes\(\) — Change file access and modification times” on page 1031](#)

futimesat() — Change timestamps of a file relative to a directory file descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <fcntl.h> /* Definition of AT_* constants */
#include <sys/time.h>

int futimesat(int dirfd, const char *pathname, const struct timeval times[2]);
```

General description

`futimesat()` operates in the same way as `utimes()` except for the following differences.

- If *pathname* is relative, it is interpreted relative to the directory referred to by the file descriptor *dirfd* (rather than relative to the current working directory of the calling process, as is done by `utimes()` for a relative *pathname*).
- If *pathname* is relative and *dirfd* is the special value `AT_FDCWD`, *pathname* is interpreted relative to the current working directory of the calling process (like `utimes()`).
- If *pathname* is absolute, *dirfd* is ignored.

Returned value

If successful, `futimesat()` returns 0.

If unsuccessful, `futimesat()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

The process does not have appropriate permissions. Possible reasons include:

- The process attempts to set access time or modification time to current time (*times* is NULL), but the effective UID of the process does not match the file's owner.
- The process does not have write permission on the file.
- The process does not have appropriate privileges.

EBADF

pathname is relative but *dirfd* is not `AT_FDCWD` or a valid file descriptor, or *dirfd* is not a valid file descriptor.

EBUSY

The file is open by a remote NFS client with a share reservation that conflicts with the requested operation.

EINVAL

- Invalid value in *flags*.
- *pathname* is NULL, *dirfd* is not `AT_FDCWD`, and *flags* contains `AT_SYMLINK_NOFOLLOW`.
- Invalid value in one of the *tv_nsec* fields (value outside range 0 to 999,999,999, and not `UTIME_NOW` or `UTIME_OMIT`); or an invalid value in one of the *tv_sec* fields.

ELOOP

A loop exists in symbolic links. This error is issued if more than POSIX_SYMLOOP symbolic links are detected in the resolution of *pathname*.

EMVSERR

An MVS environmental error is detected.

ENAMETOOLONG

pathname is longer than PATH_MAX characters, or some component of *pathname* is longer than NAME_MAX characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the *pathname* string that is substituted for a symbolic link exceeds PATH_MAX.

ENOENT

There is no file that is named *pathname*, or the *pathname* argument is an empty string.

ENOTDIR

Some component of the *pathname* prefix is not a directory.

EPERM

times is not NULL. The effective user ID of the calling process does not match the owner of the file. The calling process does not have appropriate privileges.

EROFS

pathname is on a read-only file system.

fwide() — Set stream orientation

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C Amendment ISO/ANSI C++ C99 Single UNIX Specification, Version 3 Language Environment | both | z/OS V1R7 |

Format

```
#define _MSE_PROTOS
#include <stdio.h>
#include <wchar.h>

int fwide(FILE *stream, int mode);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

int fwide_unlocked(FILE *stream, int mode);
```

General description

fwide() determines the orientation of the stream pointed to by *stream*. If *mode* is greater than 0, the function attempts to make the stream wide-oriented. If *mode* is less than 0, the function attempts to

make the stream byte-oriented. Otherwise, *mode* is 0 and the function does not alter the orientation of the stream, rather the function returns the current orientation of the stream.

If the orientation of the stream has already been determined, `fwide()` will not change it.

Streams opened as `type=record` or `type=blocked` do not have orientation.

VSAM data sets and CICS transient data queues do not have orientation. Use of `fwide()` against streams referring to VSAM data sets or CICS transient data queues will be unsuccessful.

An application wishing to check for error situations should set `errno` to 0, then call `fwide()`, then check `errno`. If `errno` is non-zero assume an error has occurred.

`fwide_unlocked()` is functionally equivalent to `fwide()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Special considerations for C++: The interaction of `fwide()` and a C++ I/O stream is undefined.

Usage notes

1. The runtime library does not prevent using byte-oriented I/O functions on a wide-oriented stream, using wide-oriented I/O functions on a byte-oriented stream, or any other mixed orientation usage. The behavior of an application doing so is undefined. As a result, the orientation of a stream reported by `fwide()` might not be consistent with the I/O functions that are being used. The stream orientation first set using `fwide()` itself, or through the first I/O operation on the stream is what will be returned. For example, if `fwide()` is used to set the orientation as byte-oriented, but only wide-oriented I/O functions are used on the stream, the orientation of the stream remains byte-oriented even though no mixing of I/O functions has occurred.

Returned value

If successful, `fwide()` returns a value greater than 0 if the stream has wide-orientation after the call. It returns a value less than 0 if the stream has byte-orientation, or 0 if the stream has no orientation after the call.

When unsuccessful, `fwide()` returns 0 and sets `errno` to one of the following:

EBADF – The stream specified by `stream` was not valid.

EINVAL – The stream specified by `stream` was opened as `type=record` or `type=blocked`, or the stream refers to a VSAM data set or CICS transient data queue.

Related information

- [“stdio.h – Standard input and output” on page 63](#)
- [“wchar.h – ISO/C Multibyte Support extensions” on page 79](#)

fwprintf(), swprintf(), wprintf() – Format and write wide characters

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C Amendment C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

Non-XPG4:

```
#include <wchar.h>

int fwprintf(FILE * __restrict__ stream, const wchar_t * __restrict__ format, ...);
int swprintf(wchar_t * __restrict__ wcs, size_t n, const wchar_t * __restrict__ format, ...);
int wprintf(const wchar_t * __restrict__ format, ...);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

int fwprintf_unlocked(FILE * __restrict__ stream, const wchar_t * __restrict__ format, ...);
int wprintf_unlocked(const wchar_t * __restrict__ format, ...);
```

XPG4:

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

int fwprintf(FILE * __restrict__ stream, const wchar_t * __restrict__ format, ...);
int swprintf(wchar_t * __restrict__ wcs, size_t n, const wchar_t * __restrict__ format, ...);
int wprintf(const wchar_t * __restrict__ format, ...);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

int fwprintf_unlocked(FILE * __restrict__ stream, const wchar_t * __restrict__ format, ...);
int wprintf_unlocked(const wchar_t * __restrict__ format, ...);
```

General description

The `fwprintf()`, `swprintf()` and `wprintf()` functions are equivalent to `fprintf()`, `sprintf()` and `printf()`, respectively, except for the following:

- For `swprintf()`, the argument `wcs` specifies an array of type `wchar_t` into which the generated output is to be written, rather than an array of type `char`.
- The argument `format` specifies an array of type `wchar_t` that describes how subsequent arguments are converted for output, rather than an array of type `char`.
- `%c` without an `l` prefix means an `int` arg is to be converted to `wchar_t`, as if `mbtowc()` were called, and then written.
- `%c` with `l` prefix means a `wint_t` is converted to `wchar_t` and then written.
- `%s` without an `l` prefix means a character array containing a multibyte character sequence is to be converted to an array of `wchar_t` and then written. The conversion will take place as if `mbrtowc()` were called repeatedly.
- `%s` with `l` prefix means an array of `wchar_t` will be written. The array is written up to but not including the terminating NULL character, unless the precision specifies a shorter output.

For `swprintf()`, a NULL wide character is written at the end of the wide characters written; the NULL wide character is not counted as part of the returned sum. If copying takes place between objects that overlap, the behavior is undefined.

`fwprintf_unlocked()` family is functionally equivalent to `fwprintf()` family with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Special behavior for XPG4: If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the `wchar` header, then you must also define the `_MSE_PROTOS` feature test macro to make the declaration of the `fwprintf()`, `swprintf()` or `wprintf()` function in the `wchar` header available when you compile your program. Please see [Table 2 on page 4](#) for a list of XPG4 and other feature test macros.

Note: The `fwprintf()` and `wprintf()` functions have a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support” on page 2123](#) for details.

Returned value

If successful, `fwprintf()`, `wprintf()`, and `swprintf()` return the number of wide characters written, not counting the terminating NULL wide character.

If unsuccessful, a negative value is returned.

If *n* or more wide characters were requested to be written, `swprintf()` returns a negative value and sets `errno` to indicate the error.

Related information

- [“wchar.h — ISO/C Multibyte Support extensions” on page 79](#)
- [“fprintf\(\), printf\(\), sprintf\(\) — Format and write data” on page 593](#)

__fwritable() — Determine if a stream is open for writing

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <stdio.h>
#include <stdio_ext.h>

int __fwritable(FILE *stream);
```

General description

The `__fwritable()` function determines if the specified stream has been opened for writing.

Returned value

The `__fwritable()` function returns nonzero if the stream is opened for writing. Otherwise, the `__fwritable()` function returns 0. If an error has occurred, `__fwritable()` returns 0 and sets `errno` to nonzero.

An application wishing to check for error situations should set `errno` to 0, then call `__fwritable()`, and then check `errno`. If `errno` is nonzero, assume that an error has occurred.

Error Code

Description

EBADF

The stream specified by *stream* is not valid.

Example

CELEBF89

```
/* CELEBF89

   This example writes and reads data to a file while querying the
   stream for information about data in the I/O buffer.

*/

#include <stdio.h>
```

```
#include <stdio_ext.h>

void main() {
    FILE *f;
    char filename[FILENAME_MAX] = "myfile.dat";
    char data[128] = "There are 34 bytes in this buffer\n";
    int datalen = strlen(data);
    size_t n = 0;

    f = fopen(filename, "wb+");
    if (f == NULL) {
        perror("fopen() failed\n");
        return;
    }

    if (__fwritable(f)) printf("Writing is allowed on the open stream\n");
    if (__freadable(f)) printf("Reading is allowed on the open stream\n");

    n = fputs(data, f);
    if (n == EOF) {
        perror("fputs() failed\n");
        return;
    }

    n = __fpending(f);
    printf("There are %d bytes in the buffer pending to be written\n", n);

    if (__fwriting(f)) printf("The last operation on the stream was a write\n");

    rewind(f);

    n = fgetc(f);

    n = __freadahead(f);
    printf("There are %d bytes remaining to be read from the buffer\n", n);

    if (__freading(f)) printf("The last operation on the stream was a read\n");

    return;
}
```

Output

```
Writing is allowed on the open stream
Reading is allowed on the open stream
There are 34 bytes in the buffer pending to be written
The last operation on the stream was a write
There are 33 bytes remaining to be read from the buffer
The last operation on the stream was a read
```

fwrite() – Write items

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```
#include <stdio.h>

size_t fwrite(const void * __restrict__buffer, size_t size, size_t count, FILE * __restrict__stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

size_t fwrite_unlocked(const void * __restrict__buffer, size_t size,
                      size_t count, FILE * __restrict__stream);
```

General description

Writes up to *count* items of size *size* from the location pointed to by *buffer* to the stream pointed to by *stream*.

When you are using `fwrite()` for record I/O output, set *size* to 1 and *count* to the length of the record to be written. You can only write one record at a time when you are using record I/O. Any string longer than the record length is truncated at the record length. A flush or reposition is required before a subsequent read.

When you are using `fwrite()` for blocked I/O output, set *size* to 1 and *count* to the length of the block to be written. You can only write one block at a time when you are using blocked I/O. Any string longer than the block length is truncated at the block length.

Because `fwrite()` may buffer output before writing it out to the stream, data from prior `fwrite()` calls may be lost where a subsequent call to `fwrite()` causes a failure when the buffer is written to the stream.

`fwrite()` has the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

`fwrite_unlocked()` is functionally equivalent to `fwrite()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

`fwrite()` returns the number of items that were successfully written.

This number can be smaller than *count* only if a write error occurred.

Example

CELEBF51

```

/* CELEBF51

   This example writes NUM long integers to a stream in binary
   format.
   It checks that the &fopen. function is successful and that
   100 items are written to the stream.

*/
#include <stdio.h>
#define NUM 100

int main(void)
{
    FILE *stream;
    long list[NUM];
    int numwritten, number;

    if((stream = fopen("myfile.dat", "w+b")) != NULL )
    {
        for (number = 0; number < NUM; ++number)
            list[number] = number;
        numwritten = fwrite(list, sizeof(long), NUM, stream);
        printf("number of long characters written is %d\n",numwritten);
    }
    else
        printf("fopen error\n");
}

```

__fwriting() — Determine if last operation on stream is a write operation

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```

#include <stdio.h>
#include <stdio_ext.h>

int __fwriting(FILE *stream);

#define _OPEN_SYS_UNLOCKED 1
#include <stdio.h>
#include <stdio_ext.h>

int __fwriting_unlocked(FILE *stream);

```

General description

The `__fwriting()` function determines if the last operation on the specified stream is a write operation or if the specified stream is open for write-only or append-only.

The `__fwrite_unlocked()` function is equivalent to the `__fwriting()` function with the exception that it is not thread-safe. This function can be safely used in a multithreaded application if it is called while the invoking thread owns the (FILE *) object, such as after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

The `__fwriting()` functions return nonzero when the last operation was a write operation or the stream is open for write-only or append-only. Otherwise, the `__fwriting()` function returns 0. If an error has occurred, the `__fwriting()` functions return 0 and set `errno` to nonzero.

An application wishing to check for error situations should set `errno` to 0, then call `__fwriting()`, and then check `errno`. If `errno` is nonzero, assume that an error has occurred.

Error Code

Description

EBADF

The stream specified by *stream* is not valid.

Example

CELEBF89

```
/* CELEBF89

   This example writes and reads data to a file while querying the
   stream for information about data in the I/O buffer.

*/

#include <stdio.h>
#include <stdio_ext.h>

void main() {
    FILE *f;
    char filename[FILENAME_MAX] = "myfile.dat";
    char data[128] = "There are 34 bytes in this buffer\n";
    int datalen = strlen(data);
    size_t n = 0;

    f = fopen(filename, "wb+");
    if (f == NULL) {
        perror("fopen() failed\n");
        return;
    }

    if (__fwritable(f)) printf("Writing is allowed on the open stream\n");
    if (__freadable(f)) printf("Reading is allowed on the open stream\n");

    n = fputs(data, f);
    if (n == EOF) {
        perror("fputs() failed\n");
        return;
    }

    n = __fpending(f);
    printf("There are %d bytes in the buffer pending to be written\n", n);

    if (__fwriting(f)) printf("The last operation on the stream was a write\n");

    rewind(f);

    n = fgetc(f);

    n = __freadahead(f);
    printf("There are %d bytes remaining to be read from the buffer\n", n);

    if (__freading(f)) printf("The last operation on the stream was a read\n");

    return;
}
```

Output

```
Writing is allowed on the open stream
Reading is allowed on the open stream
There are 34 bytes in the buffer pending to be written
The last operation on the stream was a write
There are 33 bytes remaining to be read from the buffer
The last operation on the stream was a read
```

fwscanf(), swscanf(), wscanf() — Convert formatted wide-character input

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C Amendment ISO/ANSI C++ C99 Single UNIX Specification, Version 3 Language Environment | both | z/OS V1R7 |

Format

Non-XP4:

```
#define _MSE_PROTOS
#include <stdio.h>
#include <wchar.h>

int fwscanf(FILE *__restrict__ stream,
            const wchar_t *__restrict__ format, ... );

int swscanf(const wchar_t *__restrict__ wcs,
            const wchar_t *__restrict__ format, ... );

int wscanf(const wchar_t *__restrict__ format, ... );

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

int fwscanf_unlocked(FILE *__restrict__ stream,
                    const wchar_t *__restrict__ format, ... );
int wscanf_unlocked(const wchar_t *__restrict__ format, ... );
```

XP4 and swscanf():

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

int swscanf(const wchar_t *wcs, const wchar_t *format, ... );
```

General description

The `fwscanf()`, `swscanf()`, and `wscanf()` functions are equivalent to `fscanf()`, `scanf()`, and `sscanf()` respectively, except for the following:

- The argument *wcs* specifies an array of type `wchar_t` from which the input is to be obtained, rather than an array of type `char`.
- The *format* argument specifies an array of type `wchar_t` that describes the admissible input sequences and how they are to be converted for assignment, rather than an array of type `char`.
- `%c` with no *l* prefix means one or more (depending on precision) `wchar_t` is converted to multibyte characters and copied to the character array pointed to by the corresponding argument.
- `%c` with the *l* prefix means one or more (depending on precision) `wchar_t` is copied to the array of `wchar_t` pointed to by the corresponding argument.
- `%s` with no *l* prefix means a sequence of non-white `wchar_t` will be converted and copied, including the terminating NULL character, to the character array pointed to by the corresponding argument.
- `%s` with the *l* prefix means an array of `wchar_t` will be copied, including the terminating NULL wide-character, to the array of `wchar_t` pointed to by the corresponding argument.
- `%[` with no *l* prefix means a sequence of non-white `wchar_t` will be converted and copied, including the terminating NULL character, to the character array pointed to by the corresponding argument.
- `%[` with the *l* prefix means an array of `wchar_t` will be copied, including the terminating NULL wide-character, to the array of `wchar_t` pointed to by the corresponding argument.

Note: Reaching the end of a wide-character string is equivalent to reaching the end of a `char` string for the `fscanf()` and `scanf()` functions. If copying takes place between objects that overlap, the behavior is undefined.

`fwscanf_unlocked()` family is functionally equivalent to `fwscanf()` family with the exception that they are not thread-safe. These functions can safely be used in a multithreaded application if and only if they are called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Special behavior for XPG4 and `swscanf()`: If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the `wchar` header, then you must also define the `_MSE_PROTOS` feature test macro to make the declaration of the `swscanf()` function in the `wchar` header available when you compile your program. Please see [Table 2 on page 4](#) for a list of XPG4 and other feature test macros.

Returned value

If successful, they either return the number of input items assigned, which can be fewer than provided for, or 0 in the event of an early matching failure. If an input failure occurs before any conversion, EOF is returned.

gai_strerror() — Address and name information error description

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| RFC2553 Single UNIX Specification, Version 3 | both | z/OS V1R4 |

Format

```
#define _OPEN_SYS_SOCKET_IPV6
#include <netdb.h>

char *gai_strerror(int ecode);
```

SUSV3:

```
#define _POSIX_C_SOURCE 200112L
#include <netdb.h>
const char *gai_strerror(int ecode);
```

General description

The `gai_strerror()` function returns a pointer to a text string describing the error value returned by a failure return from either the `getaddrinfo()` or `getnameinfo()` function. If the *ecode* is not one of the `EAI_XXX` values from the `<netdb.h>` header, then `gai_strerror()` returns a pointer to a string indicating an unknown error.

Subsequent calls to `gai_strerror()` will overwrite the buffer containing the text string.

Returned value

When successful, `gai_strerror()` returns a pointer to a string describing the error. Upon failure, `gai_strerror()` will return `NULL` and set `errno` to one of the following:

Error Code

Description

ENOMEM

Insufficient memory to allocate buffer for text string describing the error.

gamma() — Calculate gamma function

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| SAA XPG4 XPG4.2 | both | |

Format

SAA:

```
#include <math.h>

double gamma(double x);
```

This function must be used with the [runtime library extensions](#) or under the [SAA based language constructs](#).

General description

gamma() provides the same function as lgamma(), including the use of *signgam*. Use of lgamma() instead of gamma() is suggested by XPG4.2.

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use lgamma() instead of gamma().

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Related information

- [“math.h — Floating-point math functions” on page 40](#)

gcv() — Convert double to string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

char *gcv(double x, int ndigit, char *buf);
```

General description

The gcv() function converts double floating-point argument values to floating-point output strings. The gcv() function has been extended to determine the floating-point format (hexadecimal floating-point or IEEE Binary Floating-Point) of double argument values by using `__isBFP()`.

IBM z/OS C/C++ formatted output functions, including the gcv() function, convert IEEE Binary Floating-Point infinity and NaN argument values to special infinity and NaN floating-point number output sequences. See [“fprintf Family of Formatted Output Functions” on fprintf\(\), printf\(\), sprintf\(\) — Format and write data](#) for a description of the special infinity and NaN output sequences.

The `gcvt()` function converts *x* to a NULL-terminated string (similar to the `%g` format of “[fprintf\(\), printf\(\), sprintf\(\) — Format and write data](#)” on page 593) in the array pointed to by *buf* and returns *buf*. It produces *ndigit* significant digits (limited to an unspecified value determined by the precision of a double) in `%f` if possible, or `%e` (scientific notation) otherwise. A minus sign is included in the returned string if *value* is less than 0. A radix character is included in the returned string if *value* is not a whole number. Trailing zeros are suppressed where *value* is not a whole number. The radix character is determined by the current locale. If “[setlocale\(\) — Set locale](#)” on page 1547 has not been called successfully, the default locale, “POSIX”, is used. The default locale specifies a period (.) as the radix character. The `LC_NUMERIC` category determines the value of the radix character within the current locale.

Note: This function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The `sprintf()` function is preferred for portability.

Returned value

If successful, `gcvt()` returns the character equivalent of *x* as specified above.

If unsuccessful, `gcvt()` returns NULL.

getaddrinfo() — Get address information

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| RFC2553 | both | z/OS V1R4 |

Format

```
#define _OPEN_SYS_SOCKET_IPV6
#include <sys/socket.h>
#include <netdb.h>

int getaddrinfo(const char *nodename,
                const char *servname,
                const struct addrinfo *hints,
                struct addrinfo **res);
```

SUSV3:

```
#define _POSIX_C_SOURCE 200112L
#include <sys/socket.h>
#include <netdb.h>
int getaddrinfo(const char *__restrict__ nodename,
                const char *__restrict__ servname,
                const struct addrinfo *__restrict__ hints,
                struct addrinfo **__restrict__ res);
```

General description

The `getaddrinfo()` function translates the name of a service location (for example, a host name) and/or service name and returns a set of socket addresses and associated information to be used in creating a socket with which to address the specified service.

The *nodename* and *servname* arguments are either pointers to null-terminated strings or null pointers. One or both of these two arguments must be specified as a non-null pointer.

The format of a valid name depends on the protocol family or families. If a specific family is not given and the name could be interpreted as valid within multiple supported families, the function attempts to resolve the name in all supported families. When no errors are detected, all successful results will be returned.

If the *nodename* argument is not null, it can be a descriptive name or it can be an address string. If the specified address family is AF_INET, AF_INET6, or AF_UNSPEC, valid descriptive names include host names. If the specified address family is AF_INET or AF_UNSPEC, address strings using standard dot notation as specified in `inet_addr()` are valid. If the specified address family is AF_INET6 or AF_UNSPEC, standard IPv6 text forms described in `inet_pton()` are valid. In addition, scope information can be appended to the descriptive name or the address string using the format *nodename%scope* information. Scope information can be either an interface name or the numeric representation of an interface index suitable for use on this system.

If *nodename* is not null, the requested service location is named by *nodename*; otherwise, the requested service location is local to the caller.

If *servname* is null, the call returns network-level addresses for the specified *nodename*. If *servname* is not null, it is a null-terminated character string identifying the requested service. This can be either a descriptive name or a numeric representation suitable for use with the address family or families. If the specified address family is AF_INET, AF_INET6, or AF_UNSPEC, the service can be specified as a string specifying a decimal port number.

If the argument *hints* is not null, it refers to a structure containing input values that may direct the operation by providing options and by limiting the returned information to a specific socket type, address family and/or protocol. In the hints structure every member other than *ai_flags*, *ai_family*, *ai_socktype*, and *ai_protocol* must be zero or a null pointer. A value of AF_UNSPEC for *ai_family* means that the caller will accept any protocol family. A value of zero for *ai_socktype* means that the caller will accept any socket type. A value of zero for *ai_protocol* means that the caller will accept any protocol. If *hints* is a null pointer, the behavior must be as if it referred to a structure containing the value zero for the *ai_flags*, *ai_socktype*, and *ai_protocol* fields, and AF_UNSPEC for the *ai_family* field.

The *ai_flags* member to which the hints argument points can be set to 0 or be the bitwise inclusive OR of one or more of the following values:

- AI_PASSIVE
- AI_CANONNAME
- AI_NUMERICHOST
- AI_NUMERICSERV
- AI_V4MAPPED
- AI_ALL
- AI_ADDRCONFIG
- AI_EXTFLAGS

If the AI_PASSIVE bit is set in the *ai_flags* member of the hints structure, then the caller plans to use the returned socket address structure in a call to `bind()`. In this case, if the *nodename* argument is a null pointer, then the IP address portion of the socket address structure will be set to INADDR_ANY for an IPv4 address or IN6ADDR_ANY_INIT for an IPv6 address. If the AI_PASSIVE bit is not set in the *ai_flags* member of the hints structure, then the returned socket address structure will be ready for a call to `connect()` (for a connection-oriented protocol) or either `connect()`, `sendto()`, or `sendmsg()` (for a connectionless protocol). In this case, if the *nodename* argument is a null pointer, then the IP address portion of the socket address structure will be set to the loopback address.

If the AI_CANONNAME bit is set in the *ai_flags* member of the hints structure, then upon successful return the *ai_canonname* member of the first `addrinfo` structure in the linked list will point to a null-terminated string containing the canonical name of the specified *nodename*.

If the `AI_NUMERICHOST` bit is set in the `ai_flags` member of the hints structure, then a non-null `nodename` string must be a numeric host address string. Otherwise an error code of `EAI_NONAME` is returned. This flag prevents any type of name resolution service (for example, the DNS) from being called.

If the `AI_NUMERICSERV` flag is specified then a non-null `servname` string must be a numeric port string. Otherwise an error code `EAI_NONAME` is returned. This flag prevents any type of name resolution service (for example, NIS+ from being invoked).

If the `AI_V4MAPPED` flag is specified with the `ai_family` field using the value of `AF_INET6` or `AF_UNSPEC`, then the caller will accept IPv4-mapped IPv6 addresses.

- If the `ai_family` field is `AF_INET6`, a query for IPv4 addresses is made if the `AI_ALL` flag is specified or if no IPv6 addresses are found. Any IPv4 addresses that are found are returned as IPv4-mapped IPv6 addresses.
- If the `ai_family` field is `AF_UNSPEC`, queries are made for both IPv6 and IPv4 addresses. If IPv4 addresses are found and IPv6 is supported, the IPv4 addresses are returned as IPv4-mapped IPv6 addresses.
- Otherwise, the `AI_V4MAPPED` flag is ignored.

If the `ai_family` field has a value of `AF_INET6` and `AI_ALL` is set, the `AI_V4MAPPED` flag must also be set to indicate that the caller will accept all addresses (IPv6 and IPv4-mapped IPv6 addresses). If the `ai_family` field has a value of `AF_UNSPEC`, `AI_ALL` is accepted but has no impact on the processing. Whether `AI_ALL` is specified or not, the caller accepts IPv6 addresses and either IPv4 or IPv4-mapped IPv6 addresses. A query is first made for IPv6 addresses and if successful, the IPv6 addresses are returned. Another query is then made for IPv4 addresses, and any found are returned as IPv4 addresses (if `AI_V4MAPPED` was not set or the system does not support IPv6) or as IPv4-mapped IPv6 addresses (if `AI_V4MAPPED` was set and the system supports IPv6). Otherwise, the `AI_ALL` flag is ignored.

If the `AI_ADDRCONFIG` flag is specified then a query for IPv6 address records should occur only if the node has at least one IPv6 source address configured. A query for IPv4 address records will always occur, whether or not any IPv4 addresses are configured. The loopback address is not considered for this case as valid as a configured sources address.

If the `AI_EXTFLAGS` flag is specified then `getaddrinfo()` will look for the values stored in the extended flags field called `ai_eflags` in the `addrinfo` structure. The flags stored in the `ai_eflags` field are only meaningful if the `AI_EXTFLAGS` flag is set in the `ai_flags` field of the `addrinfo` data structure. By default, `AI_EXTFLAGS` is not set in the `ai_flags` field. If `AI_EXTFLAGS` is set in the `ai_flags` field, and the `ai_eflags` extended flags field is 0 (zero) or undefined, then `AI_EXTFLAGS` is ignored. The `ai_eflags` field can be set to any of the following:

- `IPV6_PREFER_SRC_HOME` - prefer home address as source
- `IPV6_PREFER_SRC_COA` - prefer care-of address as source
- `IPV6_PREFER_SRC_TMP` - prefer temporary address as source
- `IPV6_PREFER_SRC_PUBLIC` - prefer public address as source
- `IPV6_PREFER_SRC_CGA` - prefer CGA address as source
- `IPV6_PREFER_SRC_NONCGA` - prefer a non-CGA address as source

These flags can be combined into a flag set to express complex address preferences, but some can result in a contradictory flag set. For example, the following flags are mutually exclusive:

- `IPV6_PREFER_SRC_HOME` and `IPV6_PREFER_SRC_COA`
- `IPV6_PREFER_SRC_TMP` and `IPV6_PREFER_SRC_PUBLIC`
- `IPV6_PREFER_SRC_CGA` and `IPV6_PREFER_SRC_NONCGA`

All of the information returned by `getaddrinfo()` is dynamically allocated: the `addrinfo` structures, and the socket address structures and canonical node name strings pointed to by the `addrinfo` structures. To return this information to the system the function `freeaddrinfo()` is called.

Usage notes

1. If the caller handles only TCP and not UDP, for example, then the *ai_protocol* member of the hints structure should be set to IPPROTO_TCP when getaddrinfo() is called.
2. If the caller handles only IPV4 and not IPv6, then the *ai_family* member of the hints structure should be set to AF_INET when getaddrinfo() is called.
3. Scope information is only pertinent to IPv6 link-local addresses. It is ignored for resolved IPv4 addresses and IPv6 addresses that are not link-local addresses.

Returned value

When successful, getaddrinfo() returns 0 and a pointer to a linked list of one or more addrinfo structures through the res argument. The caller can process each addrinfo structure in this list by following the ai_next pointer, until a null pointer is encountered. In each returned addrinfo structure the three members *ai_family*, *ai_socktype*, and *ai_protocol* are the corresponding arguments for a call to the socket() function. In each addrinfo structure the *ai_addr* member points to a filled-in socket address structure whose length is specified by the *ai_addrlen* member. Upon failure, getaddrinfo() returns a non-zero error code. The error codes are as follows:

Error Code

Description

EAI_AGAIN

The name specified by the Node_Name or Service_Name parameter could not be resolved within the configured time interval, or the resolver address space has not been started. The request can be retried later.

EAI_BADEXTFLAGS

The extended flags parameter had an incorrect setting.

EAI_BADFLAGS

The flags parameter had an incorrect setting.

EAI_FAIL

An unrecoverable error occurred.

EAI_FAMILY

The family parameter had an incorrect setting.

EAI_MEMORY

A memory allocation failure occurred during an attempt to acquire an Addr_Info structure.

EAI_NONAME

One of the following conditions occurred:

1. The name does not resolve for the specified parameters. At least one of the Name or Service operands must be specified.
2. The request name parameter is valid, but it does not have a record at the name server.

EAI_SERVICE

The service that was passed was not recognized for the specified socket type.

EAI_SOCKTYPE

The intended socket type was not recognized.

EAI_SYSTEM

A system error occurred.

For more information about the above return codes, see [z/OS Communications Server: IP and SNA Codes](#).

getc(), getchar() — Read a character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdio.h>

int getc(FILE *stream);
int getchar(void);
```

General description

Reads a single character from the current *stream* position and advances the *stream* position to the next character. The `getchar()` function is identical to `getc(stdin)`.

The `getc()` and `fgetc()` functions are identical. However, `getc()` and `getchar()` are provided in a highly efficient macro form. For performance purposes, it is recommended that the macro forms be used rather than the functional forms or `fgetc()`. By default, `stdio.h` provides the macro versions of these functions.

However, to get the functional forms, do one or more of the following:

- For C only: do *not* include `stdio.h`.
- Specify `#undef`, for example, `#undef getc`
- Surround the call statement by parentheses, for example, `(getc)`

`getc()` and `getchar()` are not supported for files opened with `type=record` or `type=blocked`.

`getc()` and `getchar()` have the same restriction as any read operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

If the application is not multithreaded, then setting the `_ALL_SOURCE_NO_THREADS` feature test macro may improve performance of the application, because it allows use of the inline version of this function.

Special behavior for POSIX: In a multithreaded C application that uses `POSIX(ON)`, in the presence of the feature test macro, `_OPEN_THREADS`, these macros are in an `#undef` status because they are not thread-safe.

Note: Because the `getc()` macro reevaluates its input argument more than once, you should never pass a stream argument that is an expression with side effects.

Returned value

`getc()` and `getchar()` return the character read.

A returned value of EOF indicates either an error or an EOF condition. If a read error occurs, the error indicator is set. If an EOF is encountered, the EOF indicator is set.

Use `ferror()` or `feof()` to determine whether an error or an EOF condition occurred. Note that EOF is only reached when an attempt is made to read past the last byte of data. Reading up to and including the last byte of data does *not* turn on the EOF indicator.

Example

CELEBG02

```

/* CELEBG02

   This example gets a line of input from the stdin stream.
   You can also use getc(stdin) instead of &getchar. in the for
   statement to get a line of input from stdin.

*/
#include <stdio.h>

#define LINE 80

int main(void)
{
    char buffer[LINE+1];
    int i;
    int ch;

    printf( "Please enter string\n" );

    /* Keep reading until either:
       1. the length of LINE is exceeded or
       2. the input character is EOF or
       3. the input character is a new-line character
    */
    for ( i = 0; ( i < LINE ) && (( ch = getchar()) != EOF) &&
          ( ch != '\n' ); ++i )
        buffer[i] = ch;

    buffer[i] = '\0'; /* a string should always end with '\0' ! */
    printf( "The string is %s\n", buffer );
}

```

Output

```

Please enter string
hello world
The string is hello world

```

getc_unlocked(), getchar_unlocked(), putc_unlocked(), putchar_unlocked() — Stdio with explicit client locking

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|--------------|
| Single UNIX Specification, Version 3 | both | z/OS V1R8 |

Format

```
#define _UNIX03_SOURCE
#include <stdio.h>

int getc_unlocked(FILE *stream);
int getchar_unlocked(void);
int putc_unlocked(int c, FILE *stream);
int putchar_unlocked(int c);
```

General description

Versions of the functions `getc()`, `getchar()`, `putc()`, and `putchar()` respectively named `getc_unlocked()`, `getchar_unlocked()`, `putc_unlocked()`, and `putchar_unlocked()` are functionally equivalent to the original versions, with the exception that they are not thread-safe. These functions may safely be used in a multi-threaded program if and only if they are called while the invoking thread owns the (FILE*) object, as is the case after a successful call to the `flockfile()` or `ftrylockfile()` functions.

`getc_unlocked`, `getchar_unlocked`, `putc_unlocked`, `putchar_unlocked` are provided in a highly efficient macro form. For performance purposes, it is recommended that the macro forms be used rather than the functional forms. By default, `stdio.h` provides the macro versions of these functions.

However, to get the functional forms, do one or more of the following:

- Surround the call statement by parentheses, for example, `(getc_unlocked)`
- Specify `#undef`, for example, `#undef getc_unlocked`
- For C only: do *not* include `stdio.h`.

`getc_unlocked`, `getchar_unlocked`, `putc_unlocked`, `putchar_unlocked` are not supported for files that are opened with `type=record` or `type=blocked`.

`getc_unlocked`, `getchar_unlocked`, `putc_unlocked`, `putchar_unlocked` have the same restrictions as any read or write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

Note: Because the macro forms of these functions reevaluate their input arguments more than once, you must not pass an argument that is an expression with side effects.

Returned value

getclientid() – Get the identifier for the calling application

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _OPEN_SYS_SOCK_EXT
#include <sys/socket.h>
#include <sys/types.h>

int getclientid(int domain, struct clientid *clientid);
```

General description

The getclientid() function call returns the identifier by which the calling application is known to the TCP/IP address space. The *clientid* can be used in the givesocket() and takesocket() calls. However, this function is supplied for use by existing programs that depend on the address space name returned. Even for these programs it is recommended that the name be saved for its later use and the __getclientid() function be issued to reconstruct the clientid structure for use by givesocket() and takesocket().

Parameter

Description

domain

The address domain requested.

clientid

The pointer to a *clientid* structure to be filled.

The clientid structure is filled in by the call and returned as follows:

The clientid structure:

```
struct clientid {
    int domain;
    union {
        char name[8];
        struct {
            int NameUpper;
            pid_t pid;
        } c_pid;
    } c_name;
    char subtaskname[8];

    struct {
        char type;
        union {
            char specific[19];
            struct {
                char unused[3];
                int SockToken;
            } c_close;
        } c_func;
    } c_reserved;
};
```

Element

Description

domain

The input *domain* value returned in the domain field of the clientid structure.

c_name.name

The application program's address space name, left-justified and padded with blanks.

subtaskname

The calling program's task identifier.

c_reserved

Specifies binary zeros.

Returned value

If successful, `getclientid()` returns 0.

If unsuccessful, `getclientid()` returns -1 and sets `errno` to one of the following values:

Error Code**Description****EFAULT**

Using the *clientid* parameter as specified would result in an attempt to access storage outside the caller's address space, or storage not modifiable by the caller.

__getclientid() — Get the PID identifier for the calling application

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _OPEN_SYS_SOCK_EXT
#include <sys/socket.h>
#include <sys/types.h>

int __getclientid(int domain, struct clientid *clientid);
```

General description

The `__getclientid()` function call returns the process identifier (PID) by which the calling application is known to the TCP/IP address space. The *clientid* is used in the `givesocket()` and `takesocket()` calls. Use the `__getclientid()` function call to transfer sockets between the caller and the selected application. The `__getclientid()` function provides improved performance and integrity over the `getclientid()` function for applications that use the output of `__getclientid()` as input *clientids* for `givesocket()` and `takesocket()`.

