Defines or deletes an IPv6 dynamic VIPA. `arg` is a pointer to a **dvreq6** structure as defined in `<ezbzdvp.h>`. This option is valid only for the AF_INET6 domain.

SIOCTIEDESTHRD

Associates (ties) or disassociates (unties) a descriptor with a thread. `arg` is a pointer to an int. When `*arg` is 1, the descriptor is tied to the calling thread. When `*arg` is 0, the descriptor is untied from the calling thread. If the task should terminate before the descriptor is closed or untied from the task, z/OS UNIX file system thread termination processing will close the descriptor. This command can be used on both heavy weight and medium weight threads.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` 1 feature test macro.

Terminal and sockets returned value

If successful, `ioctl()` returns 0.

If unsuccessful, `ioctl()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

The *fdes* parameter is not a valid socket descriptor.

EINVAL

The request is not valid or not supported.

EIO

The process group of the process issuing the function is an orphaned, background process group, and the process issuing the function is not ignoring or blocking SIGTTOU.

EMVSPARM

Incorrect parameters were passed to the service.

ENODEV

The device is incorrect. The function is not supported by the device driver.

ENOTTY

An incorrect file descriptor was specified. The file type was not character special.

Example of terminal and sockets

The following is an example of the `ioctl()` call.

```
int s;
int dontblock;
int rc;
:
/* Place the socket into nonblocking mode */
dontblock = 1;
rc = ioctl(s, FIONBIO, (
char *) &dontblock);
:
```

STREAMS

The following `ioctl()` commands are used with STREAMS:

L_PUSH

Pushes the module whose name is pointed to by *arg* onto the top of the current STREAM, just below the STREAM head. It then calls the `open()` function of the newly-pushed module.

`ioctl()` with the `L_PUSH` command will fail if:

Error Code

Description

EINVAL

Non-valid module name.

ENXIO

Open function of new module failed.

ENXIO

Hang-up received on *fdes*

L_POP

Removes the module just below the STREAM pointed to by *fildes*. The *arg* argument should be 0 in an I_POP request.

ioctl() with the I_POP command will fail if:

Error Code**Description****EINVAL**

No module present in the STREAM.

ENXIO

Hang-up received on *fildes*.

L_LOOK

Retrieves the name of the module just below the STREAM head of the STREAM pointed to by *fildes* and places it in a character string pointed to by *arg*. The buffer pointed to by *arg* should be at least FMNAMESZ+1 bytes long, where FMNAMESZ is defined in <stropts.h>.

ioctl() with the I_LOOK command will fail if:

Error Code**Description****EINVAL**

No module present in the STREAM.

L_FLUSH

This request flushes read and/or write queues, depending on the value of *arg*. Valid *arg* values are:

FLUSHR

Flush all read queues.

FLUSHW

Flush all write queues.

FLUSHRW

Flush all read and all write queues.

ioctl() with the I_FLUSH command will fail if:

Error Code**Description****EAGAIN or ENOSR**

Unable to allocate buffers for flush message.

EINVAL

Non-valid *arg* value.

ENXIO

Hang-up received on *fildes*.

I_FLUSHBAND

Flushes a particular band of messages. The *arg* argument points to a bandinfo structure. The bi_flag member may be one of FLUSHER, FLUSHW, or FLUSHRW as described above. The bi_pri member determines the priority band to be flushed.

I_SETSIG

Requests that the STREAMS implementation send the SIGPOLL signal to the calling process when a particular event has occurred on the STREAM associated with *fildes*. I_SETSIG supports an asynchronous processing capability in STREAMS. The value of *arg* is a bitmask that specifies the events for which the process should be signaled. It is the bitwise OR of any combination of the following constants:

S_RDNORM

A normal (priority band set to 0) message has arrived at the head of a STREAM head read queue. A signal will be generated even if the message is of zero length.

S_RDBAND

A message with a nonzero priority band has arrived at the head of a STREAM head read queue. A signal will be generated even if the message is of zero length.

S_INPUT

A message, other than a high-priority message, has arrived at the head of a STREAM head read queue. A signal will be generated even if the message is of zero length.

S_HIPRI

A high-priority message is present on a STREAM head read queue. A signal will be generated even if the message is of zero length.

S_OUTPUT

The write queue for normal data (priority band 0) just below the STREAM head is no longer full. This notifies the process that there is room on the queue for sending (or writing) normal data downstream.

S_WRNORM

Same as S_OUTPUT.

S_WRBAND

The write queue for a nonzero priority band just below the STREAM head is no longer full. This notifies the process that there is no room on the queue for sending (or writing) priority data downstream.

S_MSG

A STREAMS signal message that contains the SIGPOLL signal has reached the front of the STREAM head read queue.

S_ERROR

Notification of an error condition has reached the STREAM head.

S_HANGUP

When used in conjunction with S_RDBAND, SIGURG is generated instead of SIGPOLL when a priority message reaches the front of the STREAM head read queue.

If *arg* is 0, the calling process will be unregistered and will not receive further SIGPOLL signals for the STREAM associated with *fildes*.

Processes that wish to receive SIGPOLL signals must explicitly register to receive them using I_SETSIG. If several processes register to receive this signal for the same event on the same STREAM, each process will be signaled when the event occurs.

ioctl() with the I_SETSIG command will fail if:

Error Code

Description

EAGAIN

There were insufficient resources to store the signal request.

EINVAL

The value of *arg* is not valid.

EINVAL

The value of *arg* is 0 and the calling process is not registered to receive the SIGPOLL signal.

I_GETSIG

Returns the events for which the calling process is currently registered to be sent a SIGPOLL signal. The events are returned as a bitmask in an int pointed to by *arg*, where the events are those specified in the description of I_SETSIG above.

ioctl() with the I_GETSIG command will fail if:

Error Code

Description

EINVAL

Process is not registered to receive the SIGPOLL signal.

I_FIND

This request compares the names of all modules currently present in the STREAM to the name pointed to by *arg*, and returns 1 if the name module is present in the STREAM, or returns 0 if the named module is not present.

ioctl() with the I_FIND command will fail if:

Error Code**Description****EINVAL**

arg does not contain a valid module name.

I_PEEK

This request allows a process to retrieve the information in the first message on the STREAM head read queue without taking the message off the queue. It is analogous to getmsg() except that this command does not remove the message from the queue. The *arg* argument points to a strpeek structure.

The maxlen member in the ctlbuf and databuf strbuf structure must be set to the number of bytes of control information and/or data information, respectively, to retrieve. The flags member may be marked RS_HIPRI or 0, as described by getmsg() - getpmsg(). If the process sets flags to RS_HIPRI, for example, I_PEEK will only look for a high-priority message on the STREAM head read queue.

I_PEEK returns 1 if a message was retrieved, and returns 0 if no message was found on the STREAM head read queue, or if the RS_HIPRI flag was set in flags and a high-priority message was not present on the STREAM head read queue. It does not wait for a message to arrive. On return, ctlbuf specifies information in the control buffer, databuf specifies information in the data buffer, and flags contains the value RS_HIPRI or 0.

I_SRDOPT

Sets the read mode using the value of the argument *arg*. Read modes are described in read(). Valid *arg* flags are:

RNORM

Byte-stream mode, the default.

RMSGD

Message-discard mode.

RMSGN

Message-nondiscarded mode.

The bitwise inclusive-OR of RMSGD and RMSGN will return EINVAL. The bitwise inclusive-OR of RNORM and either RMSGD or RMSGN will result in the other flag overriding RNORM which is the default.

In addition, treatment of control messages by the STREAM head may be changed by setting any of the following flag in *arg*:

RPROTNORM

Fail read() with EBADMSG if a message containing a control part is at the front of the STREAM head read queue.

RPROTDAT

Deliver the control part of a message as data when a process issues a read().

RPROTDIS

Discard the control part of a message, deliver any data portion, when a process issues a read().

ioctl() with the I_SRDOPT command will fail if:

Error Code**Description****EINVAL**

The *arg* argument is not valid.

I_GRDOPT

Returns the current read mode setting, as described above, in an int pointed to by the argument *arg*. Read modes are described in read().

I_NREAD

Counts the number of data bytes in the data part of the first message on the STREAM head read queue and places this value in the int pointed to by *arg*. The return value for the command is the number of messages on the STREAM head read queue. For example, if 0 is returned in *arg*, but the ioctl() return value is greater than 0, this indicates that a zero-length message is next on the queue.

I_FDINSERT

Creates a message from specified buffer(s), adds information about another STREAM, and sends the message downstream. The message contains a control part and an optional data part. The data and control parts to be sent are distinguished by placement in separate buffers, as described below. The *arg* argument points to a **strfdinsert** structure.

The **len** member in the **ctlbuf** **strbuf** structure must be set to the size of a pointer plus the number of bytes of control information to be sent with the message. The *fildev* member specifies the file descriptor of the other STREAM, and the *offset* member, which must be suitably aligned for use as a pointer, specifies the offset from the start of the control buffer where I_FDINSERT will store a pointer whose interpretation is specific to the STREAM end. The **len** member in the **databuf** **strbuf** structure must be set to the number of bytes of data information to be sent with the message, or 0 if no data part is to be sent.

The **flags** member specifies the type of message to be created. A normal message is created if **flags** is set to 0, and a high-priority message is created if **flags** is set to RS_HIPRI. For non-priority messages, I_FDINSERT will block if the STREAM write queue is full due to internal flow control conditions. For priority messages, I_FDINSERT does not block on this condition. For non-priority messages, I_FDINSERT does not block when the write queue is full and O_NONBLOCK is set. Instead, it fails and sets *errno* to EAGAIN.

I_FDINSERT also blocks, unless prevented by lack of internal resources, waiting for the availability of message blocks in the STREAM, regardless of priority or whether O_NONBLOCK has been specified. No partial message is sent.

ioctl() with the I_FDINSERT command will fail if:

Error Code**Description****EAGAIN**

A non-priority message is specified, the O_NONBLOCK flag is set, and the STREAM write queue is full due to internal flow control conditions.

EAGAIN or ENOSR

Buffers can not be allocated for the message that is to be created.

EINVAL

One of the following:

- The *fd* member of the **strfdinsert** structure is not a valid, open STREAM file descriptor.
- The size of a pointer plus *offset* is greater than the *len* member for the buffer specified through *ctlptr*
- the *offset* member does not specify a properly-aligned location in the data buffer.
- An undefined value is stored in **flags**

ENXIO

Hang-up received for *fd* or *fildev*.

ERANGE

The *len* member for the buffer specified through *databuf* does not fall within the range specified by the maximum and minimum packet sizes of the topmost STREAM module or the *len* member for the buffer specified through *databuf* is larger than the maximum configured size of the data

part of a message; or the *len* member for the buffer specified through *ctlbuf* is larger than the maximum configured size of the control part of a message.

I_STR

Constructs an internal STREAMS ioctl() message from the data pointed to by *arg*, and sends that message downstream.

This mechanism is provided to send ioctl() requests to downstream modules and drivers. It allows information to be sent with ioctl(), and returns to the process any information sent upstream by the downstream recipient. I_STR blocks until the system responds with either a positive or negative acknowledgement message, or until the request "times out" after some period of time. If the request times out, it fails with *errno* set to ETIME.

At most, one I_STR can be active on a STREAM. Further I_STR calls will block until the active I_STR completes at the STREAM head. The default timeout interval for these requests is 15 seconds. The O_NONBLOCK flag has no effect on this call.

To send requests downstream, *arg* must point to a **strioctl** structure.

The **ic_cmd** member is the internal ioctl() command intended for a downstream module or driver and **ic_timeout** is the number of seconds (-1 = infinite, 0 = use implementation-dependent timeout interval, >0 = as specified) an I_STR request will wait for acknowledgement before timing out. **ic_len** member has two uses: on input, it contains the length of the data argument passed in, and on return from the command, it contains the number of bytes being returned to the process (the *buffer* pointed to by **ic_dp** should be large enough to contain the maximum amount of data that any module or the driver in the STREAM can return.)

The STREAM head will convert the information pointed to by the **strioctl** structure to an internal ioctl() command message and send it downstream.

ioctl() with the I_STR command will fail if:

Error Code

Description

EAGAIN or ENOSR

Unable to allocate buffers for the ioctl() message.

EINVAL

This *ic_len* member is less than 0 or larger than the maximum configured size of the data part of a message, or *ic_timeout* is less than -1.

ENXIO

Hang-up received on *fildev*.

ETIME

A downstream ioctl() timed out before acknowledgement was received.

An I_STR can also fail while waiting for an acknowledgement if a message indicating an error or a hang-up is received at the STREAM head. In addition, an error code can be returned in the positive or negative acknowledgement message, in the event the ioctl() command sent downstream fails. For these cases, I_STR fails with *errno* set to the value in the message.

I_SWROPT

Sets the write mode using the value of the argument *arg*. Valid bit settings for *arg* are:

SNDZERO

Send a zero-length message downstream when a write() of 0 bytes occurs. To not send a zero-length message when a write() of 0 bytes occurs, this bit must not be set in *arg* (for example, *arg* would be set to 0).

ioctl() with the I_SWROPT command will fail if:

Error Code

Description

EINVAL

arg is not the above value.

I_GWROPT

Returns the current write mode setting as described above, in the `int` that is pointed to by the argument *arg*.

I_SENDFD

I_SENDFD creates a new reference to the open file description associated with the file descriptor *arg* and writes a message on the STREAMS-based pipes *fildev* containing the reference, together with the user ID and group ID of the calling process.

`ioctl()` with the **I_SENDFD** command will fail if:

Error Code**Description****EAGAIN**

The sending STREAM is unable to allocate a message block to contain the file pointer; or the read queues of the receiving STREAM head is full and cannot accept the message sent by **I_SENDFD**.

EBADF

The *arg* argument is not a valid, open file descriptor.

EINVAL

The *fildev* argument is not connected to a STREAM pipe.

ENXIO

Hang-up received on *fildev*.

I_RECVFD

Retrieves the reference to an open file description from a message within a STREAMS-based pipe using the **I_SENDFD** command, and allocates a new file descriptor in the calling process that refers to this open file description. The *arg* argument is a pointer to an **strrecvfd** data structure as defined in `<stropts.h>`.

The **fd** member is a file descriptor. The **uid** and **gid** members are the effective user ID and effective group ID, respectively, of the sending process.

If **O_NONBLOCK** is not set **I_RECVFD** blocks until a message is present at the STREAM head. If **O_NONBLOCK** is set, **I_RECVFD** fails with `errno` set to **EAGAIN** if no message is present at the STREAM head.

If the message at the STREAM head is a message sent by an **I_SENDFD**, a new file descriptor is allocated for the open file descriptor referenced in the message. The new file descriptor is placed in the **fd** member of the **strrecvfd** structure pointed to by *arg*.

`ioctl()` with the **I_RECVFD** command will fail if:

Error Code**Description****EAGAIN**

A message is not present at the STREAM head read queue and the **O_NONBLOCK** flag is set.

EBADMSG

The message at the STREAM head read queue is not a message containing a passed file descriptor.

EMFILE

The process has the maximum number of file descriptors currently open that is allowed.

ENXIO

Hang-up received on *fildev*.

I_LIST

This request allows the process to list all the module names on the STREAM, up to and including the topmost driver names. If *arg* is a `NULL` pointer, the return value is the number of modules, including the driver, that are on the STREAM pointed to by *fildev*. This lets the process allocate enough space for the module names. Otherwise, it should point to an **str_list** structure.

The **sl_nmods** member indicates the number of entries the process has allocated in the array. Upon return, the **sl_modlist** member of the **str_list** structure contains the list of module names. The number of entries that have been filled into the **sl_modlist** array is found in the **sl_nmode** member (the number includes the number of module including the driver). The return value from **ioctl()** is 0. The entries are filled in starting at the top of the STREAM and continuing downstream until either the end of the STREAM is reached, or the number of requested modules (**sl_nmods**) is satisfied.

ioctl() with the **I_LIST** command will fail if:

Error Code

Description

EAGAIN or ENOSR

Unable to allocate buffers.

EINVAL

The **sl_nmods** member is less than 1.

I_ATMARK

This request allows the process to see if the message at the head of the STREAM head read queue is marked by some module downstream. The *arg* argument determines how the checking is done when there may be multiple marked messages on the STREAM head read queue. It may take on the following values:

ANYMARK Check if the message is marked.

LASTMARK Check if the message is the last one marked on the queue.

The bitwise inclusive-OR of the flags ANYMARK and LASTMARK is permitted.

The return value is 1 if the mark condition is satisfied and 0 otherwise.

ioctl() with the **I_ATMARK** command will fail if:

EINVAL Non-valid *arg* value.

I_CKBAND

Check if the message of a given priority band exists on the STREAM head read queue. This returns 1 if a message of the given priority exists, 0 if no message exists, or -1 on error. *arg* should be of type int.

ioctl() with the **I_CKBAND** command will fail if :

EINVAL Non-valid *arg* value.

I_GETBAND

Return the priority band of the first message on the STREAM head read queue in the integer referenced by *arg*.

ioctl() with the **I_GETBAND** command will fail if:

ENODATA No message on the STREAM head read queue.

I_CANPUT

Check if a certain band is writable. *arg* is set to the priority band in question. The return value is 0 if the band is flow-controlled, 1 if the band is writable, or -1 on error.

ioctl() with the **I_CANPUT** command will fail if:

EINVAL Non-valid *arg* value.

I_SETCLTIME

This request allows the process to set the time the STREAM head will delay when a STREAM is closing and there is data on the write queues. Before closing each module or driver, if there is a data on its write queue, the STREAM head will delay for the specified amount of time to allow the data to drain. If, after the delay, data is still present, it will be flushed. The *arg* argument is a pointer to an integer specifying the number of milliseconds to delay, rounded up to the nearest valid value. If **I_SETCLTIME** is not performed on a STREAM, an implementation-dependent default timeout interval is used.

ioctl() with the **I_SETCLTIME** command will fail if:

EINVAL Non-valid *arg* value.

I_GETCLTIME

This request returns the close time delay in the integer pointed to by *arg*

Multiplexed STREAMS configurations: The following four commands are used for connecting and disconnecting multiplexed STREAMS configurations. These commands use an implementation-dependent default timeout interval.

I_LINK

Connects two STREAMS, where *fildev* is the file descriptor of the STREAM connected to the multiplexing driver, and *arg* is the file descriptor of the STREAM connected to another driver. The STREAM designated by *arg* gets connected below the multiplexing driver. I_LINK requires the multiplexing driver to send an acknowledgement message to the STREAM head regarding the connection. This call returns a multiplexer ID number (an identifier used to disconnect the multiplexer; see (I_UNLINK) on success, and -1 on failure.

ioctl() with the I_LINK command will fail if:

Error Code

Description

EAGAIN or ENOSR

Unable to allocate STREAMS storage to perform the I_LINK.

EBADF

The *arg* argument is not a valid, open file descriptor.

EINVAL

The *fildev* does not support multiplexing; or *arg* is not a STREAM or is already connected downstream from a multiplexer, or the specified I_LINK operation would connect the STREAM head in more than one place in the multiplexed STREAM.

ENXIO

Hang-up received on *fildev*.

ETIME

Time out before acknowledgement message was received at STREAM head.

An I_LINK can also fail while waiting for the multiplexing driver to acknowledge the request, if a message indicating an error or a hang-up is received at the STREAM head of *fildev*. In addition, an error code can be returned in the positive or negative acknowledgement message. For these cases, I_LINK fails with *errno* set to the value in the message.

I_UNLINK

Disconnects the two STREAMS specified by *fildev* and *arg*. *fildev* is the file descriptor of the STREAM connected to the multiplexing driver. The *arg* argument is the multiplexer ID number that was returned by the I_LINK ioctl() command when a STREAM was connected downstream from the multiplexing driver. If *arg* is MUXID_ALL, then all STREAMS that were connected to *fildev* are disconnected. As in I_LINK, this command requires acknowledgement.

ioctl() with the I_UNLINK command will fail if:

Error Code

Description

EAGAIN or ENOSR

Unable to allocate buffers for the acknowledgement message.

EINVAL

Non-valid multiplexer ID number.

ENXIO

Hang-up received on *fildev*.

ETIME

Time out before acknowledgement message was received at STREAM head.

An `I_UNLINK` can also fail while waiting for the multiplexing driver to acknowledge the request if a message indicating an error or a hang-up is received at the STREAM head of *fildev*. In addition, an error code can be returned in the positive or negative acknowledgement message. For these cases, `I_UNLINK` fails with `errno` set to the value in the message.

I_PLINK

Creates a *persistent connection* between two STREAMs, where *fildev* is the file descriptor of the STREAM connected to another driver. This call creates a persistent connection which can exist even if the file descriptor *fildev* associated with the upper STREAM to the multiplexing driver is closed. The STREAM designated by *arg* gets connected using a persistent connection below the multiplexing driver. `I_PLINK` requires the multiplexing driver to send an acknowledgement message to the STREAM head. This call returns a multiplexer ID number (an identifier that may be used to disconnect the multiplexer, see `I_PUNLINK`) on success, and -1 on failure.

`ioctl()` with the `I_PLINK` command will fail if:

Error Code

Description

EAGAIN or ENOSR

Unable to allocate STREAMS storage to perform the `I_PLINK`.

EBADF

The *arg* argument is not valid, open file descriptor.

EINVAL

The *fildev* argument does not support multiplexing; or *arg* is not a STREAM or is already connected downstream from a multiplexer; or the specified `I_PLINK` operation would connect the STREAM head in more than one place in the multiplexed STREAM.

ENXIO

Hang-up received on *fildev*.

ETIME

Time out before acknowledgement message was received at STREAM head.

An `I_PLINK` can also fail while waiting for the multiplexing driver to acknowledge the request, if a message indicating an error or a hang-up is received at the STREAM head of *fildev*. In addition, an error code can be returned in the positive or negative acknowledgement message. For these cases, `I_PLINK` fails with `errno` set to the value in the message.

I_PUNLINK

Disconnects the two STREAMs specified by *fildev* and *arg* from a persistent connection. The *fildev* argument is the file descriptor of the STREAM connected to the multiplexing driver. The *arg* argument is the multiplexer ID number that was returned by the `I_PLINK` `ioctl()` command when a STREAM was connected downstream from the multiplexing driver. If *arg* is `MUXID_ALL` then all STREAMs which are persistent connections to *fildev* are disconnected. As in `I_PLINK`, this command requires the multiplexing driver to acknowledge the request.

`ioctl()` with the `I_PUNLINK` command will fail if:

Error Code

Description

EAGAIN or ENOSR

Unable to allocate buffers for the acknowledgement message.

EINVAL

Non-valid multiplexer ID number.

ENXIO

Hang-up received on *fildev*.

ETIME

Time out before acknowledgement message was received at STREAM head.

An `I_PUNLINK` can also fail while waiting for the multiplexing driver to acknowledge the request if a message indicating an error or a hang-up is received at the STREAM head of *fildev*. In addition, an

error code can be returned in the positive or negative acknowledgement message. For these cases, I_PUNLINK fails with errno set to the value in the message.

STREAMS returned value

If successful, ioctl() returns a value other than -1 that depends upon the STREAMS device control function.

If unsuccessful, ioctl() returns -1 and sets errno to one of the following values.

Note: It is impossible for ioctl() to perform any STREAMS type commands successfully, since z/OS UNIX services do not provide any STREAMS-based files. The function will always return -1 with errno set to indicate the failure. See [“open\(\) — Open a file”](#) on page 1157 for more information.

Under the following general conditions, ioctl() will fail if:

Error Code

Description

EBADF

The *fdes* argument is not a valid open file descriptor.

EINTR

A signal was caught during the ioctl() operation.

EINVAL

The STREAM or multiplexer referenced by *fdes* is linked (directly or indirectly) downstream from a multiplexer.

If an underlying device driver detects an error, ioctl() will fail if:

Error Code

Description

EINVAL

The *cmd* or *arg* argument is not valid for this device.

EIO

Some physical I/O error has occurred.

ENODEV

The *fdes* argument refers to a valid STREAMS device, but the corresponding device driver does not support ioctl().

ENOTTY

The *fdes* argument is not associated with a STREAMS device that accepts control functions.

ENXIO

The *cmd* or *arg* argument is not valid for this device driver, but the service requested can not be performed on this particular sub-device.

If a STREAM is connected downstream from a multiplexer, any ioctl() command except I_UNLINK and I_PUNLINK will set errno to EINVAL.

ACLs

The following ioctl() commands are used with ACLs:

Command

Description

SETFACL

Set ACL. Used to set information into an Access Control List. *arg* specifies the user buffer containing the input ACL which is mapped by struct ACL_buf followed immediately by an array of struct ACL_ents. *arglen* specifies the combined length of the struct ACL_buf and the array of struct ACL_ents. See [z/OS UNIX System Services Programming: Assembler Callable Services Reference](#) for more information about ACL_buf and the ACL_ents.

GETFACL

Get ACL. Used to retrieve information from an Access Control List. *arg* specifies the user buffer into which the requested ACL will be returned. The data is mapped by struct ACL_BUF followed immediately by an array of struct ACL_entrys. See *z/OS UNIX System Services Programming: Assembler Callable Services Reference* for more information about ACL_buf and the ACL_entrys. *Arglen* specifies the combined length of the struct ACL and the array of struct ACL_entrys in the user buffer.

ACLs returned value

If successful, ioctl() returns 0.

If unsuccessful, ioctl() returns -1 and sets errno to one of the following values:

Error Code**Description****EBADF**

The *filde*s parameter is not a valid file descriptor.

EINVAL

The request is not valid or not supported.

EMVSPARM

Incorrect parameters were passed to the service.

ENODEV

The device is incorrect. The function is not supported by the device driver.

Example of ACLs

The following is an example of the ioctl() call.

```
int s;
int rc;
int acllen;
ext_acl_t aclbufp;
s = open("datafile", O_RDWR);
acllen = sizeof struct ACL_buf + (1024 * sizeof ACL_entry);
aclbufp = (ext_acl_t) malloc(acllen);
rc = ioctl(s, GETFACL, acllen, aclbufp)
```

Format

```
#include <__ftp.h>

struct __ipdbcss *__ipdbcs(void);
```

General description

The `__ipdbcs()` function determines the values that IP address resolution initialization found in the resolver configuration data set for the keywords `LoadDBCSTables`. If the `LoadDBCSTables` keywords are not found in the resolver configuration data set, the structure returned has a count of zero and each element in the structure list points to a NULL string.

Returned value

If successful, `__ipdbcs()` returns a NULL-terminated character string containing the complete structure `__ipdbcss` with each entry in `__ip_dbcs_list[]` initialized either to a valid name or to a NULL string. The number of valid names, up to the maximum of 8, is placed in `__ipdbcsnum`. If no table names are specified then `__ipdbcsnum` is set to zero.

If unsuccessful, `__ipdbcs()` returns NULL and stores one of the following error values in `h_errno`. `__ipdbcs()` is only unsuccessful if IP Address Resolution initialization fails to complete.

Error Code

Description

NO_RECOVERY

An error occurred that will continue to fail if tried again. Storage could not be obtained for this thread to contain the `_res` structure.

TRY_AGAIN

An error occurred while initializing the `__res_state` structure name selected, which can be retried.

Related information

__ipDomainName() – Retrieve the resolver supplied domain name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | OS/390 V2R9 |

Format

```
#include <__ftp.h>

char *__ipDomainName(void);
```

General description

Lets an application get the values which IP address resolution initialization established for the domain name (supplied by keywords Domain or DomainOrigin).

Returned value

If successful, __ipDomainName() returns the NULL-terminated character string which is the name found for the domain name or a NULL string if no domain name was found in the IP address resolution initialization.

If unsuccessful, __ipDomainName() returns NULL and stores one of the following error values in h_errno. The __ipDomainName() function is only unsuccessful if IP address resolution initialization fails to complete.

Error Code Description

NO_RECOVERY

An error occurred that will continue to fail if tried again. Storage could not be obtained for this thread to contain the _res structure.

TRY_AGAIN

An error occurred while initializing the __res_state structure name selected, which can be retried.

[__ipdspx\(\) – Retrieve the data set prefix specified](#)

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <__ftp.h>

char *__ipdspx(void);
```

General description

The __ipdspx() function determines the value that IP address resolution initialization found in the resolver configuration data set for the keyword DataSetPrefix. If no DataSetPrefix keyword is found in the resolver configuration data set, then the default value is returned.

Returned value

If successful, __ipdspx() returns the NULL-terminated character string that was supplied in the configuration data set. If the configuration data set did not supply a value for the keyword DataSetPrefix, then __ipdspx() returns the string TCPIP.

If unsuccessful, __ipdspx() returns NULL and stores one of the following error values in h_errno. __ipdspx() is only unsuccessful if IP Address Resolution initialization fails to complete.

| Error Code | Description |
|------------|-------------|
|------------|-------------|

NO_RECOVERY
An error occurred that will continue to fail if tried again. Storage could not be obtained for this thread to contain the _res structure.

__iphost() – Retrieve the resolver supplied hostname

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <__ftp.h>

char *__iphost(void);
```

General description

The __iphost() function lets an application determine the values that IP address resolution initialization found in the resolver configuration data set for the keyword HOSTname. If the keyword is not found in the resolver configuration data set, the char string returned will be a NULL string.

Returned value

If successful, __iphost() returns the NULL-terminated character string, which is the name supplied on the HOSTname keyword found in the resolver configuration file.

If unsuccessful, __iphost() returns NULL and stores one of the following error values in h_errno. __iphost() is only unsuccessful if IP Address Resolution initialization fails to complete.

Error Code Description

NO_RECOVERY

An error occurred that will continue to fail if tried again. Storage could not be obtained for this thread to contain the `_res` structure.

TRY_AGAIN

An error occurred while initializing the `__res_state` structure name selected, which can be retried.

[__ipmsgc\(\) — Determine the case to use for FTP messages](#)

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <__ftp.h>

int __ipmsgc(void);
```

General description

The `__ipmsgc()` function determines the value that IP address resolution initialization found in the resolver configuration data set for the keyword `MessageCase`. If no `MessageCase` keyword is found in the resolver configuration data set, then the default value is returned.

The *init* argument returned is one of the following set of symbols defined in the `__ftp.h` header file, each one stands for a message case selection.

__MIXED

Represents mixed case value selected for the messages FTP will send.

__UPPER

Represents uppercase value selected for the messages FTP will send.

Returned value

`__ipmsgc()` is always successful and returns either the value of the `__MIXED` or the value of `__UPPER` for all requests. `__MIXED` is the default value.

__ipnode() – Retrieve the resolver supplied node name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <__ftp.h>

char *__ipnode(void);
```

General description

The `__ipnode()` function lets an application determine the values that IP address resolution initialization found as the NodeID name used by the VMCF platform. If the VMCF nodeID name is not found, the char string returned will be a NULL string.

Returned value

If successful, `__ipnode()` returns the NULL-terminated character string, which is the name found for the VMCF platform.

If unsuccessful, `__ipnode()` returns NULL and stores one of the following error values in `h_errno`. `__ipnode()` is only unsuccessful if IP Address Resolution initialization fails to complete.

Error Code

Description

NO_RECOVERY

An error occurred that will continue to fail if tried again. Storage could not be obtained for this thread to contain the `_res` structure.

TRY_AGAIN

An error occurred while initializing the `__res_state` structure name selected, which can be retried.

__iptcpn() – Retrieve the resolver supplied jobname or user ID

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <__ftp.h>

char *__iptcpn(void);
```

General description

The `__iptcpn()` function lets an application determine the values that IP address resolution initialization found in the resolver configuration data set for either of the keywords `TCPIPuserid` or `TCPIPjobname`, whichever is the last one read. If neither keyword is found in the resolver configuration data set, the char string returned will be a NULL string.

Returned value

If successful, `__iptcpn()` returns the NULL-terminated character string which is the name supplied on the `TCPIPuserid` or `TCPIPjobname` keyword found in the resolver configuration file.

If unsuccessful, `__iptcpn()` returns NULL and stores one of the following error values in `h_errno`. `__iptcpn()` is only unsuccessful if IP Address Resolution initialization fails to complete.

Error Code

Description

NO_RECOVERY

An error occurred that will continue to fail if tried again. Storage could not be obtained for this thread to contain the `_res` structure.

TRY_AGAIN

An error occurred while initializing the `__res_state` structure name selected, which can be retried.

isalnum() to isxdigit() – Test integer value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <ctype.h>

int isalnum(int c);
int isalpha(int c);
int iscntrl(int c);
int isdigit(int c);
int isgraph(int c);
int islower(int c);
int isprint(int c);
int ispunct(int c);
```

```
int isspace(int c);
int isupper(int c);
int isxdigit(int c);
```

General description

The functions that are listed above, which are all declared in `ctype.h`, test a given integer value. The valid integer values for `c` are those representable as an *unsigned char* or EOF.

By default, the functions are defined as macros when `ctype.h` is included. For better performance, the macro forms are recommended over the functional forms.

However, to get the functional forms, do one or more of the following:

- For C only: do *not* include `ctype.h`.
- Specify `#undef`, for example, `#undef islower`
- Surround the call statement by parentheses, for example, `(islower)('a')`

Here are descriptions of each function in this group.

isalnum()

Test for an upper- or lowercase letter, or a decimal digit, as defined in the `alnum` locale source file and in the `alnum` class of the `LC_CTYPE` category of the current locale.

isalpha()

Test for an alphabetic character, as defined in the `alpha` locale source file and in the `alpha` class of the `LC_CTYPE` category of the current locale.

If the macro `_EXTEND_CTABLE` is defined, the integer values for `c` are those representable as an `unsigned char`, `signed char`, or EOF.

If the environment variable `_CTYPE_FUNC_EXT` is set, the functional forms support integer values representable as an `unsigned char`, `signed char`, or EOF.

iscntrl()

Test for any control character, as defined in the `cntrl` locale source file and in the `cntrl` class of the `LC_CTYPE` category of the current locale.

isdigit()

Test for a decimal digit, as defined in the `digit` locale source file and in the `digit` class of the `LC_CTYPE` category of the current locale.

isgraph()

Test for a printable character excluding space, as defined in the `graph` locale source file and in the `graph` class of the `LC_CTYPE` category of the current locale.

islower()

Test for a lowercase character, as defined in the `lower` locale source file and in the `lower` class of the `LC_CTYPE` category of the current locale.

isprint()

Test for a printable character including space, as defined in the `print` locale source file and in the `print` class of the `LC_CTYPE` category of the current locale.

ispunct()

Test for any nonalphanumeric printable character, excluding space, as defined in the `punct` locale source file and in the `punct` class of the `LC_CTYPE` category of the current locale.

isspace()

Test for a white space character, as defined in the `space` locale source file and in the `space` class of the `LC_CTYPE` category of the current locale.

isupper()

Test for an uppercase character, as defined in the `upper` locale source file and in the `upper` class of the `LC_CTYPE` category of the current locale.

isxdigit()

Test for a hexadecimal digit, as defined in the `xdigit` locale source file and in the `xdigit` class of the `LC_CTYPE` category of the current locale.

The space, uppercase, and lowercase characters can be redefined by their respective class of the `LC_CTYPE` in the current locale. The `LC_CTYPE` category is discussed in the “Internationalization: Locales and Character Sets” in *z/OS XL C/C++ Programming Guide*.

Returned value

If the integer satisfies the test condition, these functions return nonzero.

If the integer does not satisfy the test condition, these functions return 0.