Parameter**Description****domain**

The address domain requested.

clientid

The pointer to a *clientid* structure to be filled.

The *clientid* structure:

```
struct clientid {
    int domain;
    union {
```

```

    char name[8];
    struct {
        int NameUpper;
        pid_t pid;
    } c_pid;
} c_name;
char subtaskname[8];

struct {
    char type;
    union {
        char specific[19];
        struct {
            char unused[3];
            int SocketToken;
        } c_close;
    } c_func;
} c_reserved;
};

```

Element Description

domain

The input *domain* value returned in the domain field of the clientid structure.

c_pid.pid

Is the label in the *clientid* structure that is filled in by the function call to the PID of the requester (caller of `__getclientid()`). It should be left as set because it is used by the `takesocket()` and `givesocket()` functions.

subtaskname

Blanks

c_reserved

Binary zeros

Returned value

If successful, `__getclientid()` returns 0.

If unsuccessful, `__getclientid()` returns -1 and sets `errno` to one of the following values:

Error Code Description

EFAULT

Using the *clientid* parameter as specified would result in an attempt to access storage outside the caller's address space, or storage not modifiable by the caller.

getcontext() — Get user context

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <ucontext.h>

int getcontext(ucontext_t *ucp);
```

General description

The `getcontext()` function initializes the structure pointed to by `ucp` to the current user context of the calling process. The **`ucontext_t`** type that `ucp` points to defines the user context and includes the contents of the calling process's machine registers, the signal mask, and the current execution stack. A subsequent call to `setcontext()` restores the saved context and returns control to a point in the program corresponding to the `getcontext()` call. Execution resumes as if the `getcontext()` call had just returned. The return value from `getcontext()` is the same regardless of whether the return is from the initial invocation or using a call to `setcontext()`.

The context created by `getcontext()` may be modified by the `makecontext()` function. Refer to `makecontext` for details.

`getcontext()` is similar in some respects to `sigsetjmp()` (and `setjmp()` and `_setjmp()`). The `getcontext()`–`setcontext()` pair, the `sigsetjmp()`–`siglongjmp()` pair, the `setjmp()`–`longjmp()` pair, and the `_setjmp()`–`_longjmp()` pair cannot be intermixed. A context saved by `getcontext()` should be restored only by `setcontext()`.

Note: Some compatibility exists with `siglongjmp()`, so it is possible to use `siglongjmp()` from a signal handler to restore a context created with `getcontext()`, but it is not recommended.

Portable applications should not modify or access the **`uc_mcontext`** member of **`ucontext_t`**. A portable application cannot assume that context includes any process-wide static data, possibly including `errno`. Users manipulating contexts should take care to handle these explicitly when required.

This function is supported only in a POSIX program.

The **`<ucontext.h>`** header file defines the **`ucontext_t`** type as a structure that includes the following members:

| | | |
|-------------------------|--------------------------|--|
| <code>mcontext_t</code> | <code>uc_mcontext</code> | A machine-specific representation of the saved context. |
| <code>ucontext_t</code> | <code>*uc_link</code> | Pointer to the context that will be resumed when this context returns. |
| <code>sigset_t</code> | <code>uc_sigmask</code> | The set of signals that are blocked when this context is active. |
| <code>stack_t</code> | <code>uc_stack</code> | The stack used by this context. |

Special behavior for C++: If `getcontext()` and `setcontext()` are used to transfer control, the behavior is undefined whether the destruction of automatic C++ objects is done. The use of `getcontext()` and `setcontext()` in conjunction with `try()`, `catch()`, and `throw()` is also undefined.

Do not issue `getcontext()` in a C++ constructor or destructor, since the saved context would not be usable in a subsequent `setcontext()` or `swapcontext()` after the constructor or destructor returns.

Special behavior for XPLINK-compiled C/C++: Restrictions concerning `setjmp.h` and `ucontext.h`:

1. All XPLINK programs compiled with the V2R10 or later C compilers that are to run with Language Environment V2R10 or later libraries and use the **jmp_buf**, **sigjmp_buf** or **ucontext_t** types must not be compiled with C headers from Language Environment V2R9 or earlier.
2. Non-XPLINK functions compiled with any level of Language Environment headers must not define **jmp_buf**, **sigjmp_buf** or **ucontext_t** data items and pass them to XPLINK functions that call `getcontext()`, `longjmp()`, `_longjmp()`, `setjmp()`, `_setjmp()`, `setcontext()`, `sigsetjmp()`, or `swapcontext()` with these passed-in data items.
3. When `__XPLINK__` is defined, the Language Environment V2R10 and later headers define a larger **jmp_buf**, **sigjmp_buf** or **ucontext_t** area that is required by `setjmp()`, `getcontext()`, and related functions when they are called from an XPLINK routine. If `__XPLINK__` is not defined, the Language Environment V2R10 and later headers define a shorter **jmp_buf**, **sigjmp_buf** or **ucontext_t** area. The Language Environment headers before V2R10 also define the shorter version of these data areas. If an XPLINK function calls `setjmp()`, `getcontext()` or similar functions with a short **jmp_buf**, **sigjmp_buf** or **ucontext_t** area, a storage overlay or program check may occur when the C library tries to store past the end of the passed-in (too short) data area.

Returned value

If successful, `getcontext()` returns 0.

If unsuccessful, `getcontext()` returns -1.

There are no `errno` values defined.

Example

This example saves the context in `main` with the `getcontext()` statement. It then returns to that statement from the function `func` using the `setcontext()` statement. Since `getcontext()` always returns 0 if successful, the program uses the variable `x` to determine if `getcontext()` returns as a result of `setcontext()` or not.

```
/* This example shows the usage of getcontext() and setcontext().    */
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdio.h>
#include <ucontext.h>

void func(void);

int x = 0;
ucontext_t context, *cp = &context;

int main(void) {
    getcontext(cp);
    if (!x) {
        printf("getcontext has been called\n");
        func();
    }
    else {
        printf("setcontext has been called\n");
    }
}

void func(void) {
    x++;
    setcontext(cp);
}
```

Output

```
getcontext has been called
setcontext has been called
```

__get_cpuid() — Retrieves the system CPUID

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | OS/390 V2R10 |

Format

```
#define _OPEN_SYS_EXT 1
#include <sys/ps.h>

int __get_cpuid(char *buff);
```

General description

Retrieves the current CPU ID in the form of a string containing the readable part of the serial number concatenated with the model number. The variable *buff* is a character string of 11 bytes in length. It is a work area to build the unique cpuid.

Returned value

Always returns the serial and model number.

Related information

- [“sys/ps.h — w_getpsent\(\) function and w_psproc structure” on page 70](#)

getcwd() — Get path name of the working directory

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

char *getcwd(char *buffer, size_t size);
```

General description

Determines the path name of the working directory and stores it in *buffer*.

size

The number of characters in the *buffer* area.

buffer

The name of the buffer that will be used to hold the path name of the working directory. *buffer* must be big enough to hold the working directory name, plus a terminating NULL to mark the end of the name.

Returned value

If successful, `getcwd()` returns a pointer to the buffer.

If unsuccessful, `getcwd()` returns a NULL pointer and sets `errno` to one of the following values:

Error Code

Description

EACCES

The process did not have read or search permission on some component of the working directory's path name.

EINVAL

size is less than or equal to zero.

EIO

An input/output error occurred.

ENOENT

A component of the working directory's path name does not exist.

ENOTDIR

A directory component of the working directory's path name is not really a directory.

ERANGE

size is greater than 0, but less than the length of the working directory's path name, plus 1 for the terminating NULL.

Example

CELEBG03

```
/* CELEBG03

   This example determines the working directory.

*/
#define _POSIX_SOURCE
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
    char cwd[256];

    if (chdir("/tmp") != 0)
        perror("chdir() error");
    else {
        if (getcwd(cwd, sizeof(cwd)) == NULL)
            perror("getcwd() error");
```

```

    else
        printf("current working directory is: %s\n", cwd);
    }
}

```

Output

```
current working directory is: /tmp
```

getdate(), getdate64() — Convert user format date and time

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```

#define _XOPEN_SOURCE_EXTENDED 1
#include <time.h>

struct tm *getdate(const char *string);

extern int getdate_err;

```

```

#define _LARGE_TIME_API
#include <time.h>

struct tm *getdate64(const char *string);

```

General description

The `getdate()` function converts definable date and/or time specifications pointed to by *string* into a `tm` structure. The `tm` structure declaration is in the header `<time.h>`.

Templates are used to parse and interpret the input string. The templates are contained in text files created by the process and identified using the environment variable `DATMSK`. The `DATMSK` variable should be set to indicate the full path name of the file that contains the templates. The first line in the template that matches the input specification is used for the interpretation and conversion into the internal time format.

The following field descriptors are supported:

%%

same as %.

%a

abbreviated weekday name

%A

full weekday name

%b

abbreviated month name

%B

full month name

%c

locale's appropriate date and time representation

%C

Century number [00,99]; leading zeros are permitted but not required. Used in conjunction with %y

%d

day of month (01-31; the leading 0 is optional)

%D

date as %m/%d/%y

%e

same as %d

%h

same as %b

%H

hour (00-23; the leading 0 is optional)

%I

hour (01-12; the leading 0 is optional)

%m

month number (00-11; the leading 0 is optional)

%M

minute (00-59; the leading 0 is optional)

%n

same as \n

%p

locale's equivalent of either AM or PM

%r

locale's 12 hour time representation. In the POSIX locale this is equivalent to %I:%M:%S %p

%R

time as %H:%M

%S

Seconds [00,60]. The range goes to 60 (rather than stopping at 59) to allow positive leap seconds to be expressed. Since leap seconds cannot be predicted by any algorithm, leap second data must come from some external source.

%t

same as \t (tab)

%T

time as %H:%M:%S

%w

weekday number (0-6; 0 indicates Sunday)

%x

locale's date representation. In the POSIX locale this is equivalent to %m/%d/%y.

%X

locale's time representation. In the POSIX locale this is equivalent to %H:%M:%S.

%y

year within century. When a century is not otherwise specified, values in the range 69-99 refer to years in the twentieth century (1969 to 1999 inclusive); values in the range 00-68 refer to years in the twenty-first century (2000 to 2068 inclusive). 31-bit supports values in the range 00-37 and 64-bit supports values in the range 00-68.

%Y

year as ccyy (1969-9999)

31-bit the upper bound for %Y is 2037.

64-bit the upper bound for %Y is 9999.

%Z

time zone name or no characters if no time zone exists. If the time zone supplied for %Z is not the time zone `getdate()` expects, a non-valid input specification error will result. The `getdate()` function calculates an expected time zone based on time and date information supplied to it.

The match between the template and input specification performed by `getdate()` is case insensitive.

The month and weekday names can consist of any combination of uppercase or lowercase letters. The process can request that the input date and time specification be in a specific language by setting the `LC_TIME` category (see `setlocale()`).

Leading 0's are not necessary for the descriptors that allow leading 0's. However, at most two digits are allowed for those descriptors, including leading 0's. Extra white space in either the template file or in *string* is ignored.

The field descriptors %c, %x, and %X will not be supported if they include unsupported field descriptors.

The following rules apply for converting the input specification into a `tm` structure:

- If only weekday is given, today is assumed if the given day is equal to the current day and next week if it is less,
- If only the month is given, the current month is assumed if the given month is equal to the current month and next year if it is less and no year is given (the first day of the month is assumed if no day is given),
- If no hour, minute, and second are given, the current hour, minute and second are assumed,
- If no date is given, today is assumed if the given hour is greater than the current hour and tomorrow is assumed if it is less.

Notes:

1. When converting an input specification into a `tm` structure, the `getdate()` function assumes current time and date values for missing fields as indicated in the previous list. The function treats these values as local time, based on the customization of time zone data.
2. When neither the `TZ` (POSIX) nor `_TZ` (non-POSIX) environment variable is defined, the current locale is interrogated for time zone information. If neither `TZ` nor `_TZ` is defined and `LC_TOD` time zone information is not present in the current locale, a default value is applied to local time. POSIX programs simply default to Coordinated Universal Time (UTC), while non-POSIX programs establish an offset from UTC based on the setting of the system clock. For more information about customizing a time zone to work with local time, see "Customizing a time zone" in [z/OS XL C/C++ Programming Guide](#).

If a field descriptor in the template file is not one of the supported field descriptors, then the following behaviors exist when the descriptor is encountered:

1. In an ASCII application, it is ignored (treated as non-matching) and processing continues to the next template.
2. In an EBCDIC application, it causes the function to return unsuccessful with `getdate_err` being set to the value 8.

The function `getdate64()` will behave exactly like `getdate()` except it will convert definable date or time specifications pointed to by *string* into a `tm` structure of calendar times beyond 03:14:07 UTC on January 19, 2038 with a limit of 23:59:59 UTC on December 31, 9999.

Returned value

If successful, `getdate()` returns a pointer to a `tm` structure.

If unsuccessful, `getdate()` returns a NULL pointer and sets the external variable `getdate_err` to a value indicating the error.

The `tm` structure to which `getdate()` returns a pointer is not shared with any other functions. Also, the `getdate()` function produces a `tm` structure unique to the thread on which it runs.

As is true for all external variables, C/370 allocates storage for the `getdate_err` external variable in writable static storage which is shared among all threads. Thus, `getdate_err` is not intrinsically “thread-safe”.

C/370 allocates storage on a per thread basis for an analog of `getdate_err`. The `__gderr()` function returns a pointer to this storage. It is recommended that multithread applications and applications running from a DLL use the `__gderr()` function rather than `getdate_err` if `getdate()` returns a NULL pointer to determine in a thread-safe manner why `getdate()` was unsuccessful.

The `__gderr()` is defined as follows:

```
#include <time.h>

int *__gderr(void);
```

The `__gderr()` function returns a pointer to the thread-specific value of `getdate_err`. The `getdate64()` function affects the same pointer to the thread-specific value of `getdate_err` as the `getdate()` function does.

The following is a list of `getdate_err` settings and their description:

- 1** The DATEMSK environment variable is NULL or undefined.
- 2** The template file cannot be opened for reading.
- 3** Failed to get file status information.
- 4** The template file is not a regular file.
- 5** An error was encountered while reading the template file.
- 6** Memory allocation failed (not enough memory available).
- 7** No line in the template file matches the input specification.
- 8** Non-valid input specification. For example, February 31; or a time that can not be represented in a `time_t` (representing the time is seconds since Epoch - midnight, January 1, 1970 (UTC)).
- 9** Unable to determine current time.
Note: This value is unique for z/OS UNIX services.

getdtablesize() – Get the file descriptor table size

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int getdtablesize(void);
```

General description

The `getdtablesize()` function is equivalent to `getrlimit()` with the `RLIMIT_NOFILE` option.

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use `getrlimit()` instead of `getdtablesize()`.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

`getdtablesize()` returns the current soft limit as if obtained from a call to `getrlimit()`.

There are no `errno` values defined.

getegid() – Get the effective group ID

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

gid_t getegid(void);
```

General description

Finds the effective group ID (GID) of the calling process.

Returned value

Returns the effective group ID (GID). It is always successful.

There are no documented errno values.

Example

CELEBG04

```
/* CELEBG04

   This example finds the group ID.

*/
#define _POSIX_SOURCE
#include <stdio.h>
#include <sys/types.h>
#include <unistd.h>

main() {
    printf("my group id is %d\n", (int) getgid());
}
```

Output

```
my group id is 500
```

getentropy() — Fill a buffer with random bytes

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <unistd.h>
```

```
int getentropy(void *buffer, size_t length);
```

General description

`getentropy()` function writes `length` bytes of high-quality random data to the buffer that starts at the location that is pointed to by `buffer`. The maximum valid value for the `length` argument is 256.

Returned value

If successful, `getentropy()` returns 0.

If unsuccessful, `getentropy()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EFAULT

Part or all of the buffer that is specified by `buffer` and `length` is not in valid addressable memory.

EIO

`length` is greater than 256.

Related information

- [“getrandom\(\) — Obtain a series of random bytes” on page 766](#)

getenv() — Get value of environment variables

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdlib.h>

char *getenv(const char *varname);
```

General description

Searches the table of environment variables for an entry corresponding to `varname` and returns a pointer to a buffer containing the current string value of `varname`.

Special behavior for POSIX: Under POSIX, the value of the `char **environ` pointer is honored and used by `getenv()`. You can declare and use this pointer. Under POSIX(OFF) this is not the case: the table start cannot be modified.

Usage Note

To avoid changing the environment variables or management process, the caller must ensure not to modify or release the buffer that is pointed by the returned pointer.

Returned value

If successful, `getenv()` returns a pointer to a buffer containing the current string value of *varname*. You should copy the string that is returned because a subsequent call to `getenv()` will overwrite it.

If the *varname* is not found, `getenv()` returns a NULL pointer. The returned value is NULL if the given variable is not currently defined.

Example

CELEBG05

```
/* CELEBG05

   In this example, *pathvar points to the value of the PATH
   environment variable.
   In a POSIX environment, this variable would be from the CENV
   group ID.

*/
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    char *pathvar;

    pathvar = getenv("PATH");
    printf("pathvar=%s",pathvar);
}
```

__getenv() – Get an environment variable

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <stdlib.h>

char *__getenv(const char *varname);
```

General description

`__getenv()` returns a unique character pointer for each environmental variable. For single-threaded applications, this eliminates the need to copy the string returned by previous `__getenv()` calls.

This function should not be used by multithreaded applications. Updates to the environmental variable on another thread may invalidate the address returned by `__getenv()` before the application copies the returned value.

The format of an environment variable is made up of three parts that are combined to form:

name=value

Where:

1. The first part, *name*, is a character string that represents the name of the environment variable. It is this part of the environment variable that `__getenv()` tries to match with *varname*.
2. The second part, `=`, is a separator character (since the equal sign is used as a separator character it cannot appear in the *name*).
3. The third part, *value*, is a NULL-terminated character string that represents the value that the environment variable, *name*, is set to. This is the part of the environment variable that `__getenv()` returns a pointer to.

There are several ways to establish a set of environment variables.

- Set at program initialization time from the Language Environment runtime option ENVAR.
- Set at program initialization time from a data set.
- If the program was invoked with a `system()` call, they can be inherited from the calling enclave.
- In the z/OS UNIX environment they can also be inherited from the parent process if the program was invoked with one of the `exec` functions.
- During the running of a program they can be set with the `setenv()` function or the `putenv()` function.

For a list of the environment variables that z/OS UNIX services support, see the chapter “Using Environment Variables” in *z/OS XL C/C++ Programming Guide*.

Special behavior for POSIX: Under POSIX, the value of the `char **environ` pointer is honored and used by `getenv()`. You can declare and use this pointer. Under POSIX(OFF) this is not the case: the table start cannot be modified.

Note: The `__getenv()` function has a dependency on the level of the Enhanced ASCII Extensions. See “Enhanced ASCII support” on page 2123 for details.

Returned value

If successful, `__getenv()` returns a pointer to the string containing the value of the environment variable specified by *varname*.

If unsuccessful, `__getenv()` returns a NULL pointer. The returned value is NULL if the given variable is not currently defined or if the system does not support environment variables.

geteuid() – Get the effective user ID

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

uid_t geteuid(void);
```

General description

Finds the effective user ID (UID) of the calling process.

Returned value

Returns the effective user ID of the calling process. It is always successful.

There are no documented errno values.

Example

CELEBG06

```
/* CELEBG06

   This example returns information for your user ID.

*/
#define _POSIX_SOURCE
#include <sys/types.h>
#include <pwd.h>
#include <unistd.h>

main() {
    struct passwd *p;
    uid_t uid;

    if ((p = getpwuid(uid = geteuid())) == NULL)
        perror("getpwuid() error");
    else {
        puts("getpwuid() returned the following info for your userid:");
        printf(" pw_name  : %s\n",      p->pw_name);
        printf(" pw_uid   : %d\n", (int) p->pw_uid);
        printf(" pw_gid   : %d\n", (int) p->pw_gid);
        printf(" pw_dir   : %s\n",      p->pw_dir);
        printf(" pw_shell : %s\n",      p->pw_shell);
    }
}
```

Output

getpwuid() returns the following information for your user ID:

```
pw_name  : MVSUSR1
pw_uid   : 25
pw_gid   : 500
```

```
pw_dir   : /u/mvsusr1
pw_shell : /bin/sh
```

getgid() — Get the real group ID

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

gid_t getgid(void);
```

General description

Finds the real group ID (GID) of the calling process.

Returned value

Returns the real group ID of the calling process. It is always successful.

There are no documented errno values.

Example

CELEBG07

```
/* CELEBG07

   This example gets the real group ID.

*/
#define _POSIX_SOURCE
#include <sys/types.h>
#include <stdio.h>
#include <unistd.h>

main() {
    printf("my group id is %d\n", (int) getgid());
}
```

Output

```
my group id is 500
```

getgrent() — Get group database entry

The information for this function is included in [“endgrent\(\) — Group database entry functions” on page 419](#).

getgrgid() — Access the group database by ID**Standards**

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <grp.h>

struct group *getgrgid(gid_t gid);
```

General description

Provides information about the group specified by *gid* and its members.

Returned value

If successful, `getgrgid()` returns a pointer to a group structure containing an entry from the group database with the specified *gid*. The return value may point to static data that is overwritten by each call. This group structure, defined in the `grp.h` header file, contains the following members:

gr_name

The name of the group

gr_gid

The numerical group ID (GID)

gr_mem

A NULL-terminated vector of pointers to the individual member names

If unsuccessful, `getgrgid()` returns a NULL pointer.

There are no documented errno values.

Example

CELEBG08

```
/* CELEBG08

   This example provides the root GID and group name.

*/
#define _POSIX_SOURCE
#include <sys/types.h>
#include <grp.h>
#include <stdio.h>
#include <sys/stat.h> /*FIX: used to be <stat.h>*/

main() {
    struct stat info;
    struct group *grp;

    if (stat("/", &info) < 0)
        perror("stat() error");
    else {
        printf("The root is owned by gid %d\n", info.st_gid);
        if ((grp = getgrgid(info.st_gid)) == NULL)
            perror("getgrgid() error");
        else
            printf("This group name is %s\n", grp->gr_name);
    }
}
```

Output

```
The root is owned by gid 500
This group name is SYS1
```

Related information

getgrgid_r() — Get group database entry for a group ID

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 z/OS UNIX | both | OS/390 V2R8 |

Format

```
#define _XOPEN_SOURCE 500
#include <sys/types.h>
#include <grp.h>

int getgrgid_r(gid_t gid, struct group *grp, char *buffer,
size_t bufsize, struct group **result);

#define _POSIX_SOURCE
#include <grp.h>

int __getgrgid1(gid_t gid, struct group *grp, char *buffer,
size_t bufsize, struct group **result);
```

General description

The `getgrgid_r()` function updates the group structure pointed to by *grp* and stores a pointer to that structure at the location pointed to by *result*. The structure contains an entry from the group database with a matching *gid*. Storage referenced by the group structure is allocated from the memory provided with the *buffer* parameter, which is *bufsize* bytes in size. A NULL pointer is returned at the location pointed to by *result* on error or if the requested entry is not found.

The `__getgrgid1()` function is identical to `getgrgid_r()` except that it does not return the individual group member names. Element `gr_mem` of the group structure pointed to by *grp* will be set to NULL.

Returned value

If successful, `getgrgid_r()` or `__getgrgid1()` returns 0.

If unsuccessful, `getgrgid_r()` or `__getgrgid1()` returns an error number and sets `errno` to one of the following values:

Error Code

Description

EINVAL

One of the input arguments was not valid. Arguments *grp*, *buffer*, and *result* must not be NULL. Argument *bufsize* must not be 0.

ERANGE

Insufficient storage was supplied in *buffer* and *bufsize* to contain the data to be referenced by the resulting group structure.

EMVSSAFEXTRERR

The system authorization facility (SAF) RACROUTE EXTRACT service had an error.

EMVSSAF2ERR

The SAF Get GMAP service had an error.

getgrnam() — Access the group database by name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <grp.h>

struct group *getgrnam(const char *name);
```

General description

Accesses the group structure containing an entry from the group database with the specified *name*.

Returned value

If successful, `getgrnam()` returns a pointer to a group structure. The return value may point to static data that is overwritten by each call.

The group structure, defined in the `grp.h` header file, contains the following members:

gr_name

The name of the group

gr_gid

The numerical group ID (GID)

gr_mem

A NULL-terminated vector of pointers to the individual member names.

If unsuccessful or if the requested entry is not found, `getgrnam()` returns a NULL pointer.

There are no documented `errno` values.

Example

CELEBG09

```
/* CELEBG09

   This example provides the members of a group.

*/
#define _POSIX_SOURCE
#include <sys/types.h>
#include <grp.h>
#include <stdio.h>

main() {
    struct group *grp;
    char  grpname[]="USERS", **curr;

    if ((grp = getgrnam(grpname)) == NULL)
        perror("getgrnam() error");
    else {
        printf("The following are members of group %s:\n", grpname);
        for (curr=grp->gr_mem; (*curr) != NULL; curr++)
            printf("  %s\n", *curr);
    }
}
```

```

    }
}

```

Output

The following are members of group USERS:

```

MVSUSR1
MVSUSR2
MVSUSR3
MVSUSR4
MVSUSR5
MVSUSR6
MVSUSR7
MVSUSR8
MVSUSR9

```

getgrnam_r() — Search group database for a name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 z/OS UNIX | both | OS/390 V2R8 |

Format

```

#define _XOPEN_SOURCE 500
#include <sys/types.h>
#include <grp.h>

int getgrnam_r(const char *name, struct group *grp, char *buffer,
size_t bufsize, struct group **result);

#define _POSIX_SOURCE
#include <grp.h>

int __getgrnam1(const char *name, struct group *grp, char *buffer,
size_t bufsize, struct group **result);

```

General description

The `getgrnam_r()` function updates the group structure pointed to by `grp` and stores a pointer to that structure at the location pointed to by `result`. The structure contains an entry from the group database with a matching name. Storage referenced by the group structure is allocated from the memory provided with the `buffer` parameter, which is `bufsize` bytes in size. A NULL pointer is returned at the location pointed to by `result` on error or if the requested entry is not found.

The `__getgrnam1()` function is identical to `getgrnam_r()` except that it does not return the individual group member names. Element `gr_mem` within the group structure pointed to by `grp` will be set to `NULL`.

Returned value

If successful, `getgrnam_r()` or `__getgrnam1()` returns 0.

If unsuccessful, `getgrnam_r()` or `_getgrnam1()` returns an error number and sets `errno` to one of the following values:

Error Code

Description

EINVAL

One of the input arguments was not valid. Arguments *grp*, *buffer*, and *result* must not be `NULL`. Argument *bufsize* must not be 0.

ERANGE

Insufficient storage was supplied in *buffer* and *bufsize* to contain the data to be referenced by the resulting group structure.

EMVSSAFEXTRERR

The system authorization facility (SAF) RACROUTE EXTRACT service had an error.

EMVSSAF2ERR

The SAF Get GMAP service had an error.

getgroups() — Get a list of supplementary group IDs

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

int getgroups(int size, gid_t list[]);
```

General description

Stores the supplementary group IDs of the calling process in the *list* array. *size* gives the number of `gid_t` elements that can be stored in the *list* array.

Returned value

If successful, `getgroups()` returns the number of supplementary group IDs that it puts into *list*. This value is always greater than or equal to 1 and less than or equal to the value of **NGROUPS_MAX** (which is defined in the `limits.h` header file).

If *size* is zero, `getgroups()` returns the total number of supplementary group IDs for the process. `getgroups()` does not try to store group IDs in *list*.

If unsuccessful, `getgroups()` returns -1 and sets `errno` to one of the following values.

Error Code

Description

EINVAL

size was not equal to 0 and is less than the total number of supplementary group IDs for the process.
list may or may not contain a subset of the supplementary group IDs for the process.

Example

CELEBG10

```
/* CELEBG10

   This example provides a list of the supplementary group IDs.

*/
#define _POSIX_SOURCE
#include <sys/types.h>
#include <grp.h>
#include <stdio.h>
#include <unistd.h>

#define dim(x) (sizeof(x)/sizeof(x[0]))

main() {
    gid_t gids[500];
    struct group *grp;
    int count, curr;

    if ((count = getgroups(dim(gids), gids)) == -1)
        perror("getgroups() error");
    else {
        puts("The following is the list of my supplementary groups:");
        for (curr=0; curr<count; curr++) {
            if ((grp = getgrgid(gids[curr])) == NULL)
                perror("getgrgid() error");
            else
                printf("  %8s (%d)\n", grp->gr_name, (int) gids[curr]);
        }
    }
}
```

Output

```
The following is the list of my supplementary groups:
  SYS1 (500)
  KINGS (512)
  NOBLES (513)
  KNIGHTS (514)
  WIZARDS (515)
  SCRIBES (516)
  JESTERS (517)
  PEASANTS (518)

getgroupsbyname() — Get supplementary group IDs by user name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

int getgroupsbyname(char username[], int size, gid_t list[]);
```

General description

Stores the supplementary group IDs of the specified *username* in the array, *list*. *size* gives the number of `gid_t` elements that can be stored in the array, *list*.

Returned value

If successful, `getgroupsbyname()` returns the number of supplementary group IDs that it puts into *list*. This value is always greater than or equal to one, and less than or equal to the value of **NGROUPS_MAX**.

If *size* is zero, `getgroupsbyname()` returns the total number of supplementary group IDs for the process. `getgroupsbyname()` does not try to store group IDs in *list*.

If unsuccessful, `getgroupsbyname()` returns -1 and sets `errno` to one of the following values.

Error Code

Description

EINVAL

size was less than or equal to the total number of supplementary group IDs for the process. *list* may or may not contain a subset of the supplementary group IDs for the process.

Example

CELEBG11

```
/* CELEBG11

   This example provides a list of the supplementary group IDs for
   MVSUSR1.

*/
#define _POSIX_SOURCE
#include <sys/types.h>
#include <grp.h>
#include <stdio.h>
#include <unistd.h>

#define dim(x) (sizeof(x)/sizeof(x[0]))

main() {
    gid_t gids[500];
    struct group *grp;
    int count, curr;
    char user[]="MVSUSR1";
```

```
if ((count = getgroupsbyname(user, dim(gids), gids)) == -1)
    perror("getgroups() error");
else {
    printf("The following is the list of %s's supplementary groups:\n",
           user);
    for (curr=0; curr<count; curr++) {
        if ((grp = getgrgid(gids[curr])) == NULL)
            perror("getgrgid() error");
        else
            printf("  %8s (%d)\n", grp->gr_name, (int) gids[curr]);
    }
}
```

Output

```
The following is the list of MVSUSR1's supplementary groups:
  SYS1 (500)
  USERS (523)
```

gethostbyaddr() — Get a host entry by address

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>
extern int h_errno;

struct hostent *gethostbyaddr(const void *address, size_t len, int type);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

struct hostent *gethostbyaddr(char *address, int address_len, int domain);
```

General description

The `gethostbyaddr()` call tries to resolve the host address through a name server, if one is present. `gethostbyaddr()` searches the local host tables until a matching host address is found or an EOF marker is reached.

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

address

The pointer to a structure containing the address of the host. (An unsigned long for AF_INET.)

address_len

The size of *address* in bytes.

domain

The address domain supported (AF_INET).

If you want `gethostbyaddr()` to bypass the name server and instead resolve the host address using the local host tables, you must define the `RESOLVE_VIA_LOOKUP` symbol before including any sockets-related include files in your source program.

You can use the **X_ADDR** environment variable to specify different local host tables and override those supplied by the z/OS global resolver during initialization.

Note: For more information on these local host tables or the environment variables, see [z/OS Communications Server: IP Configuration Guide](#).

The `gethostbyaddr()` call returns a pointer to a `hostent` structure for the host address specified on the call.

`gethostent()`, `gethostbyaddr()`, and `gethostbyname()` all use the same static area to return the `hostent` structure. This static area is only valid until the next one of these functions is called on the same thread.

The **netdb.h** include file defines the `hostent` structure and contains the following elements:

| Element | Description |
|---------|-------------|
|---------|-------------|

h_addr_list

A pointer to a NULL-terminated list of host network addresses.

h_addrtype

The type of address returned; currently, it is always set to AF_INET.

h_aliases

A zero-terminated array of alternative names for the host.

h_length

The length of the address in bytes.

h_name

The official name of the host.

The following function (X/Open sockets only) is defined in **netdb.h** and should be used by multithreaded applications when attempting to reference *h_errno* return on error:

```
int *__h_errno(void);
```

Also use this function when you invoke `gethostbyaddr()` in a DLL.

This function returns a pointer to a thread-specific value for the *h_errno* variable.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

Note: The `gethostbyaddr()` and `gethostbyname()` functions have been moved to obsolescence in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The `getaddrinfo()` and `getnameinfo()` functions are preferred for portability.

Returned value

The return value points to static data that is overwritten by subsequent calls. A pointer to a `hostent` structure indicates success. A NULL pointer indicates an error or End Of File (EOF).

If unsuccessful in X/Open, `gethostbyaddr()` sets `h_errno` to indicate the error as follows:

Error Code

Description

HOST_NOT_FOUND

No such host is known.

NO_DATA

The server recognized the request and the name but no address is available. Another type of request to the name server might return an answer.

NO_RECOVERY

An unexpected server failure occurred from which there is no recovery.

TRY_AGAIN

A temporary error such as no response from a server, indicating the information is not available now but may be at a later time.

gethostbyname() — Get a host entry by name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>
extern int h_errno;

struct hostent *gethostbyname(const char *name);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

struct hostent *gethostbyname(char *name);
```

General description

The `gethostbyname()` call tries to resolve the host name through a name server, if one is present. If a name server is not present, `gethostbyname()` searches the local host tables until a matching host name is found or an EOF marker is reached.

Parameter

Description

name

The name of the host.

The `gethostbyname()` call returns a pointer to a `hostent` structure for the host name specified on the call.

`gethostent()`, `gethostbyaddr()`, and `gethostbyname()` all use the same static area to return the `hostent` structure. This static area is only valid until the next one of these functions is called on the same thread.

If you want `gethostbyname()` to bypass the name server and instead resolve the host name using the local host tables, you must define the `RESOLVE_VIA_LOOKUP` symbol before including any sockets-related include files in your source program.

If the name server is not present or the `RESOLVE_VIA_LOOKUP` option is in effect, you can use the **X_SITE** environment variable to specify different local host tables and override those supplied by the z/OS global resolver during initialization.

Note: For more information on these local host tables or the environment variables, see [z/OS Communications Server: IP Configuration Guide](#).

`gethostent()`, `gethostbyaddr()`, and `gethostbyname()` all use the same static area to return the `HOSTENT` structure. This static area is only valid until the next one of these functions is called on the same thread.

The **netdb.h** include file defines the `hostent` structure and contains the following elements:

Element**Description*****h_addr_list***

A pointer to a NULL-terminated list of host network addresses.

h_addrtype

The type of address returned; currently, it is always set to `AF_INET`.

h_aliases

A zero-terminated array of alternative names for the host.

h_length

The length of the address in bytes.

h_name

The official name of the host.

The following function (X/Open sockets only) is defined in **netdb.h** and should be used by multithreaded applications when attempting to reference `h_errno` return on error:

```
int *__h_errno(void);

gethostent() — Get the next host entry

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format**X/Open:**

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

struct hostent *gethostent(void);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

struct hostent *gethostent(void);
```

General description

The `gethostent()` call reads the next line of the local host tables.

The `gethostent()` call returns a pointer to the next entry in the local host tables. `gethostent()` uses the local host tables to get aliases.

You can use the **X_SITE** environment to specify different local host tables and override those supplied by the z/OS resolver during initialization.

Note: For more information on these local host tables or the environment variables, see [z/OS Communications Server: IP Configuration Guide](#).

gethostent(), gethostbyaddr(), and gethostbyname() all use the same static area to return the hostent structure. This static area is only valid until the next one of these functions is called on the same thread.

The **netdb.h** include file defines the hostent structure and contains the following elements:

Element

Description

h_addrtype

The type of address returned; currently, it is always set to AF_INET.

h_addr

A pointer to the network address of the host.

h_aliases

A zero-terminated array of alternative names for host.

h_length

The length of the address in bytes.

h_name

The official name of the host.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` 1 feature test macro.

Returned value

If successful, gethostent() returns a pointer to a hostent structure. The return value points to data that is overwritten by subsequent calls returning the same data structure.

If unsuccessful, gethostent() returns a NULL pointer, indicating an error or End Of File (EOF).

gethostid() — Get the unique identifier of the current host

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

long gethostid(void);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <unistd.h>
```

```
int gethostid();
```

General description

The `gethostid()` call gets the unique 32-bit identifier for the current host. This value is the default home Internet address.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` 1 feature test macro.