Example**CELEBI02**

```
/* CELEBI02

This example analyzes all characters between code 0x0 and
code UPPER_LIMIT.
The output of this example is a 256-line table showing the
characters from 0 to 255, and a notification of whether they
have the attributes tested.

*/
#include <stdio.h>
#include <ctype.h>

#define UPPER_LIMIT 0xFF

int main(void)
{
    int ch;

    for ( ch = 0; ch <= UPPER_LIMIT; ++ch )
    {
        printf("%3d ", ch);
        printf("%#04x ", ch);
        printf(" %c", isprint(ch) ? ch : ' ');
        printf("%3s", isalnum(ch) ? "Alphanumeric" : " ");
        printf("%2s", isalpha(ch) ? "Alphabetic" : " ");
        printf("%2s", iscntrl(ch) ? "Control" : " ");
        printf("%2s", isdigit(ch) ? "Digit" : " ");
        printf("%2s", isgraph(ch) ? "Graphic" : " ");
        printf("%2s", islower(ch) ? "Lower" : " ");
        printf("%3s", ispunct(ch) ? "Punctuation" : " ");
        printf("%2s", isspace(ch) ? "Space" : " ");
        printf("%3s", isprint(ch) ? "Printable" : " ");
        printf("%2s", isupper(ch) ? "Upper" : " ");
        printf("%2s", isxdigit(ch) ? "Hex" : " ");

        putchar('\n');
    }
}
```

isalpha() – Test for an alphabetic character

The information for this function is included in [“isalnum\(\) to isxdigit\(\) – Test integer value” on page 895](#).

isascii() – Test for 7-bit US-ASCII character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

_XOPEN_SOURCE:

```
#define _XOPEN_SOURCE
#include <ctype.h>

int isascii(int c);
```

_ALL_SOURCE:

```
#define _ALL_SOURCE
#include <ctype.h>

int isascii(int c);
```

General description

Special behavior for _XOPEN_SOURCE: The isascii() function tests whether c is a 7-bit US-ASCII character code. The isascii() function is defined on all integer values.

Special behavior for _ALL_SOURCE: The isascii() function tests whether the character with EBCDIC encoding c in the current locale is a member of the set of POSIX Portable Characters and POSIX Control Characters shown below.

Returned value

Special behavior for _XOPEN_SOURCE: isascii() returns nonzero if c is a 7-bit US-ASCII character code between 0 and hexadecimal 007F inclusive; otherwise it returns 0.

Special behavior for _ALL_SOURCE: isascii() returns nonzero if c is the EBCDIC encoding in the current locale for a character in the set of POSIX Portable Characters and Control Characters; otherwise it returns 0.

Following is a list of the symbolic names, IBM-1047 EBCDIC code page encoding, and ISO8859-1 ASCII encoding for the set of POSIX Portable Characters and POSIX Control Characters. Cases where EBCDIC character encoding varies across EBCDIC Country Extended Code Pages (CECPs) are noted.

| Table 34. Characters for which isascii() returns nonzero | | |

isastream() — Test a file descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stropts.h>

int isastream(int fildes);
```

General description

The `isastream()` function tests whether *fildes*, an open file descriptor, is associated with a STREAMS-based file.

Returned value

If successful, `isastream()` returns 1 if *fildes* refers to a STREAMS-based file and 0 if not.

If unsuccessful, `isastream()` returns -1 and sets `errno` to one of the following values.

Note: z/OS UNIX services do not supply any STREAMS devices or pseudodevices. It is impossible for `isastream()` to return 1 since there are no STREAMS-based file descriptors. It will return 0 unless *fildes* is not a valid open file descriptor, in which case it will return -1 with `errno` set to indicate the failure. See [“open\(\) — Open a file” on page 1157](#)

Error Code

Description

EBADF

The *fildes* argument is not a valid open file descriptor.

Related information

- [“stropts.h — Stream interface” on page 67](#)

isatty() — Test if descriptor represents a terminal

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

int isatty(int fildes);
```

General description

Determines if a file descriptor, *fildes*, is associated with a terminal.

`isatty()` only works in an environment where either a controlling terminal exists, or `stdin` and `stderr` refer to tty devices. Specifically, it does not work in a TSO environment.

Returned value

isatty() returns 1 if the given file descriptor is a terminal, or 0 otherwise.

Special behavior for XPG4

isatty() returns 1 if the given file descriptor is a terminal, or 0 otherwise and sets errno to one of the following values:

Error Code

Description

EBADF

The *filides* argument is not a valid open file descriptor.

ENOTTY

The *filides* argument is not associated with a terminal.

Example

CELEBIO3

```
/* CELEBIO3

   This example determines if a file descriptor is
   associated with a terminal.

   */
#define _POSIX_SOURCE
#include <unistd.h>
#include <stdio.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <fcntl.h>

void check_fd(int fd) {
    printf("fd %d is ", fd);
    if (!isatty(fd))
        printf("NOT ");
    puts("a tty");
}

main() {
    int p[2], fd;
    char fn[]="temp.file";

    if (pipe(p) != 0)
        perror("pipe() error");
    else {
        if ((fd = creat(fn, S_IWUSR)) < 0)
            perror("creat() error");
        else {
            check_fd(0);
            check_fd(fileno(stderr));
            check_fd(p[1]);
            check_fd(fd);
            close(fd);
            unlink(fn);
        }
        close(p[0]);
        close(p[1]);
    }
}
```

Output

```
fd 0 is a tty
fd 2 is a tty
fd 4 is NOT a tty
fd 5 is NOT a tty
```

__isBFP() — Determine application floating-point format

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | OS/390 V2R6 |

Format

```
#include <_Ieee754.h>

int __isBFP(void);
```

General description

The `__isBFP()` function determines the application floating-point mode.

Returned value

`__isBFP()` returns 1 if the floating-point mode of the caller is IEEE, and returns 0 if the floating-point mode of the caller is hexadecimal.

Related information

- [“_Ieee754.h — IEEE 754 interfaces”](#) on page 28

isblank() — Test for blank character classification

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| Language Environment Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#include <ctype.h>

int isblank(int c);
```

General description

Tests whether the current `LC_CTYPE` locale category assigns `c` the blank character attribute. The *tab* and *space* characters have the blank attribute in the POSIX locale (with name “POSIX” or “C”).

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

Note: The `isblank()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support”](#) on page 2123 for details.

Returned value

`isblank()` returns nonzero if the current `LC_CTYPE` locale category assigns `c` the blank character attribute. Otherwise, `isblank()` returns 0.

Example

```
/* This example tests if c is a blank type. */
#include <stdio.h>
#include <ctype.h>
#include <locale.h>

void check(char c) {
    if ((c != ' ') && (isprint(c)))
        printf(" %c is ", c);
    else
        printf("x%02x is ", c);
    if (!isblank(c))
        printf("not ");
    puts("a blank type character");
}

main() {
    printf("\nIn LC_CTYPE category of locale \ with name \"%s\":\n",
        setlocale(LC_CTYPE, NULL));
    check('a');
    check(' ');
    check(0x00);
    check('\n');
    check('\t');
}
```

Output:

```
In LC_CTYPE category of locale with name ".....";
 a  is not a blank type character
x40 is a blank type character
x00 is not a blank type character
x15 is not a blank type character
x05 is a blank type character
```

iscics() – Verify whether CICS is running

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <cics.h>

int iscics(void);
```

General description

Determines whether the program is running under CICS.

Returned value

If your program is currently running under CICS, `iscics()` returns nonzero.

If not running under CICS, `iscics()` returns 0.

Example

CELEBI04

```
/* CELEBI04

   This example tests to see if the program is running under CICS.
   If not, it calls a subroutine ABCPGM; otherwise, it uses a CICS EXEC
   statement to invoke ABCPGM.

*/
#define _POSIX_SOURCE
#ifdef __cplusplus
extern "C" void ABCPGM(char *);
#else
#pragma linkage(ABCPGM, OS)
void ABCPGM(char *);
#endif

#include <stdio.h>
#include <cics.h>
#include <string.h>
#include <sys/wait.h>
#include <sys/types.h>
#include <unistd.h>

int main(void)
{
    char mydata[123];

    if (iscics() == 0)
    {
        /* not a CICS environment */
        ABCPGM(mydata);
    }

    else {
        /* this is a CICS environment */
        EXEC CICS, LINK PROGRAM,("ABCPGM  "), COMMAREA(mydata);
    }
}
```

isfinite() – Determines if its argument has a finite value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| C99 Single UNIX Specification, Version 3 C/C++ DFP C++ TR1 C99 | both | z/OS V1R8 |

Format

```
#define _ISOC99_SOURCE
#include <math.h>

int isfinite(real-floating x);

#define __STDC_WANT_DEC_FP__
#include <math.h>

int isfinite(real-floating x); /* C only */
int isfinite(decimal-floating x); /*C only */
bool isfinite(real-floating x); /* C++ only */

#define _TR1_C99
#include <math.h>

bool isfinite(real-floating x); /* C++ only */
```

General description

The isfinite() macro or function template determines if its argument has a finite value.

| Function | Hex | IEEE |
|----------|-----|------|
| isfinite | X | X |

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

The isfinite() macro returns 1 if and only if its argument value is finite, else returns 0. The C++ function template returns true if and only if its argument value is finite, else returns false.

Special behavior in hex: The isfinite() macro always returns 1. The C++ function template always returns true.

The information for this function is included in [“isalnum\(\) to isxdigit\(\) – Test integer value”](#) on page 895.

isgreater() — Determines if X is greater than Y

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| C99 Single UNIX Specification, Version 3 C/C++ DFP C++ TR1 C99 | both | z/OS V1R8 |

Format

```
#define _ISOC99_SOURCE
#include <math.h>

int isgreater(real-floating x, real-floating y);

#define __STDC_WANT_DEC_FP__
#include <math.h>

int isgreater(real-floating x, real-floating y); /* C only */
int isgreater(decimal-floating x, decimal-floating y); /* C only */
bool isgreater(real-floating x, real-floating y); /* C++ only */
bool isgreater(decimal-floating x, decimal-floating y); /* C++ only */

#define _TR1_C99
#include <math.h>

bool isgreater(real-floating x, real-floating y); /* C++ onl */
```

General description

The `isgreater()` macro or function template determines whether the argument `x` is greater than `y`. It is equivalent to `(x) > (y)`, but no exception is raised if `x` or `y` are NaN.

| Function | Hex | IEEE |
|------------------------|-----|------|
| <code>isgreater</code> | X | X |

Note:

- To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

The `isgreater()` macro returns 1 if the value of `x` is greater than `y`, else returns 0. The C++ function template returns `true` if the value of `x` is greater than `y`, else returns `false`.

Related information

- [“math.h — Floating-point math functions” on page 40](#)

isgreaterqual() — Determines if X is greater than or equal to Y

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| C99 Single UNIX Specification, Version 3 C/C++ DFP C++ TR1 C99 | both | z/OS V1R8 |

Format

```
#define _ISOC99_SOURCE
#include <math.h>

int isgreaterqual(real-floating x, real-floating y);

#define __STDC_WANT_DEC_FP__
#include <math.h>

int isgreaterqual(real-floating x, real-floating y); /* C only */
int isgreaterqual(decimal-floating x, decimal-floating y); /* C only */
bool isgreaterqual(real-floating x, real-floating y); /* C++ only */
bool isgreaterqual(decimal-floating x, decimal-floating y); /* C++ only */

#define _TR1_C99
#include <math.h>

bool isgreaterqual(real-floating x, real-floating y); /* C++ only */
```

General description

The `isgreaterqual()` macro or function template determines whether the argument `x` is greater than or equal to `y`. It is equivalent to $(x) \geq (y)$, but no exception is raised if `x` or `y` are NaN.

| Function | Hex | IEEE |
|----------------------------|-----|------|
| <code>isgreaterqual</code> | X | X |

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

The `isgreaterqual()` macro returns 1 if the value of `x` is greater than or equal to `y`, else returns 0. The C++ function template returns `true` if the value of `x` is greater than or equal to `y`, else returns `false`.

Related information

int isinf(real-floating x); /* C only */
int isinf(decimal-floating x); /* C only */
bool isinf(real-floating x); /* C++ only */

#define _TR1_C99
#include <math.h>

bool isinf(real-floating x); /* C++ only */
```

General description

The `isinf()` macro or function template determines if its argument is plus or minus infinity.

| Function | Hex | IEEE |
|----------|-----|------|
| isinf | X | X |

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

The `isinf()` macro returns 1 if the argument is plus or minus infinity, else returns 0. The C++ function template returns true if the argument is plus or minus infinity, else returns false.

Special behavior in hex: The `isinf()` macro returns 0. The C++ function template returns false.

islower() — Test for lowercase

The information for this function is included in [“isalnum\(\) to isxdigit\(\) — Test integer value”](#) on page 895.

ismccollet() — Identify a multicharacter collating element

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <collate.h>

int ismccollet(coll_t c);
```

General description

Determines whether a character is a multicharacter collating element. A collating element is a glyph, usually a character, that has a value used to define its order in a collating sequence. A multicharacter collating element is a sequence of two or more characters that are to be collated as one entity.

Returned value

ismccollet() returns:

- 1**
if coll_t represents a multicharacter collating element
- 0**
if coll_t represents a single-character collating element
- 1**
if coll_t is out of range, or otherwise not valid

Example

CELEBI05

```
/* CELEBI05

   This example prints all of the collating elements in the
   collating sequence, by using the &ismc. function to determine
   if the collating element is a multi-character collating
   element.

*/
#include <collate.h>
#include <locale.h>
#include <stdio.h>
#include <wchar.h>
#include <wctype.h>

main(int argc, char *argv[]) {
    coll_t e, *rp;
    int i;

    setlocale(LC_ALL, "");
    i = collorder(&rp);
    for (; i-- > 0; rp++) {
        if (ismccollet(*rp))
            printf("%s' ", colltostr(*rp));
        else if (iswprint(*rp))
            printf("%lc' ", *rp);
        else
            printf("%x' ", *rp);
    }
}
```

isnan() — Test for NaN

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 C/C++ DFP C++ TR1 C99 | both | z/OS V1R8 |

Format

```
#define _XOPEN_SOURCE
#include <math.h>

int isnan(double x);

#define __STDC_WANT_DEC_FP__
#include <math.h>

int isnan(real-floating x); /* C only */
int isnan(decimal-floating x); /* C only */
bool isnan(real-floating x); /* C++ only */
bool isnan(decimal-floating x); /* C++ only */

#define _TR1_C99
#include <math.h>

bool isnan(double x); /* C++ only */
```

General description

The `isnan()` function tests whether `x` is NaN (not a number).

`isnan()` is available as a macro. For better performance, the macro form is recommended over the functional form. For C compiles only, to use the functional form, do one of the following:

- Do not include `math.h`.
- Specify `#undef isnan` after the inclusion of `math.h`.
- Enclose the call statement in parentheses.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

For IEEE Decimal Floating Point numbers and Binary Floating Point numbers, a non-zero value is returned if *x* is a NaN. The C++ function template returns true if *x* is a NaN.

Special behavior in Hex

The `isnan()` macro returns 0. The C++ function template returns false.

Related information

- [“math.h — Floating-point math functions”](#) on page 40

isnormal() — Determines if X is normal

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| C99 Single UNIX Specification, Version 3 C/C++ DFP C++ TR1 C99 | both | z/OS V1R8 |

Format

```
#define _ISOC99_SOURCE
#include <math.h>

int isnormal(real-floating x);

#define __STDC_WANT_DEC_FP__
#include <math.h>

int isnormal(real-floating x); /* C only */
int isnormal(decimal-floating x); /* C only */
bool isnormal(real-floating x); /* C++ only */
bool isnormal(decimal-floating x); /* C++ only */

#define _TR1_C99
#include <math.h>

bool isnormal(real-floating x); /* C++ only */
```

General description

The `isnormal()` macro or function template determines if its argument value is normal, that is, not zero, infinity, subnormal or a NaN.

| Function | Hex | IEEE |
|-----------------------|-----|------|
| <code>isnormal</code> | X | X |

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

2. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

The `isnormal()` macro returns 1 if the argument value is normal, else returns 0. The C++ template returns true if the argument value is normal, else returns false.

Special behavior in Hex: For normalized numbers, `isnormal()` returns one. For zero or an unnormalized number, `isnormal()` returns 0. The C++ function template for normalized numbers, `isnormal()` returns true. For zero or a number that is not normalized, `isnormal()` returns false.

__isPosixOn() — Test for POSIX runtime option

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <unistd.h>

int __isPosixOn(void);
```

General description

The `__isPosixOn()` function returns 1 if the kernel is active and the POSIX runtime option is in effect for the calling process.

Returned value

The `__isPosixOn()` function returns 1 if the POSIX runtime option is in effect for the calling process and returns 0 otherwise.

If POSIX is in effect, then the kernel is active, although the kernel may be active without POSIX being in effect.

There are no `errno` values defined.

bool isunordered(real-floating x, real-floating y); /* C++ only */
```

General description

The `isunordered()` macro or function template determines if either `x` or `y` is unordered, that is if `x` or `y` is a NaN.

| Function | Hex | IEEE |
|--------------------------|-----|------|
| <code>isunordered</code> | X | X |

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

The `isunordered()` macro returns 1 if either `x` or `y` is unordered, else returns 0. The C++ function template returns true if either `x` or `y` is unordered, else returns false.

Special behavior in hex: The `isunordered()` macro always returns 0. The C++ function template always returns false.

int iswprint(wint_t wc);
int iswpunct(wint_t wc);
int iswspace(wint_t wc);
int iswupper(wint_t wc);
int iswxdigit(wint_t wc);
```

General description

The functions listed above, which are all declared in wctype.h, test a given wide integer value. These functions are sensitive to locale. For locale descriptions, see “Internationalization: Locales and Character Sets” in [z/OS XL C/C++ Programming Guide](#). Here are descriptions of each function in this group.

- iswalnum()**
Test for a wide alphanumeric character, as defined in the `alnum` locale source file and in the `alnum` class of the `LC_CTYPE` category of the current locale.
- iswalpna()**
Test for a wide alphabetic character, as defined in the `alpha` locale source file and in the `alpha` class of the `LC_CTYPE` category of the current locale.
- iswcntrl()**
Test for a wide control character, as defined in the `cntrl` locale source file and in the `cntrl` class of the `LC_CTYPE` category of the current locale.
- iswdigit()**
Test for a wide decimal-digit character: 0 through 9, as defined in the `digit` locale source file and in the `digit` class of the `LC_CTYPE` category of the current locale.
- iswgraph()**
Test for a wide printing character, not a space. as defined in the `graph` locale source file and in the `graph` class of the `LC_CTYPE` category of the current locale.

iswlower()

Test for a wide lowercase letter, as defined in the `lower` locale source file and in the `lower` class of the `LC_CTYPE` category of the current locale.

iswprint()

Test for any wide printing character, as defined in the `print` locale source file and in the `print` class of the `LC_CTYPE` category of the current locale.

iswpunct()

Test for a wide nonalphanumeric, nonspace character, as defined in the `punct` locale source file and in the `punct` class of the `LC_CTYPE` category of the current locale.

iswspace()

Test for a wide white space character, as defined in the `space` locale source file and in the `space` class of the `LC_CTYPE` category of the current locale.

iswupper()

Test for a wide uppercase letter, as defined in the `upper` locale source file and in the `upper` class of the `LC_CTYPE` category of the current locale.

iswxdigit()

Test for a wide hexadecimal digit 0 through 9, a through f, or A through F, as defined in the `xdigit` locale source file and in the `xdigit` class of the `LC_CTYPE` category of the current locale.

The behavior of these wide-character function are affected by the `LC_CTYPE` category of the current locale. The space, uppercase, and lowercase characters can be redefined by their respective class of the `LC_CTYPE` in the current locale. If you change the category, undefined results can occur.

Returned value

If the wide integer satisfies the test value, these functions return nonzero.

If the wide integer does not satisfy the test value, these functions return 0.

The value for `wc` must be representable as a wide unsigned character. `WEOF` is a valid input value.

Example**CELEBI06**

```
/* CELEBI06

   This example tests for various wide integer values and prints a result.