Note: `gethostid()` is not supported for callers in an IBM z/OS Container Platform environment.

Returned value

If successful, `gethostid()` returns the 32-bit identifier of the current host, which should be unique across all hosts.

If unsuccessful, `gethostid()` returns -1 and stores the error value in `errno`. For return codes, see [z/OS UNIX System Services Messages and Codes](#).

Error Code

Description

ENOTSUP

`gethostid()` is not supported for callers in an IBM z/OS Container Platform environment.

Related information

- [“unistd.h — Implementation-specific functions” on page 77](#)
- [“gethostname\(\) — Get the name of the host processor” on page 724](#)

gethostname() — Get the name of the host processor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int gethostname(char *name, size_t namelen);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <unistd.h>

int gethostname(char *name, int namelen);
```

General description

The `gethostname()` call returns the name of the host processor that the program is running on. If a UTS namespace is previously created for the caller of the `gethostname()` call, the host name that is

associated with that UTS namespace is returned. Up to *namelen* characters are copied into the name array. The returned name is NULL-terminated unless there is insufficient room in the name array.

Parameter Description

name

The character array to be filled with the host name.

namelen

The length of *name*.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` 1 feature test macro.

Returned value

If successful, `gethostname()` returns 0.

If unsuccessful, `gethostname()` returns -1 and sets `errno` to one of the following values:

Error Code Description

EAGAIN

The resource is temporarily unavailable or the caller is not authorized to access the stack.

EMVSERR

An MVS environmental or internal error occurs. Contact IBM support.

Related information

- [“unistd.h — Implementation-specific functions” on page 77](#)

getibmopt() — Get IBM TCP/IP image

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _OPEN_SYS_SOCKET_EXT
#include <sys/socket.h>

int getibmopt(int cmd, struct ibm_gettcpinfo *bfrp);
```

General description

The `getibmopt()` function call returns -1 with `errno` EOPNOTSUPP to indicate that this function is not currently supported.

Parameter Description

cmd

The value in domain must be `AF_INET`.

bfrp

The pointer to an `ibm_gettcpinfo` structure.

Returned value

`getibmsockopt()` always returns -1, indicating that this function is not currently supported.

Error Code
Description

EOPNOTSUPP
This function is not supported.

Related information

- [“sys/socket.h — Sockets definitions” on page 70](#)

getibmsockopt() — Get IBM specific options associated with a socket

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _OPEN_SYS_SOCK_EXT
#include <sys/socket.h>

int getibmsockopt(int s, int level, int optname, char *optval, int *optlen);
```

General description

Like `getsockopt()`, the `getibmsockopt()` gets the options associated with a socket in the `AF_INET` or `AF_INET6` domain. Only `SOL_SOCKET` is supported. This call is for options specific to the IBM implementation of sockets. Currently, only the `SOL_SOCKET` level and the socket options `SO_NONBLOCKLOCAL` and `SO_IGNOREINCOMINGPUSH` are supported.

Parameter
Description

- s**
The socket descriptor.
- level**
The level for which the option is set.
- optname**
The name of a specified socket option.
- optval**
The pointer to option data.
- optlen**
The pointer to the length of the option data.

The fields `b_num_UNITSs_sent` and `b_num_UNITSs_received` represent cumulative totals for this socket since the time the application was started.

For `SO_NONBLOCKLOCAL`, `optval` should point to an integer. `getibmsockopt()` returns 0 in `optval` if the socket is in blocking mode, and returns 1 in `optval` if the socket is in nonblocking mode.

For SO_IGNOREINCOMINGPUSH, *optval* should point to an integer. `getibmssockopt()` returns 0 in *optval* if the option is not set, and returns 1 in *optval* if the option is set.

Returned value

If successful, `getibmssockopt()` returns 0.

If unsuccessful, `getibmssockopt()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

The *s* parameter is not a valid socket descriptor.

EFAULT

Using *optval* and *optlen* parameters would result in an attempt to access storage outside the caller's address space.

ENOPROTOPT

The *optname* parameter is unrecognized, or the *level* parameter is not SOL_SOCKET.

Related information

- [“sys/socket.h — Sockets definitions” on page 70](#)
- [“setibmssockopt\(\) — Set IBM specific options associated with a socket” on page 1537](#)

__getipc(), __getipc64()— Query interprocess communications

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

__getipc:

```
#define _XOPEN_SOURCE
#include <sys/__getipc.h>

int __getipc(int token_id, IPCQPROC *bufptr, size_t buflen, int cmd);
```

__getipc64:

```
#define _LARGE_TIME_API
#define _XOPEN_SOURCE
#include <sys/__getipc.h>

int __getipc64(int token_id, IPCQPROC64 *bufptr, size_t buflen, int cmd);
```

General description

The `__getipc()` and `__getipc64()` functions provide means for obtaining information about the status of interprocess communications (IPC) resources, message queues, semaphores, shared memory, and map service memory.

The `__getipc64()` function behaves exactly like `__getipc()` except `__getipc64()` supports time beyond 03:14:07 UTC on January 19, 2038 with a limit of 23:59:59 UTC on December 31, 9999.

The argument *token_id* is a number that identifies the relative position of an IPC member in the system or specifies a message queue ID, semaphore ID, or shared memory ID. Zero represents the first IPC member ID in the system. On the first call to `__getipc()`, pass the a *token_id* of zero; the function will return the

token that identifies the next IPC resource to which the caller has access. Use this token on the next call to `__getipc()`.

The argument *bufptr* is the address where the data is to be stored.

The argument *buflen* is the length of the buffer.

The argument *cmd* specifies one of the following commands:

IPCQALL

Retrieve the next shared memory, semaphore, or message queue

IPCQMSG

Retrieve the next message member

IPCQSEM

Retrieve the next semaphore member

IPCQSHM

Retrieve the next shared memory member

IPCQMAP

Retrieve the next map service memory currently allocated

IPCQOVER

Overview of system variables. Ignores the value of the first argument *token_id*.

Returned value

If successful, `__getipc()` returns 0.

If unsuccessful, `__getipc()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

Operation permission (read) is denied to the calling process for the member ID specified by *token_id*.

EFAULT

The argument *bufptr* contains an non-valid address.

EINVAL

The member ID specified in the argument *token_id* is not valid for the command specified, or the argument *cmd* is not a valid command.

getipv4sourcefilter() – Get source filter

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| RFC3678 | both | z/OS V1.9 |

Format

```
#define _OPEN_SYS_SOCK_EXT3
#include <netinet/in.h>

int getipv4sourcefilter(int s, struct in_addr interface, struct in_addr group,
                       uint32_t *fmode, uint32_t *numsrc, struct in_addr *slist);
```

General description

This function allows applications to get a previously set multicast filtering state for a tuple consisting of socket, interface, and multicast group values.

A multicast filter is described by a filter mode, which is MCAST_INCLUDE or MCAST_EXCLUDE, and a list of source addresses which are filtered.

This function is IPv4-specific, must be used only on AF_INET sockets with an open socket of type SOCK_DGRAM or SOCK_RAW.

If the function is unable to obtain the required storage, control will not return to the caller. Instead the application will terminate due to an out of memory condition (if the reserve stack is available and the caller is not XPLINK), or it will terminate with an abend indicating that storage could not be obtained.

Argument

Description

s

Identifies the socket.

interface

Holds the local IP address of the interface.

group

Holds the IP multicast address of the group.

fmode

Points to an integer that will contain the filter mode on a successful return. The value of this field will be either MCAST_INCLUDE or MCAST_EXCLUDE, which are likewise defined in <netinet/in.h>.

numsrc

It is a pointer that on input, points to the number of source addresses that will fit in the slist array. On return, points to the total number of sources associated with the filter.

slist

Points to buffer into which an array of IP addresses of included or excluded (depending on the filter mode) sources will be written. If numsrc was 0 on input, a NULL pointer may be supplied.

Returned value

If successful, the function returns 0. Otherwise, it returns -1 and sets errno to one of the following values.

errno

Description

EADDRNOTAVAIL

The tuple consisting of socket, interface, and multicast group values does not exist, or the specified interface address is incorrect for this host, or the specified interface address is not multicast capable.

EBADF

s is not a valid socket descriptor.

EINVAL

Interface or group is not a valid IPv4 address, or the socket s has already requested multicast setsockopt options.

EPROTOTYPE

The socket s is not of type SOCK_DGRAM or SOCK_RAW.

getitimer() — Get value of an interval timer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/time.h>

int getitimer(int which, struct itimerval *value);
```

General description

getitimer() gets the current value of an (previously set) interval timer. An interval timer is a timer which sends a signal after each repetition (interval) of time.

The *which* argument indicates what kind of time is being controlled. Values for *which* are:

ITIMER_REAL

This timer is marking real (clock) time. A SIGALRM signal is generated after each interval of time.

Note: alarm() also sets the real interval timer.

ITIMER_VIRTUAL

This timer is marking process virtual time. Process virtual time is the amount of time spent while executing in the process, and can be thought of as a CPU timer. A SIGVTALRM signal is generated after each interval of time.

ITIMER_PROF

This timer is marking process virtual time plus time spent while the system is running on behalf of the process. A SIGPROF signal is generated after each interval of time.

Note: In a multithreaded environment, each of the above timers is specific to a thread of execution for both the generation of the time interval and the measurement of time. For example, an ITIMER_VIRTUAL timer will mark execution time for just the thread, not the entire process.

The *value* argument is a pointer to a structure containing:

it_interval

timer interval

it_value

current timer value (time remaining)

Each of these fields is a timeval structure, and contains:

tv_sec

seconds since January 1, 1970 (UTC)

tv_usec

microseconds

Returned valueIf successful, `getitimer()` returns 0, and *value* points to the itimerval structure.If unsuccessful, `getitimer()` returns -1 and sets `errno` to one of the following values:**Error Code****Description****EINVAL***which* is not a valid timer type.**Related information**

getline() — Read an entire line from a stream

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1-2008 Single UNIX Specification, Version 4 | both | |

Format

```
#define _POSIX_C_SOURCE 200809L

#include <stdio.h>
ssize_t getline(char **__restrict__ lineptr, size_t *__restrict__ n, FILE *__restrict__ stream);
```

General description

The `getline()` function reads an entire line from *stream*, storing the address of the buffer containing the text into **lineptr*. The buffer is null-terminated and includes the newline character, if one is found.

If **lineptr* is set to NULL and **n* is set 0 before the call, `getline()` allocates a buffer for storing the line. This buffer must be freed by the user program even when `getline()` fails.

Alternatively, before calling `getline()`, `*lineptr` can contain a pointer to a buffer that is allocated by `malloc()`, which is `*n` bytes in size. If the buffer is not large enough to hold the line, `getline()` resizes it with `realloc()`, updating `*lineptr` and `*n` as necessary.

In either case, on a successful call, `*lineptr` and `*n` are updated to reflect the buffer address and allocated size respectively.

Returned value

If successful, `getline()` returns the number of characters that are read, including the newline character, but not including the terminating null byte (`'\0'`). This value can be used to handle embedded null bytes in the line read.

If unsuccessful, `getline()` returns -1 and sets `errno` to one of the following values:

Error Code
Description

EINVAL
Invalid arguments. `*lineptr` or `*n` is NULL, or `stream` is not valid.

ENOMEM
Allocation or reallocation of the line buffer fails.

ERECIO
File opened for record I/O. Cannot get single bytes.

EOVERFLOW
Line length is too large, which exceeds the maximum value that the returning type `ssize_t` can represent.

getlogin() — Get the user login name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

_POSIX_SOURCE:

```
#define _POSIX_SOURCE
#include <unistd.h>

char *getlogin(void);
```

_XOPEN_SOURCE:

```
#define _XOPEN_SOURCE
#include <unistd.h>

char *getlogin(void);
```

General description

Finds the name that the login process associated with the current terminal. This string is stored in a static data area and, therefore, may be overwritten with every call to `getlogin()`.

Special behavior for `_POSIX_SOURCE`: If called from a batch program, a TSO command, or a shell command, `getlogin()` returns the MVS user name associated with the program. With z/OS UNIX services, this name is a TSO/E user ID. When `_POSIX_SOURCE` is defined and `_XOPEN_SOURCE` is not defined, then `getlogin()` is the same as `__getlogin1()`.

Special behavior for XPG4.2: You must have a TTY at file descriptor 0, 1, or 2, and the TTY must be recorded in the `/etc/utmpx` database. Someone must have logged in using the TTY. Also, the program must be invoked from a shell session, and file descriptors 0, 1, and 2 are not all redirected.

If `getlogin()` cannot determine the login name, you can call `getuid()` to get the user ID of the process, and then call `getpwuid()` to get a login name associated with that user ID. `getpwuid()` always returns the `passwd` struct for the same user, even if multiple users have the same UID.

Returned value

If successful, `getlogin()` returns a pointer to a string that has the login name for the current terminal.

Special behavior for `_POSIX_SOURCE`: If unsuccessful, `getlogin()` returns the NULL pointer.

There are no documented `errno` values.

Special behavior for XPG4.2: If unsuccessful, `getlogin()` returns a NULL pointer and sets `errno` to one of the following values:

Error Code

Description

EMFILE

`OPEN_MAX` file descriptors are currently open in the calling process.

ENFILE

The maximum allowable number of files is currently open in the system.

ENXIO

The calling process has no controlling terminal.

Example

CELEBG12

```
/* CELEBG12

   This example gets the user login name.

*/
#define _POSIX_SOURCE
#include <stdio.h>
#include <unistd.h>

main() {
    char *user;

    if ((user = __getlogin1()) == NULL)
        perror("__getlogin1() error");
    else printf("__getlogin1() returned %s\n", user);
}
```

Output

```
getlogin() returned MEGA
```

getlogin_r() — Get login name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 | both | OS/390 V2R8 |

Format

```
#define _XOPEN_SOURCE 500
#include <unistd.h>

int getlogin_r(char *name, size_t namesize);
```

General description

The `getlogin_r()` function puts the name associated by the login activity with the control terminal of the current process in the character array pointed to by *name*. The array is *namesize* characters long and should have space for the name and the terminating NULL character. The maximum size of the login name is **LOGIN_NAME_MAX**.

If `getlogin_r()` is successful, *name* points to the name the user used at login, even if there are several login names with the same user ID.

Returned value

If successful, `getlogin_r()` returns 0.

If unsuccessful, `getlogin_r()` sets `errno` to one of the following values:

Error Code

Description

ERANGE

The value of *namesize* is smaller than the length of the string to be returned including the terminating NULL character.

Related information

__getlogin1() — Get the user login name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---------------------------|----------|--------------|
| POSIX.1 XPG4 XPG4.2 | both | |

Format

_POSIX_SOURCE:

```
#define _POSIX_SOURCE
#include <unistd.h>

char *__getlogin1(void);
```

General description

Finds the name that the login process associated with the current terminal. If called from batch, __getlogin1() finds the name associated with the batch program. With z/OS UNIX services, this name is a TSO/E user ID unless the USERIDALISTABLE is in use. If the USERIDALISTABLE is setup and a z/OS UNIX alias name exists for a given MVS(TSO, batch user, etc.) userid, then that will be returned.

If __getlogin1() cannot determine the login name, you can call getuid() to get the user ID of the process, and then call getpwuid() to get a login name associated with that user ID. getpwuid() always returns the passwd struct for the same user, even if multiple users have the same UID.

Returned value

If successful, __getlogin1() returns a pointer to a string that has the login name for the current terminal.

If unsuccessful, __getlogin1() returns the NULL pointer.

There are no documented errno values.

Example

CELEBG12

```
/* CELEBG12

   This example gets the user login name.

*/
#define _POSIX_SOURCE
#include <stdio.h>
#include <unistd.h>

main() {
    char *user;

    if ((user = __getlogin1()) == NULL)
        perror("__getlogin1() error");
    else printf("__getlogin1() returned %s\n", user);
}
```

Output

```
getlogin() returned MEGA
```

getmccoll() — Get next collating element from string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <collate.h>

collcl_t getmccoll(char **src);
```

General description

If the object pointed to by *src* is not a NULL pointer, the `getmccoll()` library function determines the longest sequence of bytes in the array pointed to by *src* that constitute a valid multicharacter collating element. It then produces the value of type `collcl_t` corresponding to that collating element. The object pointed to by *src* is assigned the address just past the last byte of the multicharacter collating element processed.

Returned value

If successful, `getmccoll()` returns the value of type `collcl_t` that represents the collating element found. If the object pointed to by *src* is a NULL pointer, or if it points to NULL character, `getmccoll()` returns 0.

getmsg(), getpmsg() – Receive next message from a STREAMS file

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stropts.h>

int getmsg(int fildes, struct strbuf *ctlptr,
           struct strbuf *dataptr, int *flagsp);
int getpmsg(int fildes, struct strbuf *ctlptr,
            struct strbuf *dataptr, int *bandp, int *flagsp);
```

General description

The `getmsg()` function retrieves the contents of a message located at the head of the STREAM head read queue associated with a STREAMS file and places the contents into one or more buffers. The message contains either a data part, a control part, or both. The data and control parts of the message are placed into separate buffers, as described below. The semantics of each part is defined by the originator of the message.

The `getpmsg()` function does the same thing as `getmsg()`, but provides finer control over the priority of the messages received. Except where noted, all requirements on `getmsg()` also pertain to `getpmsg()`.

The *fildes* argument specifies a file descriptor referencing a STREAMS-based file.

The *ctlptr* and *dataptr* arguments each point to a `strbuf` structure, in which the **buf** member points to a buffer in which the data or control information is to be placed, and the **maxlen** member indicates the maximum number of bytes this buffer can hold. On return, the **len** member contains the number of bytes of data or control information actually received. The **len** member is set to 0 if there is a zero-length control or data part and **len** is set to -1 if no data or control information is present in the message.

When `getmsg()` is called, *flagsp* should point to an integer that indicates the type of message the process is able to receive. This is described further below.

The *ctlptr* argument is used to hold the control part of the message, and *dataptr* is used to hold the data part of the message. If *ctlptr* (or *dataptr*) is a NULL pointer or the **maxlen** member is -1, the control (or data) part of the message is not processed and is left on the STREAM head read queue. If the *ctlptr* (or *dataptr*) is not a NULL pointer, **len** is set to -1. If the **maxlen** member is set to 0 and there is a zero-length control (or data) part, that zero-length part is removed from the read queue and **len** is set to 0. If the **maxlen** member is set to 0 and there are more than 0 bytes of control (or data) information, that information is left on the read queue and **len** is set to 0. If the **maxlen** member in *ctlptr* (or *dataptr*) is less than the control (or data) part of the message, **maxlen** bytes are retrieved. In this case, the remainder of the message is left on the STREAM head read queue and a nonzero return value is provided.

By default, `getmsg()` processes the first available message on the STREAM head read queue. However, a process may choose to retrieve only high-priority messages by setting the integer pointed to by *flagsp* to `RS_HIPRI`. In this case, `getmsg()` and `getpmsg()` will only process the next message if it is a high-priority message. When the integer pointed to by *flagsp* is 0, any message will be retrieved. In this case, on return, the integer pointed to by *flagsp* will be set to `RS_HIPRI` if a high-priority message was retrieved, or 0 otherwise.

For `getpmsg()`, the flags are different. The *flagsp* argument points to a bitmask with the following mutually-exclusive flags defined: `MSG_HIPRI`, `MSG_BAND`, and `MSG_ANY`. Like `getmsg()`, `getpmsg()` processes the first available message on the STREAM head read queue. A process may choose to retrieve

only high-priority messages by setting the integer pointed to by *flagsp* to MSG_HIPRI and the integer pointed to by *bandp* to 0. In this case, getpmsg() will only process the next message if it is a high-priority message. In a similar manner, a process may choose to retrieve a message from a particular priority band by setting the integer pointed to by *flagsp* to MSG_BAND and the integer pointed to by *bandp* to the priority band of interest. In this case, getpmsg() will only process the next message if it is in a priority band equal to, or greater than, the integer pointed to by *bandp*, or if it is a high-priority message. If a process just wants to get the first message off the queue, the integer pointed to by *flagsp* should be set to MSG_ANY and the integer pointed to by *bandp* should be set to 0. On return, if the message retrieved was a high-priority message, the integer pointed to by *flagsp* will be set to MSG_HIPRI and the integer pointed to by *bandp* will be set to 0. Otherwise, the integer pointed to by *flagsp* will be set to MSG_BAND and the integer pointed to by *bandp* will be set to the priority band of the message.

If O_NONBLOCK is not set, getmsg() and getpmsg() will block until a message of the type specified by *flagsp* is available at the front of the STREAM head read queue. If O_NONBLOCK is set and a message of the specified type is not present at the front of the read queue, getmsg() and getpmsg() fail and set errno to EAGAIN.

If a hang-up occurs on the STREAM from which messages are to be retrieved, getmsg() and getpmsg() continue to operate normally, as described above, until the STREAM head read queue is empty. Thereafter, they return 0 in the *len* members of *ctlptr* and *dataptr*.

The following symbolic constants are defined under _XOPEN_SOURCE_EXTENDED 1 in <stropts.h>.

MSG_ANY

Receive any message.

MSG_BAND

Receive message from specified band.

MSG_HIPRI

Send/Receive high priority message.

MORECTL

More control information is left in message.

MOREDATA

More data is left in message.

Returned value

If successful, getmsg() and getpmsg() return a nonnegative value. A value of 0 indicates that a full message was read successfully. A return value of MORECTL indicates that more control information is waiting for retrieval. A return value of MOREDATA indicates that more data is waiting for retrieval. A return value of the bitwise logical OR of MORECTL and MOREDATA indicates that both types of information remain. Subsequent getmsg() and getpmsg() calls retrieve the remainder of the message. However, if a message of higher priority has come in on the STREAM head read queue, the next call to getmsg() or getpmsg() retrieves that higher-priority message before retrieving the remainder of the previous message.

If unsuccessful, getmsg() and getpmsg() return -1 and set errno to one of the following values.

Note: z/OS UNIX services do not supply any STREAMS devices or pseudodevices. It is impossible for getmsg() and getpmsg() to get a message from a STREAMS file. It will always return -1 with errno set to indicate the failure. See [“open\(\) — Open a file”](#) on page 1157 for more information.

Error Code**Description****EAGAIN**

The O_NONBLOCK flag is set and no messages are available.

EBADF

The *fildev* argument is not a valid file descriptor open for reading.

EBADMSG

The queued message to be read is not valid for getmsg() or getpmsg() or a pending file descriptor is at the STREAM head.

EINTR

A signal was caught during `getmsg()` or `getpmsg()`

EINVAL

An illegal value was specified by *flagsp*, or the STREAM or multiplexer referenced by *fildes* is linked (directly or indirectly) downstream from a multiplexer.

ENOSTR

A STREAM is not associated with *fildes*.

In addition, `getmsg()` and `getpmsg()` will fail if the STREAM head had processed an asynchronous error before the call. In this case, the value of `errno` does not reflect the result of `getmsg()` or `getpmsg()` but reflects the prior error.

getnameinfo() — Get name information

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| RFC2553 Single UNIX Specification, Version 3 | both | z/OS V1R4 |

Format

```
#define _OPEN_SYS_SOCKET_IPV6
#include <sys/socket.h>
#include <netdb.h>

int getnameinfo(const struct sockaddr *sa, socklen_t salen,
                char *host, socklen_t hostlen,
                char *serv, socklen_t servlen,
                int flags);
```

SUSV3

```
#define _POSIX_C_SOURCE 200112L
#include <sys/socket.h>
#include <netdb.h>

int getnameinfo(const struct sockaddr *__restrict__ sa, socklen_t salen,
                char *__restrict__ host, socklen_t hostlen, char *__restrict__ serv,
                socklen_t servlen, int flags);
```

General description

The `getnameinfo()` function translates a socket address to a node name and service location. The `getnameinfo()` function looks up an IP address and port number provided by the caller in the DNS and system-specific database, and returns text strings for both in buffers provided by the caller.

The *sa* argument points to either a `sockaddr_in` structure (for IPv4) or a `sockaddr_in6` structure (for IPv6) that holds the IP address and port number. The `sockaddr_in6` structure may also contain a zone index

value, if the IPv6 address represented by this `sockaddr_in6` structure is a link-local address. The *salen* argument gives the length of the `sockaddr_in` or `sockaddr_in6` structure.

If the socket address structure contains an IPv4-mapped IPv6 address or an IPv4-compatible IPv6 address, the embedded IPv4 address is extracted and the lookup is performed on the IPv4 address.

Note: The IPv6 unspecified address (“::”) and the IPv6 loopback address (“::1”) are not IPv4-compatible addresses. If the address is the IPv6 unspecified address, a lookup is not performed, and the `EAI_NONAME` error code is returned.

The node name associated with the IP address is returned in the buffer pointed to by the *host* argument. The caller provides the size of this buffer in the *hostlen* argument. The caller specifies not to return the node name by specifying a zero value for *hostlen* or a null *host* argument. If the node's name cannot be located, the numeric form of the node's address is returned instead of its name. If a zone index value was present in the `sockaddr_in6` structure, the numeric form of the zone index, or the interface name associated with the zone index, is appended to the node name returned, using the format `node name%scope` information.

If the size of the buffer specified in the *hostlen* argument is insufficient to contain the entire node name, or node name and scope information combination, up to *hostlen* characters will be copied into the buffer as a null terminated string.

The service name associated with the port number is returned in the buffer pointed to by the *serv* argument, and the *servlen* argument gives the length of this buffer. The caller specifies not to return the service name by specifying a zero value for *servlen* or a null *serv* argument. If the service's name cannot be located, the numeric form of the service address (for example, its port number) will be returned instead of its name.

If the size of the buffer specified in the *servlen* argument is insufficient to contain the entire service name, up to *servlen* characters will be copied into the buffer as a null terminated string.

The final argument, *flags*, is a flag that changes the default actions of this function. By default the fully-qualified domain name (FQDN) for the host is returned.

If the flag bit `NI_NOFQDN` is set, only the node name portion of the FQDN is returned for local hosts.

If the flag bit `NI_NUMERICHOST` is set, the numeric form of the host's address is returned instead of its name.

If the flag bit `NI_NAMEREQD` is set, an error is returned if the host's name cannot be located.

If the flag bit `NI_NUMERICSERV` is set, the numeric form of the service address is returned (for example, its port number) instead of its name.

If the flag bit `NI_NUMERICSCOPE` is set, the numeric form of the scope identifier is returned (for example, zone index) instead of its name. This flag is ignored if the *sa* argument is not an IPv6 address.

If the flag bit `NI_DGRAM` is set, this specifies that the service is a datagram service, and causes `getservbyport()` to be called with a second argument of "udp" instead of its default of "tcp". This flag is required for the few ports (for example, [512,514]) that have different services for UDP and TCP.

Note: The three `NI_NUMERICxxx` flags are required to support the "-n" flag that many commands provide.

Special behavior for SUSv3: Starting with z/OS V1.9, environment variable `_EDC_SUSV3` can be used to control the behavior of `getnameinfo()` with respect to detecting if the buffer pointed to by the *host* or *serv* argument is too small to contain the entire resolved name. The function will fail and return `EAI_OVERFLOW`. By default, `getnameinfo()` will truncate the values pointed to by *host* or *serv* and return successfully. When `_EDC_SUSV3` is set to 1, `getnameinfo()` will check for insufficient size buffers to contain the resolved name.

Returned value

Upon successful completion, `getnameinfo()` returns the node and service names, if requested, in the buffers provided. The returned names are always null-terminated strings.

A zero return value for `getnameinfo()` indicates successful completion; a non-zero return value indicates failure. The possible values for the failures are listed as follows.

Error Code
Description

EAI_AGAIN

The specified host address could not be resolved within the configured time interval, or the resolver address space has not been started. The request can be retried later.

EAI_BADFLAGS

The flags parameter had an incorrect value.

EAI_FAIL

An unrecoverable error occurred.

EAI_FAMILY

The address family was not recognized, or the address length was not valid for the specified family.

EAI_MEMORY

A memory allocation failure occurred.

EAI_NONAME

The name does not resolve for the supplied parameter. One of the following occurred:

1. `NI_NAMEREQD` is set, and the host name cannot be located.
2. Both host name and service name were null.
3. The requested address is valid, but it does not have a record at the name server.

EAI_OVERFLOW

An argument buffer overflowed. The buffer specified for the host name or the service name was not sufficient to contain the entire resolved name, and the caller previously specified `_EDC_SUSV3=1`, indicating that truncation was not permitted.

EAI_SYSTEM

An unrecoverable error occurred.

For more information on the above error codes, refer to [z/OS Communications Server: IP and SNA Codes](#).

getnetbyaddr() — Get a network entry by address

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

XPG4.2:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

struct netent *getnetbyaddr(ip_addr_t net, int type);
```

SUSV3:

```
#define _POSIX_C_SOURCE 200112L
#include <netdb.h>
struct netent *getnetbyaddr(uint32_t net, int type);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <netdb.h>

struct netent *getnetbyaddr(unsigned long net, int type);
```

General description

The `getnetbyaddr()` call searches the `tcpip.HOSTS.ADDRINFO` data set for the specified network address.

Parameter

Description

net

The network address.

type

The address domain supported (AF_INET).

If the name server is not present or the `RESOLVE_VIA_LOOKUP` option is in effect, you can use the **X_ADDR** environment variable to specify a data set other than `tcpip.HOSTS.ADDRINFO`.

Note: For more information on these data sets and environment variables, `tcpip.HOSTS.LOCAL`, `tcpip.HOSTS.ADDRINFO`, and `tcpip.HOSTS.SITEINFO`, see [z/OS Communications Server: IP Configuration Guide](#).

`getnetbyaddr()`, `getnetbyname()`, and `getnetent()` all use the same static area to return the `netent` structure. This static area is only valid until the next one of these functions is called on the same thread.

The `netent` structure is defined in the **netdb.h** include file and contains the following elements:

Element

Description

n_addrtype

The type of network address returned. The call always sets this value to AF_INET.

n_aliases

An array, terminated with a NULL pointer, of alternative names for the network.

n_name

The official name of the network.

n_net

The network number, returned in host byte order.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

Returned value

If successful, `getnetbyaddr()` returns a pointer to a `netent` structure. The return value points to data that is overwritten by subsequent calls returning the same data structure.

If unsuccessful, `getnetbyaddr()` returns a NULL pointer, indicating an error or End Of File (EOF).

getnetbyname() — Get a network entry by name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

struct netent *getnetbyname(const char *name);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

struct netent *getnetbyname(name);
```

General description

The `getnetbyname()` call searches the `tcpip.HOSTS.SITEINFO` data set for the specified network name.

Parameter

Description

name

The pointer to a network name.

You can use the **X_SITE** environment variable to specify a data set other than `tcpip.HOSTS.SITEINFO`.

Note: For more information on these data sets and environment variables, `tcpip.HOSTS.LOCAL`, `tcpip.HOSTS.SITEINFO`, and `tcpip.HOSTS.SITEINFO`, see [z/OS Communications Server: IP Configuration Guide](#).

The `getnetbyname()` call returns a pointer to a `netent` structure for the network name specified on the call. `getnetbyaddr()`, `getnetbyname()`, and `getnetent()` all use the same static area to return the `netent` structure. This static area is only valid until the next one of these functions is called on the same thread.

The netent structure is defined in the **netdb.h** include file and contains the following elements:

Element
Description

- n_addrtype***
The type of network address returned. The call always sets this value to AF_INET.
- n_aliases***
An array, terminated with a NULL pointer, of alternative names for the network.
- n_name***
The official name of the network.
- n_net***
The network number, returned in host byte order.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

Returned value

If successful, `getnetbyname()` returns a pointer to a `netent` structure. The return value points to static data that is overwritten by subsequent calls.

If unsuccessful, `getnetbyname()` returns a NULL pointer, indicating an error or End Of File (EOF).

getnetent() — Get the next network entry

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

struct netent *getnetent(void);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

struct netent *getnetent(void);
```

General description

The `getnetent()` call reads the next entry of the `tcpip.HOSTS.ADDRINFO` data set.

You can use the **X_ADDR** environment variable to specify a data set other than `tcpip.HOSTS.ADDRINFO`.

Note: For more information on these data sets and environment variables, `tcpip.HOSTS.LOCAL`, `tcpip.HOSTS.ADDRINFO`, and `tcpip.HOSTS.SITEINFO`, see [z/OS Communications Server: IP Configuration Guide](#).

The `getnetent()` call returns a pointer to the next entry in the `tcpip.HOSTS.SITEINFO` data set.

`getnetbyaddr()`, `getnetbyname()`, and `getnetent()` all use the same static area to return the `netent` structure. This static area is only valid until the next one of these functions is called on the same thread.

The `netent` structure is defined in the **netdb.h** include file and contains the following elements:

| Element | Description |
|---------|-------------|
|---------|-------------|

| | |
|--------------------------------|---|
| <code>n_addrtype</code> | The type of network address returned. The call always sets this value to <code>AF_INET</code> . |
|--------------------------------|---|

| | |
|-------------------------------|---|
| <code>n_aliases</code> | An array, terminated with a NULL pointer, of alternative names for the network. |
|-------------------------------|---|

| | |
|----------------------------|-----------------------------------|
| <code>n_name</code> | The official name of the network. |
|----------------------------|-----------------------------------|

| | |
|---------------------------|--|
| <code>n_net</code> | The network number, returned in host byte order. |
|---------------------------|--|

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` 1 feature test macro.

Returned value

If successful, `getnetent()` returns a pointer to a `netent` structure. The return value points to data that is overwritten by subsequent calls returning the same data structure.

If unsuccessful, `getnetent()` returns a NULL pointer, indicating an error or End Of File (EOF).

getopt() — Command option parsing

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <stdio.h>
int getopt(int argc, char *const argv[], const char *optstring);

extern char *optarg;
extern int optind, opterr, optopt;
```

SUSV3:

```
#define _XOPEN_SOURCE 600
#include <unistd.h>

int getopt(int argc, char *const argv[], const char *optstring);

extern char *optarg;
extern int optind, opterr, optopt;
```

General description

The `getopt()` function is a command-line parser that can be used by applications that follow Utility Syntax Guidelines 3, 4, 5, 6, 7, 9 and 10 in *X/Open CAE Specification, System Interface Definitions, Issue 4, Version 2* Section 10.2, Utility Syntax Guidelines. The `getopt()` function provides the identical functionality described in the X/Open CAE Specification System Interfaces and Headers, Issue 4, Version 2 for the `getopt()` function with the following extensions:

- If the external variable `optind` is set to zero, the `getopt()` function treats this as an indication to restart the scan at the first byte of `argv[1]`.

If `getopt()` encounters an option character that is not contained in `optstring`, it returns the question-mark (?) character. If it detects a missing option-argument, it returns the colon character (:) if the first character of `optstring` was a colon, or a question-mark character (?) otherwise. In either case, `getopt()` sets the variable `optopt` to the option character that caused the error. If the application has not set the variable `opterr` to 0 and the first character of `optstring` is not a colon, `getopt()` also prints a diagnostic message to `stderr` in the format specified for the `getopts` utility.