*/
#include <stdio.h>
#include <wctype.h>

int main(void)
{
    wint_t wc;

    for (wc=0; wc <= 0xFF; wc++) {
        printf("%3d", wc);
        printf(" %#4x ", wc);
        printf("%3s", iswalnum(wc) ? "AN" : " ");
        printf("%2s", iswalph(wc) ? "A" : " ");
        printf("%2s", iswcntl(wc) ? "C" : " ");
        printf("%2s", iswdigit(wc) ? "D" : " ");
        printf("%2s", iswgraph(wc) ? "G" : " ");
        printf("%2s", iswlower(wc) ? "L" : " ");
        printf(" %c", iswprint(wc) ? wc : ' ');
        printf("%3s", iswpunct(wc) ? "PU" : " ");
        printf("%2s", iswspace(wc) ? "S" : " ");
        printf("%3s", iswprint(wc) ? "PR" : " ");
        printf("%2s", iswupper(wc) ? "U" : " ");
        printf("%2s", iswxdigit(wc) ? "X" : " ");

        putchar('\n');
    }
}
```

iswblank() — Test for blank character classification

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| Language Environment C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#include <wctype.h>

int iswblank(wint_t wc);
```

C99:

```
#define _ISOC99_SOURCE
#include <wctype.h>

int iswblank(wint_t wc);
```

General description

Tests for a wide blank character.

The space, uppercase, and lowercase characters can be redefined by their respective classes of the LC_CTYPE in the current locale.

For use as a C library function: To avoid infringing on the user's name space, this nonstandard function has two names. One name, `__iswblk()`, and the other as shown above. The name shown above is exposed only when under the [extended language level](#) or define the `_EXT` feature test macro.

For use as a z/OS UNIX function: Define the `_OPEN_SYS` feature test macro.

Note: The `iswblank()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support” on page 2123](#) for details.

Returned value

If the wide integer satisfies the test value, `iswblank()` returns nonzero.

If the wide integer does not satisfy the test value, `iswblank()` returns 0.

The value for `wc` must be representable as a wide unsigned char. WEOF is a valid input value.

The behavior of `iswblank()` is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Related information

- [“wctype.h — Wide character properties” on page 81](#)
- [“isblank\(\) — Test for blank character classification” on page 905](#)
- [“iswalnum\(\) to iswxdigit\(\) — Test wide integer value” on page 920](#)

iswcntrl() — Test for control classification

The information for this function is included in [“iswalnum\(\) to iswxdigit\(\) — Test wide integer value”](#) on page 920.

iswctype() — Test for character property

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <wctype.h>

int iswctype(wint_t wc, wctype_t wc_prop);
```

General description

Determines whether the wide character *wc* has the property *wc_prop*. If the value of *wc* is neither WEOF nor any value of the wide character that corresponds to a multibyte character, the behavior is undefined. If the value of *wc_prop* is not valid (that is, not obtained by a previous call to *wctype()*, or *wc_prop* has been invalidated by a subsequent call to *setlocale()* that has affected category LC_CTYPE), the behavior is undefined.

These twelve strings are reserved for the standard (basic) character classes: *alnum*, *alpha*, *blank*, *cntrl*, *digit*, *graph*, *lower*, *print*, *punct*, *space*, *upper*, and *xdigit*.

The functions are shown below with their equivalent *isw*()* function:

```
iswctype(wc, wctype("alnum")); - iswalnum(wc);
iswctype(wc, wctype("alpha")); - iswalpha(wc);
iswctype(wc, wctype("blank")); - iswblank(wc);
iswctype(wc, wctype("cntrl")); - iswcntrl(wc);
iswctype(wc, wctype("digit")); - iswdigit(wc);
iswctype(wc, wctype("graph")); - iswgraph(wc);
iswctype(wc, wctype("lower")); - iswlower(wc);
iswctype(wc, wctype("print")); - iswprint(wc);
iswctype(wc, wctype("punct")); - iswpunct(wc);
iswctype(wc, wctype("space")); - iswspace(wc);
iswctype(wc, wctype("upper")); - iswupper(wc);
iswctype(wc, wctype("xdigit")); - iswxdigit(wc);
```

Returned value

iswctype() returns nonzero (true) if the wide character *wc* has the property *wc_prop*.

Example

CELEBI07

```
/* CELEBI07

This example test various wide characters for certain properties and
prints the result.
```

```

    */
#include <stdio.h>
#include <wchar.h>
#include <wctype.h>

int main(void)
{
    int wc;

    for (wc=0; wc <= 0xFF; wc++) {
        printf("%3d", wc);
        printf(" %#4x ", wc);
        printf("%3s", iswctype(wc, wctype("alnum")) ? "AN" : " ");
        printf("%2s", iswctype(wc, wctype("alpha")) ? "A" : " ");
        printf("%2s", iswctype(wc, wctype("cntrl")) ? "C" : " ");
        printf("%2s", iswctype(wc, wctype("digit")) ? "D" : " ");
        printf("%2s", iswctype(wc, wctype("graph")) ? "G" : " ");
        printf("%2s", iswctype(wc, wctype("lower")) ? "L" : " ");
        printf("%c", iswctype(wc, wctype("print")) ? wc : ' ');
        printf("%3s", iswctype(wc, wctype("punct")) ? "PU" : " ");
        printf("%2s", iswctype(wc, wctype("space")) ? "S" : " ");
        printf("%3s", iswctype(wc, wctype("print")) ? "PR" : " ");
        printf("%2s", iswctype(wc, wctype("upper")) ? "U" : " ");
        printf("%2s", iswctype(wc, wctype("xdigit")) ? "X" : " ");

        putchar('\n');
    }
}

```

itoa() — Convert int into a string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R5 |

Format

```
#define _OPEN_SYS_ITOA_EXT
#include <stdlib.h>

char * itoa(int n, char * buffer, int radix);
```

General description

The `itoa()` function converts the integer `n` into a character string. The string is placed in the buffer passed, which must be large enough to hold the output. The radix values can be OCTAL, DECIMAL, or HEX. When the radix is DECIMAL, `itoa()` produces the same result as the following statement:

```
(void) sprintf(buffer, "%d", n);
```

with `buffer` the returned character string. When the radix is OCTAL, `itoa()` formats integer `n` into an unsigned octal constant. When the radix is HEX, `itoa()` formats integer `n` into an unsigned hexadecimal constant. The hexadecimal value will include lower case `abcdef`, as necessary.

Returned value

String pointer (same as `buffer`) will be returned. When passed a non-valid radix argument, function will return NULL and set `errno` to `EINVAL`.

Portability considerations

This is a non-standard function. Even though the prototype given is commonly used by compilers on other platforms, there is no guarantee that this function will behave the same on all platforms, in all cases. You can use this function to help port applications from other platforms, but you should avoid using it when writing new applications, in order to ensure maximum portability.

Example

CELEBI12

```

/* CELEBI12

   This example reads an int and formats it to decimal, unsigned
   octal, and unsigned hexadecimal constants converted to a
   character string.

*/

#define _OPEN_SYS_ITOA_EXT
#include <stdio.h>
#include <stdlib.h>

int main ()
{
    int i;
    char buffer [sizeof(int)*8+1];
    printf ("Enter a number: ");
    if (scanf ("%d",&i) == 1) {
        itoa (i,buffer,DECIMAL);
        printf ("decimal: %s\n",buffer);
        itoa (i,buffer,HEX);
        printf ("hexadecimal: %s\n",buffer);
        itoa (i,buffer,OCTAL);
        printf ("octal: %s\n",buffer);
    }
    return 0;
}

```

Output

If the input is 1234, then the output should be:

```

decimal: 1234
hexadecimal: 4d2
octal: 2322

```

JoinWorkUnit() — Join a WLM work unit

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```

#include <sys/_wlm.h>

int JoinWorkUnit(wlmetok_t *enclavetoken);

```

General description

The JoinWorkUnit function provides the ability for an application to join a WLM work unit.

***enclavetoken**

Points to a work unit enclave token that was returned from a call to either CreateWorkUnit() or ContinueWorkUnit().

Returned value

If successful, JoinWorkUnit() returns 0.

If unsuccessful, JoinWorkUnit() returns -1 and sets errno to one of the following values:

Error Code

Description

EFAULT

An argument of this function contained an address that was not accessible to the caller.

EINVAL

An argument of this function contained an incorrect value.

EMVSSAF2ERR

An error occurred in the security product.

EMVSWLMERROR

The WLM join enclave failed. Use __errno2() to obtain the WLM service reason code for the failure.

EPERM

The calling thread's address space is not permitted to the BPX.WLMSERVER Facility class. The caller's address space must be permitted to the BPX.WLMSERVER Facility class if it is defined. If BPX.WLMSERVER is not defined, the calling process is not defined as a superuser (UID=0).

jrand48() — Pseudo-random number generator

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <stdlib.h>

long int jrand48(unsigned short int x16v[3]);
```

General description

The drand48(), erand48(), jrand48(), lrand48(), mrand48() and nrand48() functions generate uniformly distributed pseudo-random numbers using a linear congruential algorithm and 48-bit integer arithmetic.

The functions drand48() and erand48() return nonnegative, double-precision, floating-point values, uniformly distributed over the interval [0.0,1.0).

The functions lrand48() and nrand48() return nonnegative, long integers, uniformly distributed over the interval [0,2**31).

The functions mrand48() and jrand48() return signed long integers, uniformly distributed over the interval [-2**31,2**31).

The jrand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, X(i), according to the linear congruential formula:

$$X(n+1) = (aX(n) + c) \bmod (2^{**}48) \quad n \geq 0$$

The jrand48() function uses storage provided by the argument array, x16v[3], to save the most recent 48-bit integer value in the sequence, X(i). The jrand48() function uses x16v[0] for the low-order (rightmost) 16 bits, x16v[1] for the middle-order 16 bits, and x16v[2] for the high-order 16 bits of this value.

The initial values of a, and c are:

```
a  = 5deece66d (base 16)
c  = b         (base 16)
```

The values a and c, may be changed by calling the lcong48() function. The initial values of a and c are restored if either the seed48() or srand48() function is called.

Special behavior for z/OS UNIX Services: You can make the jrand48() function and other functions in the drand48 family thread-specific by setting the environment variable _RAND48 to the value THREAD before calling any function in the drand48 family.

If you do not request thread-specific behavior for the drand48 family, C/370 serializes access to the storage for X(n), a and c by functions in the drand48 family when they are called by a multithreaded application.

If thread-specific behavior is requested and the jrand48() function is called from thread t, the jrand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, X(t,i), for the thread according to the linear congruential formula:

$$X(t,n+1) = (a(t)X(t,n) + c(t)) \bmod (2^{**}48) \quad n \geq 0$$

The jrand48() function uses storage provided by the argument array, x16v[3], to save the most recent 48-bit integer value in the sequence, X(t,i). The jrand48() function uses x16v[0] for the low-order (rightmost) 16 bits, x16v[1] for the middle-order 16 bits, and x16v[2] for the high-order 16 bits of this value.

The initial values of a(t) and c(t) on the thread t are:

```
a(t) = 5deece66d (base 16)
c(t) = b         (base 16)
```

The values a(t) and c(t) may be changed by calling the lcong48() function from the thread t. The initial values of a(t) and c(t) are restored if either the seed48() or srand48() function is called from the thread.

Returned value

`jrand48()` saves the generated 48-bit value, $X(n+1)$, in storage provided by the argument array, `x16v[3]`. `jrand48()` transforms the generated 48-bit value to a signed long integer value on the interval $[-2^{31}, 2^{31})$ and returns this transformed value.

Special behavior for z/OS UNIX Services: If thread-specific behavior is requested for the `drand48` family and the `jrand48()` function is called on thread `t`, the `jrand48()` function saves the generated 48-bit value, $X(t, n+1)$, in storage provided by the argument array, `x16v[3]`. The `jrand48()` function transforms the generated 48-bit value to a signed long integer value on the interval $[-2^{31}, 2^{31})$ and returns this transformed value.

j0(), j1(), jn() — Bessel functions of the first kind

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| SAA XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

SAA:

```
#include <math.h>

double j0(double x);
double j1(double x);
double jn(int n, double x);
```

This function must be used with the [runtime library extensions](#) or under the [SAA based language constructs](#).

General description

The `j0()`, `j1()`, and `jn()` functions are Bessel functions of the *first kind*, for orders 0, 1, and n , respectively. Bessel functions are solutions to certain types of differential equations. The argument x must be positive. The argument n should be greater than or equal to 0. If n is less than 0, there will be a negative exponent in the result.

Note: This function works in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

Returned value

If successful, the calculated value is returned.

For j0(), j1(), y0(), or y1(), if the absolute value of x is too large, the function sets errno to ERANGE to indicate a value that is out of range, and returns 0.

Special behavior for IEEE: If x is negative, y0(), y1(), and yn() return the value NaNQ. If x is 0, y0(), y1(), and yn() return the value -HUGE_VAL. In all cases, errno remains unchanged.

Example

CELEBJ01

```
/* CELEBJ01

   This example computes y to be the order 0 Bessel function of
   the first kind for x, and z to be the order 3 Bessel function
   of the second kind for x.

*/
#include <math.h>
#include <stdio.h>

int main(void)
{
    double x, y, z;
    x = 4.27;

    y = j0(x);      /* y = -0.3660 is the order 0 bessel */
                   /* function of the first kind for x */
    z = yn(3,x);    /* z = -0.0875 is the order 3 bessel */
                   /* function of the second kind for x */
    printf("x = %f\n y = %f\n z = %f\n", x, y, z);
}
```

kill() — Send a signal to a process

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _POSIX_SOURCE
#include <signal.h>
```

```
int kill(pid_t pid, int sig);
```

General description

Sends a signal to a process or process group. A process has permission to send a signal if the real or effective user ID of the sender is the same as the real or effective user ID of the intended recipient. A process can also send signals if it has appropriate privileges. If `_POSIX_SAVED_IDS` is defined in the `unistd.h` header file, the saved set user ID of the intended recipient is checked instead of its effective user ID.

Regardless of user ID, a process can always send a `SIGCONT` signal to a process that is a member of the same session (same session ID) as the sender.

You can use either `signal()` or `sigaction()` to specify how a signal will be handled when `kill()` is invoked.

A process can use `kill()` to send a signal to itself. If the signal is not blocked or ignored, at least one pending unblocked signal is delivered to the sender before `kill()` returns. If there are no other pending unblocked signals, the delivered signal is `sig`.

`pid` can be used to specify these processes:

pid_t pid;

Specifies the processes that the caller wants to send a signal to:

- If `pid` is greater than 0, `kill()` sends its signal to the process whose ID is equal to `pid`.
- If `pid` is equal to 0, `kill()` sends its signal to all processes whose process group ID is equal to that of the sender, except for those that the sender does not have appropriate privileges to send a signal to.
- If `pid` is -1, `kill()` returns -1.
- **Special behavior for XPG4.2:** If `pid` is -1, `kill()` sends the signal, `sig`, to all processes, except for those to which the sender does not have appropriate privileges to send a signal.
- If `pid` is less than -1, `kill()` sends its signal to all processes whose process group ID is equal to the absolute value of `pid`, except for those that the sender does not have appropriate privileges to send a signal to.

int sig;

The signal that should be sent to the processes specified by `pid`. (For a list of signals, see Table 57 on page 1606.) This must be 0 or one of the signals defined in the `signal.h` header file. If `sig` is 0, `kill()` performs error checking but does not send a signal. You can code `sig` as 0 to check whether the `pid` argument is valid.

This function is supported only in a POSIX program. You can use it to pass `SIGIOERR`.

Usage notes

The use of the `SIGTSTP` and `SIGTCONT` signal is not supported with this function.

Returned value

`kill()` returns 0 if it has permission to send `sig` to any of the processes specified by `pid`.

If `kill()` fails to send a signal, it returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

The value of `sig` is incorrect or is not the number of a supported signal.

EPERM

The caller does not have permission to send the signal to any process specified by `pid`.

ESRCH

There are no processes or process groups corresponding to `pid`.