Because the `getopt()` function returns thread-specific data the `getopt()` function can be used safely from a multithreaded application.

Returned value

If successful, `getopt()` returns the value of the next option character from `argv` that matches a character in `optstring`.

A colon (:) is returned if `getopt()` detects a missing argument and the first character of `optstring` was a colon (:).

A question-mark (?) is returned if `getopt()` encounters an option character not in `optstring` or detects a missing argument and the first character of `optstring` was not a colon (:).

Otherwise `getopt()` returns -1 when all command line arguments have been parsed or an unexpected error is encountered in the command line.

`getopt()` sets the external variables `optind`, `optarg` and `optopt` as described in the X/Open CAE Specification System Interfaces and Headers, Issue 4, Version 2 for the `getopt()` function.

The following functions defined in `<stdio.h>` should be used by multithreaded applications when attempting to reference or change the `optind`, `optopt`, `optarg` and `opterr` external variables:

```
int *__opindf(void);
int *__opoptf(void);
char **__opargf(void);
int *__operrf(void);
```

Also use these functions when you invoke `getopt()` in a DLL. These functions return a pointer to a thread-specific value for each variable.

`getopt()` does not return any `errno` values.

If `getopt()` detects a missing argument or an option character not in `optstring` it will write an error message to `stderr` describing the option character in error and the invoking program.

getopt_long() — Command long option parsing

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <stdio.h>
#include <getopt.h>

int getopt_long(int argc, char *const argv[], const char *optstring, const struct option
*longopts, int *longindex);
```

General description

`getopt_long()` function is similar to `getopt()` except that it accepts long options, which begin with two dashes. (If the program accepts only long options, `optstring` must be specified as an empty string (""), not NULL.) Long option names might be abbreviated if the abbreviation is unique or is an exact match for some defined option. A long option might take a parameter of the form `--option=arg` or `--option arg`.

`longopts` is a pointer to the first element of an array of `struct option` that is declared in `<getopt.h>`.

```
struct option {
    const char *name;
    int      has_arg;
    int      *flag;
    int      val;
};
```

name

The name of the long option.

has_arg

This argument has one of the following values:

- `no_argument` (or 0) if the option does not take an argument.
- `required_argument` (or 1) if the option requires an argument.
- `optional_argument` (or 2) if the option takes an optional argument. In this case, `getopt_long()` can only parse the argument setting in the form of `--option=arg`.

flag

Specifies how results are returned for a long option. If `flag` is NULL, `getopt_long()` returns `val`. Otherwise, `getopt_long()` returns 0, and `flag` points to a variable that is set to `val` if the option is found, but left unchanged if the option is not found.

val

The value to return or to load into the variable that is pointed to by `flag`.

The last element of the array must be filled with zeros.

If `longindex` is not NULL, it points to a variable that is set to the index of the long option that is relative to `longopts`.

Returned value

If successful, `getopt_long()` returns the option character if a short option is recognized. For a long option, it returns `val` if `flag` is NULL; otherwise it returns 0 and stores `val` in the location pointed to by `flag`.

If `getopt_long()` encounters an unknown option, '?' is returned. If `getopt_long()` encounters an option with a missing argument, the return value depends on the first character in `optstring`: if it is ':', ':' is returned; otherwise, '?' is returned.

If an option is specified with an argument but the option is defined to be `no_argument` in `longopts`, `getopt_long()` returns '?'.

If `getopt_long()` detects a missing argument or an option string not in `longopts`, it writes an error message to `stderr` to describe the option character or string in error and the invoking program.

`getopt_long()` returns -1 when all command line arguments are parsed or an unexpected error is encountered in the command line. `getopt_long()` does not return any `errno` values.

If `getopt_long()` detects a missing argument or an option string not in `longopts`, it writes an error message to `stderr` describing the option character or string in error and the invoking program.

getpagesize() — Get the current page size

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int getpagesize(void);
```

General description

The `getpagesize()` function returns the current page size. The `getpagesize()` function is equivalent to `sysconf(_SC_PAGE_SIZE)` and `sysconf(_SC_PAGESIZE)`.

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use `sysconf(_SC_PAGESIZE)` instead of `getpagesize()`.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

`getpagesize()` returns the current page size.

Related information

- [“unistd.h — Implementation-specific functions” on page 77](#)

getpass() — Read a string of characters without echo

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4 XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE
#include <unistd.h>

char *getpass(const char *prompt);
```

General description

The `getpass()` function opens the process's controlling terminal, writes to that device the NULL-terminated string *prompt*, disables echoing, reads a string of characters up to the next newline character or EOF, restores the terminal state and closes the terminal.

`getpass()` only works in an environment where either a controlling terminal exists, or `stdin` and `stderr` refer to tty devices. Specifically, it does not work in a TSO environment.

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

If successful, `getpass()` returns a pointer to a NULL-terminated string of at most **PASS_MAX** bytes that were read from the terminal device.

If unsuccessful, `getpass()` returns a NULL pointer and the terminal state is restored.

Related information

- [“unistd.h — Implementation-specific functions” on page 77](#)

getpeername() – Get the name of the peer connected to a socket

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int getpeername(int socket, struct sockaddr *__restrict__ name,
                socklen_t *__restrict__ namelen);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>

int getpeername(int socket, struct sockaddr *name,
                int *namelen);
```

General description

The `getpeername()` call returns the name of the peer connected to socket descriptor *socket*. *namelen* must be initialized to indicate the size of the space pointed to by *name* and is set to the number of bytes copied into the space before the call returns. The size of the peer name is returned in bytes. If the actual length of the address is greater than the length of the supplied *sockaddr*, the stored address is truncated. The *sa_len* member of the store structure contains the length of the untruncated address.

Parameter

Description

socket

The socket descriptor.

name

The Internet address of the connected socket that is filled by `getpeername()` before it returns. The exact format of *name* is determined by the domain in which communication occurs.

namelen

Must initially point to an integer that contains the size in bytes of the storage pointed to by *name*. On return, that integer contains the size required to represent the address of the connecting socket. If this value is larger than the size supplied on input, then the information contained in *sockaddr* is truncated to the length supplied on input. If *name* is NULL, *namelen* is ignored.

Sockets in the AF_INET6 domain: For an AF_INET6 socket, the address is returned in a `sockaddr_in6` address structure. The `sockaddr_in6` structure is defined in the header file `netinet/in.h`.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

Note: The `getpeername()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support”](#) on page 2123 for details.

Returned value

If successful, `getpeername()` returns 0.

If unsuccessful, `getpeername()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

The *socket* parameter is not a valid socket descriptor.

EFAULT

Using the *name* and *namelen* parameters as specified would result in an attempt to access storage outside of the caller's address space.

EINVAL

The *namelen* parameter is not a valid length. The socket has been shut down.

ENOBUFS

`getpeername()` is unable to process the request due to insufficient storage.

ENOTCONN

The socket is not in the connected state.

ENOTSOCK

The descriptor is for a file, not for a socket.

EOPNOTSUPP

The operation is not supported for the socket protocol.

getpgid() — Get process group ID

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

pid_t getpgid(pid_t pid);
```

General description

The `getpgid()` function returns the process group ID of the process whose process ID is equal to *pid*. If *pid* is 0, `getpgid(0)` returns the process group ID of the calling process.

A test execution returns the following results:

- `getpgid(0)` 67439341
- `getpgid(getpid())` 67439341

Returned value

If successful, `getpgid()` returns a process group ID.

If unsuccessful, `getpgid()` returns `(pid_t)-1` and sets `errno` to one of the following values:

Error Code
Description

EPERM
The process whose process ID is equal to *pid* is not the same session as the calling process, and the implementation does not allow access to the process group ID of that process from the calling process.

ESRCH
There is no process with a process ID equal to *pid*.

`getpgid()` may fail if:

Error Code
Description

EINVAL
The value of the *pid* argument is not valid.

getpgrp() — Get the process group ID

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

pid_t getpgrp(void);
```

General description

Finds the process group ID of the calling process.

Returned value

Returns the found value. It is always successful.

There are no documented errno values.

Example

CELEBG13

```
/* CELEBG13

   This example gets all the process group IDs.

*/
#define _POSIX_SOURCE
#include <unistd.h>
#include <sys/wait.h>

main() {
    int status;

    if (fork() == 0) {
        if (fork() == 0) {
            printf("grandchild's pid is %d, process group id is %d\n",
                (int) getpid(), (int) getpgrp());
            exit(0);
        }
        printf("child's pid is %d, process group id is %d\n",
            (int) getpid(), (int) getpgrp());
        wait(&status);
        exit(0);
    }
    printf("parent's pid is %d, process group id is %d\n",
        (int) getpid(), (int) getpgrp());
    printf("the parent's parent's pid is %d\n", (int) getppid());
    wait(&status);
}
```

Output

```
parent's pid is 5373959, process group id is 5111816
the parent's parent's pid is 5111816
child's pid is 5832710, process group id is 5111816
grandchild's pid is 196617, process group id is 5111816
```

getpid() — Get the process ID

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

pid_t getpid(void);
```

General description

Finds the process ID (PID) of the calling process.

Returned value

getpid() returns the found value. It is always successful.

There are no documented errno values.

Example

CELEBG14

```
/* CELEBG14 */
#define _POSIX_SOURCE
#include <stdio.h>
#include <sys/types.h>
#include <signal.h>
#include <unistd.h>

void catcher(int signum) {
    puts("catcher has control!");
}

main() {
    struct sigaction sact;

    sigemptyset(&sact.sa_mask);
    sact.sa_flags = 0;
    sact.sa_handler = catcher;
    sigaction(SIGUSR1, &sact, NULL);

    printf("sending SIGUSR1 to pid %d\n", (int) getpid());
    kill(getpid(), SIGUSR1);
}
```

Output

```
sending SIGUSR1 to pid 5570567
catcher has control!
```

getpmsg() — Receive next message from a STREAMS file

The information for this function is included in [“getmsg\(\), getpmsg\(\) — Receive next message from a STREAMS file” on page 737](#).

getppid() — Get the parent process ID

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

pid_t getppid(void);
```

General description

Gets the parent process ID (PPID).

Returned value

getppid() returns the parent process ID. It is always successful.

There are no documented errno values.

Example

CELEBG15

```
/* CELEBG15 */
#define _POSIX_SOURCE
#include <stdio.h>
#include <sys/types.h>
#include <signal.h>
#include <unistd.h>
#include <sys/wait.h> /*FIX: used to be <wait.h>*/

volatile short footprint=0;

void catcher(int signum) {
    switch (signum) {
        case SIGALRM: puts("caught SIGALRM");
                     break;
        case SIGUSR2: puts("caught SIGUSR2");
                     break;
        default: printf("caught unexpected signal %d\n", signum);
    }
}
```

```
    footprint++;
}

main() {
    struct sigaction sact;
    int status;

    sigemptyset(&sact.sa_mask);
    sact.sa_flags = 0;
    sact.sa_handler = catcher;
    sigaction(SIGUSR2, &sact, NULL);

    sigemptyset(&sact.sa_mask);
    sact.sa_flags = 0;
    sact.sa_handler = catcher;
    sigaction(SIGALRM, &sact, NULL);

    printf("parent (pid %d) is about to fork child\n", (int) getpid());

    if (fork() == 0) {
        printf("child is sending SIGUSR2 to pid %d\n", (int) getppid());
        kill(getppid(), SIGUSR2);
        exit(0);
    }

    alarm(30);
    while (footprint == 0);
    wait(&status);
    puts("parent is exiting");
}
```

Output

```
parent (pid 6094854) is about to fork child
is sending SIGUSR2 to pid 6094854
caught SIGUSR2
parent is exiting
```

| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/resource.h>

int getpriority(int which, id_t who);
```

General description

getpriority() obtains the current priority of a process, process group or user.

Processes are specified by the values of the *which* and *who* arguments. The *which* argument may be any one of the following set of symbols defined in the *sys/resource.h* include file:

PRIO_PROCESS

indicates that the *who* argument is to be interpreted as a process ID

PRIO_PGRP

indicates that the *who* argument is to be interpreted as a process group ID

PRIO_USER

indicates that the *who* argument is to be interpreted as a user ID

The *who* argument specifies the ID (process, process group, or user). A 0 (zero) value for the *who* argument specifies the current process, process group or user ID.

Returned value

If successful, getpriority() returns the priority of the process, process group, or user ID requested in *who*. The priority is returned as an integer in the range -20 to 19 (the lower the numerical value, the higher the priority).

If more than one process is specified, getpriority() returns the highest priority pertaining to any of the specified processes.

If unsuccessful, getpriority() returns -1 and sets errno to one of the following values:

Error Code

Description

EINVAL

The symbol specified in the *which* argument was not recognized, or the value of the *who* argument is not a valid process ID, process group ID or user ID.

ESRCH

No process could be located using the *which* and *who* argument values specified.

Because getpriority() can return the value -1 on successful completion, it is necessary to set the external variable errno to 0 before a call to getpriority(). If getpriority() returns -1, then errno can be checked to see if an error occurred or if the value is a legitimate priority.

getprotobyname() — Get a protocol entry by name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

struct protoent *getprotobyname(const char *name);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

struct protoent *getprotobyname(char name);
```

General description

The `getprotobyname()` call searches the `/etc/protocol` or `tcpip.ETC.PROTO` data set for the specified protocol name.

Parameter

Description

name

The name of the protocol.

The `getprotobyname()` call returns a pointer to a `protoent` structure for the network protocol specified on the call. `getprotobyname()`, `getprotobynumber()`, and `getprotoent()` all use the same static area to return the `protoent` structure. This static area is only valid until the next one of these functions is called on the same thread.

The `protoent` structure is defined in the **netdb.h** include file and contains the following elements:

Element

Description

p_aliases

An array, terminated with a NULL pointer, of alternative names for the protocol.

p_name

The official name of the protocol.

p_proto

The protocol number.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

Returned value

If successful, `getprotobyname()` returns a pointer to a `protoent` structure. The return value points to data that is overwritten by subsequent calls returning the same data structure.

If unsuccessful, `getprotobyname()` returns a NULL pointer, indicating an error or End Of File (EOF).

Related information

getprotobynumber() — Get a protocol entry by number

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

struct protoent *getprotobynumber(int proto);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

struct protoent *getprotobynumber(int proto);
```

General description

The `getprotobynumber()` call searches the `/etc/protocol` or `tcpip.ETC.PROTO` data set for the specified protocol number.

Parameter

Description

proto

The protocol number.

The `getprotobynumber()` call returns a pointer to a `protoent` structure for the network protocol specified on the call. `getprotobyname()`, `getprotobynumber()`, and `getprotoent()` all use the same static area to return the `protoent` structure. This static area is only valid until the next one of these functions is called on the same thread.

The `protoent` structure is defined in the `netdb.h` include file and contains the following elements:

Element

Description

p_aliases

An array, terminated with a NULL pointer, of alternative names for the protocol.

p_name

The official name of the protocol.

p_proto

The protocol number.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

Returned value

If successful, `getprotobynumber()` returns a pointer to a `protoent` structure. The return value points to data that is overwritten by subsequent calls returning the same data structure.

If unsuccessful, `getprotobynumber()` returns a NULL pointer, indicating an error or End Of File (EOF).

getprotoent() — Get the next protocol entry

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

struct protoent *getprotoent(void);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

struct protoent *getprotoent(void);
```

General description

The `getprotoent()` call reads */etc/protocol* or the *tcpip.ETC.PROTO* data set.

The `getprotoent()` call returns a pointer to the next entry in the */etc/protocol* or the *tcpip.ETC.PROTO* data set.

`getprotobyname()`, `getprotobynumber()`, and `getprotoent()` all use the same static area to return the `protoent` structure. This static area is only valid until the next one of these functions is called on the same thread.

The `protoent` structure is defined in the **netdb.h** include file and contains the following elements:

Element

Description

p_aliases

An array, terminated with a NULL pointer, of alternative names for the protocol.

p_name

The official name of the protocol.

p_proto

The protocol number.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

Returned value

If successful, `getprotoent()` returns a pointer to a `protoent` structure. The return value points to data that is overwritten by subsequent calls returning the same data structure.

If unsuccessful, `getprotoent()` returns a NULL pointer, indicating an error or End Of File (EOF).

getpwent() — Get user database entry

The information for this function is included in “[endpwent\(\) — User database functions](#)” on page 423.

getpwent_r() — Get user database entry reentrantly

The information for this function is included in “[endpwent\(\) — User database functions](#)” on page 423.

getpwnam() — Access the user database by user name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <pwd.h>

struct passwd *getpwnam(const char *name);
```

General description

Accesses the `passwd` structure (defined in the `pwd.h` header file), which contains the following members:

pw_name

User name

pw_uid

User ID (UID) number

pw_gid

Group ID (GID) number

pw_dir

Initial working directory

pw_shell

Initial user program

Returned value

If successful, `getpwnam()` returns a pointer to a `passwd` structure containing an entry from the user database with the specified *name*. Return values might point to the static data that is overwritten on each call.

If unsuccessful, `getpwnam()` returns a NULL pointer.

There are no documented `errno` values.

Example**CELEBG16**

```
/* CELEBG16

   This example provides information for the user data
   base, MEGA.

*/
#define _POSIX_SOURCE
#include <sys/types.h>
#include <pwd.h>

main() {
    struct passwd *p;
    char user[]="MEGA";

    if ((p = getpwnam(user)) == NULL)
        perror("getpwnam() error");
    else {
        printf("getpwnam() returned the following info for user %s:\n",
               user);
        printf(" pw_name   : %s\n",      p->pw_name);
        printf(" pw_uid    : %d\n", (int) p->pw_uid);
        printf(" pw_gid    : %d\n", (int) p->pw_gid);
        printf(" pw_dir    : %s\n",      p->pw_dir);
        printf(" pw_shell  : %s\n",      p->pw_shell);
    }
}
```

Output

```
pw_name   : MEGA
pw_uid    : 0
pw_gid    : 512
pw_dir    : /u/mega
pw_shell  : /bin/sh
```

getpwnam_r() — Search user database for a name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 | both | OS/390 V2R8 |

Format

```
#define _XOPEN_SOURCE 500
#include <sys/types.h>
#include <pwd.h>

int getpwnam_r(const char *nam, struct passwd *pwd,
char *buffer, size_t bufsize, struct passwd **result);
```

General description

The `getpwnam_r()` function updates the `passwd` structure pointed to by `pwd` and stores a pointer to that structure at the location pointed to by `result`. The structure will contain an entry from the user database with a matching name. Storage referenced by the structure is allocated from the memory provided with the `buffer` parameter, which is `bufsize` characters in size. A NULL pointer is returned at the location pointed to by `result` on error or if the requested entry is not found.

Returned value

If successful, `getpwnam_r()` returns 0.

If unsuccessful, `getpwnam_r()` sets `errno` to one of the following values:

Error Code

Description

EINVAL

One of the input arguments was not valid. Arguments `pwd`, `buffer`, and `result` must not be NULL. Argument `bufsize` must not be 0.

ERANGE

Insufficient storage was supplied in `buffer` and `bufsize` to contain the data to be referenced by the resulting `passwd` structure.

getpwuid() — Access the user database by user ID

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <pwd.h>

struct passwd *getpwuid(uid_t uid);
```

General description

Gets information about a user with the specified *uid*. `getpwuid()` returns a pointer to a `passwd` structure containing an entry from the user database for the specified *uid*. This structure (defined in the `pwd.h` header file), contains the following members:

pw_name

User name

pw_uid

User ID (UID) number

pw_gid

Group ID (GID) number

pw_dir

Initial working directory

pw_shell

Initial user program

Return values may point to the static data that is overwritten on each call.

Returned value

If successful, `getpwuid()` returns a pointer.

If unsuccessful, `getpwuid()` returns a NULL pointer and sets `errno` to one of the following values:

Error Code

Description

EMVSSAF2ERR

The system authorization facility (SAF) or RACF Get GMAP or Get UMAP service had an error.

EMVSSAFEXTRERR

The SAF or RACF RACROUTE EXTRACT service had an error.

Example

CELEBG17

```
/* CELEBG17
   This example provides information for user ID 0.
```

```

*/
#define _POSIX_SOURCE
#include <sys/types.h>
#include <pwd.h>

main() {
    struct passwd *p;
    uid_t uid=0;

    if ((p = getpwuid(uid)) == NULL)
        perror("getpwuid() error");
    else {
        printf("getpwuid() returned the following info for uid %d:\n",
               (int) uid);
        printf(" pw_name  : %s\n",      p->pw_name);
        printf(" pw_uid   : %d\n",      (int) p->pw_uid);
        printf(" pw_gid   : %d\n",      (int) p->pw_gid);
        printf(" pw_dir   : %s\n",      p->pw_dir);
        printf(" pw_shell : %s\n",      p->pw_shell);
    }
}

```

Output

```

getpwuid() returned the following info for uid 0:
pw_name  : MEGA
pw_uid   : 0
pw_gid   : 512
pw_dir   : /u/mega
pw_shell : /bin/sh

```

getpwuid_r() — Search user database for a user ID

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|--------------|
| Single UNIX Specification, Version 2 | both | OS/390 V2R8 |
| Single UNIX Specification, Version 3 | | |

Format

```

#define _XOPEN_SOURCE 500
#include <sys/types.h>
#include <pwd.h>

int getpwuid_r(uid_t uid, struct passwd *pwd,
               char *buffer, size_t bufsize, struct passwd **result);

```

General description

The `getpwuid_r()` function updates the `passwd` structure pointed to by *pwd* and stores a pointer to that structure at the location pointed to by *result*. The structure will contain an entry from the user database with a matching uid. Storage referenced by the structure is allocated from the memory provided with the *buffer* parameter, which is *bufsize* characters in size. A NULL pointer is returned at the location pointed to by *result* on error or if the requested entry is not found.

Returned value

If successful, `getpwuid_r()` returns 0.

If unsuccessful, `getpwuid_r()` returns a NULL pointer and sets `errno` to one of the following values:

Error Code

Description

EINVAL

One of the input arguments was not valid. Arguments *pwd*, *buffer*, and *result* must not be NULL. Argument *bufsize* must not be 0.

EMVSSAF2ERR

The system authorization facility (SAF) or RACF Get GMAP or Get UMAP service had an error.

EMVSSAFEXTRERR

The SAF or RACF RACROUTE EXTRACT service had an error.

ERANGE

Insufficient storage was supplied in *buffer* and *bufsize* to contain the data to be referenced by the resulting `passwd` structure.

getrandom() — Obtain a series of random bytes

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <sys/random.h>

ssize_t getrandom(void *buf, size_t buflen, unsigned int flags);
```

General description

`getrandom()` fills the buffer that is pointed to by *buf* with up to *buflen* random bytes. These bytes can be used to seed user-space random number generators or for cryptographic purposes.

The *flags* argument is a bit mask that can contain zero or more of the following values that are ORed together:

GRND_RANDOM

This bit is ignored. Random bytes are drawn from the random source. The number of bytes that are returned is only limited by the buffer size.

GRND_NONBLOCK

This bit is ignored. `getrandom()` does not block and returns the data that is specified in the *buflen*. Blocking for `getrandom()` is not supported.

Returned value

If successful, `getrandom()` returns the number of bytes that are copied to the buffer *buf*.

If unsuccessful, `getrandom()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EFAULT

The address that is referred to by *buf* is outside the accessible address space.

EINTR

The call is interrupted by a signal handler.

EINVAL

An invalid flag is specified in *flags*.

Related information

- [“getentropy\(\) — Fill a buffer with random bytes” on page 704](#)

getrlimit() — Get current or maximum resource consumption

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/resource.h>

int getrlimit(int resource, struct rlimit *rlp);
```

General description

The `getrlimit()` function gets resource limits for the calling process. A resource limit is a pair of values; one specifying the current (soft) limit, the other a maximum (hard) limit.

The value `RLIM_INFINITY` defined in `sys/resource.h`, is considered to be larger than any other limit value. If a call to `getrlimit()` returns `RLIM_INFINITY` for a resource, it means the implementation does not enforce limits on that resource.

The *resource* argument specifies which resource to get the hard and/or soft limits for, and may be one of the following values:

RLIMIT_CORE

The maximum size of a dump of memory (in bytes) allowed for the process. A value of 0 (zero) prevents file creation. Dump file creation will stop at this limit.

RLIMIT_CPU

The maximum amount of CPU time (in seconds) allowed for the process. If the limit is exceeded, a SIGXCPU signal is sent to the process and the process is granted a small CPU time extension to allow for signal generation and delivery. If the extension is used up, the process is terminated with a SIGKILL signal.

RLIMIT_DATA

The maximum size of the break value for the process, in bytes. In this implementation, this resource always has a hard and soft limit value of RLIM_INFINITY.

RLIMIT_FSIZE

The maximum file size (in bytes) allowed for the process. A value of 0 (zero) prevents file creation. If the size is exceeded, a SIGXFSZ signal is sent to the process. If the process is blocking, catching, or ignoring SIGXFSZ, continued attempts to increase the size of a file beyond the limit will fail with an errno of EFBIG.

RLIMIT_MEMLIMIT

The maximum amount of usable storage above the 2 gigabyte bar (in 1 megabyte segments) that can be allocated.

RLIMIT_NOFILE

The maximum number of open file descriptors allowed for the process. This number is one greater than the maximum value that may be assigned to a newly created descriptor. (That is, it is one-based.) Any function that attempts to create a new file descriptor beyond the limit will fail with an EMFILE errno.

RLIMIT_STACK

The maximum size of the stack for a process, in bytes. Note that in z/OS UNIX services, the stack is a per-thread resource. In this implementation, this resource always has a hard and soft limit value of RLIM_INFINITY. A call to setrlimit() to set this resource to any value other than RLIM_INFINITY will fail with an errno of EINVAL.

RLIMIT_AS

The maximum address space size for the process, in bytes. If the limit is exceeded, malloc() and mmap() functions will fail with an errno of ENOMEM. Automatic stack growth will also fail.

The *rlp* argument points to a `rlimit` structure. This structure contains the following members:

rlim_cur

The current (soft) limit

rlim_max

The maximum (hard) limit

See the <sys/resource.h> header for more detail.

The resource limit values are propagated across exec and fork.

Special behavior for z/OS UNIX System Services: An exception exists for exec processing in conjunction with daemon support. If a daemon process invokes exec and it had previously invoked setuid() before exec, the RLIMIT_CPU, RLIMIT_AS, RLIMIT_CORE, RLIMIT_FSIZE, and RLIMIT_NOFILE limit values are set based on the limit values specified in the kernel parmlib member BPXPRMxx.

For processes which are not the only process within an address space, the RLIMIT_CPU and RLIMIT_AS limits are shared with all the processes within the address space. For RLIMIT_CPU, when the soft limit is exceeded, action will be taken on the first process within the address space. If the action is termination, all processes within the address space will be terminated.

In addition to the RLIMIT_CORE limit values, the dump file defaults are set by SYSMDUMP defaults. Refer to *z/OS MVS Initialization and Tuning Reference* for information on setting up SYSMDUMP defaults using the IEADMR00 parmlib member.

Dumps of memory are taken in 4160 byte increments. Therefore, RLIMIT_CORE values affect the size of memory dumps in 4160 byte increments. For example, if the RLIMIT_CORE soft limit value is 4000, the dump will contain no data. If the RLIMIT_CORE soft limit value is 8000, the maximum size of a memory dump is 4160 bytes.

Large file support for z/OS UNIX files: Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the [long long data type support](#) enabled and define the _LARGE_FILES feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the _LARGE_FILES feature test macro as well.

Returned value

If successful, getrlimit() returns 0.

If unsuccessful, getrlimit() returns -1 and sets errno to one of the following values:

Error Code

Description

EINVAL

A non-valid *resource* was specified.

getrusage() — Get information about resource utilization

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/resource.h>

int getrusage(int who, struct rusage *r_usage);
```

General description

The getrusage() function provides measures of the resources used by the current process or its terminated and waited-for-child processes. If the value of the *who* argument is RUSAGE_SELF, information is returned about resources used by the current process. If the value of the *who* argument is RUSAGE_CHILDREN, information is returned about resources used by the terminated and waited-for-children of the current process. If the child is never waited for (for instance, if the parent has SA_NOCLDWAIT set or sets SIGCHLD to SIG_IGN), the resource information for the child process is discarded and not included in the resource information provided by getrusage()

The *r_usage* argument is a pointer of an object of type struct rusage in which the returned information is stored.

Returned value

If successful, getrusage() returns 0.
If unsuccessful, getrusage() returns -1 and sets errno to one of the following values:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

| | |
|--------|--|
| EINVAL | The value of the <i>who</i> argument is not valid. |
|--------|--|

gets() — Read a string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```
#include <stdio.h>

char *gets(char *buffer);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

char *gets_unlocked(char *buffer);
```

General description

Reads bytes from the standard input stream `stdin`, and stores them in the array pointed to by *buffer*. The line consists of all characters up to and including the first newline character (`\n`) or EOF. The `gets()` function discards any newline character, and the NULL character (`\0`) is placed immediately after the last byte read. If there is an error, the value stored in *buffer* is undefined.

`gets()` is not supported for files opened with `type=record` or `type=blocked`.

`gets()` has the same restriction as any read operation, such as a read immediately following a write, or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

`gets_unlocked()` is functionally equivalent to `gets()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

If successful, `gets()` returns its argument.

If unsuccessful, `gets()` returns a NULL pointer to indicate an error or an EOF condition with no characters read.

Use `ferror()` or `feof()` to determine which of these conditions occurred. Note that EOF is only reached when an attempt is made to read past the last byte of data. Reading up to and including the last byte of data does *not* turn on the EOF indicator.

Example

CELEBG18

```
/* CELEBG18

   This example gets a line of input from stdin.
*/
#include <stdio.h>
#define MAX_LINE 100

int main(void)
{
    char line[MAX_LINE];
    char *result;

    printf("Enter string:\n");
    if ((result = gets(line)) != NULL)
        printf("string is %s\n", result);
    else
        if (ferror(stdin))
            printf("Error\n");
}
```

getservbyname() — Get a server entry by name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

struct servent *getservbyname(const char *name, const char *proto);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

struct servent *getservbyname(char *name, char *proto);
```

General description

The `getservbyname()` call searches the `/etc/services` or `tcpip.ETC.SERVICES` data set for the first entry that matches the specified service name and protocol name. If `proto` is `NULL`, only the service name must match.

Parameter

Description

name

The service name.

proto

The protocol name.

The `getservbyname()` call returns a pointer to a *servent* structure for the network service specified on the call. `getservbyname()`, `getservbyport()`, and `getservent()` all use the same static area to return the *servent* structure. This static area is only valid until the next one of these functions is called on the same thread.

The *servent* structure is defined in the **netdb.h** include file and contains the following elements:

Element

Description

s_aliases

An array, terminated with a `NULL` pointer, of alternative names for the service.

s_name

The official name of the service.

s_port

The port number of the service.

s_proto

The protocol required to contact the service.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

Returned value

The return value points to data that is overwritten by subsequent calls returning the same data structure.

If successful, `getservbyname()` returns a pointer to a *servent* structure.

If unsuccessful or End Of File (EOF), `getservbyname()` returns a NULL pointer.

getservbyport() — Get a service entry by port

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format**X/Open:**

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

struct servent *getservbyport(int port, const char *proto);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

struct servent *getservbyport(int port, char *proto);
```

General description

The `getservbyport()` call searches the */etc/services* or the *tcpip.ETC.SERVICES* data set for the first entry that matches the specified port number and protocol name. If *proto* is NULL, only the port number must match.

Parameter Description

port

The port number.

proto

The protocol name.

The `getservbyport()` call returns a pointer to a *servent* structure for the port number specified on the call. `getservbyname()`, `getservbyport()`, and `getservent()` all use the same static area to return the *servent* structure. This static area is only valid until the next one of these functions is called on the same thread.

The *servent* structure is defined in the **netdb.h** include file and contains the following elements:

Element Description

s_aliases

An array, terminated with a NULL pointer, of alternative names for the service.

s_name

The official name of the service.

s_port

The port number of the service.

s_proto

The protocol required to contact the service.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` 1 feature test macro.

Returned value

The return value points to data that is overwritten by subsequent calls returning the same data structure.

If successful, `getservbyport()` returns a pointer to a *servent* structure.

If unsuccessful or End Of File (EOF), `getservbyport()` returns a NULL pointer.

getservent() — Get the next service entry

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

struct servent *getservent(void);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

struct servent *getservent(void);
```

General description

The `getservent()` call reads the next line of the */etc/services* or the *tcpip.ETC.SERVICES* data set.

The `getservent()` call returns a pointer to the next entry in the */etc/services* or the *tcpip.ETC.SERVICES* data set.

`getservbyname()`, `getservbyport()`, and `getservent()` all use the same static area to return the *servent* structure. This static area is only valid until the next one of these functions is called on the same thread.

The *servent* structure is defined in the **netdb.h** include file and contains the following elements:

Element

Description

s_aliases

An array, terminated with a NULL pointer, of alternative names for the service.

s_name

The official name of the service.

s_port

The port number of the service.

s_proto

The protocol required to contact the service.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

Returned value

The return value points to data that is overwritten by subsequent calls returning the same data structure.

If successful, `getservent()` returns a pointer to a *servent* structure.

If unsuccessful or End Of File (EOF), `getservent()` returns a NULL pointer.

getsid() — Get process group ID of session leader

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

pid_t getsid(pid_t pid);
```

General description

The `getsid()` function obtains the process group ID of the process that is the session leader of the process specified by *pid*. If *pid* is 0, the system uses the PID of the process calling `getsid()`.

Returned value

If successful, `getsid()` returns the process group ID of the session leader of the specified process.

If unsuccessful, `getsid()` returns `(pid_t)-1` and sets `errno` to one of the following values:

Error Code

Description

EPERM

The process specified by *pid* is not in the same session as the calling process, and the implementation does not allow access to the process group ID of the session leader of that process from the calling process.

ESRCH

There is no process with a process ID equal to *pid*.

getsockname() – Get the name of a socket

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int getsockname(int socket, struct sockaddr *__restrict__ name,
                socklen_t *__restrict__ namelen);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>

int getsockname(int socket, struct sockaddr *name,
                int *namelen);
```

General description

The `getsockname()` call stores the current name for the socket specified by the *socket* parameter into the structure pointed to by the *name* parameter. It returns the address to the socket that has been bound. If the socket is not bound to an address, the call returns with the family set, and the rest of the structure set to zero. For example, an unbound socket in the Internet domain would cause the name to point to a **sockaddr_in** structure with the *sin_family* field set to `AF_INET` and all other fields zeroed.

If the actual length of the address is greater than the length of the supplied *sockaddr*, the stored address is truncated. The *sa_len* member of the store structure contains the length of the untruncated address.

Parameter

Description

socket

The socket descriptor.

name

The address of the buffer into which `getsockname()` copies the name of *socket*.

namelen

Must initially point to an integer that contains the size in bytes of the storage pointed to by *name*.

On return, that integer contains the size required to represent the address of the connecting socket.

If this value is larger than the size supplied on input, then the information contained in *sockaddr* is truncated to the length supplied on input. If *name* is NULL, *namelen* is ignored.

The `getsockname()` call is often used to discover the port assigned to a socket after the socket has been implicitly bound to a port. For example, an application can call `connect()` without previously calling `bind()`. In this case, the `connect()` call completes the binding necessary by assigning a port to the socket. This assignment can be discovered with a call to `getsockname()`.

Sockets in the AF_INET6 domain: For an `AF_INET6` socket, the address is returned in a *sockaddr_6* address structure. The *sockaddr_in6* structure is defined in the header file **netinet/in.h**.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` 1 feature test macro.

Note: The `getsockname()` function has a dependency on the level of the Enhanced ASCII Extensions. See “Enhanced ASCII support ” on page 2123 for details.

Returned value

If successful, `getsockname()` returns 0.

If unsuccessful, `getsockname()` returns -1 and sets `errno` to one of the following values:

**Error Code
Description**

EBADF
The *socket* parameter is not a valid socket descriptor.

EFAULT
Using the *name* and *namelen* parameters as specified would result in an attempt to access storage outside of the caller's address space.

ENOBUFS
`getsockname()` is unable to process the request due to insufficient storage.

ENOTCONN
The socket is not in the connected state.

ENOTSOCK
The descriptor is for a file, not for a socket.

EOPNOTSUPP
The operation is not supported for the socket protocol.

getsockopt() — Get the options associated with a socket

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int getsockopt(int socket, int level, int option_name,
```

```
void *__restrict__ option_value,
socklen_t *__restrict__ option_len);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>

int getsockopt(int socket, int level, int option_name,
               char *option_value,
               int *option_len);
```

IPv6: To include support for IPv6 socket options, add the following code:

```
#define _OPEN_SYS_SOCK_IPV6 1
#include <netinet/in.h>
```

icmp6_filter structure: To include the icmp6_filter structure in your program, add the following code:

```
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/icmp6.h>
```

General description

The `getsockopt()` call gets options associated with a socket. Not all options are supported by all address families. See each option for details. Options can exist at multiple protocol levels.