Example

CELEBK01

```

/* CELEBK01 */
#define _POSIX_SOURCE
#include <signal.h>
#include <stdio.h>
#include <sys/types.h>
#include <unistd.h>
#include <sys/wait.h> /*FIX: used to be <wait.h>*/

main() {
    sigset_t sigset;
    int     p[2], status;
    char    c='z';
    pid_t   pid;

    if (pipe(p) != 0)
        perror("pipe() error");
    else {
        if ((pid = fork()) == 0) {
            sigemptyset(&sigset);
            puts("child is letting parent know he's ready for signal");
            write(p[1], &c, 1);
            puts("child is waiting for signal");
            sigsuspend(&sigset);
            exit(0);
        }

        puts("parent is waiting for child to say he's ready for signal");
        read(p[0], &c, 1);
        puts("child has told parent he's ready for signal");

        kill(pid, SIGTERM);

        wait(&status);
        if (WIFSIGNALED(status))
            if (WTERMSIG(status) == SIGTERM)
                puts("child was ended with a SIGTERM");
            else
                printf("child was ended with a %d signal\n", WTERMSIG(status));
            else puts("child was not ended with a signal");

        close(p[0]);
        close(p[1]);
    }
}

```

Output

```

parent is waiting for child to say he's ready for signal
child is letting parent know he's ready for signal
child is waiting for signal
child has told parent he's ready for signal
child was ended with a SIGTERM

```

killpg() — Send a signal to a process group

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <signal.h>

int killpg(pid_t pgrp, int sig);
```

General description

The `killpg()` function sends a signal to a process group.

A process has permission to send a signal if the real or effective user ID of the sender is the same as the real or effective user ID of the intended recipient. A process can also send signals if it has appropriate privileges. If `_POSIX_SAVED_IDS` is defined in the `<unistd.h>` include file, the saved set user ID of the intended recipient is checked instead of its effective user ID.

Regardless of user ID, a process can always send a `SIGCONT` signal to a process group that is a member of the same session (same session ID) as the sender.

pid_t pgrp;

Specifies the process group that the caller wants to send a signal to:

- If *pgrp* is greater than one, `killpg()` sends the signal, *sig*, to the process whose process group ID is equal to *pgrp* and which the sender has appropriate privileges to send a signal.
- If *pgrp* is equal to or less than one, `killpg()` returns a -1 and sets `errno` to `EINVAL`.

int sig;

The signal that should be sent to the processes specified by *pid*. (For a list of signals, see [Table 57 on page 1606](#).) This must be zero, or one of the signals defined in the `<signal.h>` include file. If *sig* is zero, `killpg()` performs error checking but doesn't really send a signal. You can code *sig* as zero to check whether the *pid* argument is valid.

This function is supported only in a POSIX program.

Usage notes

The use of the `SIGTSTP` and `SIGTCONT` signal is not supported with this function.

Returned value

If successful, `killpg()` returns 0 if it has permission to send *sig* to any of the processes in the process group ID specified by *pgrp*.

If unsuccessful, `killpg()` returns -1 and sets `errno` to one of the following values:

Error Code
Description

EINVAL

The value of *sig* is incorrect or is not the number of a supported signal, or the value of *pgrp* is less than or equal to one.

EPERM

The caller does not have permission to send the signal to any process in the process group ID specified by *pgrp*.

ESRCH

There are no process groups corresponding to *pgrp*.

labs() — Calculate long absolute value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdlib.h>

long int labs(long int n);
```

General description

Calculates the absolute value of its long integer argument *n*. The result is undefined when the argument is equal to LONG_MIN, the smallest available long integer (-2 147 483 648). The value LONG_MIN is defined in the limits.h header file.

Returned value

Returns the absolute value of the long integer argument *n*.

Example

CELEBL01

```
/* CELEBL01

   This example computes y as the absolute value of
   the long integer -41567.

*/
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    long x, y;

    x = -41567L;
    y = labs(x);

    printf("The absolute value of %ld is %ld\n", x, y);
}
```

Output

```
The absolute value of -41567 is 41567
```

__lchattr(), __lchattr64() — Change the attributes of a file or directory when they point to a symbolic or external link

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R5 |

Format

__lchattr:

```
#define _OPEN_SYS_FILE_EXT 1
#include <sys/stat.h>

int __lchattr (char *pathname, attrib_t *attributes, int attributes_len);
```

__lchattr64:

```
#define _LARGE_TIME_API
#define _OPEN_SYS_FILE_EXT 1
#include <sys/stat.h>

int __lchattr64(char *pathname, attrib64_t *attributes, int attributes_len);
```

Compile requirement: Use of the `__lchattr64` function requires the `long long` data type. For more information on how to make the `long long` data type available, see [z/OS XL C/C++ Language Reference](#).

General description

The `__lchattr()` function modifies the attributes that are associated with a file. The *pathname* specifies a symbolic or external link (a pointer to another file, directory, or data set).

The `__lchattr()` service changes the attributes of the symbolic link itself, provided the attributes requested can apply to a symbolic link. Only the owner and security label can be changed for a symbolic link, all other attributes do not apply and will be ignored.

The attributes argument is the address of an `attrib_t` structure which is used to identify the attributes to be modified and the new values desired. The `attrib_t` type is an `f_attributes` structure as defined in `<sys/stat.h>` for use with the `__lchattr()` function. For proper behavior, the user should ensure that this structure has been initialized to zeros before it is populated. The `f_attributes` structure is defined as indicated in [Table 20 on page 262](#).

The `__lchattr64()` function behaves exactly like `__lchattr()` except `__lchattr64()` uses `struct attrib64_t` instead of `struct attrib_t` to support time beyond 03:14:07 UTC on January 19, 2038.

The `attrib64_t` type is an `f_attributes64` structure as defined in `<sys/stat.h>` for use with the `__lchattr64()` function.

Returned value

If successful, `__lchattr()` returns 0.

If unsuccessful, `__lchattr()` returns -1 and sets `errno` to one of the following values:

EACCES

The calling process did not have appropriate permissions. Possible reasons include:

- The calling process was attempting to set access time or modification time to current time, and the effective UID of the calling process does not match the owner of the file; the process does not have write permission for the file; or the process does not have appropriate privileges.
- The calling process was attempting to truncate the file, and it does not have write permission for the file.

EFBIG

The calling process was attempting to change the size of a file, but the specified length is greater than the maximum file size limit for the process.

EINVAL

The attributes structure containing the requested changes is not valid.

ELOOP

A loop exists in symbolic links that were encountered during resolution of the *pathname* argument. This error is issued if more than 24 symbolic links are detected in the resolution of *pathname*.

ENAMETOOLONG

pathname is longer than 1023 characters, or a component of the *pathname* is longer than 255 characters (Filename truncation is not supported).

ENOENT

No file named *pathname* was found.

ENOTDIR

Some component of *pathname* is not a directory.

EPERM

The operation is not permitted for one of the following reasons:

- The calling process was attempting to change the mode or the file format, but the effective UID of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges.
- The calling process was attempting to change the owner, but it does not have appropriate privileges.
- The calling process was attempting to change the general attribute bits, but it does not have write permission for the file.
- The calling process was attempting to set a time value (not current time), but the effective user ID does not match the owner of the file, and it does not have appropriate privileges.
- The calling process was attempting to set the change time or reference time to current time, but it does not have write permission for the file.
- The calling process was attempting to change auditing flags, but the effective UID of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges.
- The calling process was attempting to change the Security Auditor's auditing flags, but the user does not have auditor authority.
- Attributes indicate that the security label is to be set, and one or more of the following conditions applies:
 - The calling process does not have RACF SPECIAL authorization and appropriate privileges.
 - The security label currently associated with the file is already set.

EROFS

pathname specifies a file that is on a read-only file system.

Related information

- [“sys/stat.h — z/OS UNIX files and access” on page 70](#)
- [“__fchattr\(\), __fchattr64\(\) — Change the attributes of a file or directory by file descriptor” on page 471](#)
- [“__chattr\(\), __chattr64\(\) — Change the attributes of a file or directory” on page 261](#)

lchown() — Change owner and group of a file

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int lchown(const char *path, uid_t owner, gid_t group);
```

General description

The `lchown()` function has the same effect as `chown()` except in the case where the named file is a symbolic link. In this case `lchown()` changes the ownership of the symbolic link file itself, while `chown()` changes the ownership of the file or directory to which the symbolic link refers.

Returned value

If successful, `lchown()` returns 0.

If unsuccessful, `lchown()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

Search permission is denied on a component of the path prefix of *path*.

EINVAL

The owner or group id is not a value supported by the implementation.

ELOOP

Too many symbolic links were encountered in resolving *path*

ENAMETOOLONG

The length of a pathname exceeds **PATH_MAX** or a pathname component is longer than **NAME_MAX**.

ENOENT

A component of *path* does not name an existing file or *path* is an empty string.

ENOTDIR

A component of the path prefix of *path* is not a directory.

EOPNOTSUPP

The *path* argument names a symbolic link and the implementation does not support setting the owner or group of a symbolic link.

EPERM

The effective user ID does not match the owner of the file and the process does not have appropriate privileges.

EROFS

The file resides on a read-only file system.

The `lchown()` function may fail if:

Error Code

Description

EINTR

A signal was caught during execution of the function.

EIO

An I/O error occurred while reading or writing to the file system.

ENAMETOOLONG

Pathname resolution of a symbolic link produced an intermediate result whose length exceeds **PATH_MAX**.

Related information

- [“unistd.h — Implementation-specific functions” on page 77](#)

lcong48() – Pseudo-random number initializer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <stdlib.h>

void lcong48(unsigned short int param[7]);
```

General description

The drand48(), erand48(), jrand48(), lrand48(), mrand48() and nrand48() functions generate uniformly distributed pseudo-random numbers using a linear congruential algorithm and 48-bit integer arithmetic.

The lcong48(), seed48(), and srand48() functions are initialization functions, one of which should be invoked before either the drand48(), lrand48() or mrand48() function is called.

The drand48(), lrand48() and mrand48() functions generate a sequence of 48-bit integer values, X(i), according to the linear congruential formula:

$$X(n+1) = (aX(n) + c) \bmod (2^{**}48) \quad n \geq 0$$

The initial values of X, a, and c are:

```
X(0) = 1
a    = 5deece66d (base 16)
c    = b          (base 16)
```

C/370 provides storage to save the most recent 48-bit integer value of the sequence, X(i). This storage is shared by the drand48(), lrand48() and mrand48() functions. The lcong48() function is used to reinitialize the most recent 48-bit value in this storage. The lcong48() function replaces the low-order (rightmost) 16 bits of this storage with *param*[0], the middle-order 16 bits with *param*[1], and the high-order 16 bits with *param*[2].

The values a and c, may also be changed by calling the lcong48() function. The lcong48() function replaces the low-order (rightmost) 16 bits of a with *param*[3], the middle-order 16 bits with *param*[4], and the high-order 16 bits with *param*[5]. The lcong48() function replaces c with *param*[6].

Special behavior for z/OS UNIX Services: You can make the lcong48() function and other functions in the drand48 family thread-specific by setting the environment variable `_RAND48` to the value `THREAD` before calling any function in the drand48 family.

If you do not request thread-specific behavior for the drand48 family, C/370 serializes access to the storage for X(n), a and c by functions in the drand48 family when they are called by a multithreaded application.

If thread-specific behavior is requested, calls to the drand48(), lrand48() and mrand48() functions from thread *t* generate a sequence of 48-bit integer values, X(t,i), according to the linear congruential formula:

$$X(t,n+1) = (a(t)X(t,n) + c(t)) \bmod (2^{**}48) \quad n \geq 0$$

C/370 provides thread-specific storage to save the most recent 48-bit integer value of the sequence, X(t,i). When the lcong48() function is called from thread *t*, it reinitializes the most recent 48-bit value

in this storage. The `lcong48()` function replaces the low-order (rightmost) 16 bits of this storage with `param[0]`, the middle-order 16 bits with `param[1]`, and the high-order 16 bits with `param[2]`.

The `lcong48()` function may also be used to change values of `a(t)` and `c(t)` for the thread `t`. The `lcong48()` function replaces the low-order (rightmost) 16 bits of `a(t)` with `param[3]`, the middle-order 16 bits with `param[4]`, and the high-order 16 bits with `param[5]`. The `lcong48()` function replaces `c(t)` with `param[6]`.

Returned value

After `lcong48()` has used values from the argument array, `param[7]`, to change the values of `a` and `c` and to reinitialized storage for the most recent 48-bit integer value in the sequence, `X(i)`, it returns.

Special behavior for z/OS UNIX Services: If thread-specific behavior is requested for the `drand48` family and `lcong48()` is called on thread `t`, it uses the argument array, `param[7]`, to change the values of `a(t)` and `c(t)` and to reinitialize storage for the most recent 48-bit integer value in the sequence, `X(t,i)`, for the thread. Then it returns.

ldexp(), ldexpf(), ldexpl() — Multiply by a power of two

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#include <math.h>

double ldexp(double x, int exp);
float ldexp(float x, int exp);          /* C++ only */
long double ldexp(long double x, int exp); /* C++ only */
float ldexpf(float x, int exp);
long double ldexpl(long double x, int exp);
```

General description

Calculates the value of $x \cdot (2^{\text{exp}})$.

Restriction: The `ldexpf()` and `ldexpl()` functions do not support the `_FP_MODE_VARIABLE` feature test macro.

Returned value

Returns the calculated value.

Otherwise, if the correct calculated value is outside the range of representable values, `±HUGE_VAL` is returned, according to the sign of the value. The value `ERANGE` is stored in `errno` to indicate that the result was out of range.

Special behavior for XPG4.2:

Error Code

Description

ERANGE

The result underflowed. `ldexp()` returns 0.0.

Example

CELEBL02

```
/* CELEBL02
   This example computes y = 1.5*2**5.
*/
#include <math.h>
#include <stdio.h>

int main(void)
{
    double x, y;
    int p;

    x = 1.5;
    p = 5;
    y = ldexp(x,p);

    printf("%lf times 2 to the power of %d is %Lf\n", x, p, y);
}
```

Output

```
1.500000 times 2 to the power of 5 is 48.000000
```

Related information

ldexpd32(), ldexpd64(), ldexpd128() — Multiply by a power of ten

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 ldexpd32(_Decimal32 x, int exp);
_Decimal64 ldexpd64(_Decimal64 x, int exp);
_Decimal128 ldexpd128(_Decimal128 x, int exp);

_Decimal32 ldexp(_Decimal32 x, int exp); /* C++ only */
_Decimal64 ldexp(_Decimal64 x, int exp); /* C++ only */
_Decimal128 ldexp(_Decimal128 x, int exp); /* C++ only */
```

General description

Calculates the value of $x \cdot 10^{\text{exp}}$.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

Returns the calculated value.

Otherwise, if the correct calculated value is outside the range of representable values, $\pm\text{HUGE_VAL_D32}$, $\pm\text{HUGE_VAL_D64}$, or $\pm\text{HUGE_VAL_D128}$ is returned, according to the sign of the value. The value ERANGE is stored in errno to indicate that the result was out of range.

Example

```
/* CELEBL19

   This example illustrates the ldexpd32() function.

   This example computes y = 1.5*10**5

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal32 x, y;
    int p;

    x = 1.5DF;
    p = 5;
    y = ldexpd32(x, p);

    printf("%Hf times 10 to the power of %d is %Hf\n", x, p, y);
}
```

ldiv() — Compute quotient and remainder of integral division

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdlib.h>

ldiv_t ldiv(long int numerator, long int denominator);
```

General description

Calculates the quotient and remainder of the division of *numerator* by *denominator*.

Returned value

Returns a structure of type `ldiv_t`, containing both the quotient `long int quot` and the remainder `long int rem`.

If the value cannot be represented, the returned value is undefined. If *denominator* is 0, a divide by 0 exception is raised.

Example

CELEBL03

```
/* CELEBL03

   This example uses the &ldiv. function to calculate the
   quotients and remainders for a set of two dividends and two
   divisors.

*/
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    long int num[2] = {45,-45};
    long int den[2] = {7,-7};
    ldiv_t ans; /* ldiv_t is a struct type containing two long ints:
                  'quot' stores quotient; 'rem' stores remainder */
    short i,j;

    printf("Results of long division:\n");
    for (i = 0; i < 2; i++)
        for (j = 0; j < 2; j++)
        {
            ans = ldiv(num[i], den[j]);
            printf("Dividend: %6ld Divisor: %6ld", num[i], den[j]);
            printf(" Quotient: %6ld Remainder: %6ld\n", ans.quot, ans.rem);
        }
}
```

Output

```
Results of long division:
Dividend: 45 Divisor: 7 Quotient: 6 Remainder: 3
Dividend: 45 Divisor: -7 Quotient: -6 Remainder: 3
Dividend: -45 Divisor: 7 Quotient: -6 Remainder: -3
Dividend: -45 Divisor: -7 Quotient: 6 Remainder: -3
```

LeaveWorkUnit() — Leave a WLM work unit

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <sys/__wlm.h>

int LeaveWorkUnit(wlmetok_t *enclavetoken);
```

General description

The LeaveWorkUnit() function provides the ability for an application to leave a WLM work unit.

***enclavetoken**

Points to a work unit enclave token that was returned from a call to CreateWorkUnit() or ContinueWorkUnit().

Returned value

If successful, LeaveWorkUnit() returns 0.

If unsuccessful, LeaveWorkUnit() returns -1 and sets errno to one of the following values:

Error Code**Description****EFAULT**

An argument of this function contained an address that was not accessible to the caller.

EINVAL

An argument of this function contained an incorrect value.

EMVSSAF2ERR

An error occurred in the security product.

EMVSWLMERROR

The WLM leave enclave failed. Use __errno2() to obtain the WLM service reason code for the failure.

EPERM

The calling thread's address space is not permitted to the BPX.WLMSEVER Facility class. The caller's address space must be permitted to the BPX.WLMSEVER Facility class if it is defined. If BPX.WLMSEVER is not defined, the calling process is not defined as a superuser (UID=0).

__le_ceegtjs() — Retrieve the value of an exported JCL symbol

Standards

| Standards / Extensions | C or C++ | Dependencies |
|-------------------------|----------|--------------|
| Language Environment | both | AMODE 64 |

Format

```
#include <__le_api.h>

void __le_ceegtjs(_INT4 * function_code,
                 _VSTRING * symbol_name,
                 _CHAR255 * symbol_value,
                 _INT4 * value_length,
                 _FEEDBACK * fc);
```

General description

The `__le_ceegtjs()` function retrieves and returns to the caller the symbol value and length of the requested exported JCL symbol.

Parameter Description

function_code

A fullword integer containing the function code of the following value:

1

Retrieve the value and its associate length of an exported JCL symbol.

symbol_name

A halfword length-prefixed character string(VSTRING), representing the name of an exported JCL symbol to be retrieved.

symbol_value

A 255-byte fixed-length string. On return from this service, the *symbol_value* contains the value of the exported JCL symbol. If the length of the exported JCL symbol is shorter than 255 characters, the returned string is padded with blanks.

value_length

A fullword integer containing the length of the value of the specified JCL symbol.

fc

A 16-byte Feedback Code indicating the results of this function.

| Table 35. Feedback Codes for __le_ceegtjs() | | | |
|---|----------|----------------|--|
| Code | Severity | Message Number | Message Text |
| CEE000 | 0 | - - | The function completed successfully. |
| CEE3L9 | 0 | 3753 | The input symbol cannot be found in the current job step. |
| CEE3LA | 3 | 3754 | Incorrect parameters detected. |
| CEE3QS | 1 | 3932 | The system service failed with return code <i>return_code</i> and reason code <i>reason_code</i> . |

Usage notes

1. Lower case characters in the *symbol_name* will be converted to upper case by the __le_ceegtjs function.
2. For more information about JCL symbols and their usage, see "Using System Symbols and JCL symbols" in [z/OS MVS JCL Reference](#).

Example

CELEBL31

```

/* CELEBL31

   This example retrieves the value of an exported JCL symbol.

*/
#include <stdio.h>
#include <string.h>
#include <__le_api.h>

int main()
{
    _FEEDBACK fc;
    _INT4 funcode;
    _CHAR255 symvalue;
    _VSTRING symname;
    _INT4 valuelen;
    char *symbol="SYM1";

    /* Setting the function code */
    funcode=1;

    /* Preparing the JCL symbol name */
    symname.length=strlen(symbol);
    memcpy(symname.string, symbol,strlen(symbol));

    /* Retrieving the value of the JCL symbol */
    _le_ceegtjs(&funcode,&symname,symvalue,&valuelen,&fc);
    if( fc.tok_sev > 0) {
        printf("__le_ceegtjs failed with message number %d\n",
               fc.tok_msgno);
        exit(1);
    }
    symvalue[valuelen]='\0';
    printf("The value of JCL symbol %s is %s. The length
           of the value is %d\n",symbol,symvalue,valuelen);
}

```

Output

Use the following JCL to run CELEBL31:

```

//JOB1      JOB      FELE,MSGLEVEL=(2,0)
//STEP1     EXEC     PGM=CELEBL31

```

```
//E1      EXPORT SYMLIST=(SYM1,SYM2,SYM3)
//S1      SET    SYM1=XXXX
//S2      SET    SYM2=YYYY
//STEPLIB DD     DSN=USER.LOADLIB,DISP=SHR
//SYSPRINT DD     SYSOUT=*
//SYSOUT  DD     SYSOUT=*
```

Running this example would produce the following output:

```
The value of JCL symbol SYM1 is XXXX. The length of the value is 4.
```

__le_ceemict() — Manage the interoperability state of current task

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | Both | AMODE 64 |

Format

```
#include<__le_api.h>
void __le_ceemict (_INT4 *function_code, POINTER *MICT_ptr, FEED_BACK *fc)
```

General description

The `__le_ceemict()` function allows high level language programs to manage the interoperability state of current task.

Parameter

Description

function_code (input)

A required parameter; a fullword integer containing the function code of one of the following values:

- 1** QUERY: Get `state_ptr` and `state_flag`.
- 2** SET: Set `state_flag` for current task.
- 3** UNSET: Unset `state_flag` for current task.

MICT_ptr (input/output)

A pointer that points to the `MICT_CB` structure, which describes the input/output parameters of `__le_ceemict()`.

| Table 36. <i>MICT_CB</i> structure | |
|------------------------------------|---------------------|
| Name | Description |
| <code>state_flag</code> | A 32-bit flag |
| <code>state_ptr</code> | A full word pointer |

fc

A 12-byte Feedback Code that indicates the results of the service. The following symbolic conditions can result from the service:

| Table 37. Feedback Codes for __le_ceemict() | | | |
|---|----------|----------------|-------------------------------------|
| Code | Severity | Message Number | Message Text |
| CEE000 | 0 | N/A | The service completed successfully. |
| CEE3LA | 3 | 3754 | Incorrect parameters detected. |

Usage

The usage of MICT_CB is decided by *function_code* as shown in the [Table 38 on page 948](#).

| Table 38. MICT_CB and function_code | |
|-------------------------------------|--|
| function_code | MICT_CB description |
| 1 (QUERY) | <p>state_flag (output) A 32-bit flag that obtains or sets state_flag.</p> <ul style="list-style-type: none"> Bit 0 (leftmost bit): The current TCB shares a Db2® connection in the Java Interlanguage Batch environment using RRSAF. Bit 1-31: Reserved. All reserved bits are initialized to zero by Language Environment. <p>state_ptr (output) A full word pointer that contains the address of SW3164. If state_ptr is not zero, the current task is in AMODE 31 and AMODE 64 switching state.</p> |
| 2 (SET) | <p>state_flag (input) A 32-bit mask that sets state_flag. If a bit within the mask is set to 1, the corresponding flag bit is turned ON; otherwise, the flag bit is unchanged.</p> <p>state_ptr (output) Not used.</p> |
| 3 (UNSET) | <p>state_flag (input) A 32-bit mask that sets state_flag. If a bit within the mask is set to 1, the corresponding flag bit is turned OFF; otherwise, the flag bit is unchanged.</p> <p>state_ptr (output) Not used.</p> |

__le_ceedsgd() – Usage data collection service

Standards

| Standards / Extensions | C or C++ | Dependencies |
|-------------------------|----------|--------------|
| Language Environment | Both | AMODE 64 |

Format

```
#include<__le_api.h>
void __le_ceedsgd(_INT4 *function_code, void **in_buf, void **out_buf,
                 unsigned char *fbfe, _FEEDBACK *fc);
```

Compile requirement:

- Use of this function requires the long long data type.
- Use of this function requires [hexadecimal floating point representation](#) when **FORMAT=FLOAT** is specified.

General description

function_code

(Input) A required parameter, a fullword integer that contains the function code of one of the following values:

1

REGISTER: Identify Product for Usage Data Collection and provide the Domain and Scope options to be used.

2

DEREGISTER: End Data Collection for the Product in the current Domain and Scope.

3

FUNCTIONBEGIN: Collect Function-level Data for the Product in the current Domain and Scope.

4

FUNCTIONDATA: Provide Product-Specific Usage Data for the Product in the current Domain and Scope.

5

FUNCTIONEND: End Collecting Function-level Data for the Product in the current Domain and Scope.

6

STATUS: Check the status (Available and Active) of the Usage Data Collection Service and the installation recording request for the System-Wide Usage Data Record (Type 89).

in_buf

(Input) A pointer points to an input structure. The structure type is decided by *function_code*:

When *function_code*= 1, the *in_buf* structure is:

```
typedef struct __ceedsgd_reg_in{
    unsigned char product_owner[16];
    unsigned char product_name[16];
    unsigned char product_version[8];
    unsigned char product_qualifier[8];
    unsigned char product_ID[8];
    unsigned char domain;
    unsigned char scope;
    unsigned char unauth_serv;
} __ceedsgd_reg_in;
```

product_owner

A 16-character field stands for Product's Owner or Vendor Name for this request.

product_name

A 16-character field stands for the Name of the product for the request.

product_version

An 8-character field stands for the Version of the product for the request. The input value of None followed by 4 white spaces (8 characters total) indicates that the *product_version* is not set.

product_qualifier

An 8-character field stands for the Qualifier of the product for the request. The input value of None followed by 4 white spaces (8 characters total) indicates that the *product_qualifier* is not set.

product_ID

An 8-character field stands for the ID of the Product. For example, the PID Number. The input value of None followed by 4 white spaces (8 characters total) indicates that the *product_ID* is not set.

domain

A field stands for the level of data to be collected for this product. Only the following choices can be used:

- `__DOMAIN_ADDRSP`: Provide Data Collection at the Address Space Level. `__DOMAIN_ADDRSP` is used by default for unexpected input.
- `__DOMAIN_TASK`: Request Data Collection for the current task.

scope

A field stands for the level of data collection within the task that is being requested. Need to be set when domain is `__DOMAIN_TASK`. When domain is `__DOMAIN_ADDRSP`, input value of 0 indicates that scope is not set. Only the following choices can be used:

- `__SCOPE_ALL`: Requests that all the CPU Time in the task that is associated with the requesting product. `__SCOPE_ALL` is used by default for unexpected input.
- `__SCOPE_FUNCTION`: Requests that only the CPU time that is accumulated during the invocation of the FUNCTION - BEGIN and END requests be associated with this product. More invocations of the IFAUSAGE macro for FUNCTIONBEGIN and FUNCTIONEND requests are expected.

unauthserv

A field stands for the level of authorized services to which the unauthorized caller requires access. Authorized callers can use all services without SAF authorization. Only the following choices can be used:

- `__UNAUTHSERV_BASE`: Specifies that the unauthorized caller does not need access to any IFAUSAGE services other than REGISTER and STATUS. Unauthorized invokers that do not have SAF authorization are limited to 2 IFAUSAGE REGISTER requests per address space. `__UNAUTHSERV_BASE` is used by default for unexpected input.
- `__UNAUTHSERV_LEVEL1`: Specifies that the unauthorized caller requires access to IFAUSAGE services that are available to authorized callers. These include: Unregister, FUNCTIONBEGIN, FUNCTIONEND, and FUNCTIONDATA. In addition, the unauthorized caller might issue more than 2 IFAUSAGE REGISTER requests. The SAF facility is used to validate that the installation has authorized the user ID associated with this job or task to use LEVEL1 features.

When *function_code* equals 2, 3, or 5, the *in_buf* structure is:

```
typedef struct __ceedsgd_dereg_fbegend_in{
    unsigned char  prtoken[8];
    unsigned char  product_owner[16];
    unsigned char  product_name[16];
    unsigned char  product_version[8];
    unsigned char  product_qualifier[8];
}
```

```
    unsigned char product_ID[8];
} __ceedsgd_dereg_fbegin_in;
```

prtoken

An 8-character field stands for the Product token that is returned on the associated function code 1 REGISTER request.

product_owner

A 16-character field stands for Product's Owner or Vendor Name for this request.

product_name

A 16-character field stands for the Name of the product for the request.

product_version

An 8-character field that stands for the Version of the product for the request.

product_qualifier

An 8-character field stands for the Qualifier of the product for the request.

product_ID

An 8-character field stands for the ID of the Product. For example, the PID Number.

Notes:

- *prtoken* cannot be specified when *product_owner*, *product_name*, *product_version*, *product_qualifier*, and *product_ID* are all specified. You can either specify *prtoken* or *product_owner* + *product_name* + *product_version* + *product_qualifier* + *product_ID*.
- *product_name*, *product_version*, *product_qualifier*, and *product_ID* take effects only when *product_owner* is specified.
- The input value of None followed by 4 or 12 white spaces (8 or 16 characters total) indicates that the field is not set.

When *function_code* equals 4, the *in_buf* structure is:

```
typedef struct __ceedsgd_fundata_in{
    unsigned char prtoken[8];
    unsigned char product_owner[16];
    unsigned char product_name[16];
    unsigned char product_version[8];
    unsigned char product_qualifier[8];
    unsigned char product_ID[8];
    union{
        long long data_cputime_binary;
        /* when format is __FORMAT_CPUTIME or __FORMAT_BINARY*/
        double data_longfloat;
        /* when format is __FORMAT_FLOAT */
    } __data;
    unsigned char format;
    /*values are __FORMAT_CPUTIME, __FORMAT_BINARY, __FORMAT_FLOAT*/
} __ceedsgd_fundata_in;
```

prtoken

An 8-character field stands for the Product token that is returned on the associated function code 1 REGISTER request.

product_owner

A 16-character field stands for Product's Owner or Vendor Name for this request.

product_name

A 16-character field stands for the Name of the product for the request.

product_version

An 8-character field that stands for the Version of the product for the request.

product_qualifier

An 8-character field stands for the Qualifier of the product for the request.

product_ID

An 8-character field stands for the ID of the Product. For example, the PID Number.

__data

An 8-byte field contains resource data to be accumulated. Fixed-type data are right justified and padded with hex 0's. The data type is determined by *format*.

__data.data_cputime_binary

When *format* is `__FORMAT_CPUTIME` or `__FORMAT_BINARY`, use `long` as data type.

__data.data_longfloat

When *format* is `__FORMAT_FLOAT`, use `double` as data type.

format

A field stands for the data type of value in data parameter. Only the following choices can be used:

__FORMAT_CPUTIME

The value in the data is a CPU Time, in STCK format. `__FORMAT_CPUTIME` is used by default for unexpected input.

__FORMAT_BINARY

The value in the data is in 64-bit binary format.

__FORMAT_FLOAT

The value in the data is in long floating point hex format.

Note: Use of this function requires hexadecimal floating point representation when **FORMAT=FLOAT** is specified.

When function_code equals 6

User specified *in_buf* is not needed and ignored.

out_buf

(Output) A pointer points to an output structure. The structure type is decided by *function_code*.

| Table 39. out_buf structure and function_code | |
|---|--|
| function_code | out_buf structure |
| 1 | An 8-character field stands for the Product token that is returned on the associated function code 1 REGISTER request. |
| 2 or 5 | <pre>typedef struct __ceedsgd_dereg_fend_out{ unsigned char endtime[8]; unsigned char enddata[8]; } __ceedsgd_dereg_fend_out;</pre> <p>endtime An 8-character field where ending TCB time level is returned to the invoker.</p> <p>enddata An 8-character field where ending product specific data is returned to the invoker.</p> |
| 3 | An 8-character field where beginning CPU time level is returned. |
| 4 | An 8-character field where current resource level is returned to the invoker (after adding the input value). |
| 6 | User specified <i>out_buf</i> is not needed and ignored. |

fbfe

(Input) A field stands for whether the caller intends to use FUNCTIONBEGIN and FUNCTIONEND to account for time. Only the following choices can be used:

__FBFE_NO

Specifies that FUNCTIONBEGIN/FUNCTIONEND is not to be done. `__FBFE_NO` is used by default for unexpected input.

__FEBE_YES

Specifies that FUNCTIONBEGIN/FUNCTIONEND is to be done.

fc

(Output) A 16-byte Feedback Code indicating the results of this function.

| Table 40. Feedback Codes for __le_ceedsgd() | | | |
|---|----------|----------------|---|
| Code | Severity | Message number | Message text |
| CEE000 | 0 | - | The service completed successfully. |
| CEE3LA | 3 | 3754 | Incorrect parameters detected. |
| CEE3QS | 1 | 3932 | The system service service failed with return_code and reason_code. |

Related information

__le_cib_get() — Get condition information block

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | AMODE 64 |

Format

```
#include <__le_api.h>
struct cib *__le_cib_get(void);
```

General description

Returns the Condition Information Block (CIB) structure associated with the current signal.

Notes:

1. This function is valid when called while a Language Environment exception handler is running.
2. This function is valid when called while a POSIX(OFF) signal catcher is running.
3. This function is valid when called while a POSIX(ON) signal catcher is running, if the signal is generated and caught immediately to the same thread. __le_cib_get() will fail if called from POSIX(ON) signal catchers that are driven as a result of signals generated by another thread or process. It may also fail when called from a catcher, if the caught signal is from the same thread but was delayed by blocking or by other signals being delivered at the same time.

Returned value

If there is an active condition the returned value is a pointer to the currently active CIB. If there is more than one active condition, the returned CIB will be for the most recent (most deeply nested) condition.

NULL is returned there is no active CIB, and the errno will be set to EMVSERR.

Error Code
Description

EMVSERR
No active CIB is available.

__le_condition_token_build() – Build a Language Environment condition token

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | AMODE 64 |

Format

```
#include <__le_api.h>

void *__le_condition_token_build(_INT2 * c_1, _INT2 * c_2,
                                _INT2 * format, _INT2 * severity,
                                _INT2 * control, _CHAR3 facility_ID,
                                _INT4 * i_s_info,
                                _FEEDBACK * cond_token,
                                _FEEDBACK * fc);
```

General description

Dynamically constructs a 16-byte Language Environment condition token. The condition token is only to be used to retrieve messages from a Language Environment message file.

Parameter
Description

c_1
c_1 is a 2-byte binary integer representing the value of the first 2 bytes of the 4-byte condition_ID. c_1 and c_2 make up the condition_ID portion of the condition token.

c_2
c_2 is a 2-byte binary integer representing the value of the second 2 bytes of the 4-byte condition_ID.

For format 1, this is the Msg_No; for format 2, the cause_code.

format
A 2-byte binary integer defining the format of the condition_ID portion of the token.

severity
A 2-byte binary integer indicating the condition's severity. In both format 1 and 2 conditions, this field is used to test the condition's severity. For format 1 conditions, the value of this field is the same as the severity value specified in the condition_ID.

Possible severity Values:

0 = Information only, if entire token is 0 there is no information.

- 1 = Warning
- 2 = Error
- 3 = Severe Error
- 4 = Critical Error

control

A 2-byte binary integer containing flags describing or controlling various aspects of condition handling. Valid values for the control field are 1 and 0. 1 indicates the *facility_ID* assigned by IBM, 0 indicates the *facility_ID* assigned by the user.

facility_ID

A 3 character field containing three alphanumeric characters (A-Z, a-z, and 0-9) identifying the product or component of a product generating this condition or feedback information, for example, CEE.

The *facility_ID* is associated with the repository of the runtime messages. If a unique ID is required (for IBM and non-IBM products), an ID can be obtained by contacting an IBM project office.

If you create a new *facility_ID* to use with a message table, created using the CEEBLDTX utility, be aware that the *facility_ID* must be part of the Language Environment message table name. For more information about the CEEBLDTX utility, see *z/OS Language Environment Programming Guide*. It is important to follow the naming guidelines below in order to have a module name that does not cause your application to abend.