Parameter

Description

socket

The socket descriptor.

level

The level for which the option is set.

option_name

The name of a specified socket option.

option_value

The pointer to option data.

option_len

The pointer to the length of the option data.

When manipulating socket options, you must specify the level at which the option resides and the name of the option. To manipulate options at the socket level, the *level* parameter must be set to `SOL_SOCKET` as defined in `sys/socket.h`. To manipulate options at the IPv4 or IPv6 level, the *level* parameter must be set to `IPPROTO_IP` as defined in `sys/socket.h` or `IPPROTO_IPV6` as defined in `netinet/in.h`. To manipulate options at any other level, such as the TCP level, supply the appropriate protocol number for the protocol controlling the option. The `getprotobyname()` call can be used to return the protocol number for a named protocol.

The *option_value* and *option_len* parameters are used to return data used by the particular get command. The *option_value* parameter points to a buffer that is to receive the data requested by the get command. The *option_len* parameter points to the size of the buffer pointed to by the *option_value* parameter. It must be initially set to the size of the buffer before calling `getsockopt()`. On return it is set to the actual size of the data returned.

All the socket level options except `SO_LINGER`, `SO_RCVTIMEO` and `SO_SNDTIMEO`, expect *option_value* to point to an integer and *option_len* to be set to the size of an integer. When the integer is nonzero, the option is enabled. When it is zero, the option is disabled. The `SO_LINGER` option expects *option_value* to point to a linger structure as defined in `sys/socket.h`. This structure is defined in the following example:

```
struct linger
{
    int    l_onoff;          /* option on/off */
```

```

    int    l_linger;          /* linger time */
};

```

The `l_onoff` field is set to zero if the `SO_LINGER` option is being disabled. A nonzero value enables the option. The `l_linger` field specifies the amount of time to linger on close.

The following options are recognized at the IPv4 level:

Option

Description

IP_MULTICAST_IF

(RAW and UDP) Used to get the interface IP address used for sending outbound multicast datagrams. The IP address is passed using the `in_addr` structure.

IP_MULTICAST_LOOP

(RAW and UDP) Used to determine whether loopback is enabled or disabled. The loopback indicator is passed as an `u_char`. The value 0 indicates loopback is disabled and the value 1 indicates it is enabled.

IP_MULTICAST_TTL

(RAW and UDP) Returns the IP time-to-live of outgoing multicast datagrams. The TTL value is passed as an `u_char`.

IP_RECVPKINFO

(RAW and UDP) Indicates whether returning the destination IP address of an incoming packet and the interface over which the packet was received is enabled or disabled. If the `setsockopt()` function is used to set this option, the set value is returned. The option value is passed as an `int`. The value 0 indicates the option is disabled and the value 1 indicates the option is enabled. When the option is enabled, the information is returned as `IP_PKTINFO` ancillary data on `recvmsg()` function calls.

This option is protected by the `_OPEN_SYS_SOCKET_EXT4` feature test macro.

IP_TTL

(TCP and UDP) This option is used to retrieve the time-to-live value that is set in the IP header for the `SOCK_STREAM`(TCP) and `SOCK_DGRAM` (UDP) sockets.

Note: `IP_TTL` can be used only when `_XPLATFORM_SOURCE` is defined.

The following options are recognized at IPv6 level:

Option

Description

IPV6_ADDR_PREFERENCES

(TCP and UDP) Used to get the source address selection preference flags for a given socket. The flags are defined as bits within the 32 bit unsigned integer returned option value. The flags returned will be either the default preference flags or will be the flags previously set by `setsockopt()`. The constants for the flag bit values are defined in `netinet/in.h`.

IPV6_CHECKSUM

(RAW) Used to determine if checksum processing is enabled for a RAW (non-ICMPv6) socket. The option value returned is the offset into the user data where the checksum is located. It is passed as `int`. A value of -1 means the function is disabled.

IPV6_DONTFRAG

(RAW and UDP) This option turns off the automatic inserting of a fragment header in the packet for UDP and raw sockets.

IPV6_DSTOPTS

(RAW and UDP) The application can remove any sticky destination options header by calling `setsockopt()` for this option with a zero option length.

IPV6_HOPOPTS

(RAW and UDP) The application can remove any sticky hop-by-hop options header by calling `setsockopt()` for this option with a zero option length.

IPV6_MULTICAST_HOPS

(RAW and UDP) Returns the hop limit value for outbound multicast datagrams. The hop limit value is passed as an int.

IPV6_MULTICAST_IF

(RAW and UDP) Returns the interface index for the interface used for sending outbound multicast datagrams. The interface index is passed as an u_int.

IPV6_MULTICAST_LOOP

(RAW and UDP) Used to determine whether loopback of outgoing multicast packets is enabled or disabled. The loopback indicator is passed as u_int. The value 0 indicates the option is disabled and the value 1 indicates it is enabled.

IPV6_NEXTHOP

(RAW and UDP) Specifies the next hop for the datagram as a socket address structure.

IPV6_RECVDSTOPTS

(RAW and UDP) To receive destination options header this option must be enabled.

IPV6_RECVHOPLIMIT

(RAW, TCP, and UDP) Returns the received hop limit as IPV6_HOPLIMIT ancillary data on recvmsg() function calls. The option value is passed as an int. The value 0 indicates the option is disabled and the value 1 indicates the option is enabled.

IPV6_RECVHOPTS

(RAW and UDP) To receive a hop-by-hop options header this option must be enabled.

IPV6_RECVPATHMTU

(RAW and UDP) Returns the path MTU as IPV6_PATHMTU ancillary data on recvmsg() function calls.

IPV6_RECVPKTINFO

(RAW and UDP) Indicates whether returning the destination IP address of an incoming packet and the interface over which the packet was received is enabled or disabled. The option value is passed as an int. The value 0 indicates the option is disabled and the value 1 indicates the option is enabled. When the option is enabled, the information is returned as IPV6_PKTINFO ancillary data on recvmsg() function calls.

IPV6_RECVRTHDR

(RAW and UDP) To receive a routing header this option must be enabled.

IPV6_RECVTCLASS

(RAW, TCP, and UDP) To receive the traffic class this option must be enabled.

IPV6_RTHDR

(RAW and UDP) The application can remove any sticky routing header by calling setsockopt() for this option with a zero option length.

IPV6_RTHDRDSTOPTS

(RAW and UDP) The application can remove any sticky destination options header by calling setsockopt() for this option with a zero option length.

IPV6_TCLASS

(RAW, TCP, and UDP) To specify the traffic class value this option must be enabled.

IPV6_UNICAST_HOPS

(RAW and UDP) Returns the hop limit value for outbound unicast datagrams. The hop limit value is passed as an int.

IPV6_USE_MIN_MTU

(RAW, TCP, and UDP) Indicates whether the IP layer will use the minimum MTU size (1280) for sending packets, bypassing path MTU discovery. The option value is passed as an int. A value of -1 causes the default values for unicast (disabled) and multicast (enabled) destinations to be used. A value of 0 disables this option for unicast and multicast destinations. A value of 1 enables this option for unicast and multicast destinations and the minimum MTU size will be used. If a setsockopt() call has not been made prior to a getsockopt() call, the default value of -1 is returned.

IPV6_V6ONLY

(RAW, TCP, and UDP) Used to determine whether a socket is restricted to IPv6 communications only. The option value is passed as an int. A non-zero value means the option is enabled (socket can only be used for IPv6 communications). 0 means the option is disabled.

The following option is recognized at ICMPv6 level:

Option**Description****ICMP6_FILTER**

(RAW) Used to filter ICMPv6 messages. It returns the filter value being used for this socket. It is back in an icmp6_filter structure as defined in `netinet/icmp6.h`.

The following options are recognized at the socket level:

Option**Description****SO_ACCEPTCONN**

The socket had a listen() call.

SO_BROADCAST

Toggles the ability to broadcast messages. If this option is enabled, it allows the application to send broadcast messages over *socket*, if the interface specified in the destination supports the broadcasting of packets. This option has no meaning for stream sockets. This option is valid only for the AF_INET domain.

SO_DEBUG

Reports whether debugging information is being recorded. This option stores an int value.

SO_ERROR

Returns any pending error on the socket and clears the error status. You can use SO_ERROR to check for asynchronous errors on connected datagram sockets or for other asynchronous errors (errors that are not returned explicitly by one of the socket calls).

SO_KEEPAIVE

Toggles the TCP keep-alive mechanism for a stream socket. When activated, the keep-alive mechanism periodically sends a packet on an otherwise idle connection. If the remote TCP does not respond to the packet or to retransmissions of the packet, the connection is ended with the error ETIMEDOUT. Processes writing to that socket are notified with a SIGPIPE signal. This option stores an int value. This option is valid only for the AF_INET and AF_INET6 domains.

SO_LINGER

Lingers on close if data is present. When this option is enabled and there is unsent data present when close() is called, the calling application is blocked during the close() call until the data is transmitted or the connection has timed out. If this option is disabled, the TCP/IP address space waits to try to send the data. Although the data transfer is usually successful, it cannot be guaranteed, because the TCP/IP address space waits only a finite amount of time trying to send the data. The close() call returns without blocking the caller. This option has meaning only for stream sockets.

SO_OOINLINE

Toggles reception of out-of-band data. When this option is enabled, out-of-band data is placed in the normal data input queue as it is received; it is then available to recv(), recvfrom(), and recvmsg() without the need to specify the MSG_OOB flag in those calls. When this option is disabled, out-of-band data is placed in the priority data input queue as it is received; it is then available to recv(), recvfrom(), and recvmsg() only if the MSG_OOB flag is specified in those calls. This option has meaning only for stream sockets.

_SO_PROPAGATEUSERID

Toggles propagating a user ID (UID) over an AF_UNIX stream socket. When enabled, user (UID) information is extracted from the system when the connect() function is invoked. Then, when the accept() function is invoked, the acceptor assumes the identity of the connector until the accepted socket is closed.

SO_RCVBUF

Reports receive buffer size information. This option stores an int value.

SO_RCVTIMEO

Reports the timeout value with the amount of time an input function waits until it completes.

If a receive operation has blocked for this much time without receiving additional data, it returns with a partial count or errno set to EWOULDBLOCK if no data is received. The default for this option is zero, which indicates that a receive operation does not time out.

SO_REUSEADDR

Toggles local address reuse. When enabled, this option allows local addresses that are already in use to be bound. SO_REUSEADDR alters the normal algorithm used in the bind() call.

The system checks at connect time to ensure that the local address and port do not have the same foreign address and port. The error EADDRINUSE is returned if the association already exists.

After the 'SO_REUSEADDR' option is active, the following situation is supported:

A server can bind() the same port multiple times as long as every invocation uses a different local IP address and the wildcard address INADDR_ANY is used only one time per port.

This option is valid only for the AF_INET and AF_INET6 domains.

SO_SECINFO

Toggles receiving security information. When enabled on an AF_UNIX UDP socket, the recvmsg() function will return security information about the sender of each datagram as ancillary data. This information contains the sender's user ID, uid, gid, and jobname and it is mapped by the secsinfo structure in sys/socket.h.

SO_SNDBUF

Reports send buffer size information. This option stores an int value.

SO_SNDTIMEO

Reports the timeout value specifying the amount of time that an output function blocks due to flow control preventing data from being sent.

If a send operation has blocked for this time, it returns with a partial count or with errno set to EWOULDBLOCK if no data is sent. The default for this option is zero, which indicates that a send operation does not time out.

SO_TYPE

This option returns the type of the socket. On return, the integer pointed to by *option_value* is set to SOCK_STREAM or SOCK_DGRAM. This option is valid for the AF_UNIX, AF_INET and AF_INET6 domains.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Returned value

If successful, getsockopt() returns 0.

If unsuccessful, getsockopt() returns -1 and sets errno to one of the following values:

Error Code**Description****EBADF**

The *socket* parameter is not a valid socket descriptor.

EFAULT

Using *option_value* and *option_len* parameters would result in an attempt to access storage outside the caller's address space.

EINVAL

The specified option is not valid at the specified socket level.

ENOBUFS

Buffer space is not available to send the message.

ENOPROTOPT

The *option_name* parameter is unrecognized, or the *level* parameter is not SOL_SOCKET.

ENOSYS

The function is not implemented. You attempted to use a function that is not yet available.

ENOTSOCK

The descriptor is for a file, not for a socket.

EOPNOTSUPP

The operation is not supported by the socket protocol. At least the following options are not supported:

- IPV6_JOIN_GROUP
- IPV6_LEAVE_GROUP
- IP_ADD_SOURCE_MEMBERSHIP
- IP_DROP_SOURCE_MEMBERSHIP
- IP_DROP_MEMBERSHIP
- IP_ADD_MEMBERSHIP
- IP_BLOCK_SOURCE
- IP_UNBLOCK_SOURCE
- MCAST_JOIN_GROUP
- MCAST_LEAVE_GROUP
- MCAST_BLOCK_SOURCE
- MCAST_UNBLOCK_SOURCE
- MCAST_JOIN_SOURCE_GROUP
- MCAST_LEAVE_SOURCE_GROUP

Example

The following are examples of the getsockopt() call. See [“setsockopt\(\) — Set options associated with a socket”](#) on page 1573 for examples of how the setsockopt() call options are set.

```
int rc;
int s;
int option_value;
int option_len;
struct linger l;
int getsockopt(int s, int level, int option_name,
char *option_value,
int *option_len);

:
/* Is out-of-band data in the normal input queue? */
option_len = sizeof(int);
rc = getsockopt(
    s, SOL_SOCKET, SO_OOBINLINE, (
char *) &option_value, &option_len);
if (rc == 0)
{
    if (option_len == sizeof(int))
    {
        if (option_value)
            /* yes it is in the normal queue */
        else
            /* no it is not
            */
        }
    }
}
```

```

:
/* Do I linger on close? */
option_len = sizeof(l);
rc = getsockopt(
    s, SOL_SOCKET, SO_LINGER, (char *) &l, &option_len);
if (rc == 0)
{
    if (option_len == sizeof(l))
    {
        if (l.l_onoff)
            /* yes I linger */
        else
            /* no I do not */
        }
    }
}

```

getsourcefilter() — Get source filter

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| RFC3678 | both | z/OS V1.9 |

Format

```

#define _XOPEN_SYS_SOCKET_EXT3
#include <netinet/in.h>

int getsourcefilter(int s, uint32_t interface, struct sockaddr *group,
    socklen_t grouplen, uint32_t *fmode, uint32_t *numsrc,
    struct sockaddr_storage *slist);

```

General description

This function allow applications to get a previously set multicast filtering state for a tuple consisting of socket, interface, and multicast group values.

A multicast filter is described by a filter mode, which is MCAST_INCLUDE or MCAST_EXCLUDE, and a list of source addresses which are filtered.

This function is protocol-independent. It can be on either AF_INET or AF_INET6 sockets of the type SOCK_DGRAM or SOCK_RAW.

If the function is unable to obtain the required storage, control will not return to the caller. Instead the application will terminate due to an out of memory condition (if the reserve stack is available and the caller is not XPLINK), or it will terminate with an abend indicating that storage could not be obtained.

Argument

Description

s

Identifies the socket.

interface

Holds the index of the interface.

group

Points to either a sockaddr_in structure for IPv4 or a sockaddr_in6 structure for IPv6 that holds the IP multicast address of the group.

grouplen

Gives the length of the sockaddr_in or sockaddr_in6 structure.

fmode

Points to an integer that will contain the filter mode on a successful return. The value of this field will be either MCAST_INCLUDE or MCAST_EXCLUDE, which are likewise defined in <netinet/in.h>.

numsrc

It is a pointer that on input, points to the number of source addresses that will fit in the slist array. On return, points to the total number of sources associated with the filter.

slist

Points to buffer into which an array of IP addresses of included or excluded (depending on the filter mode) sources will be written. If numsrc was 0 on input, a NULL pointer may be supplied.

Returned value

If successful, the function returns 0. Otherwise, it returns -1 and sets errno to one of the following values.

errno

Description

EADDRNOTAVAIL

The tuple consisting of socket, interface, and multicast group values does not exist; or the specified interface address is not multicast capable.

EAFNOSUPPORT

The address family of the input sockaddr is not AF_INET or AF_INET6.

EBADF

s is not a valid socket descriptor.

EINVAL

Interface or group is not a valid address, or the socket s has already requested multicast setsockopt options (refer to z/OS Communications Server: IP Sockets Application Programming Interface Guide and Reference for details.) Or if the group address family is AF_INET and grouplen is not at least size of sockaddr_in or if the group address family is AF_INET6 and grouplen is not at least size of sockaddr_in6 or if grouplen is not at least size of sockaddr_in.

ENXIO

The specified interface index provided in the interface parameter does not exist.

EPROTOTYPE

The socket s is not of type SOCK_DGRAM or SOCK_RAW.

- [“setsourcefilter\(\) — Set source filter” on page 1581](#)

getstablesize() — Get the socket table size

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _OPEN_SYS_SOCK_EXT
#include <sys/socket.h>

int getstablesize(void);
```

General description

Bulk mode sockets are not supported. Do not use this function.

Returned value

If successful, `getstablesize()` returns the current limit for this process.

If it has not been changed by the `maxdesc()` function, then the default is returned. The default is the hard limit returned by `getrlimit()` for `RLIMIT_NOFILE`. This is the value set by a BPXPRMnn parmlib member on its MAXFILEPROC statement.

There are no `errno` values defined.

Related information

- [“sys/socket.h — Sockets definitions” on page 70](#)
- [“getrlimit\(\) — Get current or maximum resource consumption” on page 767](#)
- [“maxdesc\(\) — Get socket numbers to extend beyond the default range” on page 1043](#)

getsubopt() — Parse suboption arguments

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

int getsubopt(char **optionp, char *const *tokens, char **valuep);
```

General description

The `getsubopt()` function parses suboption arguments in a flag argument that was initially parsed by `getopt()`. These suboption arguments must be separated by commas and may consist of either a single token, or a token-value pair separated by an equal sign. Because commas delimit suboption arguments in the option string, they are not allowed to be part of the suboption arguments or the value of a suboption argument. Similarly, because the equal sign separates a token from its value, a token must not contain an equal sign.

The `getsubopt()` function takes the address of a pointer to the option argument string, a vector of possible tokens, and the address of a value string pointer. If the option argument string at *optionp* contains only one suboption argument, `getsubopt()` updates *optionp* to point to the NULL at the end of the string. Otherwise, it isolates the suboption argument by replacing the comma separator with a NULL, and updates *optionp* to point to the start of the next suboption argument. If the suboption argument has an associated value, `getsubopt()` updates *valuep* to point to the value's first character. Otherwise it sets *valuep* to a NULL pointer.

The token vector is organized as a series of pointers to strings. The end of the token vector is identified by a NULL pointer.

When `getsubopt()` returns, if *valuep* is not a NULL pointer, then the suboption argument processed included a value. The calling program may use this information to determine if the presence or lack of a value for the suboption is an error.

Additionally, when `getsubopt()` fails to match the suboption argument with the tokens in the *tokens* array, the calling program should decide if this is an error, or if the unrecognized option should be passed on to another program.

Because the `getsubopt()` function returns thread-specific data the `getsubopt()` function can be used safely from a multithreaded application.

Returned value

If successful, `getsubopt()` returns the index of the matched token string.

If no token strings were matched, `getsubopt()` returns -1.

`getsubopt()` does not return any `errno` values.

getsyntax() — Return LC_SYNTAX characters

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <variant.h>

struct variant *getsyntax(void);
```

General description

Determines the encoding of the special characters defined in the LC_SYNTAX category of the current locale, and stores the encoding values in the structure of type *variant*. For details of the variant structure, see [“variant.h — LC_SYNTAX characters” on page 79](#).

Returned value

Returns the pointer to the structure containing the values of the special characters.

If the information about the special characters is not available in the current locale, getsyntax() returns a NULL pointer.

The structure returned is not modified by the program that this function is used in. The structure may be invalidated by calls to the setlocale() function with LC_ALL, LC_CTYPE, LC_COLLATE, or LC_SYNTAX.

Example

CELEBG19

```
/* CELEBG19 */
#include <stdio.h>
#include <stdlib.h>
#include <variant.h>
#include <wchar.h>

int main(void)
{
    struct variant *var;

    var = getsyntax();
    printf("codeset           : %s\n", var->codeset      );
    printf("backslash        : %3d\n", var->backslash     );
    printf("right_bracket       : %3d\n", var->right_bracket    );
    printf("left_bracket        : %3d\n", var->left_bracket     );
    printf("right_brace         : %3d\n", var->right_brace      );
    printf("left_brace          : %3d\n", var->left_brace       );
    printf("circumflex          : %3d\n", var->circumflex      );
    printf("tilde               : %3d\n", var->tilde           );
    printf("exclamation_mark: %3d\n", var->exclamation_mark);
    printf("number_sign        : %3d\n", var->number_sign     );
    printf("vertical_line       : %3d\n", var->vertical_line    );
    printf("dollar_sign         : %3d\n", var->dollar_sign     );
    printf("commercial_at      : %3d\n", var->commercial_at    );
    printf("grave_accent       : %3d\n", var->grave_accent     );
}
```

__get_system_settings() — Retrieves system parameters

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | OS/390 V2R10 |

Format

```
#define _OPEN_SYS_EXT 1
#include <sys/ps.h>

struct _Optn *__get_system_settings(void);
```

General description

The `__get_system_settings()` function retrieves system parameter information from the BPXPRM member used during IPL, or updated by the OMVS operator command.

Returned value

If successful, `__get_system_settings()` returns a pointer to an `_Optn` structure containing the values set for the BPXPRMxx member process during IPL, or updated by the OMVS operator command.

If unsuccessful, `__get_system_settings()` returns NULL and may set `errno` to one of the following values:

Error Code

Description

ENOMEM

Insufficient memory available to allocate `_Optn` structure.

Related information

- [“sys/ps.h — w_getpsent\(\) function and w_psproc structure” on page 70](#)

gettimeofday(), gettimeofday64() — Get date and time

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1

#undef _ALL_SOURCE
#include <sys/time.h>

int gettimeofday(struct timeval *__restrict__ tp,
                 void *__restrict__ tzp);

#define _ALL_SOURCE
#include <sys/time.h>

int gettimeofday(struct timeval *__restrict__ tp,
                 struct timezone *__restrict__ tzp);

#define _LARGE_TIME_API
#include <sys/time.h>

int gettimeofday64(struct timeval64 *__restrict__ tp,
                  void *__restrict__ tzp);
```

General description

The `gettimeofday()` function obtains the current time, expressed as seconds and microseconds since 00:00:00 Coordinated Universal Time (UTC), January 1, 1970, and stores it in the `timeval` structure pointed to by *tp*.

Special behavior for `_ALL_SOURCE`: The `gettimeofday()` function has two prototypes. Which one is used depends on whether or not you define the `_ALL_SOURCE` feature test macro when you compile your program. If `_ALL_SOURCE` is NOT defined when the C/370 preprocessor processes the `<sys/time.h>` header, it includes a prototype for `gettimeofday()` which defines the second argument, *tzp*, as a void pointer and includes a C/370 pragma map statement for a C/370 version of `gettimeofday()` which ignores *tzp*.

If `_ALL_SOURCE` is defined, the C/370 preprocessor includes a prototype for `gettimeofday()` which defines *tzp* as a pointer to a `timezone` structure and includes a pragma map statement for a C/370 version of `gettimeofday()` which stores time zone information in the `timezone` structure to which the second argument points. The `timezone` structure contains the following members:

```
int tz_minuteswest; /* Time west of Greenwich in minutes */
int tz_dsttime;     /* Type of DST correction to apply   */
```

When `_ALL_SOURCE` is defined, the `gettimeofday()` function:

1. invokes `tzset()` to set the values of the `timezone` and `daylight` external variables.
2. converts the value of the `timezone` external variable to minutes and stores the converted value, rounded up to the nearest minute, in `tzp->tz_minuteswest`.
3. stores the value of the `daylight` external variable in `tzp->tz_dsttime`.

The function `gettimeofday64()` will behave exactly like `gettimeofday()` except it will support calendar times beyond 03:14:07 UTC on January 19, 2038.

There is no support for an `_ALL_SOURCE` version of `gettimeofday64()`.

Returned value

If successful, `gettimeofday()` returns 0.

If overflow occurs, `gettimeofday()` returns nonzero. Overflow occurs when the current time in seconds since 00:00:00 UTC, January 1, 1970 exceeds the capacity of the `tv_sec` member of the `timeval` structure pointed to by *tp*. The `tv_sec` member is type `time_t`.

getuid() – Get the real user ID

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

uid_t getuid(void);
```

General description

Finds the real user ID (UID) of the calling process.

Returned value

getuid() returns the found value. It is always successful.

There are no documented errno values.

Example

CELEBG20

```
/* CELEBG20

   This example provides information for your user ID.

*/
#define _POSIX_SOURCE
#include <pwd.h>
#include <sys/types.h>
#include <unistd.h>

main() {
    struct passwd *p;
    uid_t uid;

    if ((p = getpwuid(uid = getuid())) == NULL)
        perror("getpwuid() error");
    else {
        puts("getpwuid() returned the following info for your userid:");
        printf(" pw_name  : %s\n",      p->pw_name);
        printf(" pw_uid   : %d\n", (int) p->pw_uid);
        printf(" pw_gid   : %d\n", (int) p->pw_gid);
        printf(" pw_dir   : %s\n",      p->pw_dir);
        printf(" pw_shell : %s\n",      p->pw_shell);
    }
}
```

Output

```
pw_name  : MVSUSR1
pw_uid   : 25
pw_gid   : 500
pw_dir   : /u/mvsusr1
pw_shell : /bin/sh
```

__getuserid() — Retrieve the active MVS user ID

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | OS/390 V2R9 |

Format

```
#define _OPEN_SYS_EXT
#include <sys/ps.h>

int __getuserid(char *userid, int userlen);
```

General description

Retrieves the current active user ID for the requester. When successful, the output in user ID is the active MVS user ID.

userid is an output parameter. It points to the active MVS user ID that is a NULL terminated string.
userlen is an input parameter. It represents the length of the active MVS user ID that contains a NULL terminator.

Returned value

If successful, `__getuserid()` returns 0.

If unsuccessful, `__getuserid()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

One of the following error conditions exists:

- The length supplied by *userlen* does not allow enough storage in the string to retrieve the MVS user ID.
- The z/OS UNIX system service returned a failure.

Related information

- [“sys/ps.h — w_getpsent\(\) function and w_psproc structure” on page 70](#)

getutxent(), getutxent64() – Read next entry in utmpx database

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

getutxent:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <utmpx.h>

struct utmpx *getutxent(void);
```

getutxent64:

```
#define _XOPEN_SOURCE_EXTENDED 1
#define _LARGE_TIME_API
#include <utmpx.h>

struct utmpx64 *getutxent64(void);
```

General description

The `getutxent()` function reads in the next entry from the `utmpx` database. If the database is not already open, it opens it. If it reaches the end of the database, it fails.

The `pututxline()` function obtains an exclusive lock in the `utmpx` database on the byte range of the record which is ready to write and releases the lock before returning to its caller. The functions `getutxent()`, `getutxid()`, and `getutxline()` might continue to read and are not affected by `pututxline()`.

Because the `getutxent()` function returns thread-specific data the `getutxent()` function can be used safely from a multithreaded application. If multiple threads in the same process open the database, then each thread opens the database with a different file descriptor. The thread's database file descriptor is closed when the calling thread terminates or the `endutxent()` function is called by the calling thread.

The name of the database file defaults to `/etc/utmpx`. To process a different database file name use the `__utmpxname()` function.

For all entries that match a request, the `ut_type` member indicates the type of the entry. Other members of the entry will contain meaningful data based on the value of the `ut_type` member as follows:

EMPTY

No other members have meaningful data.

BOOT_TIME

`ut_tv` is meaningful.

__RUN_LVL

`ut_tv` and `ut_line` are meaningful

OLD_TIME

`ut_tv` is meaningful.

NEW_TIME

`ut_tv` is meaningful.

USER_PROCESS

`ut_id`, `ut_user` (login name of the user), `ut_line`, `ut_pid`, and `ut_tv` are meaningful.

INIT_PROCESS

ut_id, ut_pid, and ut_tv are meaningful.

LOGIN_PROCESS

ut_id, ut_user (implementation-specific name of the login process), ut_pid, and ut_tv are meaningful.

DEAD_PROCESS

ut_id, ut_pid, and ut_tv are meaningful.

The `getutxent64()` function behaves exactly like `getutxent()` except `getutxent64()` uses structure `utmpx64` instead of `struct utmpx` to support time beyond 03:14:07 UTC on January 19, 2038.

Returned value

If successful, `getutxent()` returns a pointer to a `utmpx` structure containing a copy of the requested entry in the user accounting database.

If unsuccessful, `getutxent()` returns a NULL pointer.

No errors are defined for this function.

Related information

- [“utmpx.h — User accounting database” on page 78](#)

getutxid(), getutxid64() — Search by ID utmpx database

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format**getutxid:**

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <utmpx.h>

struct utmpx *getutxid(const struct utmpx *id);
```

getutxid64:

```
#define _XOPEN_SOURCE_EXTENDED 1
#define _LARGE_TIME_API
#include <utmpx.h>

struct utmpx64 *getutxid64(const struct utmpx64 *id);
```

General description

The `getutxid()` function searches forward from the current point in the `utmpx` database. If the database is not already open, it opens it. If the `ut_type` value of the `utmpx` structure pointed to by *id* is **BOOT_TIME**, **__RUN_LVL**, **OLD_TIME**, or **NEW_TIME**, then it stops when it finds an entry with a matching `ut_type` value. If the `ut_type` value is **INIT_PROCESS**, **LOGIN_PROCESS**, **USER_PROCESS**, or **DEAD_PROCESS**, then it stops when it finds an entry whose type is one of these four and whose `ut_id` member matches the `ut_id` member of the `utmpx` structure pointed to by *id*. If the `ut_type` value is **EMPTY**, `getutxid()` fails (returns `NULL`) without repositioning the `utmpx` database to the end. If the end of the database is reached without a match, `getutxid()` fails.

The `pututxline()` function obtains an exclusive lock in the `utmpx` database on the byte range of the record which is ready to write and releases the lock before returning to its caller. The functions `getutxent()`, `getutxid()`, and `getutxline()` might continue to read and are not affected by `pututxline()`.

Because the `getutxid()` function returns thread-specific data the `getutxid()` function can be used safely from a multithreaded application. If multiple threads in the same process open the database, then each thread opens the database with a different file descriptor. The thread's database file descriptor is closed when the calling thread terminates or the `endutxent()` function is called by the calling thread.

The name of the database file defaults to `/etc/utmpx`. To process a different database file name use the `__utmpxname()` function.

For all entries that match a request, the `ut_type` member indicates the type of the entry. Other members of the entry will contain meaningful data based on the value of the `ut_type` member as follows:

EMPTY

No other members have meaningful data.

BOOT_TIME

`ut_tv` is meaningful.

__RUN_LVL

`ut_tv` and `ut_line` are meaningful

OLD_TIME

`ut_tv` is meaningful.

NEW_TIME

`ut_tv` is meaningful.

USER_PROCESS

`ut_id`, `ut_user` (login name of the user), `ut_line`, `ut_pid`, and `ut_tv` are meaningful.

INIT_PROCESS

`ut_id`, `ut_pid`, and `ut_tv` are meaningful.

LOGIN_PROCESS

`ut_id`, `ut_user` (implementation-specific name of the login process), `ut_pid`, and `ut_tv` are meaningful.

DEAD_PROCESS

`ut_id`, `ut_pid`, and `ut_tv` are meaningful.

The `getutxid64()` function behaves exactly like `getutxid()` except `getutxid64()` uses structure `utmpx64` instead of `struct utmpx` to support time beyond 03:14:07 UTC on January 19, 2038.

Returned value

If successful, `getutxid()` returns a pointer to a `utmpx` structure containing a copy of the requested entry in the user accounting database.

If unsuccessful, `getutxid()` returns a `NULL` pointer.

No errors are defined for this function.

getutxline(), getutxline64() — Search by line utmpx database

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

getutxline:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <utmpx.h>

struct utmpx *getutxline(const struct utmpx *line);
```

getutxline64:

```
#define _XOPEN_SOURCE_EXTENDED 1
#define _LARGE_TIME_API
#include <utmpx.h>

struct utmpx64 *getutxline64(const struct utmpx64 *line);
```

General description

The `getutxline()` function searches forward from the current point in the utmpx database until it finds an entry of the type **LOGIN_PROCESS** or **USER_PROCESS** which also has a `ut_line` value matching that in the utmpx structure pointed to by argument `line`. If the database is not already open, it opens it. If it reaches the end of the database, it fails.

The `pututxline()` function obtains an exclusive lock in the utmpx database on the byte range of the record which is ready to write and releases the lock before returning to its caller. The functions `getutxent()`, `getutxid()`, and `getutxline()` might continue to read and are not affected by `pututxline()`.

Because the `getutxline()` function returns thread-specific data the `getutxline()` function can be used safely from a multithreaded application. If multiple threads in the same process open the database, then each thread opens the database with a different file descriptor. The thread's database file descriptor is closed when the calling thread terminates or the `endutxent()` function is called by the calling thread.

The name of the database file defaults to `/etc/utmpx`. To process a different database file name use the `__utmpxname()` function.

The functions `getutxent()`, `getutxid()`, and `getutxline()` cache the last entry read from the database. For this reason, to use `getutxline()` function to search for multiple occurrences, it is necessary to zero out the utmpx structure pointed to by the return value from these functions.

For all entries that match a request, the `ut_type` member indicates the type of the entry. Other members of the entry will contain meaningful data based on the value of the `ut_type` member as follows:

EMPTY

No other members have meaningful data.

BOOT_TIME

`ut_tv` is meaningful.

__RUN_LVL

`ut_tv` and `ut_line` are meaningful

OLD_TIME

`ut_tv` is meaningful.

NEW_TIME

`ut_tv` is meaningful.

USER_PROCESS

`ut_id`, `ut_user` (login name of the user), `ut_line`, `ut_pid`, and `ut_tv` are meaningful.

INIT_PROCESS

`ut_id`, `ut_pid`, and `ut_tv` are meaningful.

LOGIN_PROCESS

`ut_id`, `ut_user` (implementation-specific name of the login process), `ut_pid`, and `ut_tv` are meaningful.

DEAD_PROCESS

`ut_id`, `ut_pid`, and `ut_tv` are meaningful.

The `getutxline64()` function behaves exactly like `getutxline()` except `getutxline64()` uses structure `utmpx64` instead of `struct utmpx` to support time beyond 03:14:07 UTC on January 19, 2038.

Returned value

If successful, `getutxline()` returns a pointer to a `utmpx` structure containing a copy of the requested entry in the user accounting database.

If unsuccessful, `getutxline()` returns a NULL pointer.

No errors are defined for this function.

getw() — Get a machine word from a stream

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4 XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE
#include <stdio.h>

int getw(FILE *stream);
```

General description

The `getw()` function reads the next word from the *stream*. The size of the word is the size of an `int`, and varies from machine to machine. The `getw()` function presumes no special alignment in the file.

The `getw()` function may mark the `st_atime` field of the file associated with *stream* for update. The `st_atime` field will be marked for update by the first successful execution of `fgetc()`, `fgets()`, `fread()`, `getc()`, `getchar()`, `gets()`, `fscanf()` or `scanf()` using *stream* that returns data not supplied by a prior call to `ungetc()`.

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use character-based input functions to replace `getw()` for portability.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

If successful, `getw()` returns the next word from the input stream pointed to by *stream*. If the stream is at End Of File (EOF), the End Of File indicator for the stream is set and `getw()` returns EOF. If a read error occurs, the error indicator for the stream is set, `getw()` returns EOF and sets `errno` to indicate the error.

Refer to [“fgetc\(\) — Read a character” on page 533](#) for `errno` values.

Because the representation of EOF is a valid integer, applications wishing to check for errors should use `ferror()` and `feof()`.

getwc() — Get a wide character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```
#include <wchar.h>

wint_t getwc(FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

wint_t getwc_unlocked(FILE *stream);
```

General description

Obtains the next multibyte character from `stdin`, converts it to a wide character, and advances the associated file position indicator for `stdin`.

The `getwc()` function is equivalent to the `fgetwc()` function. Therefore, the argument should never be an expression with side effects.

The behavior of this wide-character function is affected by the `LC_CTYPE` category of the current locale. If you change the category, undefined results can occur.

Using non-wide-character functions with `getwc()` results in undefined behavior. This happens because `getwc()` processes a whole multibyte character and does not expect to be “within” such a character. In addition, `getwc()` expects state information to be set already. Because functions like `fgetc()` and `fputc()` do not obey such rules, their results fail to meet the assumptions made by `getwc()`.

`getwc()` has the same restriction as any read operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

`getwc_unlocked()` is functionally equivalent to `getwc()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

Returns the next wide character from the input stream pointed to by *stream* or else the function returns WEOF.

If there is an error, `getwc()` sets the error indicator. If the EOF is encountered, it sets the EOF indicator. If an encoding error is encountered, it sets EILSEQ in `errno`.

Use `ferror()` or `feof()` to determine whether an error or an EOF condition occurred. Note that EOF is only reached when an attempt is made to read past the last byte of data. Reading up to and including the last byte of data does *not* turn on the EOF indicator.

Example

CELEBG21

```
/* CELEBG21 */
#include <errno.h>
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>

int main(void)
{
    FILE    *stream;
    wint_t   wc;

    if ((stream = fopen("myfile.dat", "r")) == NULL) {
        printf("Unable to open file.");
        exit(1);
    }
```

```

}

errno = 0;
while ((wc = getwc(stream)) != WEOF)
    printf("wc=0x%lx\n", wc);

if (errno == EILSEQ) {
    printf("An invalid wide character was encountered.\n");
    exit(1);
}

fclose(stream);
}

```

Related information

getwchar() — Get a wide character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```

#include <wchar.h>

wint_t getwchar(void)

#define _OPEN_SYS_UNLOCKED_EXT 1;
#include <wchar.h>

wint_t getwchar_unlocked(void)

```

General description

The `getwchar()` function is equivalent to `getwc()` with the argument `stdin`.

The behavior of this wide-character function is affected by the `LC_CTYPE` category of the current locale. If you change the category, undefined results can occur.

`getwchar_unlocked()` is functionally equivalent to `getwchar()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

Returns the next wide character from the input stream pointed to by `stdin` or else the function returns `WEOF`. If the stream is at EOF, the EOF indicator for the stream is set and `fgetwc()` returns `WEOF`. If a read error occurs, the error indicator for the stream is set and `fgetwc()` returns `WEOF`. If an encoding error occurs, the value of the macro `EILSEQ` is stored in `errno` and `WEOF` is returned.

Use `ferror()` or `feof()` to determine whether an error or an EOF condition occurred. Note that EOF is only reached when an attempt is made to read past the last byte of data. Reading up to and including the last byte of data does *not* turn on the EOF indicator.

Example

CELEBG22

```
/* CELEBG22 */
#include <errno.h>
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>

int main(void)
{
    wint_t    wc;

    errno = 0;
    while ((wc = getwchar()) != WEOF)
        printf("wc=0x%X\n", wc);

    if (errno == EILSEQ) {
        printf("An invalid wide character was encountered.\n");
        exit(1);
    }
}
```

getwd() — Get the current working directory

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

char *getwd(char *path_name);
```

General description

The `getwd()` function determines an absolute path name of the current working directory of the calling process, and copies that path name into the array pointed to by *path_name* argument.

If the length of the path name of the current working directory is greater than (**PATH_MAX**+1) including the NULL byte, `getwd()` fails and returns a NULL pointer.

For portability to implementations conforming to earlier versions of the standards, `getcwd()` is preferred over this function.

Note: The `getwd()` function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The `getcwd()` function is preferred for portability.

Returned value

If successful, `getwd()` returns a pointer to the string containing the absolute path name of the current working directory.

If unsuccessful, `getwd()` returns a NULL pointer and the contents of the array pointed to by *path_name* are undefined.

There are no `errno` values defined.

Related information

- [“unistd.h — Implementation-specific functions” on page 77](#)

getwmccoll() — Get next collating element from wide string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C Library | both | |

Format

```
#include <collate.h>

collcl_t getwmccoll(wchar_t **src);
```

General description

If the object pointed to by *src* is not a NULL pointer, the `getwmccoll()` library function determines the longest sequence of wide characters in the array pointed to by *str* that constitute a valid multi-wide-character collating element. It then produces the value of type `collcl_t` corresponding to that collating element. The object pointed to by *src* is assigned the address just past the last wide character of the multi-wide-character collating element processed.

Returned value

If successful, `getwmccoll()` returns the value of type `collcl_t` that represents the collating element found.

If the object pointed to by *src* is a NULL pointer or if it points to a NULL wide character, `getwmccoll()` returns 0.

If the object pointed to by *src* points to a non-valid wide character, `getwmccoll()` returns -1 and sets `errno` to `EILSEQ`.

Related information

getxattr(), lgetxattr(), fgetxattr() — Retrieve an extended attribute value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <sys/xattr.h>

ssize_t getxattr(const char *path, const char *name, void *value, size_t size);
ssize_t lgetxattr(const char *path, const char *name, void *value, size_t size);
ssize_t fgetxattr(int fd, const char *name, void *value, size_t size);
```

General description

Extended attributes are extensions to the normal attributes that are associated with all inodes in the system. They are used as name : value pairs that are associated with files and directories to provide more functions to a file system.

getxattr() retrieves the value of the extended attribute that is identified by *name* and associated with the given path in the file system. The attribute value is placed in the buffer that is pointed to by *value* and *size* specifies the size of that buffer. If *size* is specified as zero, only the current size of the named extended attribute is returned, and the buffer pointed by *value* remains unchanged.

lgetxattr() is identical to getxattr() except that lgetxattr() interrogates a symbolic link but not the file that it refers to.

fgetxattr() is identical to getxattr() except that fgetxattr() interrogates the open file that is referred to by *fd* in place of *path*.

Returned value

If successful, the size of the extended attribute value in bytes is returned.
If unsuccessful, -1 is returned and errno is set to one of the following values:

Error Code

| Description |
|---|
| ENOATTR The specified attribute is not set. Attribute name is NULL or blank. |
| ENAMETOOLONG <i>pathname</i> is longer than PATH_MAX characters. |

ENODATA

The specified attribute is not set.
Attribute name is NULL or blank.

ENOTSUP

Extended attributes are not supported by the file system.

ERANGE

The size of the value buffer is too small to hold the result.
Attribute name is longer than PATH_MAX characters.

Related information

givesocket() — Make the specified socket available

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _OPEN_SYS_SOCK_EXT
#include <sys/socket.h>

int givesocket(int d, struct clientid *clientid);
```

General description

The givesocket() call makes the specified socket available to a takesocket() call issued by another program. Any socket can be given. Typically, givesocket() is used by a main program that obtains sockets by means of accept() and gives them to application programs that handle one socket at a time.

Parameter**Description****d**

The descriptor of a socket to be given to another application.

clientid

A pointer to a client ID structure specifying the program to which the socket is to be given.

To pass a socket, the giving program first calls givesocket() with the client ID structure filled in as follows:

The clientid structure:

```
struct clientid {
    int domain;
    union {
        char name[8];
        struct {
            int NameUpper;
            pid_t pid;
        } c_pid;
    } c_name;
    char subtaskname[8];
```

```

    struct {
        char type;
        union {
            char specific[19];
            struct {
                char unused[3];
                int SockToken;
            } c_close;
        } c_func;
    } c_reserved;
};

```

Element**Description*****domain***

The domain of the input socket descriptor.

c_name.name

If the *clientid* was set by a `getclientid()` call, *c_name.name* can be

- set to the application program's address space name, left-justified and padded with blanks. The application program can run in the same address space as the main program, in which case this field is set to the main program's address space.
- set to blanks, so any z/OS address space can take the socket.

subtaskname

If the *clientid* was set by a `getclientid()` call, *subtaskname* can be

- set to the task identifier of the taker. This, combined with a *c_name.name* value, allows only a process with this *c_name.name* and *subtaskname* to take the socket.
- set to blanks. If *c_name.name* has a value and *subtaskname* is blank, any task with that *c_name.name* can take the socket.

c_pid.pid

If the *clientid* was set by a `__getclientid()` call, *c_pid.pid* should be set to the process id (PID) of the taker, so only a process with that PID can take the socket. The *subtaskname* field is ignored when the *c_pid* has a value.

c_reserved.type

When set to `SO_CLOSE`, this indicates the socket should be automatically closed by `givesocket()`, and a unique socket identifying token is to be returned in *c_close.SockToken*. The *c_close.SockToken* should be passed to the taking program to be used as input to `takesocket()` instead of the socket descriptor. The now closed socket descriptor could be re-used by the time the `takesocket()` is called, so the *c_close.SockToken* should be used for `takesocket()`.

When set to `_SO_SELECT`, this indicates that the application intends to block on the `select()` for exception, waiting for the `takesocket()` to occur before closing the socket. If *c_reserved.type* is set to `_SO_SELECT` and the caller of `givesocket()` closes the socket before it has been taken, the connection will be severed. `_SO_SELECT` also allows `select()` to return exception status if `select()` is done after the socket was taken with `takesocket()`.

When set to zero, this indicates that the application will not be calling `select()` to coordinate with the taker of the socket. Either the socket is not going to be closed or the giver and taker have some other method of coordination for the giver to know when the taker has called `takesocket()`. Note that if `select()` for exception is called before `takesocket()`, the `select` will return when `takesocket()` is called but if `select()` is called after `takesocket()`, it will hang. `_SO_SELECT` should be used if `select()` is going to be called by the giver.

Also, if the given socket is closed before the `takesocket()` is issued, it is possible for that socket descriptor number to be reused in the giver's process. A sequence of `accept()`, `givesocket()`, and `close()` calls issued several times before any `takesocket()` calls can result in several sockets with the same descriptor number waiting to be taken. In this case, the oldest given socket will be taken; that is, in FIFO order. Note that if `select()` is called when there are several given sockets with the same

descriptor number waiting to be taken, `select()` will operate on the current active socket for that descriptor. It effectively waits for the last (newest) given socket to be taken; that is, in LIFO order.

`c_close.SockToken`

The unique socket identifying token returned by `givesocket()` to be used as input to `takesocket()`, instead of the socket descriptor when `c_reserved.type` has been set to `SO_CLOSE`.

`c_reserved`

Specifies binary zeros if an automatic close of a socket is not to be done by `givesocket()`.

Using name and subtaskname for givesocket/takesocket:

1. The giving program calls `getclientid()` to obtain its client ID. The giving program calls `givesocket()` to make the socket available for a `takesocket()` call. The giving program passes its client ID along with the descriptor of the socket to be given to the taking program by the taking program's startup parameter list.
2. The taking program calls `takesocket()`, specifying the giving program's client ID and socket descriptor.
3. Waiting for the taking program to take the socket, the giving program uses `select()` to test the given socket for an exception condition. When `select()` reports that an exception condition is pending, the giving program calls `close()` to free the given socket.
4. If the giving program closes the socket before a pending exception condition is indicated, the connection is immediately reset, and the taking program's call to `takesocket()` is unsuccessful. Calls other than the `close()` call issued on a given socket return -1, with `errno` set to `EBADF`.

Note: For backward compatibility, a client ID can point to the struct client ID structure obtained when the target program calls `getclientid()`. In this case, only the target program, and no other programs in the target program's address space, can take the socket.

Using process id (PID) for givesocket/takesocket:

1. The giving program calls `__getclientid()` to obtain its client ID. The giving program sets the `c_pid.pid` in the clientid structure to the PID of the taking program that will take the socket (that is, issue the `takesocket()` call). This ensures only a process that has obtained the giver's PID can take the specified socket. If the giving program wants the socket to be automatically closed by `givesocket()`, `c_reserved.type` should be set to `SO_CLOSE`. The giving program calls `givesocket()` to make the socket available for a `takesocket()` call. The giving program passes its client ID, the descriptor of the socket to be given, and the giving program's PID to the taking program by the taking program's startup parameter list.
2. The taking program sets the `c_pid.pid` in the clientid structure to the PID of the giving program to identify the process from which the socket is to be taken. If the `c_reserved.type` field was set to `SO_CLOSE` on `givesocket()`, the `c_close.SockToken` should be used as input to the `takesocket()` instead of the normal socket descriptor. The taking program calls `takesocket()`, specifying the giving program's client ID and either the socket descriptor or `c_close.SockToken`.
3. If the `c_reserved.type` field in the clientid structure was set to `SO_CLOSE` on the `givesocket()` call, the socket is closed and the giving program does not have to wait for the taking program to issue the `takesocket()`. Otherwise, steps 3 and 4 of "Using name and subtaskname for givesocket/takesocket" should be followed.

Returned value

If successful, `givesocket()` returns 0.

If unsuccessful, `givesocket()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

The *d* parameter is not a valid socket descriptor. The socket has already been given.

EFAULT

Using the *clientid* parameter as specified would result in an attempt to access storage outside the caller's address space.

EINVAL

The *clientid* parameter does not specify a valid client identifier or the *clientid* domain does not match the domain of the input socket descriptor.

glob() — Generate path names matching a pattern

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <glob.h>

int glob(const char *__restrict__ pattern, int flags,
        int (*errfunc)(const char *epath, int eerrno),
        glob_t *__restrict__ pglob);
```

General description

The *glob()* function is a path name generator that implements the rules defined in topic about pattern matching notation in *X/Open CAE Specification, Commands and Utilities, Issue 4, Version 2*, with optional support for rule 3 in the topic about patterns used for file name expansion.

The structure *glob_t* is defined in the header *<glob.h>* and includes at least the following members:

gl_pathc

Count of paths matched by *pattern*.

gl_pathv

Pointer to a list of matched file names.

gl_offs

Slots to reserve at the beginning of *gl_pathv*.

The argument *pattern* is a pointer to a path name pattern to be expanded. The *glob()* function matches all accessible path names against this pattern and develops a list of all path names that match. In order to have access to a path name, *glob()* requires search permission on every component of a path except the

last, and read permission on each directory of any file name component of *pattern* that contains any of the following special characters:

* ? [

The `glob()` function stores the number of matched path names into `pglob->gl_pathc` and a pointer to a list of pointers to path names into `pglob->gl_pathv`. The path names are in sort order as defined by the current setting of the `LC_COLLATE` category, see *X/Open CAE Specification, System Interface Definitions, Issue 4, Version 2* Section 5.3.2, `LC_COLLATE`. The first pointer after the last path name is a NULL pointer. If the pattern does not match any path names, the returned number of matched paths is set to 0, and the contents of `pglob->gl_pathv` are implementation-dependent.

It is the caller's responsibility to create the structure pointed to by `pglob`. The `glob()` function allocates other space as needed, including the memory pointed to by `gl_pathv`.

The *flags* argument is used to control the behavior of `glob()`. The value of *flags* is a bitwise inclusive-OR of zero or more of the following constants, which are defined in the header `<glob.h>`:

GLOB_APPEND

Append path names generated to the ones from a previous call to `glob()`.

GLOB_DOOFFS

Make use of `pglob->gl_offs`. If this flag is set, `pglob->gl_offs` is used to specify how many NULL pointers to add to the beginning of `pglob->gl_pathv`. In other words, `pglob->gl_pathv` will point to `pglob->gl_offs` NULL pointers, followed by `pglob->gl_pathc` path name pointers, followed by a NULL pointer.

GLOB_ERR

Causes `glob()` to return when it encounters a directory that it cannot open or read. Ordinarily, `glob()` continues to find matches.

GLOB_MARK

Each path name that is a directory that matches *pattern* has a slash appended.

GLOB_NOCHECK

Support rule 3 in the XCU specification, Section 2.13.3, Patterns Used for Filename Expansion. If *pattern* does not match any path name, then `glob()` returns a list consisting of only *pattern*, and the number of matched path names is 1.

GLOB_NOESCAPE

Disable backslash escaping.

GLOB_NOSORT

Ordinarily, `glob()` sorts the matching path names according to the current setting of the `LC_COLLATE` category, see the XBD specification, Section 5.3.2, `LC_COLLATE`. When this flag is used the order of path names returned is unspecified.

The `GLOB_APPEND` flag can be used to append a new set of path names to those found in a previous call to `glob()`. The following rules apply when two or more calls to `glob()` are made with the same value of `pglob` and without intervening calls to `globfree()`:

1. The first such call must not set `GLOB_APPEND`. All subsequent calls must set it.
2. All calls must set `GLOB_DOOFFS`, or all must not set it.
3. After the second call, `pglob->gl_pathv` points to a list containing the following:
 - a. Zero or more NULL pointers, as specified by `GLOB_DOOFFS` and `pglob->gl_offs`.
 - b. Pointers to the path names that were in the `pglob->gl_pathv` list before the call, in the same order as before.
 - c. Pointers to the new path names generated by the second call, in the specified order.
4. The count returned in `pglob->gl_pathc` will be the total number of path names from the two calls.
5. The application can change any of the fields after a call to `glob()`. If it does, it must reset them to the original value before a subsequent call, using the same `pglob` value, to `globfree()` or `glob()` with the `GLOB_APPEND` flag.

If, during the search, a directory is encountered that cannot be opened or read and *errfunc* is not a NULL pointer, *glob()* calls (**errfunc()*) with two arguments:

- 1. The *epath* argument is a pointer to the path that failed.
- 2. The *eerrno* argument is the value of *errno* from the failure, as set by *opendir()*, *readdir()* or *stat()*. (Other values may be used to report other errors not explicitly documented for those functions.)

Returned value

If successful, *glob()* returns 0. The argument *pglob->gl_pathc* returns the number of matched path names and the argument *pglob->gl_pathv* contains a pointer to a NULL-terminated list of matched and sorted path names. However, if *pglob->gl_pathc* is 0, the content of *pglob->gl_pathv* is undefined.

If *glob()* terminates due to an error, it returns one of the following nonzero constants defined in *<glob.h>* as error return values for *glob()*:

GLOB_ABORTED

The scan was stopped because *GLOB_ERR* was set or (**errfunc()*) returned nonzero.

GLOB_NOMATCH

The pattern does not match any existing path name, and *GLOB_NOCHECK* was notset in *flags*.

GLOB_NOSPACE

An attempt to allocate memory failed.

If (**errfunc()*) is called and returns nonzero, or if the *GLOB_ERR* flag is set in *flags*, *glob()* stops the scan and returns *GLOB_ABORTED* after setting *gl_pathc* and *gl_pathv* in *pglob* to reflect the paths already scanned. If *GLOB_ERR* is not set and either *errfunc* is a NULL pointer or (**errfunc()*) returns 0, the error is ignored.

globfree() — Free storage allocated by glob()

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <glob.h>

void globfree(glob_t *pglob);
```

General description

The `globfree()` function frees storage associated with *pglob* by a previous call to `glob()`.

Returned value

`globfree()` returns no values.

Related information

- “[glob.h — Pathname pattern matching types](#)” on page 27
- “[glob\(\) — Generate path names matching a pattern](#)” on page 808

gmtime(), gmtime64() — Convert time to broken-down UTC time

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```
#include <time.h>

struct tm *gmtime(const time_t *timer);

#define _LARGE_TIME_API
#include <time.h>

struct tm *gmtime64(const time64_t *timer);
```

General description

Converts the calendar time pointed to by *timer* into a broken-down time, expressed as Coordinated Universal Time (UTC).

²

The value pointed to by *timer* is usually obtained by a call to the `time()` function.

The relationship between a time in seconds since the Epoch used as an argument to `gmtime()` and the `tm` structure (defined in the `<time.h>` header) is that the result is as specified in the expression given in the definition of seconds since the Epoch, where the names in the structure and in the expression correspond.

The function `gmtime64()` will behave exactly like `gmtime()` except it will break down a `time64_t` value pointing to a calendar time beyond 03:14:07 UTC on January 19, 2038 with a limit of 23:59:59 UTC on December 31, 9999.

² Coordinated Universal Time (UTC) was formerly known as Greenwich Mean Time (GMT).

Returned value

Returns a pointer to a *tm* structure containing the broken-down time, expressed in Coordinated Universal Time (UTC) corresponding to calendar time pointed to by *timer*. The fields in *tm* are shown in [Table 16 on page 76](#). If the calendar time pointed to by *timer* cannot be converted to broken-down time (in UTC), `gmtime()` returns a NULL pointer.

Error code

Description

EOVERFLOW

The result cannot be represented.

Notes:

1. The range (0-60) for *tm_sec* allows for as many as one leap second.
2. The `gmtime()` and `localtime()` functions may use a common, statically allocated buffer for the conversion. Each call to one of these functions may alter the result of the previous call.
3. The calendar time returned by the `time()` function begins at the epoch, which was at 00:00:00 Coordinated Universal Time (UTC), January 1, 1970.

Example

CELEBG23

```
/* CELEBG23

   This example uses the &gmtime. function to convert a
   time_t representation to a Coordinated Universal Time
   character string and then converts it to a printable string
   using &asctime..

*/
#include <stdio.h>
#include <time.h>

int main(void)
{
    time_t ltime;
    time(&ltime);
    printf ("Coordinated Universal Time is %s\n",
           asctime(gmtime(&ltime)));
}
```

Output

```
Coordinated Universal Time (UTC) is Fri Jun 16 21:01:44 2006
```

gmtime_r(), gmtime64_r() — Convert a time value to broken-down UTC time

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 Language Environment | both | OS/390 V2R8 |

Format

```
#define _XOPEN_SOURCE 500
#include <time.h>

struct tm *gmtime_r(const time_t *__restrict__ clock,
                    struct tm *__restrict__ result);
```

```
#define _LARGE_TIME_API
#include <time.h>

struct tm *gmtime64_r(const time64_t *__restrict__ clock,
                     struct tm *__restrict__ result);
```

General description

The `gmtime_r()` function converts the calendar time pointed to by *clock* into a broken-down time expressed as Coordinated Universal Time (UTC). The broken-down time is stored in the structure referred to by *result*. The `gmtime_r()` function also returns the address of the same structure.

The relationship between a time in seconds since the Epoch used as an argument to `gmtime()` and the `tm` structure (defined in the `<time.h>` header) is that the result is as specified in the expression given in the definition of seconds since the Epoch, where the names in the structure and in the expression correspond.

The function `gmtime64_r()` will behave exactly like `gmtime_r()` except it will break down a `time64_t` value pointing to a calendar time beyond 03:14:07 UTC on January 19, 2038 with a limit of 23:59:59 UTC on December 31, 9999.

Returned value

If successful, `gmtime_r()` returns the address of the structure pointed to by the argument *result*.

If an error is detected or UTC is not available, `gmtime_r()` returns a NULL pointer.

There are no documented `errno` values.

Error Code

Description

EOVERFLOW

The result cannot be represented.

grantpt() — Grant access to the subsidiary pseudoterminal device

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

int grantpt(int fildev);
```

General description

The `grantpt()` function changes the mode and ownership of the subsidiary pseudoterminal device. *fildev* should be the file descriptor of the corresponding manager pseudoterminal. The user ID of the subsidiary is set to the real UID of the calling process and the group ID is set to the group ID associated with the group name specified by the installation in the `TTYGROUP()` initialization parameter. The permission mode of the subsidiary pseudoterminal is set to readable and writable by the owner, and writable by the group.

You can provide secure connections by either using `grantpt()` and `unlockpt()`, or by simply issuing the first open against the subsidiary pseudoterminal from the first userid or process that opened the manager terminal.

Returned value

If successful, `grantpt()` returns 0.

If unsuccessful, `grantpt()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

The subsidiary pseudoterminal was opened before `grantpt()`, or a `grantpt()` was already issued. In either case, subsidiary pseudoterminal permissions and ownership have already been updated. If you use `grantpt()` to change subsidiary pseudoterminal permissions, you must issue `grantpt()` between the manager open and the first pseudoterminal open, and `grantpt()` can only be issued once.

EBADF

The *fil*des argument is not a valid open file descriptor.

EINVAL

The *fil*des argument is not associated with a manager pseudoterminal device.

ENOENT

The subsidiary pseudoterminal device was not found during lookup.

Related information

hcreate() — Create hash search tables

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <search.h>

int hcreate(size_t nel);
```

General description

The `hcreate()` function allocates sufficient space for a hash table containing *nel* elements, and must be called before `hsearch()` is used.

The *nel* argument is an estimate of the maximum number of entries that the table will contain. This number may be adjusted upward by `hcreate()` for the actual table allocation in order to obtain certain mathematically favorable circumstances.

Threading Behavior: see [“hsearch\(\) — Search hash tables” on page 818](#).

Returned value

If successful, `hcreate()` returns nonzero.

If `hcreate()` cannot allocate sufficient space for the table, it returns 0 and sets `errno` to one of the following values:

Error Code**Description****ENOMEM**

Insufficient storage space is available.

Related information

- [“tsearch\(\) — Binary tree search” on page 1903](#)

hdestroy() — Destroy hash search tables

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <search.h>

void hdestroy(void);
```

General description

The `hdestroy()` function disposes of the search table, and may be followed by another call to `hcreate()`. After the call to `hdestroy()`, the data can no longer be considered accessible.

Threading Behavior: see [“hsearch\(\) — Search hash tables” on page 818](#).

Returned value

`hdestroy()` returns no values.

Related information

- [“search.h — Searching tables” on page 58](#)
- [“bsearch\(\) — Search arrays” on page 221](#)
- [“hcreate\(\) — Create hash search tables” on page 815](#)

__heaprpt() — Obtain dynamic heap storage report

Standards

| Standards / Extensions | C or C++ | Dependencies |
|-------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <stdlib.h>

typedef struct{long __uheap_size;
               long __uheap_bytes_alloc;
               long __uheap_bytes_free;
            } hreport_t;

int __heaprpt(hreport_t *heap_report_structure);
```

General description

__heaprpt() gets statistics about the application's storage utilization and places them in the area pointed to by the *heap_report_structure* argument. The storage report is similar in content to the user heap storage report that is generated with the RPTSTG(ON) runtime option.

To use this function, the calling program must obtain storage where the user's heap storage report will be stored. The address of this storage is passed as an argument to __heaprpt().

Returned value

If successful, __heaprpt() fills the struct hreport_t with the user's heap storage report information.

If the address is not valid, __heaprpt() returns -1 and sets errno to EFAULT.

Example

```
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    hreport_t * strptr;

    strptr = (hreport_t *) malloc(sizeof(hreport_t));

    if (__heaprpt(strptr) != 0)
        perror("__heaprpt() error");

    else
    {
        printf("Total amount of user heap storage      : %ld\n",
              strptr->__uheap_size);
        printf("Amount of user heap storage in use      : %ld\n",
              strptr->__uheap_bytes_alloc);
        printf("Amount of available user heap storage: %ld\n",
              strptr->__uheap_bytes_free);
    }
}
```

Related information

- [“stdlib.h — Standard library functions” on page 65](#)

hsearch() — Search hash tables

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <search.h>

ENTRY *hsearch(ENTRY item, ACTION action);
```

General description

The `hsearch()` function is a hash-table search routine. It returns a pointer into a hash table indicating the location at which an entry can be found. The *item* argument is a structure of type `ENTRY` (defined in the `<search.h>` header) containing two pointers: *item.key* points to the comparison key (a `char *`), and *item.data* (a `void *`) points to any other data to be associated with that key. The comparison function used by `hsearch()` is `strcmp()`. The *action* argument is a member of an enumeration type `ACTION` indicating the disposition of the entry if it cannot be found in the table. *ENTER* indicates that the item should be inserted in the table at an appropriate point. *FIND* indicates that no entry should be made.

Threading Behavior: The `hcreate()` function allocates a piece of storage for use as the hash table. This storage is not exposed to the user, and is referred to by all threads. In other words, these functions operate on one hash table global to the process. The library serializes access to the table and attendant data across threads using an internal mutex.

Returned value

`hsearch()` returns a `NULL` pointer if either the action is *FIND* and the item could not be found or the action is *ENTER* and the table is full.

If an error occurs, `hsearch()` sets `errno` to one of the following values:

Error Code

Description

ENOMEM

Insufficient storage space is available.

htonl() — Translate address host to network long

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

XPG4.2

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <arpa/inet.h>

in_addr_t htonl(in_addr_t hostlong);
```

SUSV3

```
#define _POSIX_C_SOURCE 200112L
#include <arpa/inet.h>

uint32_t htonl(uint32_t hostlong);
```

Berkeley Sockets

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <arpa/inet.h>
#include <netinet/in.h>

unsigned long htonl(unsigned long a);
```

General description

The `htonl()` function translates a long integer from host byte order to network byte order.

Parameter

Description

a

The unsigned long integer to be put into network byte order.

`in_addr_t hostlong`

Is typed to the unsigned long integer to be put into network byte order.

Notes:

1. For MVS, host byte order and network byte order are the same.
2. Since this function is implemented as a macro, you need one of the feature test macros and the `inet` header file.

Returned value

`htonl()` returns the translated long integer.

htons() — Translate an unsigned short integer into network byte order

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

XPG4.2

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <arpa/inet.h>

in_port_t htons(in_port_t hostshort);
```

SUSV3

```
#define _POSIX_C_SOURCE 200112L
#include <arpa/inet.h>

uint16_t htons(uint16_t hostshort);
```

Berkeley Sockets

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <netinet/in.h>
#include <arpa/inet.h>

unsigned short htons(unsigned short a);
```

General description

The `htons()` function translates a short integer from host byte order to network byte order.

Parameter

Description

a

The unsigned short integer to be put into network byte order.

in_port_t hostshort

Is typed to the unsigned short integer to be put into network byte order.

Notes:

1. For MVS, host byte order and network byte order are the same.
2. Since this function is implemented as a macro, you need one of the feature test macros and the `inet` header file.

Returned value

`htons()` returns the translated short integer.

hypot(), hypotf(), hypotl() — Calculate the square root of the squares of two arguments

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| SAA XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

SAA:

```
#include <math.h>

double hypot(double side1, double side2);
```

This function must be used with the [runtime library extensions](#) or under the [SAA based language constructs](#).

XPG4:

```
#define _XOPEN_SOURCE
#include <math.h>

double hypot(double side1, double side2);
```

C99:

```
#define _ISOC99_SOURCE
#include <math.h>

float hypotf(float side1, float side2);
long double hypotl(long double side1, long double side2);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

float hypot(float side1, float side2);
long double hypot(long double side1, long double side2);
```

General description

The hypot() family of functions calculates the length of the hypotenuse of a right-angled triangle based on the lengths of two sides *side1* and *side2*. A call to hypot() is equal to:

```
sqrt(side1* side1 + side2 * side2);
```

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

| Function | SPC | Hex | IEEE |
|----------|-----|-----|------|
| hypot | X | X | X |
| hypotf | | X | X |
| hypotl | | X | X |

Restriction: The hypotf() function does not support the _FP_MODE_VARIABLE feature test macro.

Returned value

The hypot() family of functions returns the calculated length of the hypotenuse.

If the correct value is outside the range of representable values, ±HUGE_VAL is returned, according to the sign of the value. The value of the macro ERANGE is stored in errno, to show the calculated value is out of range. If the correct value would cause an underflow, zero is returned and the value of the macro ERANGE is stored in errno.

Special behavior for IEEE: If successful, The hypot() family of functions returns the calculated length of the hypotenuse. If the correct value overflows, hypot() sets errno to ERANGE and returns HUGE_VAL.

Example

CELEBH01

```
/* CELEBH01

   This example calculates the hypotenuse of a right-angled
   triangle with sides of 3.0 and 4.0.

*/
#include <math.h>
#include <stdio.h>

int main(void)
{
    double x, y, z;

    x = 3.0;
    y = 4.0;
    z = hypot(x,y);

    printf("The hypotenuse of the triangle with sides %lf and %lf"
           " is %lf\n", x, y, z);
}
```

Output

```
The hypotenuse of the triangle with sides 3.000000 and 4.000000 is 5.000000
```

hypotd32(), hypotd64(), hypotd128() – Calculate the square root of the squares of two arguments

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.11 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 hypotd32(_Decimal32 x, _Decimal32 y);
_Decimal64 hypotd64(_Decimal64 x, _Decimal64 y);
_Decimal128 hypotd128(_Decimal128 x, _Decimal128 y);

_Decimal32 hypot(_Decimal32 x, _Decimal32 y);    /* C++ only */
_Decimal64 hypot(_Decimal64 x, _Decimal64 y);    /* C++ only */
_Decimal128 hypot(_Decimal128 x, _Decimal128 y); /* C++ only */
```

General description

The `hypot()` family of functions calculates the length of the hypotenuse of a right-angled triangle based on the lengths of two sides `x` and `y`. A call to `hypot()` is equal to:

```
sqrt(x* x + y * y);
```

Notes:

1. These functions work in IEEE decimal floating-point format. See [“IEEE decimal floating-point”](#) on page 97 IEEE Decimal Floating-Point for more information.
2. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

If successful, The `hypot()` family of functions returns the calculated length of the hypotenuse.

If the correct value overflows, `hypot()` sets `errno` to `ERANGE` and returns `HUGE_VAL_D32`, `HUGE_VAL_D64`, or `HUGE_VAL_D128` accordingly.

Example

```
/* CELEBH03
   This example illustrates the hypotd64() function.
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

void main(void)
{
    _Decimal64 x, y, z;

    x = 3.0DD;
    y = 4.0DD;
    z = hypotd64(x,y);

    printf("The hypotenuse of a triangle with sides %Df and %Df"
```

```
        " is %Df\n", x, y, z);
    }
```

ibmsflush() — Flush the application-side datagram queue

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _OPEN_SYS SOCK_EXT
#include <sys/socket.h>

int ibmsflush(int s);
```

General description

Bulk mode sockets are not supported. This function always returns 0.

Returned value

ibmsflush() always returns 0.