First, begin a non-IBM assigned product *facility_ID* with letters J through Z. (See the *control* parameter above to indicate whether the *facility_ID* has been assigned by IBM.) Secondly, special characters, including blank spaces, cannot be used in a *facility_ID*. Lastly, there are no other constraints (besides the alphanumeric requirement) on a non-IBM assigned *facility_ID*.

i_s_info

A fullword binary integer identifying the ISI, that contains insert data.

cond_token

A 16-byte representation of the constructed condition token.

fc

A 16-byte Feedback Code indicating the results of this function.

| Table 41. Feedback Codes for __le_condition_token_build() | | | |
|---|----------|----------------|--|
| Code | Severity | Message Number | Message Text |
| CEE000 | 0 | - - | The function completed successfully. |
| CEE0CH | 3 | 401 | A non-valid case code <i>case-code</i> was passed to routine <i>routine-name</i> . |
| CEE0CI | 3 | 402 | A non-valid control code <i>control-code</i> was passed to routine <i>routine-name</i> . |
| CEE0CJ | 3 | 403 | A non-valid severity code <i>severity-code</i> was passed to routine <i>routine-name</i> . |
| CEE0CK | 3 | 404 | Facility ID, <i>facility-id</i> , with non-alphanumeric characters was passed to routine <i>routine-name</i> . |
| CEE0E4 | 1 | 452 | An invalid facility ID <i>facility-id</i> was passed to routine <i>routine-name</i> . |

Usage notes

1. The structure of the condition token (type `_FEEDBACK`) is described in the "`__le_api.h`" header file shipped with Language Environment. You can assign values directly to the fields of the token in the header file without using the `__le_condition_token_build()` function.

2. This condition token is **only** to be used to retrieve messages from a Language Environment message table.

`__le_debug_set_resume_mch()` — Move the resume cursor to a predefined location represented by a machine state

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | AMODE 64 |

Format

```
#include <__le_api.h>

void __le_debug_set_resume_mch(__mch_t * position, _FEEDBACK * fc);
```

General description

Moves the resume cursor to a predefined location represented by the machine state.

Parameter

Description

position

A pointer to a valid machine state block to which the resume cursor is moved.

fc

A 16-byte Feedback Code indicating the results of this function.

| Table 42. Feedback Codes for <code>__le_debug_set_resume_mch()</code> | | | |
|---|----------|----------------|---|
| Code | Severity | Message Number | Message Text |
| CEE000 | 0 | - - | The function completed successfully. |
| CEE07V | 3 | 255 | <i>Position</i> parameter not a machine state |

`__le_msg_add_insert()` — Add insert to a Language Environment message

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | AMODE 64 |

Format

```
#include <__le_api.h>

void *__le_msg_add_insert(_FEEDBACK * cond_token,
                          _INT4 * insert_seq_num,
                          _VSTRING * insert_data,
                          _FEEDBACK * fc);
```

General description

Copies message insert data and loads the address of that data into the Instance Specific Information (ISI) associated with the condition being processed. The number of ISIs per thread is limited to 15.

Parameter Description

cond_token

A 16-byte condition token that defines the condition for which the q_data_token is retrieved.

insert_seq_num

A 4-byte integer that contains the insert sequence number (such as insert 1 insert 2). It corresponds to an insert number specified with an :ins. tag in the message source file created by the CEEBLDTX utility. For more information about the CEEBLDTX utility see [z/OS Language Environment Programming Guide](#).

insert_data

A halfword-prefixed length string, used without truncation, that represents the insert data. DBCS strings must be enclosed within shift-out (0x0E) and shift-in (0x0F) characters.

Note: The maximum size for an individual insert item is 254 bytes.

fc

A 16-byte Feedback Code indicating the results of this function.

| Table 43. Feedback Codes for __le_msg_add_insert() | | | |
|--|----------|----------------|--|
| Code | Severity | Message Number | Message Text |
| CEE000 | 0 | - - | The function completed successfully. |
| CEE0EB | 3 | 459 | Not enough storage was available to create a new Instance Specific Information block. |
| CEE0EC | 1 | 460 | Multiple instances of the condition token with message number <i>message-number</i> and facility ID <i>facility-id</i> were detected. |
| CEE0ED | 3 | 461 | The maximum number of unique message insert blocks was reached. This condition token had it's I_S_info field set to 1. |
| CEE0EE | 3 | 462 | Instance Specific Information for the condition token with message number <i>message-number</i> and facility ID <i>facility-id</i> could not be found. |
| CEE0EF | 3 | 463 | The maximum size for an insert data item was exceeded be located. |
| CEE0H9 | 3 | 553 | An internal error was detected in creating the inserts for a condition. |

Usage notes

1. z/OS UNIX System Services consideration – In multithreaded applications, __le_msg_add_insert() applies to message insert data for only the invoking thread.

Related information

- “[__le_api.h — AMODE 64 C functions in Language Environment](#)” on page 34
- “[__le_msg_get\(\) — Get a Language Environment message](#)” on page 958

__le_msg_get() — Get a Language Environment message

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | AMODE 64 |

Format

```
#include <__le_api.h>

void *__le_msg_get(_FEEDBACK * cond_token,
                  _CHAR80 message_area,
                  _INT4 * msg_index,
                  _FEEDBACK * fc);
```

General description

Retrieves, formats, and stores, in a passed message area, a Language Environment message corresponding to a user supplied condition token. The caller can later retrieve the message to modify or to write as output.

Parameter

Description

cond_token

A 16-byte condition token supplied by the invoker.

message_area

A fixed-length 80 character string, where the message is placed.

Note: The message is left-justified and padded on the right with blanks.

msg_index

A 4-byte binary integer returned to the invoker.

The *msg_index* should be set to zero on the first invocation of `__le_msg_get()`. If a message is too large to be contained in the *message_area*, *msg_index* is returned as an index into the message. This index is used on subsequent invocations to retrieve the remaining portion of the message. Feedback Code is also returned, indicating the message has been truncated. When the entire message is returned, *msg_index* is zero.

msg_idx contains different results based on the length of the message.

- If a message contains fewer than 80 characters, the entire message is returned on the first invocation. *msg_index* contains 0.
- If a message contains exactly 80 characters, the entire message is returned on the first invocation. *msg_index* contains 0.
- If the message is more than 80 characters it is split into segments. The *msg_index* does not contain the cumulative index for the entire message returned, but contains only the index of the segment that was just returned. It is up to the user to maintain the cumulative count if needed. When a message is too long, the following can occur:

- If a message contains more than 80 characters and at least one blank is contained in the first 80 characters, the string up to and including the last blank is returned on the first invocation.
- If the 80th character is non-blank (even if the 81st character is a blank), *msg_index* contains the index of the last blank (something less than 80), and the next invocation starts with the next character.
- If the 80th character is a blank, *msg_index* contains 80 and the next invocation starts with the 81st character, blank or non-blank.
- If a message contains more than 80 characters and at least the first 80 are all non-blank, the first 80 are returned. The next invocation does not add any blanks and starts with the 81st character. *msg_index* contains 80.

fc

A 16-byte Feedback Code indicating the results of this function.

| Table 44. Feedback Codes for __le_msg_get() | | | |
|---|----------|----------------|--|
| Code | Severity | Message Number | Message Text |
| CEE000 | 0 | - - | The function complete successfully. |
| CEE036 | 3 | 102 | An unrecognized condition token was passed to the function and could not be used. |
| CEE0E2 | 3 | 450 | The message inserts for the condition token with message number <i>message-number</i> and facility ID <i>facility-id</i> could not be located. |
| CEE0E6 | 3 | 454 | The message number <i>message-number</i> could not be found for facility ID <i>facility-id</i> . |
| CEE0E7 | 1 | 455 | The message with message number <i>message-number</i> and facility ID <i>facility-id</i> was truncated. |
| CEE0EA | 1 | 458 | The message repository <i>repository-name</i> could not be located. |

Usage notes

1. z/OS UNIX System Services consideration – In multithreaded applications, __le_msg_get() affects only the invoking thread. However, __le_msg_get() uses the NATLANG value of the enclave. Any subsequent calls to __le_msg_get(), for a given condition, use the NATLANG value in effect at the time of the first invocation.

Related information

__le_msg_get_and_write() – Get and output a Language Environment message

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | AMODE 64 |

Format

```
#include <__le_api.h>

void *__le_msg_get_and_write(_FEEDBACK * cond_token,
                             _INT4 * destination_code,
                             _FEEDBACK * fc);
```

General description

Retrieves, formats, and stores, in a passed message area, a Language Environment message corresponding to a user supplied condition token. The caller can later retrieve the message to modify or to write as output.

Parameter

Description

cond_token

A 16-byte condition token supplied by the invoker.

destination_code

A 4-byte binary integer written to 'stderr'. The only acceptable value for is 2.

fc

A 16-byte Feedback Code indicating the results of this function.

| Table 45. Feedback Codes for __le_msg_get_and_write() | | | |
|---|----------|----------------|--|
| Code | Severity | Message Number | Message Text |
| CEE000 | 0 | - - | The function completed successfully. |
| CEE0E2 | 3 | 450 | The message inserts for the condition token with message number <i>message-number</i> and facility ID <i>facility-id</i> could not be located. |
| CEE0E3 | 3 | 451 | An invalid destination code <i>destination-code</i> was passed to routine <i>routine</i> . |
| CEE0E6 | 3 | 454 | The message number <i>message-number</i> could not be found for facility ID <i>facility-id</i> . |
| CEE0E9 | 1 | 457 | The message file destination <i>ddname</i> could not be located. |
| CEE0EA | 1 | 458 | The message repository <i>repository-name</i> could not be located. |
| CEE3CT | 3 | 3,485 | An internal message service error occurred while locating the message number within a message file. |

Table 45. Feedback Codes for __le_msg_get_and_write() (continued)

| Code | Severity | Message Number | Message Text |
|--------|----------|----------------|---|
| CEE3CU | 3 | 3,486 | An internal message service error occurred while formatting a message. |
| CEE3CV | 3 | 3,487 | An internal message service error occurred while locating a message number within the ranges specified in the repository. |

Usage notes

1. z/OS UNIX System Services consideration – In multithreaded applications, __le_msg_get_and_write() affects only the invoking thread. When multiple threads write to 'stderr' the output is interwoven by line. To group lines of output, serialize 'stderr' access (for example, by using a mutex).

Related information

__le_msg_write() – Output a Language Environment message to stderr

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | AMODE 64 |

Format

```
#include <__le_api.h>

void __le_msg_write(_VSTRING * message_string,
                   _INT4 * destination_code,
                   _FEEDBACK * fc);
```

General description

Writes a user-defined Language Environment message string to 'stderr'.

Parameter

Description

message_string

A halfword-prefixed printable character string containing a message. DBCS characters must be enclosed within shift-out (0x0F) and shift-in (0x0E) characters.

Insert data cannot be placed in the message with __le_msg_write(). The halfword-prefixed message string must contain only printable characters and be a length greater than zero. Unpredictable results will occur if the byte following the halfword prefix is 0x00.

destination_code

A 4-byte binary integer written to 'stderr'. The only acceptable value is 2.

fc

A 16-byte Feedback Code indicating the results of this function.

| Table 46. Feedback Codes for __le_msg_write() | | | |
|---|----------|----------------|--|
| Code | Severity | Message Number | Message Text |
| CEE000 | 0 | - - | The function completed successfully. |
| CEE0E3 | 3 | 451 | An invalid destination code <i>destination-code</i> was passed to routine <i>routine</i> . |
| CEE0E9 | 3 | 457 | The message file destination <i>ddname</i> could not be located. |

Usage notes

1. z/OS UNIX System Services consideration – In multithreaded applications, __le_msg_write() affects only the invoking thread. When multiple threads write to 'stderr' the output is interwoven by line. To group lines of output, serialize 'stderr' access (for example, by using a mutex).

__le_record_dump() – Record information for the active condition

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | AMODE 64 |

Format

```
#include <__le_api.h>

int __le_record_dump(int function_code,
                    void *information);
```

General description

The __le_record_dump() function records information of an active condition, so that the information can be retrieved from the condition information block (CIB) later. Use this function only during condition handling.

Parameter

Description

function_code

A fullword integer that contains the function code of the following value:

1

Record the dataset name of a dump for the active condition.

information

The information to be recorded. When the value of *function_code* is 1, the information is a halfword length-prefixed EBCDIC character string, which is expected to be the dataset name of a dump for the active condition. Language Environment will validate that the length is positive and it does not exceed 44.

Returned value

If successful, `__le_record_dump()` returns 0.

If unsuccessful, `__le_record_dump()` returns nonzero and sets `errno` to one of the following values:

Error Code**Description****EMVSERR**

No active CIB is available.

EINVAL

Incorrect parameters detected.

Usage notes

1. After the condition handling functions return control to your application, CIB that represents the condition is no longer valid, therefore the recorded information is no longer accessible.
2. If `__le_record_dump()` is called more than once for the same condition, the information of the last call is recorded.
3. This function is valid when it is called while a Language Environment exception handler is running.
4. You can use `__le_record_dump()` only in signal catchers that are driven for synchronous signals because the CIB is used for synchronous signals only.

__le_traceback() – Call chain traceback service

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|-----------------------|
| Language Environment | both | z/OS V1.9 AMODE 64 |

Format

```
#include <__le_api.h>

void __le_traceback(int cmd, void* cmd_parms, _FEEDBACK *fc);
```

General description

The `__le_traceback()` function assists in tracing the call chain. It identifies the language, program unit, entry point, current location, caller's DSA, and other information from the address of a DSA for a program unit. This is essential for creating meaningful traceback messages.

Parameter**Description****cmd**

The `__le_traceback()` command to be used. The following commands can be used:

__TRACEBACK_FIELDS

Information that can be used to create a traceback message is returned in individual fields.

cmd_parms

A pointer to a structure that contains additional command specific parameters. For the command __TRACEBACK_FIELDS, this parameter must point to a __tf_parms_t.

fc

A 16-byte feedback code indicating the results of this function.

| Table 47. Feedback Codes for __le_traceback() | | | |
|---|----------|----------------|---|
| Code | Severity | Message number | Message text |
| CEE000 | 0 | - - | The service completed successfully. |
| CEE310 | 3 | 3104S | Information could not be successfully extracted for this DSA. It is likely that the dsaptr parameter does not point to an actual DSA or save area. |
| CEE316 | 2 | 3110E | The <i>cmd</i> parameter is not a valid command for __le_traceback(). |
| CEE3NS | 1 | 3836W | A statement number is not available for this DSA. DWARF data in the load module is corrupted. |
| CEE3NT | 1 | 3837W | Statement numbers are not available. The explicit DLL load of DLL CDAEQED failed with feedback code <i>fc</i> . |
| CEE3NU | 1 | 3838W | Statement numbers are not available. The explicit DLL load of DLL CDAEQDPI failed with feedback code <i>fc</i> . |
| CEE3NV | 1 | 3839W | Statement numbers are not available. The explicit DLL load of DLL CELQDSNF failed with feedback code <i>fc</i> . |
| CEE300 | 1 | 3840 | Statement numbers are not available. dllqueryfn() failed for a function in the DLL CELQDSNF. |
| CEE301 | 1 | 3841 | A statement number is not available for this DSA. An internal routine failed with return code <i>return-code</i> and reason code <i>reason-code</i> . |

The __tf_parms_s structure is defined as follows:

```
typedef struct __tf_string_s {
    size_t    __tf_bufflen;

    char*     __tf_buff;
} __tf_string_t;

typedef struct __tf_parms_s {
    /******
    /* Input
    /******
    void*     __tf_dsa_addr;
    void*     __tf_caa_addr;
    void*     __tf_call_instruction;
    /******
    /* Output related to input DSA
    /******
    void*     __tf_pu_addr;
```

```

void* __tf_entry_addr;
struct __cib* __tf_cib_addr;
uint8_t __tf_member_id;
int __tf_is_main:1;
int :23;
int :32;
__tf_string_t __tf_pu_name;
__tf_string_t __tf_entry_name;
__tf_string_t __tf_statement_id;
/*****
/* Output related to caller's DSA */
*****/
void* __tf_caller_dsa_addr;
void* __tf_caller_call_instruction;
} __tf_parms_t;

```

The following are members of the structure:

Member Description

void* __tf_dsa_addr

The address of the DSA for the current routine in the traceback. When this field is zero on input, the address of the DSA for the caller of `__le_traceback()` will be used and the address will be returned. No attempt is made to verify that the input is a DSA. Incorrect input can lead to unpredictable results.

void* __tf_caa_addr

The address of the CAA associated with the DSA. When this field is zero on input, the address of the CAA for the current thread will be used and the address will be returned. No attempt is made to verify that the input is a CAA. Incorrect input can lead to unpredictable results.

void* __tf_call_instruction

The address of the instruction that caused transfer out of the routine. This is either the address of a BASR, BRAS or BRASL instruction if transfer was made by subroutine call, or the address of the interrupted statement if transfer was caused by an exception. When multiple calls are made to `__le_traceback()` to scan the call chain, the `callers_call_instruction` (described below) returned from the previous call can be used here. If the address is not known, this field should be set to zero. When this field is zero on input and the address can be determined, it will be returned.

void* __tf_pu_addr

The address of the start of the program unit for the routine associated with the DSA is returned in this field. If the program unit address cannot be determined, this field is set to zero.

void* __tf_entry_addr

The address of the entry point into the routine associated with the DSA is returned in this field. If the entry point address cannot be determined, this parameter is set to zero.

struct __cib* __tf_cib_addr

The address of the CIB (struct `__cib`) associated with the DSA, if an exception occurred, is returned in this field. If no exception occurred, this field is set to zero. Note that if an exception caused transfer out of the routine, the state of the registers after the last instruction ran in the routine is saved in the CIB, rather than in the DSA.

uint8_t __tf_member_id

The member identifier for the routine associated with the DSA will be returned in this field. If the member ID cannot be determined, this field is set to negative one.

int __tf_is_main:1

One of two values is returned in this field: 0 (the routine associated with the DSA is not the main program) or 1 (the routine associated with the DSA is the main program).

__tf_string_t __tf_pu_name

A structure that will be used to return the name of the program unit containing the routine associated with the DSA. The structure has the following fields:

char* __tf_buff

The address of a buffer in which the program unit name will be returned. The name will be returned in the buffer as a null terminated string.

size_t __tf_bufflen

The size of the buffer

If the program unit name cannot be determined, the buffer is set to a null string. If the program unit name cannot fit within the supplied string, it is truncated. (Truncation of DBCS preserves even byte count and SI/SO pairing.) If __tf_buff is NULL or __tf_bufflen is zero, the program unit name is not returned.