Related information

- [“sys/socket.h — Sockets definitions” on page 70](#)

iconv() — Code conversion

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#include <iconv.h>

size_t iconv(iconv_t cd, char **__restrict__ inbuf,
             size_t *__restrict__ inbytesleft, char **__restrict__ outbuf,
             size_t *__restrict__ outbytesleft);
```

General description

Converts a sequence of characters, indirectly pointed to by *inbuf*, from one encoded character set into a sequence of corresponding characters in another encoded character set. The resulting character sequence is then stored into the array indirectly pointed to by *outbuf*. The encoded character sets are those specified in the `iconv_open()` call that returned the conversion descriptor, *cd*. If the descriptor refers to the state-dependent encoding, then before it is first used, the *cd* descriptor is in its initial shift state.

The *inbuf* argument points to a variable that points to the first character in the input buffer. *inbytesleft* indicates the number of bytes to the end of the buffer to be converted. The *outbuf* argument points to a variable that points to the first character in the output buffer. *outbytesleft* indicates the number of available bytes to the end of the buffer.

If the output character set refers to the state-dependent encoding—if it contains the multibyte characters with shift-states—the conversion descriptor *cd* is placed in its initial state by a call for which *inbuf* is a NULL pointer, or for which *inbuf* points to a NULL pointer. When `iconv()` is called in this way, and if *outbuf* is not a NULL pointer or a pointer to a NULL pointer, and *outbytesleft* points to a positive value, `iconv()` places in the output buffer the byte sequence to change the output buffer to the initial shift state. If the output buffer is not large enough to hold the entire reset sequence, `iconv()` fails, and sets `errno` to `E2BIG`. Subsequent calls with *inbuf* as other than a NULL pointer or a pointer to a NULL pointer cause conversion from the current state of the conversion descriptor.

If a sequence of input bytes does not form a valid character in the specified encoded character set, conversion stops after the previous successfully converted character, and `iconv()` sets `errno` to `EILSEQ`. If the input buffer ends with an incomplete character or shift sequence, conversion stops after the previous successfully converted bytes, and `iconv()` sets `errno` to `EINVAL`. If the output buffer is not large enough to hold the entire converted input, conversion stops just before the input bytes that would cause the output buffer to overflow.

The variable pointed to by *inbuf* is updated to point to the byte following the last byte of a successfully converted character. The value pointed to by *inbytesleft* is decremented to reflect the number of bytes still not converted in the input buffer. The variable pointed to by *outbuf* is updated to point to the byte following the last byte of converted output data. The value pointed to by *outbytesleft* is decremented to reflect the number of bytes still available in the output buffer. For state-dependent encoding, the conversion descriptor is updated to reflect the shift state in effect at the end of the last successfully converted byte sequence.

If `iconv()` encounters a character in the input buffer that is valid, but for which a conversion is not defined in the conversion descriptor *cd*, the substitution character (SUB code point) of the target character set is put in the target buffer and the conversion continues. The definition of SUB code point is based on IBM's Character Data Representation Architecture (CDRA).

The `<iconv.h>` header file declares the `iconv_t` type that is a pointer to the object capable of storing the information about the converters used to convert characters in one coded character set to another. For state-dependent encoding, the object must be capable of storing the encoded information about the current shift state.

Special considerations for bidirectional language support: If the `_BIDION` environment variable is set to `TRUE`, `iconv()` performs bidirectional layout transformation to the converted characters. The required attributes for bidirectional layout transformation can be specified using the environment variable `_BIDIATTR`. For example, `export _BIDIATTR="@ls typeoftext=visual:implicit, orientation=ltr:ltr,numerals=nominal:national"`. For a detailed description of the bidirectional layout transformation, see [Bidirectional language support in z/OS XL C/C++ Programming Guide](#). If the environment variable `_BIDIATTR` is not set, the default values will be used.

`iconv()` can perform bidirectional layout transformation while converting the data from the `fromCodePage` to the `toCodePage`. Bidirectional layout transformation will take place only if bidirectional language support is activated, see [“iconv_open\(\) — Allocate code conversion descriptor” on page 828](#) for more information about activating bidirectional layout transformation. In case `iconv` encounters any error in input or output buffers in the bidirectional part it will bypass the bidirectional layout transformation and continue its normal function as usual.

Special behavior for POSIX C: In the POSIX environment, a conversion descriptor returned from a successful `iconv_open()` may be used safely within a single thread. In addition, it may be opened on one thread (`iconv_open()`), used on a second thread (`iconv()`), and closed (`iconv_close()`) on a third thread. However, you must ensure correct cross-thread sequencing and synchronization (that is: `iconv_open()`, followed by optional `iconv()` calls, followed by `iconv_close()`). The use of a shared conversion descriptor by `iconv()` across multiple threads may result in undefined behavior.

Special behavior for UTF-8: When the `_ICONV_OVERLONG_CHECK` environment variable is set to ON, if an overlong byte sequence of UTF-8 encoding is detected, `iconv()` returns `(size_t) - 1` and sets `errno` to `EILSEQ`.

Returned value

If successful, `iconv()` updates the variables pointed to by the arguments to reflect the extent of the conversion and returns the number of nonidentical conversions performed.

If the entire string in the input buffer is converted, the value pointed to by *inbytesleft* will be 0. If the input conversion is stopped because of any conditions mentioned above, the value pointed to by *inbytesleft* will be nonzero and `errno` is set to indicate the condition.

If an error occurs, `iconv()` returns `(size_t) - 1` and sets `errno` to one of the following values:

Error Code

Description

EBADF

cd is not a valid descriptor.

ECUNNOENV

A `CUN_RS_NO_UNI_ENV` error was issued by Unicode Conversion Services.

See [z/OS Unicode Services User's Guide and Reference](#) documentation for user action.

ECUNNOCONV

A `CUN_RS_NO_CONVERSION` error was issued by Unicode Conversion Services.

See [z/OS Unicode Services User's Guide and Reference](#) documentation for user action.

ECUNNOTALIGNED

A `CUN_RS_TABLE_NOT_ALIGNED` error was issued by Unicode Conversion Services.

See [z/OS Unicode Services User's Guide and Reference](#) documentation for user action.

ECUNERR

Function `iconv()` encountered an unexpected error while using Unicode Conversion Services.

See message EDC6258 for additional information.

EILSEQ

Input conversion stopped due to an input byte that does not belong to the input codeset.

EINVAL

Input conversion stopped due to an incomplete character or shift sequence at the end of the input buffer.

E2BIG

Input conversion stopped due to lack of space in the output buffer.

Example

CELEBI01

```
/* CELEBI01
```

```
   This example converts an array of characters coded in encoded character
   set IBM-1047 to an array of characters coded in encoded character set
```

```

IBM-037.
Input is in inbuf, output will be in outbuf.

*/
#include <iconv.h>
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

main ()
{
    char    *inptr; /* Pointer used for input buffer */
    char    *outptr; /* Pointer used for output buffer */
    char    inbuf[20] =
        "ABCDEFGH!@#$1234";
                                /* input buffer */
    unsigned char    outbuf[20]; /* output buffer */
    iconv_t          cd; /* conversion descriptor */
    size_t           inleft; /* number of bytes left in inbuf */
    size_t           outleft; /* number of bytes left in outbuf */
    int              rc; /* return code of iconv() */

    if ((cd = iconv_open("IBM-037", "IBM-1047")) == (iconv_t)(-1)) {
        fprintf(stderr, "Cannot open converter from %s to %s\n",
                "IBM-1047", "IBM-037");
        exit(8);
    }

    inleft = 16;
    outleft = 20;
    inptr = inbuf;
    outptr = (char*)outbuf;

    rc = iconv(cd, &inptr, &inleft, &outptr, &outleft);
    if (rc == -1) {
        fprintf(stderr, "Error in converting characters\n");
        exit(8);
    }
    iconv_close(cd);
}

```

iconv_close() — Deallocate code conversion descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```

#include <iconv.h>

int iconv_close(iconv_t cd);

```

General description

Deallocates the conversion descriptor *cd* and all other associated resources allocated by the `iconv_open()` function. For an illustration of using `iconv_open()`, see [“Example” on page 826](#).

Returned value

If successful, `iconv_close()` returns 0.
If unsuccessful, `iconv_close()` returns -1 and sets `errno` to one of the following values:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

| | |
|--------------|--------------------------------------|
| EBADF | <i>cd</i> is not a valid descriptor. |
|--------------|--------------------------------------|

iconv_open() — Allocate code conversion descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#include <iconv.h>

iconv_t iconv_open(const char *tocode, const char *fromcode);
```

General description

Performs all the initialization needed to convert characters from the encoded character set specified in the array pointed to by the *fromcode* argument to the encoded character set specified in the array pointed to by the *tocode* argument.

The conversion descriptor relates the two encoded character sets.

For state-dependent encodings, the conversion descriptor will be in an encoded-character-set-dependent initial shift state, ready for immediate use with `iconv()`. The conversion descriptor remains valid until it is closed with `iconv_close()`.

Settings of *fromcode*, *tocode*, and their permitted combinations are implementation-dependent.

Note: The `iconv()` family of functions has been modified to utilize character conversion services provided by Unicode Services. The `iconv_open()`, `iconv()` and `iconv_close()`’s function interfaces will remain

unchanged except for the addition of four new errno values and two new environment variables described in the following paragraphs.

There are differences in externals between the iconv() family of functions and Unicode Services. However, these differences will be managed by the iconv() family of functions except where noted in the *z/OS XL C/C++ Compiler and Runtime Migration Guide for the Application Programmer*. All conversions listed in the section of the *z/OS XL C/C++ Programming Guide* entitled “Code Set Converters Supplied” will continue to work as they did prior to the integration of Unicode Services, as long as _ICONV_TECHNIQUE is left undefined. If the application does not define the _ICONV_TECHNIQUE environment variable, iconv_open() uses a default value of LMREC.

Unicode Services supports conversions between thousands of additional character sets not listed in the *z/OS XL C/C++ Programming Guide*. A complete list of conversions supported by Unicode Services can be found in the *z/OS Unicode Services User's Guide and Reference*. To set up a conversion using iconv_open() for any of the character sets listed in these tables, the user needs to use a character string representing the CCSID's for *fromcode* and *toCode*. For example, to set up a conversion from CCSID 00256 to CCSID 00870 using conversion technique R, the user would set the _ICONV_TECHNIQUE environment variable to R and call iconv_open() as follows:

```
cd = iconv_open("00870", "00256");
```

and continue to use iconv() and iconv_close() as in previous releases.

iconv() uses the following environment variables.

_ICONV_UCS2

Tells iconv_open(Y, X) what type of conversion method to setup when there is a choice between "direct" conversion from X to Y and "indirect" X to UCS-2 to Y.

_ICONV_UCS2_PREFIX

Tells iconv_open() what z/OS dataset name prefix to use to find UCS-2 tables if they cannot be found.

_ICONV_MODE

Selects the behavior mode for iconv_open(), iconv() and iconv_close()..

_ICONV_TECHNIQUE

This is the technique value used while using Unicode Conversion Services. For more information regarding the Unicode Conversion Services technique value, refer to Chapter 3 - Creating a Unicode Environment section of the *z/OS Unicode Services User's Guide and Reference*.

For illustration of using iconv_close(), see “Example” on page 826.

Special considerations for bidirectional language support: Performs all the initialization needed to activate the bidirectional layout transformation to be used by iconv. The following three conditions must be satisfied to enable the bidirectional layout transformation:

1. The _BIDION environment variable must be set to TRUE.
2. The current locale environment at iconv_open() time must be an Arabic or Hebrew locale (eg. Ar_AA or Iw_IL).
3. The conversion code set must be an Arabic or Hebrew code set.

Conversion code sets differ in the following three cases:

1. Case fromCodeSet is UCS-2 and toCodeSet is single byte code set. In this case toCodeSet must be an Arabic or Hebrew code set.
2. Case fromCodeSet is single byte code set and toCodeSet is UCS-2. In this case fromCodeSet must be an Arabic or Hebrew code set.
3. Case both fromCodeSet and toCodeSet are single byte code sets. In this case toCodeSet must be an Arabic or Hebrew code set.

iconv_open() checks for the existence of the environment variable _BIDIATTR to get the bidirectional layout transformation attributes. It will use default values in case _BIDIATTR is not defined, is unset, or in case of the existence of some erroneous values in the _BIDIATTR environment variable. The default values are code set dependent according to the Arabic or Hebrew code set used. For the Arabic 420 code

set the default values will be: orientation RTL, type of text visual, shaping shaped, numerals national and swapping on. For the Hebrew 424 code set the default values will be: orientation RTL, type of text visual and swapping on. For the rest of the Arabic code sets the default values will be: orientation RTL, type of text implicit, shaping nominal, numerals national and swapping on.

iconv_open() uses the following environment variables.

_BIDION

Tells iconv_open() whether to activate bidirectional handling of the converted data or not. _BIDION can be assigned either the value TRUE, if you want to turn on bidirectional layout transformation, or the value FALSE, if you want to turn off the BiDi layout transformation. Bidirectional layout transformation can also be turned off if the variable _BIDION is not defined in the environment.

_BIDIATTR

Holds the bidirectional layout transformation attributes which will be used later by iconv, _BIDIATTR will be read only in iconv_open() time. The _BIDIATTR environment variable is in the form of input/output pairs separated by colon, at the beginning of the string there is an @ that identifies the beginning of the attributes list, then followed by the attributes in the form of <attribute_name1>=<input1>:<output1>, <attribute_name2>=<input2>:<output2> (eg. export _BIDIATTR="@ls typeoftext=visual:implicit,orientation=ltr:ltr, numerals=nominal:national").

Returned value

If successful, iconv_open() returns a conversion descriptor.

If unsuccessful, iconv_open() returns (iconv_t)-1 and sets errno to one of the following values:

Error Code

Description

EINVAL

The conversion between encoded character sets specified is not supported.

ECUNNOENV

A CUN_RS_NO_UNI_ENV error was issued by Unicode Conversion Services.

See [z/OS Unicode Services User's Guide and Reference](#) for user action.

ECUNNOCONV

A CUN_RS_NO_CONVERSION error was issued by Unicode Conversion Services.

See [z/OS Unicode Services User's Guide and Reference](#) for user action.

ECUNNOTALIGNED

A CUN_RS_TABLE_NOT_ALIGNED error was issued by Unicode Conversion Services.

See [z/OS Unicode Services User's Guide and Reference](#) for user action.

ECUNERR

Function iconv() encountered an unexpected error while using Unicode Conversion Services.

Refer to message EDC6258 for additional information.

if_freenameindex() — Free the memory allocated by if_nameindex()

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| RFC2553 Single UNIX Specification, Version 3 | both | z/OS V1R4 |

Format

```
#define _OPEN_SYS_SOCKET_IPV6
#include <net/if.h>

void if_freenameindex(struct if_nameindex *ptr);
```

SUSV3:

```
#define _POSIX_C_SOURCE 200112L
#include <net/if.h>

void if_freenameindex(struct if_nameindex *ptr);
```

General description

The `if_freenameindex()` function frees the memory allocated by `if_nameindex()`. The *ptr* argument must be a pointer that was returned by `if_nameindex()`.

Returned value

No return value is defined.

Related information

if_indextoname() — Map a network interface index to its corresponding name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| RFC2553 Single UNIX Specification, Version 3 | both | z/OS V1R4 |

Format

```
#define _OPEN_SYS_SOCKET_IPV6
#include <net/if.h>

char *if_indextoname(unsigned int ifindex, char *ifname);
```

SUSV3:

```
#define _POSIX_C_SOURCE 200112L
#include <net/if.h>

char *if_indextoname(unsigned int ifindex, char *ifname);
```

General description

The if_indextoname() function maps an interface index to its corresponding interface name. When this function is called, ifname must point to a buffer of at least IF_NAMESIZE bytes into which the interface name corresponding to interface index ifindex is returned. Otherwise, the function shall return a NULL pointer and set errno to indicate the error.

Returned value

| Error Code | Description |
|------------|-------------|
|------------|-------------|

- EINVAL**
The ifindex parameter was zero, or the ifname parameter was NULL, or both.
- ENOMEM**
Insufficient storage is available to obtain the information for the interface name.
- ENXIO**
The ifindex does not yield an interface name.

Related information

- [“if_freenameindex\(\) — Free the memory allocated by if_nameindex\(\)” on page 831](#)
- [“if_nameindex\(\) — Return all network interface names and indexes” on page 832](#)

if_nameindex() — Return all network interface names and indexes

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| RFC2553 Single UNIX Specification, Version 3 | both | z/OS V1R4 |

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <net/if.h>

struct if_nameindex *if_nameindex(void);
```

SUSV3:

```
#define _POSIX_C_SOURCE 200112L
#include <net/if.h>

struct if_nameindex *if_nameindex(void);
```

General description

The `if_nameindex()` function returns an array of `if_nameindex` structures, one structure per interface. The end of the array is indicated by a structure with an `if_index` of zero and an `if_name` of `NULL`.

The `if_nameindex` structure holds the information about a single interface and is defined as a result of including the `<net/if.h>` header.

```
struct if_nameindex {
    unsigned int if_index; /* 1, 2, ... */
    char        *if_name; /* null terminated name: "le0", ... */
};
```

The memory used for this array of structures along with the interface names pointed to by the `if_name` members is obtained dynamically. This memory is freed by calling the `if_freenameindex()` function.

Returned value

When successful, `if_nameindex()` returns a pointer to an array of `if_nameindex` structures. Upon failure, `if_nameindex()` returns `NULL` and sets `errno` to one of the following:

Error Code

Description

ENOMEM

Insufficient storage is available to supply the array.

Related information

- [“if_freenameindex\(\) — Free the memory allocated by if_nameindex\(\)” on page 831](#)

if_nametoindex() — Map a network interface name to its corresponding index

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| RFC2553 Single UNIX Specification, Version 3 | both | z/OS V1R4 |

Format

```
#define _OPEN_SYS_SOCKET_IPV6
#include <net/if.h>

unsigned int if_nametoindex(const char *ifname);
```

SUSV3:

```
#define _POSIX_C_SOURCE 200112L
#include <net/if.h>

unsigned int if_nametoindex(const char *ifname);
```

General description

The `if_nametoindex()` function returns the interface index corresponding to the interface name *ifname*.

Returned value

When successful, if_nametoindex() returns the interface index corresponding to the interface name *ifname*. Upon failure, if_nametoindex() returns 0 and sets errno to one of the following:

Error Code
Description

EINVAL
Non-valid parameter was specified. The *ifname* parameter was NULL.

ENOMEM
Insufficient storage is available to obtain the information for the interface name.

ENXIO
The specified interface name provided in the *ifname* parameter does not exist.

Related information

ilogb(), ilogbf(), ilogbl() — Integer unbiased exponent

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <math.h>

int ilogb(double x);
```

C99:

```
#define _ISOC99_SOURCE
#include <math.h>

int ilogbf(float x);
int ilogbl(long double x);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

int ilogb(float x);
int ilogb(long double x);
```

General description

The ilogb() functions returns the unbiased exponent of its argument x as an integer.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------|-----|------|
| ilogb | X | X |
| ilogbf | X | X |
| ilogbl | X | X |

Returned value

If successful, the `ilogb()` functions return the unbiased exponent of x as an integer.

If x is 0, the value `FP_ILOGB0` is returned.

if x is a NaN, `ilogb()` will return `FP_ILOGBNAN`

if x is infinity, `ilogb()` will return `INT_MAX`

If the correct value is greater than `{INT_MAX}`, `{INT_MAX}` is returned and a domain error occurs.

If the correct value is less than `{INT_MIN}`, `{INT_MIN}` is returned and a domain error occurs.

Special behavior for hex: This function will return the unbiased exponent minus 1 (Because hex representation has no hidden bit, this treatment is needed to satisfy the `logb()` inequality).

Error Code

Description

EDOM

The x argument is zero, NaN, or $\pm\text{inf}$, or the correct value is not representable as an integer.

Related information

- [“math.h — Floating-point math functions”](#) on page 40
- [“logb\(\), logbf\(\), logbl\(\) — Unbiased exponent”](#) on page 996

ilogbd32(), ilogbd64(), ilogbd128() — Integer unbiased exponent

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

int ilogbd32(_Decimal32 x);
int ilogbd64(_Decimal64 x);
int ilogbd128(_Decimal128 x);
int ilogb(_Decimal32 x); /* C++ only */
int ilogb(_Decimal64 x); /* C++ only */
int ilogb(_Decimal128 x); /* C++ only */
```

General description

Returns the unbiased exponent of its argument x as an integer. For typical numbers, the value returned is the logarithm of $|x|$ rounded down (toward $-\text{INF}$) to the nearest integer value.

Notes:

- 1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- 2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, these functions return the unbiased exponent of x as an integer.

If x is equal to 0.0, `ilogb()` will return `_FP_DEC_ILOGB0` (`= -INT_MAX`).

If x is a NaN or infinity, `ilogb()` will return `INT_MAX`.

Example

```
/* CELEBI11
   This example illustrates the ilogbd128() function.
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal128 x = -12345.678901DL;
    int y;

    y = ilogbd128(x);

    printf("The result of ilogbd128(%DDf) is %d\n", x, y);
}
```

Related information

imaxabs() — Absolute value for intmax_t

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _ISOC99_SOURCE
#include <inttypes.h>

intmax_t imaxabs(intmax_t j);
```

Compile requirement: Function `imaxabs()` requires `long long` to be available.

General description

The `imaxabs()` function computes the absolute value of j . When the input value is `INTMAX_MIN`, the value is undefined. The `imaxabs()` function is similar to `labs()` and `llabs()`. The only difference being that the return value and the argument passed in are of type `intmax_t`.

Returned value

The `imaxabs` function returns the absolute value of j .

Example

```
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>
int main(void)
{
    intmax_t a = -1234;

    intmax_t b = imaxabs(a);

    printf("%jd \n", b );
}
```

Output:

1234

Related information

- `inttypes.h`
- `labs()`
- `llabs()`

imaxdiv() — Quotient and remainder for `intmax_t`

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _ISOC99_SOURCE
#include <inttypes.h>

imaxdiv_t imaxdiv(intmax_t numer, intmax_t denom);
```

Compile requirement: Function `imaxdiv()` requires `long long` to be available.

General description

The `imaxdiv()` function computes `number / denom` and `number % denom` in a single operation. The `imaxdiv` function is similar to `lldiv()` and `ldiv()`. The only difference being that the return value is of type `imaxdiv_t` and those being passed in are of type `intmax_t`.

Returned value

`imaxdiv()` returns a structure of type `imaxdiv_t` comprising both the quotient and the remainder. If either part of the result cannot be represented, the behavior is undefined. If the denominator is zero, a divide by zero exception is raised.

Example

```
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>

int main(void)
{
    intmax_t num = 45;
    intmax_t den = 7;
    imaxdiv_t res;
    printf("Original numerator: %jd and denominator: %jd "
           , num, den);
    res = imaxdiv(num, den);
    printf("Quotient: %jd Remainder: %jd\n"
           , res.quot, res.rem);
}

Output

Original numerator: 45 and denominator: -7 Quotient: -6 Remainder: 3
```

Related information

- `inttypes.h`
- `ldiv()`
- `lldiv()`

ImportWorkUnit() – WLM import service

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | OS/390 V2R9 |

Format

```
#include <sys/__wlm.h>

int ImportWorkUnit(wlmtok_t *exporttoken,
                  wlmetok_t *enclavetoken,
                  unsigned int *conntoken);
```

General description

Imports an enclave that has been previously exported using the `ExportWorkUnit()` function. The caller must invoke `UnDoImportWorkUnit()` when it no longer needs access to the enclave.

The `ImportWorkUnit()` function uses the following parameters:

***enclavetoken**

Points to a work unit export token that was returned from a call to ExportWorkUnit().

***exporttoken**

Points to a data field of type wlmetok_t where the ImportWorkUnit() function is to return the WLM work unit enclave token.

***conntoken**

Specifies the connect token that represents the WLM connection.

Returned value

If successful, ImportWorkUnit() returns 0.

If unsuccessful, ImportWorkUnit() returns -1 and sets errno to one of the following values:

Error Code**Description****EFAULT**

An argument of this function contained an address that was not accessible to the caller.

EINVAL

An argument of this function contained a value that is not correct.

EMVSSAF2ERR

An error occurred in the security product.

EMVSWLMERROR

A WLM service failed. Use __errno2() to obtain the WLM service reason code for the failure.

EPERM

The calling thread's address space is not permitted to the BPX.WLMSEVER Facility class. The caller's address space must be permitted to the BPX.WLMSEVER Facility class, if the BPX.WLMSEVER class is defined. If BPX.WLMSEVER is not defined, the calling process is not defined as a superuser (UID=0).

index() — Search for character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <strings.h>

char *index(const char *string, int c);
```

General description

The `index()` function locates the first occurrence of `c` (converted to an unsigned char) in the string pointed to by *string*. The character `c` can be the NULL character (`\0`); the ending NULL is included in the search.

The string argument to the function must contain a NULL character (`\0`) marking the end of the string.

The `index()` function is identical to [“strchr\(\) — Search for character” on page 1720](#).

Note: The `index()` function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The `strchr()` function is preferred for portability.

Returned value

If successful, `index()` returns a pointer to the first occurrence of `c` (converted to an unsigned character) in the string pointed to by *string*.

If unsuccessful because `c` was not found, `index()` returns a NULL pointer.

There are no `errno` values defined.

inet6_is_srcaddr() - Socket address verification

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| RFC 5014 | both | |

Format

```
#define _OPEN_SYS_SOCKET_IPV6
#include <netinet/in.h>

short inet6_is_srcaddr(struct sockaddr_in6 *srcaddr, uint32_t flags);
```

General description

The `inet6_is_srcaddr()` function validates source address selection preference flags against the given socket address.

Argument

Description

srcaddr

A non-NULL pointer to a `sockaddr_in6` structure initialized as follows:

- Clear the entire structure for `sizeof(struct sockaddr_in6)`.
- *sin6_family* must be set to `AF_INET6`.

- Set *sin6_len* to the correct length for AF_INET6.
- Set *sin6_addr* to a 128-bit IPv6 source address to validate against the flags.
- The *sin6_scope_id* must be set if the address is link-local.

flags

The source preference flags which can be set to any of the following:

- IPV6_PREFER_SRC_HOME - prefer home address as source
- IPV6_PREFER_SRC_COA - prefer care-of address as source
- IPV6_PREFER_SRC_TMP - prefer temporary address as source
- IPV6_PREFER_SRC_PUBLIC - prefer public address as source
- IPV6_PREFER_SRC_CGA - prefer CGA address as source
- IPV6_PREFER_SRC_NONCGA - prefer a non-CGA address as source

These flags can be combined into a flag set to express complex address preferences, but some can result in a contradictory flag set.

For example, the following flags are mutually exclusive:

- IPV6_PREFER_SRC_HOME and IPV6_PREFER_SRC_COA
- IPV6_PREFER_SRC_TMP and IPV6_PREFER_SRC_PUBLIC
- IPV6_PREFER_SRC_CGA and IPV6_PREFER_SRC_NONCGA

Returned value

When the IPv6 address corresponds to a valid address in the node and satisfies the given preference flags, `inet6_is_srcaddr()` returns 1.

If the input address matches an address in the node, but does not satisfy the preference flags indicated, the function returns 0.

If unsuccessful, `inet6_is_srcaddr()` returns -1 and sets `errno` to the following:

Error Code

Description

EADDRNOTAVAIL

The address provided does not match a home address in the node.

EAFNOSUPPORT

The address provided does not have a family of AF_INET6.

EAGAIN

A TCP/IP stack is not active to process the request.

EINVAL

Undefined flags were used, or a link-local IPv6 address was used with a zero scopeid, or a global address was used with a non-zero scopeid.

inet6_opt_append() – Add an option with length "len" and alignment "align"

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| RFC3542 | both | z/OS V1R7 |

Format

```
#define _OPEN_SYS_SOCKET_IPV6
#include <netinet/in.h>

int inet6_opt_append(void *extbuf, socklen_t extlen, int offset,
                    uint8_t type, socklen_t len, uint8_t align,
                    void **databufp);
```

General description

inet6_opt_append() returns the updated total length after adding an option with length *len* and alignment *align*. If *extbuf* is not NULL, it inserts any necessary padding and sets the type and length fields. A pointer to the location for the option content in *databufp* is then returned.

offset should be the length returned by inet6_opt_init() or the previous inet6_opt_append(). *type* is the 8-bit option type and *len* is the length of the option data (excluding the option type and option length fields).

Returned value

If successful, inet6_opt_append() returns the updated total length of the extension header.

Upon failure, returns -1 and errno is set to one of the following:

EINVAL If one of the following is true:

- *extbuf* is NULL and *extlen* is non-zero;
- *extbuf* is non-NULL and *extlen* is not a positive multiple of 8;
- *offset* is less than the size of the empty extension header;
- *type* is not valid (specifies one of the PAD options);
- *len* is less than 0 or greater than 255;
- *align* is not 1, 2, 4, or 8;
- *align* is greater than *len*;
- new updated total length would exceed *extlen* (*extbuf* is non-NULL);
- *databufp* is NULL (*extbuf* is non-NULL).

Usage notes

1. The option, *type*, must have a value from 2 to 255 (0 and 1 are reserved for the Pad1 and PadN options).
2. The option data length must have a value between 0 and 255, including the values 0 and 255. It is the length of the option data that follows.
3. The *align* parameter must have a value of 1, 2, 4, or 8 and can not exceed the value of *len*.
4. Once inet6_opt_append() has been called, the application can use *databufp* directly or use inet6_opt_set_val() to specify the content of the option.

Related information

inet6_opt_find() — Search for an option specified by the caller

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| RFC3542 | both | z/OS V1R7 |

Format

```
#define _OPEN_SYS_SOCKET_IPV6
#include <netinet/in.h>

int inet6_opt_find(void *extbuf, socklen_t extlen, int offset,
                  uint8_t type, socklen_t *lenp, void **databufp);
```

General description

inet6_opt_find() is similar to inet6_opt_next(), except it lets the caller specify the option type to be searched for.

Returned value

If successful, inet6_opt_find() returns the updated "previous" total length computed by advancing past the option that was returned and past any options that did not match the type.

Upon failure, returns -1 and errno is set to one of the following:

EINVAL If one of the following is true:

- *extbuf* is NULL;
- *extlen* is not a positive multiple of 8;
- *offset* is less than 0 or greater than or equal to *extlen*;
- *lenp* or *databufp* is NULL;
- the option was not located;
- the extension header is malformed.

Usage notes

The returned "previous" length can be passed to subsequent calls of inet6_opt_find() for finding the next occurrence of the same option type.

Related information

- [“netinet/in.h — Internet protocol family” on page 50](#)

- [“inet6_opt_append\(\) — Add an option with length "len" and alignment "align" ” on page 842](#)

inet6_opt_finish() — Return the updated total length of extension header

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| RFC3542 | both | z/OS V1R7 |

Format

```
#define _OPEN_SYS_SOCKET_IPV6
#include <netinet/in.h>

int inet6_opt_finish(void *extbuf, socklen_t extlen, int offset);
```

General description

inet6_opt_finish() returns the updated total length taking into account the final padding of the extension header to make it a multiple of 8 bytes. If *extbuf* is not NULL the function also initializes the option by inserting a Pad1 or PadN option of the proper length.

Returned value

If successful, inet6_opt_finish() returns the total length of the extension header including the final padding.

Upon failure, returns -1 and errno is set to one of the following:

EINVAL If one of the following is true:

- *extbuf* is NULL and *extlen* is non-zero;
- *extbuf* is non-NULL and *extlen* is not a positive multiple of 8;
- *extbuf* is non-NULL and offset is greater than *extlen*;
- *offset* is less than the size of the empty extension header.

Usage notes

offset should be the length returned by inet6_opt_init() or inet6_opt_append().

Related information

inet6_opt_get_val() — Extract data items in the data portion of the option

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| RFC3542 | both | z/OS V1R7 |

Format

```
#define _OPEN_SYS_SOCKET_IPV6
#include <netinet/in.h>

int inet6_opt_get_val(void *databuf, int offset,
                    void *val, socklen_t vallen);
```

General description

inet6_opt_get_val() extracts data items of various sizes in the data portion of the option.

Returned value

If successful, inet6_opt_get_val() returns the offset for the next field (*offset + vallen*) that can be used when extracting option content with multiple fields.

Upon failure, returns -1 and sets errno to one of the following:

EINVAL If one of the following is true:

- *databuf* is NULL;
- *val* is null;
- *offset* is less than 0;
- *offset + vallen* is greater than the option length.

Usage notes

1. *databuf* should be a pointer returned by inet6_opt_next() or inet6_opt_find().
2. *val* should point to the destination for the extracted data.
3. *offset* specifies from where in the data portion of the option the value should be extracted; the first byte after the option type and length is accessed by specifying an *offset* of zero.

Related information

- [“netinet/in.h — Internet protocol family”](#) on page 50

inet6_opt_init() — Return the number of bytes for empty extension header

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| RFC3542 | both | z/OS V1R7 |

Format

```
#define _OPEN_SYS_SOCKET_IPV6
#include <netinet/in.h>

int inet6_opt_init(void *extbuf, socklen_t extlen);
```

General description

inet6_opt_init() returns the number of bytes needed for the empty extension header. If *extbuf* is not NULL, the extension header is initialized to have the correct length field and the *extlen* value must be a positive, non-zero, multiple of 8, or the function will fail.

Returned value

If successful, inet6_opt_init() returns the number of bytes needed for the empty extension header.

Upon failure, returns -1 and errno is set to one of the following:

EINVAL If one of the following is true:

- *extbuf* is NULL and *extlen* is non-zero;
- *extbuf* is non-NULL and *extlen* is not a positive multiple of 8.

inet6_opt_next() — Parse received option headers returning the next option

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| RFC3542 | both | z/OS V1R7 |

Format

```
#define _OPEN_SYS_SOCKET_IPV6
#include <netinet/in.h>

int inet6_opt_next(void *extbuf, socklen_t extlen, int offset,
                  uint8_t *typep, socklen_t *lenp, void **databufp);
```

General description

inet6_opt_next() parses received option extension headers and returns the next option.

Returned value

If successful, inet6_opt_next() returns the updated "previous" length computed by advancing past the option that was returned. This returned "previous" length can then be passed to subsequent calls to inet6_opt_next(). This function does not return any PAD1 or PADN options.

Upon failure, returns -1 and errno is set to one of the following:

EINVAL If one of the following is true:

- *extbuf* is NULL;
- *extlen* is not a positive multiple of 8;
- *offset* is less than 0 or greater than or equal to *extlen*;
- *typep*, *lenp*, or *databufp* is NULL;
- there are no more options;
- the extension header is malformed.

Usage notes

1. *extbuf* and *extlen* specifies the extension header.
2. *offset* should either be zero (for the first option) or the length returned by a previous call to inet6_opt_next() or inet6_opt_find(). It specifies the position to continue scanning the extension buffer. The next option is returned by updating *typep*, *lenp*, and *databufp*.
3. *typep* points to the option type field.
4. *lenp* stores the length of the option data (excluding the option type and option length fields).
5. *databufp* points to the data field of the of the option.

inet6_opt_set_val() — Insert data items into the data portion of the option

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| RFC3542 | both | z/OS V1R7 |

Format

```
#define _OPEN_SYS_SOCKET_IPV6
#include <netinet/in.h>

int inet6_opt_set_val(void *databuf, int offset,
                     void *val, socklen_t vallen);
```

General description

inet6_opt_set_val() inserts items of various sizes in the data portion of the option.

Returned value

If successful, inet6_opt_set_val() returns the *offset* for the next field (*offset* + *vallen*) that can be used when composing option content with multiple fields.

Upon failure, returns -1 and errno is set to one of the following:

EINVAL If one of the following is true:

- *databuf* is NULL;
- *val* is NULL;
- *offset* is less than 0;
- *offset* + *vallen* is greater than the option length.

Usage notes

1. *databuf* should be a pointer returned by inet6_opt_append().
2. *val* should point to the data to be inserted.
3. *offset* specifies where in the data portion of the option the value should be inserted; the first byte after the option type and length is accessed by specifying an *offset* of 0.

inet6_rth_add() — Add an IPv6 address to end of the routing header

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| RFC3542 | both | z/OS V1R7 |

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

int inet6_rth_add(void *bp, const struct in6_addr *addr);
```

General description

inet6_rth_add() adds the IPv6 address pointed to by *addr* to the end of the routing header that is being constructed.

Returned value

If successful, inet6_rth_add() returns 0 and the segleft member of the routing header is updated to account for the new address.

Upon failure, returns -1 and errno is set to one of the following:

EINVAL If one of the following is true:

- *bp* is NULL;
- the routing header indicates an unsupported header type;
- the routing header contains a non-valid number of segments for the type;
- there is not enough room to add the address.

Related information

- [“netinet/in.h — Internet protocol family” on page 50](#)

inet6_rth_getaddr() — Return pointer to the IPv6 address specified

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| RFC3542 | both | z/OS V1R7 |

Format

```
#define _OPEN_SYS_SOCKET_IPV6
#include <netinet/in.h>

struct in6_addr *inet6_rth_getaddr(const void *bp, int index);
```

General description

inet6_rth_getaddr() returns a pointer to the IPv6 address specified by *index* in the routing header described by *bp*.

Returned value

If successful, inet6_rth_getaddr() returns a pointer to the IPv6 address.

Upon failure, returns NULL and errno is set to one of the following:

EINVAL If one of the following is true:

- *bp* is NULL;
- the routing header indicates an unsupported header type;
- the routing header contains a non-valid number of segments;
- *index* is less than 0 or greater than or equal to the number of segments.

Usage notes

1. To obtain the number of segments in the routing header, a call to inet6_rth_segments() should be made first.
2. *index* must have a value between 0 and one less than the value returned by inet6_rth_segments().

inet6_rth_init() – Initialize an IPv6 routing header buffer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| RFC3542 | both | z/OS V1R7 |

Format

```
#define _OPEN_SYS_SOCKET_IPV6
#include <netinet/in.h>

void *inet6_rth_init(void *bp, socklen_t bp_len,
                    int type, int segments);
```

General description

inet6_rth_init() initializes the buffer pointed to by *bp* to contain a routing header of the specified *type* and sets *ip6r_len* based on the *segments* parameter.

Returned value

When successful, inet6_rth_init() returns the pointer to the buffer, *bp*. This is then used as the first argument to the inet6_rth_add() function.

Upon failure, returns NULL and *errno* is set to one of the following:

EINVAL If one of the following is true::

- *bp* is NULL;
- *type* indicates an unsupported header type;
- *segments* is not valid for the *type*;
- the buffer is not large enough, *bp_len* is too small.

Usage notes

1. The caller must allocate the buffer; its size can be determined by calling inet6_rth_space().
2. Any cmsghdr fields must be initialized when the application uses ancillary data.

Related information

inet6_rth_reverse() — Reverse the order of the addresses

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| RFC3542 | both | z/OS V1R7 |

Format

```
#define _OPEN_SYS_SOCKET_IPV6
#include <netinet/in.h>

int inet6_rth_reverse(const void *in, void *out);
```

General description

inet6_rth_reverse() takes a routing header, pointed to by *in*, and writes a new routing header that sends datagrams along the reverse of that route. It reverses the order of the addresses and sets the *segleft* member in the new routing header to the number of segments required to send the datagram back to where it originated. Both arguments are allowed to point to the same buffer (the reversal can occur in place).

Returned value

If successful, `inet6_rth_reverse()` returns 0.

Upon failure, returns -1 and `errno` is set to one of the following:

EINVAL If one of the following is true:

- *in* is NULL or *out* is NULL;
- the input routing header indicates an unsupported header type;
- the input routing header contains a non-valid number of segments;
- *in* and *out* overlap, but *in* and *out* are not the same buffer.

Related information

inet6_rth_segments() – Return number of segments contained in header

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| RFC3542 | both | z/OS V1R7 |

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>

int inet6_rth_segments(const void *bp);
```

General description

`inet6_rth_segments()` returns the number of segments (addresses) contained in the routing header described by *bp*.

Returned value

If successful, `inet6_rth_segments()` returns the number of segments or 0, if there are none in the header.

Upon failure, returns -1 and `errno` is set to one of the following:

EINVAL If one of the following is true:

- *bp* is NULL;
- the routing header indicates an unsupported header type;
- the routing header contains a non-valid number of segments.

Related information

- [“netinet/in.h — Internet protocol family” on page 50](#)
- [“inet6_rth_add\(\) — Add an IPv6 address to end of the routing header ” on page 849](#)

- [“inet6_rth_space\(\) — Return number of bytes for a routing header ” on page 853](#)

inet6_rth_space() — Return number of bytes for a routing header

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| RFC3542 | both | z/OS V1R7 |

Format

```
#define _OPEN_SYS_SOCKET_IPV6
#include <netinet/in.h>

socklen_t inet6_rth_space(int type, int segments);
```

General description

inet6_rth_space() calculates the number of bytes required to hold a routing header for the specified *type* containing the specified number of *segments* (addresses).

Returned value

If successful, inet6_rth_space() returns the number of bytes, space required, for the routing header.

Upon failure, returns 0 and errno is set to one of the following:

EINVAL If one of the following is true:

- *type* indicates an unsupported header type;
- *segments* is not valid for the *type*.

Usage notes

1. This function returns the size but does not allocate the space required for the ancillary data. This allows an application to allocate a larger buffer, if other ancillary data objects are desired, because all the ancillary data objects must be specified to sendmsg() as a single msg_control buffer.
2. For an IPv6 Type 0 routing header, the number of *segments* must be between 0 and 127, inclusive. When the application uses ancillary data it must pass the returned length to CMSG_SPACE() to determine how much memory is needed for the ancillary data object (including the cmsghdr structure).

inet_addr() — Translate an Internet address into network byte order

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <arpa/inet.h>

in_addr_t inet_addr(const char *cp);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>
#include <netinet/in.h>
#include <arpa/inet.h>

unsigned long inet_addr(char *cp);
```

General description

The `inet_addr()` function interprets character strings representing host addresses expressed in standard dotted-decimal notation and returns host addresses suitable for use as an Internet address.

Parameter

Description

cp

A character string in standard dotted-decimal (.) notation.

Values specified in standard dotted-decimal notation take one of the following forms:

```
a.b.c.d
a.b.c
a.b
a
```

When a 4-part address is specified, each part is interpreted as a byte of data and assigned, from left to right, to one of the 4 bytes of an Internet address.

When a three-part address is specified, the last part is interpreted as a 16-bit quantity and placed in the two rightmost bytes of the network address. This makes the three-part address format convenient for specifying class-B network addresses as **128.net.host**.

When a two-part address is specified, the last part is interpreted as a 24-bit quantity and placed in the three rightmost bytes of the network address. This makes the two-part address format convenient for specifying class-A network addresses as **net.host**.

When a one-part address is specified, the value is stored directly in the network address space without any rearrangement of its bytes.

Numbers supplied as address parts in standard dotted-decimal notation can be decimal, hexadecimal, or octal. Numbers are interpreted in C language syntax. A leading 0x implies hexadecimal; a leading 0 implies octal. A number without a leading 0 implies decimal.

The address must be terminated with a null or other white space character to be valid. Any or all of the parts of the address may be empty strings. Each empty part resolves to the value 0. Input character strings that begin with a null or other white space character is treated as an empty address and will result in the value INADDR_ANY being returned.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` 1 feature test macro.

Notes:

1. To provide an ASCII input/output format for applications using this function, define the feature test macro `__LIBASCII` as described in topic “`__LIBASCII`” on page 6.
2. The `inet_addr()` function has a dependency on the level of the Enhanced ASCII Extensions. See “Enhanced ASCII support” on page 2123 for details.

Returned value

If successful, `inet_addr()` returns the Internet address in network byte order.

If the input character string is not in the correct format, the value `INADDR_NONE` is returned and `errno` is set to `EINVAL`.

inet_aton() — Convert Internet address format from text to binary

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <arpa/inet.h>

int inet_aton(const char *cp, struct in_addr *inp);
```

General description

The `inet_aton()` function converts the Internet host address *cp* from the IPv4 numbers-and-dots notation into binary form in network byte order and stores it in the structure that *inp* points to. The address that is supplied in *cp* can be in one of the following forms:

a.b.c.d

Each of the four numeric parts specifies a byte of the address. The bytes are assigned in left-to-right order to produce the binary address.

a.b.c

Parts *a* and *b* specify the first 2 bytes of the binary address. Part *c* is interpreted as a 16-bit value that defines the rightmost 2 bytes of the binary address. This notation is suitable for specifying (outmoded) Class B network addresses.

a.b

Part *a* specifies the first byte of the binary address. Part *b* is interpreted as a 24-bit value that defines the rightmost 3 bytes of the binary address. This notation is suitable for specifying (outmoded) Class A network addresses.

a

The value *a* is interpreted as a 32-bit value that is stored directly into the binary address without any byte rearrangement.

In all these forms, components of the dotted address can be specified in decimal, octal with a leading 0, or hexadecimal with a leading 0X. Addresses in any of these forms are collectively termed IPv4 numbers-and-dots notation. The form that uses exactly four decimal numbers is referred to as IPv4 dotted decimal notation, or sometimes IPv4 dotted-quad notation.

Returned value

`inet_aton()` returns 1 if the supplied string is successfully interpreted.

`inet_aton()` returns 0 if the string is invalid. `errno` is not set on error.

inet_lnaof() — Translate a local network address into host byte order

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <arpa/inet.h>

in_addr_t inet_lnaof(struct in_addr in);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>
#include <netinet/in.h>
#include <arpa/inet.h>

unsigned long inet_lnaof(struct in_addr in);
```

General description

The `inet_lnaof()` function breaks apart the Internet host address and returns the local network address portion.

Parameter

Description

in

The host Internet address.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

Returned value

The local network address is returned in host byte order.

Related information

struct in_addr inet_makeaddr(in_addr_t net, in_addr_t lna);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>
#include <netinet/in.h>
#include <arpa/inet.h>

struct in_addr inet_makeaddr(unsigned long net, unsigned long lna);
```

General description

The `inet_makeaddr()` function takes a network number and a local network address and constructs an Internet address.

Parameter

Description

net

The network number.

lna

The local network address.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

Returned value

The Internet address is returned in network byte order.

#include <sys/socket.h>
#include <netinet/in.h>
#include <arpa/inet.h>

unsigned long inet_network(char cp);
```

General description

The `inet_network()` function interprets character strings representing addresses expressed in standard dotted-decimal notation and returns numbers suitable for use as a network number.

Parameter

Description

cp

A character string in standard, dotted-decimal (.) notation.

Note: The input value is handled as an octal number when there are 3 integers within the dotted-decimal notation. For example, the input value of `inet_network("40.001.016.000")` validly returns `X'28010e00'` (40.1.14.0) since the 016 is treated as an octal number.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

Note: The `inet_network()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support”](#) on page 2123 for details.

Returned value

The network number is returned in host byte order.

inet_ntoa() — Get the decimal Internet host address

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <arpa/inet.h>

char *inet_ntoa(struct in_addr in);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>
#include <netinet/in.h>
#include <arpa/inet.h>

char *inet_ntoa(struct in_addr in);
```

General description

The `inet_ntoa()` function returns a pointer to a string expressed in the dotted-decimal notation. `inet_ntoa()` accepts an Internet address expressed as a 32-bit quantity in network byte order and returns a string expressed in dotted-decimal notation.

Parameter

Description

in

The host Internet address.

To provide an ASCII input/output format for applications using this function, define feature test macro `__LIBASCII` as described “[__LIBASCII](#)” on page 6.

Note: The `inet_ntoa()` function has a dependency on the level of the Enhanced ASCII Extensions. See “[Enhanced ASCII support](#)” on page 2123 for details.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

Returned value

Returns a pointer to the Internet address expressed in dotted-decimal notation. The storage pointed to exists on a per-thread basis and is overwritten by subsequent calls.

inet_ntop() — Convert Internet address format from binary to text

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| RFC2553 Single UNIX Specification, Version 3 | both | z/OS V1R2 |

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <arpa/inet.h>

const char *inet_ntop(int af, const void *src, char *dst, socklen_t size);
```

SUSV3:

```
#define _POSIX_C_SOURCE 200112L
#include <arpa/inet.h>

const char *inet_ntop(int af, const void *__restrict__ src,
                     char * __restrict__ dst, socklen_t size);
```

General description

The `inet_ntop()` function converts from an Internet address in binary format, specified by *src*, to standard text format, and places the result in *dst*, when *size*, the space available in *dst*, is sufficient. The argument *af* specifies the family of the Internet address. This can be `AF_INET` or `AF_INET6`.

The argument *src* points to a buffer holding an IPv4 Internet address if the *af* argument is `AF_INET`, or an IPv6 Internet address if the *af* argument is `AF_INET6`. The address must be in network byte order.

The argument *dst* points to a buffer where the function will store the resulting text string. The *size* argument specifies the size of this buffer. The application must specify a non-NULL *dst* argument. For IPv6 addresses, the buffer must be at least 46 bytes. For IPv4 addresses, the buffer must be at least 16 bytes.

In order to allow applications to easily declare buffers of the proper size to store IPv4 and IPv6 addresses in string form, the following two constants are defined in `<netinet/in.h>`:

```
#define INET_ADDRSTRLEN 16
#define INET6_ADDRSTRLEN 46
```

Note: The `inet_ntop()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support”](#) on page 2123 for details.

Returned value

If successful, `inet_ntop()` returns a pointer to the buffer containing the converted address.

If unsuccessful, `inet_ntop()` returns NULL and sets `errno` to one of the following values:

Error Code

Description

EINVAL

The address family specified in *af* is unsupported.

ENOSPC

The destination buffer *size* is too small.

Note: For Enhanced ASCII usage, the `inet_ntop()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support”](#) on page 2123 for details.

Example

```
#define _OPEN_SYS_SOCKET_IPV6 1
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <arpa/inet.h>
#include <netinet/in.h>

int main(){
    char ipstripv4[INET_ADDRSTRLEN];
    unsigned int ipv4 = 0x0A0A647B;
    const char* result=inet_ntop(AF_INET,&ipv4,ipstripv4,INET_ADDRSTRLEN);

    if(result==NULL){
        perror("inet_ntop");
        return 1;
    }
    printf("The IP address is %s\n",ipstripv4);
    return 0;
}
```

inet_pton() — Convert Internet address format from text to binary

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| RFC2553 Single UNIX Specification, Version 3 | both | z/OS V1R2 |

Format

```
#define _OPEN_SYS_SOCK_IPV6
#include <arpa/inet.h>

int inet_pton(int af, const char *src, void *dst);
```

SUSV3:

```
#define _POSIX_C_SOURCE 200112L
#include <arpa/inet.h>

int inet_pton(int af, const char *__restrict__ src, void *__restrict__ dst);
```

General description

The `inet_pton()` function converts an Internet address in its standard text format into its numeric binary form. The argument *af* specifies the family of the address.

Note: AF_INET and AF_INET6 address families are currently supported.

The input argument *src* is a null terminated string. It points to the string being passed in. The argument *dst* points to a buffer into which `inet_pton()` stores the numeric address. The address is returned in network byte order. The caller must ensure that the buffer pointed to by *dst* is large enough to hold the numeric address.

If the *af* argument is AF_INET, `inet_pton()` accepts a string in the standard IPv4 dotted-decimal form:

```
ddd.ddd.ddd.ddd
```

where *ddd* is a 1 to 3 digit decimal number between 0 and 255.

If the *af* argument is AF_INET6, the *src* string must be in one of the following standard IPv6 text forms:

1. The preferred form is *x:x:x:x:x:x:x:x*, where the *x*'s are the hexadecimal values of the eight 16-bit pieces of the address. Leading zeros in individual fields can be omitted, but there should be at least one numeral in every field.
2. A string of contiguous zero fields in the preferred form can be shown as *::*. The *::* can only appear once in an address. Unspecified addresses (*0:0:0:0:0:0:0:0*) may be represented simply as *::*.
3. A third form that is sometimes more convenient when dealing with a mixed environment of IPv4 and IPv6 is *x:x:x:x:x:d.d.d.d*, where *x*'s are the hexadecimal values of the six high-order 16-bit pieces of the address, and the *d*'s are the decimal values of the four low-order 8-bit pieces of the address (standard IPv4 representation).

Notes:

1. A more extensive description of the IPv6 standard representations can be found in RFC2373.
2. The `inet_pton()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support ” on page 2123](#) for details.

Returned value

If successful, `inet_pton()` returns 1 and stores the binary form of the Internet address in the buffer pointed to by *dst*.

If unsuccessful because the input buffer pointed to by *src* is not a valid string, `inet_pton()` returns 0.

If unsuccessful because the *af* argument is unknown, `inet_pton()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

The address family specified in *af* is unsupported.

initgroups() — Initialize the supplementary group ID list for the process

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _OPEN_SYS
#include <sys/types.h>
#include <grp.h>

int initgroups(const char *user, const gid_t basegid);
```

General description

The `initgroups()` function obtains the supplementary group membership of *user*, and sets the current process supplementary group IDs to that list. The *basegid* is also included in the supplementary group IDs list.

The caller of this function must be a superuser or must specify the password of the target user name specified on the `initgroups()` call - issue the `passwd()` function before `initgroups()`.

Returned value

If successful, `initgroups()` returns 0.

If unsuccessful, `initgroups()` returns -1 and sets `errno` to one of the following values:

Error Code Description

EINVAL

The number of supplementary groups for the specified user plus the basegid group exceeds the maximum number of groups allowed, or a non-valid *user* is specified.

EMVSERR

An MVS environmental or internal error occurred.

EMVSSAF2ERR

The Security Authorization Facility (SAF) had an error.

EPERM

The caller is not authorized, only authorized users are allowed to alter the supplementary group IDs list.

Related information

initstate() — Initialize generator for random()

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

char *initstate(unsigned seed, char *state, size_t size);
```

General description

The `initstate()` function allows a state array, pointed to by the *state* argument, to be initialized for future use in calls to the `random()` functions by the calling thread. The *size* argument, which specifies the size in bytes of the state array, is used by the `initstate()` function to decide how sophisticated a random-number generator to use; the larger the state array, the more random the numbers. Values for the amount of state information are 8, 32, 64, 128, and 256 bytes. While other amounts are rounded down to the nearest known value. The *seed* argument specifies a starting point for the random-number sequence and provides for restarting at the same point. The `initstate()` function returns a pointer to the previous state information array.

Returned value

If successful, `initstate()` returns a pointer to the previous state array.

If unsuccessful, `initstate()` returns a NULL pointer. If `initstate()` is called with *size* less than 8, it will return NULL.

inotify_add_watch() — Add a watch to an initialized inotify instance

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <sys/inotify.h>

int inotify_add_watch(int fd, const char *pathname, uint32_t mask);
```

General description

`inotify_add_watch()` manipulates the watch list that is associated with an `inotify` instance that is returned by `inotify_init()`. Each watched item in the watch list specifies *pathname* of a file or directory, along with some set of events that the kernel monitors for the file that is referred to by *pathname*. `inotify_add_watch()` either creates a new watch item or modifies an existing watch. Each watch has a unique watch descriptor, which is an integer that is returned by the call to `inotify_add_watch()` when the watch item is created.

Parameter

Description

fd

File descriptor that refers to the `inotify` instance whose watch list is to be modified.

pathname

Path name of a file or directory.

mask

Bit-mask form of the events to be monitored. Valid values are:

IN_ACCESS

File is accessed.

IN_ATTRIB

Metadata is changed.

IN_CLOSE_WRITE

File that is opened for writing is closed.

IN_CLOSE_NOWRITE

File or directory that is not opened for writing is closed.

IN_CREATE

File or directory is created in watched directory.

IN_DELETE

File or directory is deleted from watched directory.

IN_DELETE_SELF

Watched file or directory is itself deleted.

IN_MODIFY

File is modified.

IN_MOVE_SELF

Watched file or directory is itself moved.

IN_MOVED_FROM

Generated for the directory that contains the old filename when a file is renamed.

IN_MOVED_TO

Generated for the directory that contains the new filename when a file is renamed.

IN_OPEN

File or directory is opened.

IN_ALL_EVENTS

Defined as a bit mask of all of the previous events.

IN_MOVE

Equates to `IN_MOVED_FROM | IN_MOVED_TO`.

IN_CLOSE

Equates to `IN_CLOSE_WRITE | IN_CLOSE_NOWRITE`.

IN_DONT_FOLLOW

Do not dereference *pathname* if it is a symbolic link.

IN_EXCL_UNLINK

By default, when watching events on the children of a directory, events are generated for children even after they are unlinked from the directory. This can result in large numbers of uninteresting events for some applications (for example, many applications create temporary files whose names are immediately unlinked in the `/tmp` folder). Specifying `IN_EXCL_UNLINK` changes the default behavior, so that events are not generated for children after they are unlinked from the watched directory.

IN_MASK_ADD

If a watch instance exists for the filesystem object corresponding to *pathname*, add (OR) the events in mask to the watch mask (instead of replacing the mask); the error `EINVAL` results if `IN_MASK_CREATE` is also specified.

IN_ONESHOT

Monitor the filesystem object corresponding to *pathname* for one event, then remove from watch list.

IN_ONLYDIR

Watch *pathname* only if it is a directory; the error `ENOTDIR` results if *pathname* is not a directory. Using this flag provides an application with a race-free way of ensuring that the monitored object is a directory.

IN_MASK_CREATE

Watch *pathname* only if it does not have a watch that is associated with it; the error `EEXIST` results if *pathname* is watched.

When events occur for monitored files and directories, those events are made available to the application as structured data that can be read from the `inotify` file descriptor by `read()`. Each successful `read()` call returns a buffer that contains one or more of the following structure.

Compile requirement: Using this structure requires the compiler support for C99.

```
struct inotify_event {
    int      wd;           /* Watch descriptor */
    uint32_t mask;         /* Mask describing event */
    uint32_t cookie;       /* Unique cookie associating related events */
    uint32_t len;          /* Size of name field */
    char     name[];       /* Optional null-terminated name */
}
```

wd identifies the watch for which this event occurs. It is one of the watch descriptors that are returned by a previous call to `inotify_add_watch()`.

mask contains bits that describe the event that occurred. The following bits might be set in the mask field that is returned by `read()`.

IN_IGNORED

Watch is removed by calling `inotify_rm_watch()` or when the file is deleted or the filesystem is unmounted.

IN_ISDIR

Subject of this event is a directory.

IN_Q_OVERFLOW

Event queue overflows.

IN_UNMOUNT

The file system that contains watched object is unmounted.

Returned value

If successful, `inotify_add_watch()` returns a watch descriptor, which is a nonnegative integer.

If unsuccessful, `inotify_add_watch()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

Read access to the given file is not permitted.

EBADF

The given file descriptor is not valid.

EEXIST

mask contains `IN_MASK_CREATE` and *pathname* refers to a file that is watched by the same *fd*.

EFAULT

pathname points outside of the process's accessible address space.

EINVAL

The given event mask contains no valid events, or *mask* contains both `IN_MASK_ADD` and `IN_MASK_CREATE`, or *fd* is not an `inotify` file descriptor.

ENAMETOOLONG

pathname is too long.

ENOENT

A directory component in *pathname* does not exist or is a dangling symbolic link.

ENOMEM

Kernel memory is insufficient.

ENOSPC

The user limit on the total number of `inotify` watches is reached, or the kernel fails to allocate a needed resource.

ENOTDIR

mask contains `IN_ONLYDIR` and *pathname* is not a directory.

Related information

- [“sys/inotify.h — Monitor and notify file system change functions” on page 68](#)
- [“inotify_init\(\), inotify_init1\(\) — Initialize an inotify instance” on page 870](#)

inotify_init(), inotify_init1() – Initialize an inotify instance

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <sys/inotify.h>

int inotify_init(void);
int inotify_init1(int flags);
```

General description

`inotify_init()` creates a new `inotify` instance and returns a file descriptor that is associated with a new `inotify` event queue. The returned `inotify` instance can then be used to add interest in watching in particular file descriptors by using the `inotify_add_watch()` function.

`inotify_init1()` is similar to `inotify_init()` but accepts a *flags* argument. If *flags* is 0, `inotify_init1()` is the same as `inotify_init()`. The following values can be bitwise ORed in *flags* to obtain different behavior:

IN_NONBLOCK

Set the Non-Block file status flag on the file description that is referred to by the new file descriptor. This is the same as the `O_NONBLOCK` flag in the `open()` function.

IN_CLOEXEC

Set the close-on-exec flag on the new file descriptor. See the description of the `O_CLOEXEC` flag in the `open()` function for more information.

Returned value

If successful, `inotify_init()` and `inotify_init1()` return a new file descriptor.

If unsuccessful, `inotify_init()` and `inotify_init1()` return -1 and set `errno` to one of the following values:

Error Code

Description

EINVAL

An invalid value is specified in *flags* for `inotify_init1()`.

EMFILE

The user limit on the total number of `inotify` instances or the per-process limit on the number of open file descriptors is reached.

ENFILE

The system-wide limit on the total number of open files is reached.

ENOMEM

Kernel memory is insufficient.

Related information

- [“sys/inotify.h – Monitor and notify file system change functions” on page 68](#)
- [“open\(\) – Open a file” on page 1157](#)

inotify_rm_watch() — Remove an existing watch from an inotify instance

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <sys/inotify.h>

int inotify_rm_watch(int fd, int wd);
```

General description

`inotify_rm_watch()` removes the watch that is associated with the watch descriptor, which is returned by `inotify_add_watch()` from the `inotify` instance that is associated with the file descriptor. Removing a watch causes an `IN_IGNORED` event to be generated for this watch descriptor.

Parameter

Description

fd

File descriptor of an `inotify` instance.

wd

File descriptor of a watched item.

Returned value

If successful, `inotify_rm_watch()` returns 0.

If unsuccessful, `inotify_rm_watch()` returns -1 and set `errno` to one of the following values:

Error Code

Description

EBADF

fd is not a valid file descriptor.

EINVAL

The watch descriptor *wd* is not valid; or *fd* is not an `inotify` file descriptor.

Related information

- [“sys/inotify.h — Monitor and notify file system change functions” on page 68](#)

insque() — Insert an element into a doubly-linked list

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <search.h>

void insque(void *element, void *pred);
```

General description

The insque() function inserts the element pointed to by *element* into a doubly-linked list immediately after the element pointed to by *pred*. The function operates on pointers to structures which have a pointer to their successor in the list as their first element, and a pointer to their predecessor as the second. The application is free to define the remaining contents of the structure, and manages all storage itself. To insert the first element into a linear (non-circular) list, an application would call *insque(element, NULL)*;. To insert the first element into a circular list, the application would set the element's forward and back pointers to point to the element.

Returned value

insque() returns no values.

Related information

- [“search.h — Searching tables” on page 58](#)
- [“remque\(\) — Remove an element from a double linked list” on page 1431](#)

ioctl() — Control device

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

Terminals:

```
#include <sys/ioctl.h>

int ioctl(int fildes int cmd, ... /* arg */);
```

Sockets:

```
#define _XOPEN_SOURCE_EXTENDED 1

/**      OR      **/

#define _OE_SOCKETS

#include <sys/ioctl.h>
#include <net/rtroute.h>
#include <net/if.h>
int ioctl(int fildes, int cmd, ... /* arg */);
```

STREAMS:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stropts.h>
int ioctl(int fildes int cmd, ... /* arg */);
```

General description

`ioctl()` performs a variety of control functions on devices. The *cmd* argument and an optional third argument (with varying type) are passed to and interpreted by the device associated with *fdes*.

The *cmd* argument selects the control function to be performed and will depend on the device being addressed.

The *arg* argument represents additional information that is needed by this specific device to perform the requested function. The type of *arg* depends upon the particular control request, but it is either an integer or a pointer to a device-specific data structure.

`ioctl()` information is divided into the following section s:

- Terminals
- Sockets
- STREAMS
- ACLs

Terminals

The following `ioctl()` commands are used with terminals:

Command Description

TIOCSWINSZ

Set window size. Used as the second operand in an `ioctl()` against a terminal. The window size information pointed to by the third operand is copied into an area in the kernel associated with the terminal, and a SIGWINCH signal is generated against the foreground process group.

TIOCGWINSZ

Get window size. Used as the second operand in an `ioctl()` against a terminal. The current window size is returned in the area pointed to by the third operand - a `winsize` structure.

The `winsize` structure is the third operand in an `ioctl()` call when you use `TIOCSWINSZ` or `TIOCGWINSZ`. The structure contains four unsigned short integers:

Field Description

ws_row

Number of rows in the window, in characters.

ws_col

Number of columns in the window, in characters. This assumes single-byte characters. Multibyte characters may take more room.

ws_xpixel

Horizontal size of the window, in pixels.

ws_ypixel

Vertical size of the window, in pixels.

Sockets

The following `ioctl()` commands are used with sockets:

Command Description

FIONBIO

Sets or clears nonblocking I/O for a socket. *arg* is a pointer to an integer. If the integer is 0, nonblocking I/O on the socket is cleared. Otherwise, the socket is set for nonblocking I/O.

FIONREAD

Gets the number of immediately readable bytes for the socket. *arg* is a pointer to an integer. Sets the value of the integer to the number of immediately readable characters for the socket.

FIONWRITE

Returns the number of bytes that can be written to the connected peer AF_UNIX stream socket before the socket blocks or returns EWOULDBLOCK. The number of bytes returned is not guaranteed unless there is serialization by the using applications.

FIOGETOWN

Returns the PID that has been set that designates the recipient of signals.

FIOSETOWN

Sets the PID to be used when sending signals

FIOGETOWN and FIOSETOWN are equivalent to the F_GETOWN and F_SETOWN commands of fcntl(). For information on the values for pid, refer to that function. This function is only valid for AF_INET stream sockets.

SECIGET

Gets the peer socket's security identity values for an AF_UNIX connected stream socket. The MVS user ID, effective UID, and effective GID of the peer process are returned in the **seci** structure, which is mapped by BPXYSECI. This option is valid only for the AF_UNIX domain.

SECIGET_T

Returns both the process and, if available, the task level security information of the peer for an AF_UNIX stream connected to the socket. The task level security information is from the task that issued the connect() or accept(). The security information is returned in a struct **__sect_s** as defined in <sys/ioctl.h>. The security information is not available until accept() completes. The availability of the peer's task level security data is determined by the task level userid length field. If zero, the peer does not have task level security data.

SIOCADDRT

Adds a routing table entry. *arg* is a pointer to a **rtentry** structure, as defined in <net/rtroute.h>. The routing table entry, passed as an argument, is added to the routing tables. This option is valid only for the AF_INET domain.

SIOCATMARK

Queries whether the current location in the data input is pointing to out-of-band data. *arg* is a pointer to an integer. SIOCATMARK sets the argument to 1 if the socket points to a mark in the data stream for out-of-band data; otherwise, it sets the argument to 0. Refer to recv(), recvfrom() and recvmsg() for more information on receiving out-of-band data.

SIOCDELRT

Deletes a routing table entry. *arg* is a pointer to a **rtentry** structure, as defined in <net/rtroute.h>. If it exists, the routing table entry passed as an argument is deleted from the routing tables. This option is valid only for the AF_INET domain.

SIOCGIFADDR

Gets the network interface address. *arg* is a pointer to an **ifreq** structure, as defined in <net/if.h>. The interface address is returned in the argument. This option is valid only for the AF_INET domain.

This macro is protected by the _OPEN_SYS_IF_EXT feature.

SIOCGIFBRDADDR

Gets the network interface broadcast address. *arg* is a pointer to an **ifreq** structure, as defined in <net/if.h>. The interface broadcast address is returned in the argument. This option is valid only for the AF_INET domain.

This macro is protected by the _OPEN_SYS_IF_EXT feature.

SIOCGIFCONF

Gets the network interface configuration. *arg* is a pointer to an **ifconf** structure, as defined in <net/if.h>. The interface configuration is returned in the buffer pointed to by the **ifconf** structure. The

returned data's length is returned in the field that had originally contained the length of the buffer. This option is valid only for the AF_INET domain.

This macro is protected by the _OPEN_SYS_IF_EXT feature.

SIOCGIFCONF6

Gets the name, address, and other information about the IPv6 network interfaces that are configured. This is similar to the SIOCGIFCONF command for IPv4.

To request OSM interfaces, the application must have READ authorization to the EZB.OSM.sysname.tcpname resource.

A struct `__net_ifconf6header_s` is passed as the argument of the ioctl. This structure specifies the buffer where the configuration information is to be written and is returned with the number of entries and entry length of each struct, and `__net_ifconf6entry_s` that was written to the output buffer. These structures are defined in `<sys/ioctl.h>`.

If `__nif6h_buflen` and `__nif6h_buffer` are both zero, a query function is performed and the header is returned with:

`__nif6h_version`

The maximum supported version.

Note: If the version number is supplied (not zero), the entry length returned will be for the specified version. (If it is supported)

`__nif6h_entries`

The total number of entries that will be output.

`__nif6h_entrylen`

The length of each individual entry.

If a call to get information fails with either

```
errno = ERANGE, or
errno = EINVAL and __nif6h_version has changed
```

The call was converted into a query function and the header has been filled in as described above. In these cases, the content of the output buffer is undefined.

If Common INET is configured and multiple TCP/IP stacks are attached to the socket, the output from each stack that is enabled for IPv6 will be concatenated in the output buffer and the header will contain the total number of entries returned from all the stacks. The version returned with the query function will be the highest version supported by all the stacks.

This ioctl can be issued on an AF_INET or AF_INET6 socket.

Error Code

Description

EINVAL

No IPv6 enabled TCP/IP stacks are active.

EINVAL

The input version number is not supported.

ERANGE

The buffer is too small to contain all of the IPv6 network interface entries.

SIOCGIFDSTADDR

Gets the network interface destination address. *arg* is a pointer to an **ifreq** structure, as defined in `<net/if.h>`. The interface destination (point-to-point) address is returned in the argument. This option is valid only for the AF_INET domain.

This macro is protected by the _OPEN_SYS_IF_EXT feature.

SIOCGIFFLAGS

Gets the network interface flags. *arg* is a pointer to an **ifreq** structure, as defined in <net/if.h>. The interface flags are returned in the argument. This option is valid only for the AF_INET domain.

This macro is protected by the _OPEN_SYS_IF_EXT feature.

SIOCGIFMETRIC

Gets the network interface routing metric. *arg* is a pointer to an **ifreq** structure, as defined in <net/if.h>. The interface routing metric is returned in the argument. This option is valid only for the AF_INET domain.

This macro is protected by the _OPEN_SYS_IF_EXT feature.

SIOCGIFMTU

Gets the network interface MTU (maximum transmission unit). *arg* is a pointer to an ifreq structure, as defined in <net/if.h>. The interface MTU is returned in the argument, *arg->ifr_mtu*. This option is only valid for the AF_INET domain.

This macro is protected by the _OPEN_SYS_IF_EXT feature.

SIOCGIFNETMASK

Gets the network interface network mask. *arg* is a pointer to an **ifreq** structure, as defined in <net/if.h>. The interface network mask is returned in the argument. This option is valid only for the AF_INET domain.

This macro is protected by the _OPEN_SYS_IF_EXT feature.

SIOCGSPLXFQDN

Gets the fully qualified domain name for a given server and domain name in a sysplex. This is an special purpose command to support applications that have registered with WorkLoad Manager (WLM) for connection optimization services using the Domain Name System (DNS). 'arg' is a pointer to sysplexFqDn structure, as defined in <ezbzsdc.h>. sysplexFqDn contains pointer to sysplexFqDnData structure, as defined in <ezbzsdc.h>.

sysplexFqDnData structure contains server name(input), group name(input) and fully qualified domain name(output).

ioctl() with the SIOCGSPLXFQDN command will fail if:

Error Code**Description****EFAULT**

Write user storage failed

EINVAL

One of the following:

- Group name required
- Buffer length not valid
- Socket call parameter error

ENXIO

One of the following:

- Sysplex address not found
- Res not found In DNS
- Time out
- Time Unexpected Error

Example: The following is an example of the `ioctl()` call used with `SIOCGSPLXFQDN`.

```
#include <ezbzdnc.h>
sysplexFqDn      splxFqDn;
sysplexFqDnData  splxData;
int              rc;

splxFqDn.splxVersion = splxDataVersion;
splxFqDn.splxBuflen  = sizeof(sysplexFqDnData);
splxFqDn.splxBufAddr = &splxData;

/* Assign values to splxData.groupName, */
/* splxData.serverName if required      */
/*                                     */
/*                                     */
/* Get the fully qualified domain name */
rc = ioctl(s, SIOCGSPLXFQDN, (char *) &splxFqDn);

/* splxData.domainName contains the fully */
/* qualified domain name.                  */
/*                                     */
```

SIOCSECNVR

Used to SET or GET the security environment for a server socket. `arg` points to a struct `__seco_s` where element `__seco_argument` is set to 1 for a SET and 2 for a GET request.

When used with the SET argument, the AF_UNIX stream socket server will designate the server socket as one that requires the full security environment of the connecting client to be available before the connect will complete successfully. During connect processing, connect obtains the security environment of the connector and anchors it off the connector's socket for use by the server. If the security environment cannot be obtained during connect processing, the connect will fail. This command has no effect on sockets that do not become server sockets.

When used with the GET argument, the AF_UNIX stream socket server will copy the previously SET security environment from the connector's address space to the server's address space so it can be used as input on calls to the security product. This command has meaning only for server sockets that previously issued SIOCSECNVR with the SET argument.

SIOCSIFMETRIC

Sets the network interface routing metric. `arg` is a pointer to an **ifreq** structure, as defined in `<net/if.h>`. SIOCSIFMETRIC sets the interface routing metric to the value passed in the argument. This option is valid only for the AF_INET domain.

This macro is protected by the `_OPEN_SYS_IF_EXT` feature.

SIOCSPARTNERINFO

Sets an indicator to retrieve the partner security credentials during connection setup and saves the information, enabling an application to issue a SIOCGPARTNERINFO ioctl without suspending the application, or at least minimizing the time to retrieve the information. The SIOCSPARTNERINFO ioctl must be issued prior to the SIOCGPARTNERINFO ioctl. For more information, see [z/OS Communications Server: IP Programmer's Guide and Reference](#).

SIOCSVIPA

Defines or deletes an IPv4 dynamic VIPA. `arg` is a pointer to a **dvreq** structure as defined in `<ezbzdvp.h>`. This option is valid only for the AF_INET domain.

SIOCSVIPA6