__tf_string_t __tf_entry_name

A structure that will be used to return the name of the entry point into the routine associated with the DSA. The structure has the following fields:

char* __tf_buff

The address of a buffer in which the entry point name will be returned. The name will be returned in the buffer as a null terminated string.

size_t __tf_bufflen

The size of the buffer

If the entry point name cannot be determined, the buffer is set to a null string. If the entry point name cannot fit within the supplied string, it is truncated. (Truncation of DBCS preserves even byte count and SI/SO pairing.) If __tf_buff is NULL or __tf_bufflen is zero, the entry point name is not returned

__tf_string_t __tf_statement_id

A structure that will be used to return the identifier of the statement containing the instruction which caused transfer out of the routine associated with the DSA. The structure has the following fields:

char* __tf_buff

The address of a buffer in which the statement id will be returned. The statement id will be returned in the buffer as a null terminated string.

size_t __tf_bufflen

The size of the buffer

If the statement id cannot be determined, the buffer is set to a null string. If the statement id cannot fit within the supplied string, it is truncated. (Truncation of DBCS preserves even byte count and SI/SO pairing.) If __tf_buff is NULL or __tf_bufflen is zero, the statement id is not returned

void* __tf_callers_dsa_addr

The address of the DSA for the caller is returned in this field. If the address of the caller's DSA cannot be determined or is not valid (points to inaccessible storage), then this field is set to zero.

void* __tf_callers_call_instruction

The address of the instruction that caused transfer out of the caller is returned in this field. This is either the address of a BASR, BRAS or BRASL instruction if transfer was made by subroutine call, or the address of the interrupted statement if transfer was caused by an exception. If the address cannot be determined, this parameter is set to zero.

Example

```
#include <__le_api.h>
#include <stdlib.h>

int main() {
    __tf_parms_t    tbck_parms;
    char            pu_name[256];
    char            entry_name[256];
    char            statement_id[256];
    _FEEDBACK      fc;
    int             rc;

    tbck_parms.__tf_pu_name.__tf_bufflen = sizeof(pu_name);
    tbck_parms.__tf_entry_name.__tf_bufflen = sizeof(entry_name);
    tbck_parms.__tf_statement_id.__tf_bufflen = sizeof(statement_id);

    tbck_parms.__tf_pu_name.__tf_buff = pu_name;
    tbck_parms.__tf_entry_name.__tf_buff = entry_name;
    tbck_parms.__tf_statement_id.__tf_buff = statement_id;
```

```

tbck_parms.__tf_dsa_addr = 0;
tbck_parms.__tf_cca_addr = 0;
tbck_parms.__tf_call_instruction = 0;

do {
    _le_traceback(__TRACEBACK_FIELDS, &tbck_parms, &fc);

    if ( fc.tok_sev >= 2 ) {
        printf("Error: __le_traceback() failed.\n");
        break;
    }

    printf("Entry=%s Offset=%c%x Line=%s\n",
        tbck_parms.__tf_entry_name.__tf_buff,
        tbck_parms.__tf_call_instruction
        < tbck_parms.__tf_entry_addr ? '-' : '+',
        abs((int)((long)tbck_parms.__tf_call_instruction
        - (long)tbck_parms.__tf_entry_addr)),
        tbck_parms.__tf_statement_id.__tf_buff
    );

    tbck_parms.__tf_dsa_addr = tbck_parms.__tf_caller_dsa_addr;
    tbck_parms.__tf_call_instruction =
        tbck_parms.__tf_caller_call_instruction;

} while (!tbck_parms.__tf_is_main);

return 0;
}

```

Output

```

Entry=main Offset=+da Line=28
Entry=CELQINIT Offset=+134c Line=

```

Related information

- “[__le_api.h — AMODE 64 C functions in Language Environment](#)” on page 34

lfind() — Linear search routine

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```

#define _XOPEN_SOURCE
#include <search.h>

void *lfind(const void *key, const void *base, size_t *nelp,
            size_t width, int (*compar)(const void *, const void *));

```

General description

The `lfind()` function is the same as a `lsearch()` except that if the entry is not found, it is not added to the table. Instead, a NULL pointer is returned.

Special behavior for C++: Because C and C++ linkage conventions are incompatible, `lfind()` cannot receive a C++ function pointer as the comparator argument. If you attempt to pass a C++ function pointer

to `lfind()`, the compiler will flag it as an error. You can pass a C or C++ function to `lfind()` by declaring it as `extern "C"`.

Returned value

If the searched-for entry is found, `lfind()` returns a pointer to it.

If not found, `lfind()` returns a NULL pointer.

No errors are defined.

lgamma(), lgammaf(), lgammal() — Log gamma function

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#define _XOPEN_SOURCE
#include <math.h>

double lgamma(double x);
extern int signgam;
int *__signgam(void);
```

C99:

```
#define _ISOC99_SOURCE
#include <math.h>

double lgamma(double x);
float lgammaf(float x);
long double lgammal(long double x);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

float lgamma(float x);
long double lgamma(long double x);
```

General description

The `lgamma()` function computes the

$\log_e |\Gamma(x)|$

where

$\Gamma(x)$

is defined as

$$\int_0^{\infty} e^{-t} t^{(x-1)} dt$$

The sign of

$\Gamma(x)$

is returned in the external integer *signgam*. The argument *x* may not be a non-positive integer.

In a multithreaded process, each thread has its own instance of the *signgam* variable. Threads access their instances of the variable by calling the `__signgam()` function. See “[__signgam\(\) — Return signgam reference](#)” on page 1640. The `math.h` header (see “[math.h — Floating-point math functions](#)” on page 40) redefines the string “*signgam*” to an invocation of the `__signgam` function. The actual *signgam* external variable is used to store the *signgam* value for the IPT.

Note: The following table shows the viable formats for these functions. See “[IEEE binary floating-point](#)” on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------|-----|------|
| lgamma | X | X |
| lgammaf | X | X |
| lgammal | X | X |

Returned value

If successful, `lgamma()` returns the above function of its argument.

`lgamma()` will fail under the following conditions:

- If the result overflows, the function will return `HUGE_VAL` and set `errno` to `ERANGE`.
- If *x* is a non-positive integer and `_XOPEN_SOURCE` is defined, `lgamma()` returns `HUGE_VAL` and sets `errno` to `EDOM`.
- If *x* is a non-positive integer and `_ISOC99_SOURCE` is defined, `lgamma()` returns `HUGE_VAL` and sets `errno` to `ERANGE`.

Note: If both `_XOPEN_SOURCE` and `_ISOC99_SOURCE` are defined, the `_ISOC99_SOURCE` behavior will take precedence.

Special behavior for IEEE: Even when `_XOPEN_SOURCE` is defined and `_ISOC99_SOURCE` not, `lgamma()` returns `HUGE_VAL` and sets `errno` to `ERANGE`.

Example

```
/*
 * This example uses lgamma() to calculate ln(|G(x)|), where x = 42.
 */
#include <math.h>
#include <stdio.h>

int main(void)
{
    double x=42, g_at_x;

    g_at_x = exp(lgamma(x)); /* g_at_x = 3.345253e+49 */
    printf ("The value of G(%4.2f) is %7.2e\n", x, g_at_x);
}
```

Output

```
The value of G(42.00) is 3.35e+49
```

lgammad32(), lgammad64(), lgammad128() - Log gamma function

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.10 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 lgammad32(_Decimal32 x);
_Decimal64 lgammad64(_Decimal64 x);
_Decimal128 lgammad128(_Decimal128 x);
_Decimal32 lgamma(_Decimal32 x); /* C++ only */
_Decimal64 lgamma(_Decimal64 x); /* C++ only */
_Decimal128 lgamma(_Decimal128 x); /* C++ only */
```

General description

The lgamma() function computes the $\log_e |\Gamma(x)|$

is defined as

$$\int_0^\infty e^{-t} t^{(x-1)} dt$$

The sign of $\Gamma(x)$

is returned in the external integer signgam. The argument x may not be a non-positive integer.

In a multithreaded process, each thread has its own instance of the *signgam* variable. Threads access their instances of the variable by calling the __signgam() function. The math.h header redefines the string *signgam* to an invocation of the __signgam function. The actual signgam external variable is used to store the signgam value for the IPT.

These functions work in IEEE decimal floating-point format. See [“IEEE decimal floating-point” on page 97](#) for more information.

Note: To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

If successful, lgamma() returns the above function of its argument.

lgamma() will fail under the following conditions:

- If the result overflows, the function will return +HUGE_VAL_D32, +HUGE_VAL_D64 or +HUGE_VAL_D128 and set errno to ERANGE.
- If x is a non-positive integer, lgamma() returns +HUGE_VAL_D32, +HUGE_VAL_D64 or +HUGE_VAL_D128 and sets errno to ERANGE.

Example

CELEBL26

```
/* CELEBL26

   This exaxmple illustrates the lgammad64() function.
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>
int main(void)
{
    _Decimal64 x, y;

    x = 42.0DD;
    y = lgammad64(x);

    printf ("lgammad64(%Df) = %Df\n", x, y);
}
```

__librel() — Query release level

Standards

| Table 48. Standards | | |
|------------------------|----------|--------------|
| Standards / Extensions | C or C++ | Dependencies |
| Language Environment | both | |

Format

```
#include <stdlib.h>

int __librel(void);
```

General description

The __librel() function provides the release level of the z/OS C/C++ runtime library. To use this function, you must enable the [runtime library extensions](#).

Returned value

The __librel() function returns the z/OS C/C++ runtime library release level that your application is using. The value is printed in hexadecimal format. The first byte of the value returned contains the product and version, second byte the release, and the third and fourth bytes contain the modification level.

Figure 4 on page 972 shows the format of the hexadecimal value returned by the __librel() function.

Figure 4. Format of the __librel() function return value

Table 49 on page 972 correlates library release level with the corresponding __librel() return value.

| Table 49. Library release level and value returned by the __librel() function | |
|---|--------------|
| Library release level | Return value |
| z/OS 3.2 | 0x43020000 |
| z/OS 3.1 | 0x43010000 |
| z/OS 2.5 | 0x42050000 |

Example

CELEBL04

```
/* CELEBL04

This example calls the __librel() function that returns
the library release level your program is currently
using in the following hexadecimal format 0xPVRMMMMM.

*/
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    printf("The current release of the library is: %X\n",__librel());
}
```

Output

The current release of the library is: 43020000

link() — Create a link to a file

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

int link(const char *oldfile, const char *newname);
```

General description

Provides an alternative pathname for the existing file, so that the file can be accessed by either the old or the new name. `link()` creates a link from the pathname *newname* to an existing file, with the pathname *oldfile*. The link can be stored in the same directory as the original file or in a completely different one.

Links are allowed to files only, not to directories.

This is a hard link, which ensures the existence of a file even after its original name has been removed.

If `link()` successfully creates the link, it increments the *link count* of the file. The link count tells how many links there are to the file. At the same time, `link()` updates the change time of the file, and the change time and modification time of the directory that contains *newname* (that is, the directory that holds the link). If `link()` fails, the link count is not incremented.

If *oldfile* names a symbolic link, `link()` creates a link that refers to the file that results from resolving the pathname contained in the symbolic link. If *newname* names a symbolic link, `link()` fails and sets `errno` to `EEXIST`.

Returned value

If successful, `link()` returns 0.

If unsuccessful, `link()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

The process did not have appropriate permissions to create the link. Possible reasons include no search permission on a pathname component of *oldfile* or *newname*, no write permission on the directory intended to contain the link, or no permission to access *oldfile*.

EEXIST

Either *newname* refers to a symbolic link, or a file or directory with the name *newname* already exists.

EINVAL

Either *oldfile* or *newname* is incorrect, because it contains a NULL.

ELOOP

A loop exists in symbolic links. This error is issued if the number of symbolic links encountered during resolution of *oldfile* or *newname* is greater than `POSIX_SYMLLOOP`.

EMLINK

oldfile already has its maximum number of links. The maximum number of links to a file is given by **LINK_MAX**, which you can determine by using `pathconf()` or `fpathconf()`.

ENAMETOOLONG

oldfile or *newname* is longer than **PATH_MAX**, or a component of one of the pathnames is longer than **NAME_MAX** while `_POSIX_NO_TRUNC` is in effect. For symbolic links, the length of the pathname string substituted for a symbolic link in *oldfile* or *newname* exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values can be determined using `pathconf()`.

ENOENT

A pathname component of *oldfile* or *newname* does not exist, or *oldfile* itself does not exist, or one of the two arguments is an empty string.

ENOSPC

The directory intended to contain the link cannot be extended to contain another entry.

ENOTDIR

A pathname component of one of the arguments is not a directory.

EPERM

oldfile is the name of a directory, and links to directories are not supported.

EROFS

Creating the link would require writing on a read-only file system.

EXDEV

oldfile and *newname* are on different file systems.

Example

```
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#include <stdlib.h>
#include <stdio.h>

main() {
    char fn[]="link.example.file";
    char ln[]="link.example.link";
    int fd;

    if ((fd = creat(fn, S_IWUSR)) < 0)
        perror("creat() error");
    else {
        close(fd);
        if (link(fn, ln) != 0) {
            perror("link() error");
            unlink(fn);
        }
        else {
            unlink(fn);
            unlink(ln);
        }
    }
}
```

linkat() — Create a link to a file relative to directory file descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1-2008 Single UNIX Specification, Version 4 | both | |

Format

```
#define _POSIX_C_SOURCE 200809L
#include <fcntl.h>          /* Definition of AT_* constants */
#include <unistd.h>

int linkat(int olddirfd, const char *oldpath, int newdirfd, const char *newpath, int flags);
```

General description

linkat() operates in the same way as link() except for the following differences.

- If the path name that is given in *oldpath* is relative, it is interpreted relative to the directory that is referred to by the file descriptor *olddirfd* (rather than relative to the current working directory of the calling process, as is done by link() for a relative path name).
- If *oldpath* is relative and *olddirfd* is the special value AT_FDCWD, *oldpath* is interpreted relative to the current working directory of the calling process (like link()).
- If *oldpath* is absolute, *olddirfd* is ignored.
- The interpretation of *newpath* is as for *oldpath* except that a relative path name is interpreted relative to the directory referred to by the file descriptor *newdirfd*.
- The following values can be bitwise ORed in flags:

AT_EMPTY_PATH

If *oldpath* is an empty string, create a link to the file that is referenced by *olddirfd*. In this case, *olddirfd* can refer to any type of file except a directory. This generally does not work if a file has a link count of zero (files that are created with O_TMPFILE and without O_EXCL are an exception).

AT_SYMLINK_FOLLOW

By default, linkat() does not dereference *oldpath* if it is a symbolic link (like link()). The flag AT_SYMLINK_FOLLOW can be specified in *flags* to cause *oldpath* to be dereferenced if it is a symbolic link.

Returned value

If successful, linkat() returns 0.

If unsuccessful, linkat() returns -1 and sets errno to one of the following values:

Error Code

Description

EACCES

The process does not have appropriate permissions to create the link. Possible reasons include:

- No search permission on a path name component of *oldpath* or *newpath*.
- No write permission on the directory that is intended to contain the link.
- No permission to access *oldpath*.

EBADF

oldpath (or *newpath*) is relative but *olddirfd* (or *newdirfd*) is not `AT_FDCWD` or a valid file descriptor.

EEXIST

Either *newpath* refers to a symbolic link, or a file or directory with the name *newpath* exists.

EINVAL

Either *oldpath* or *newpath* is incorrect because it contains a NULL or an invalid flag value was specified in *flags*.

ELOOP

A loop exists in symbolic links. This error is issued if the number of symbolic links that are encountered during the resolution of *oldpath* or *newpath* is greater than `POSIX_SYMLINK_MAX`.

EMLINK

oldpath has its maximum number of links. The maximum number of links to a file is given by `LINK_MAX`, which can be determined by using `pathconf()` or `fpathconf()`.

ENAMETOOLONG

oldpath or *newpath* is longer than `PATH_MAX`, or a component of one of the path names is longer than `NAME_MAX` while `_POSIX_NO_TRUNC` is in effect. For symbolic links, the length of the path name string that is substituted for a symbolic link in *oldfile* or *newname* exceeds `PATH_MAX`. The `PATH_MAX` and `NAME_MAX` values can be determined by using `pathconf()`.

ENOENT

- A path name component of *oldpath* or *newpath* does not exist.
- *oldpath* does not exist.
- One of the two arguments is an empty string.
- *oldpath* is a relative path name and *olddirfd* refers to a directory that is deleted.
- *newpath* is a relative path name and *newdirfd* refers to a directory that is deleted.

ENOSPC

The directory that is intended to contain the link cannot be extended to contain another entry.

ENOTDIR

- A path name component of one of the arguments is not a directory.
- *oldpath* is relative and *olddirfd* is a file descriptor that refers to a file other than a directory.
- *newpath* is relative and *newdirfd* is a file descriptor that refers to a file other than a directory.

EPERM

oldpath is the name of a directory and links to directories are not supported.

EROFS

Creating the link requires writing on a read-only file system.

EXDEV

oldpath and *newpath* are on different file systems.

Related information

listen() — Prepare the server for incoming client requests

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int listen(int socket, int backlog);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/socket.h>

int listen(int socket, int backlog);
```

General description

The `listen()` function applies only to stream sockets. It indicates a readiness to accept client connection requests, and creates a connection request queue of length *backlog* to queue incoming connection requests. Once full, additional connection requests are rejected.

Parameter

Description

socket

The socket descriptor.

backlog

Defines the maximum length for the queue of pending connections.

The `listen()` call indicates a readiness to accept client connection requests. It transforms an active socket into a passive socket. Once called, *socket* can never be used as an active socket to initiate connection requests. Calling `listen()` is the third of four steps that a server performs to accept a connection. It is called after allocating a stream socket with `socket()`, and after binding a name to *socket* with `bind()`. It must be called before calling `accept()`.

If the backlog is less than 0, *backlog* is set to 0. If the backlog is greater than `SOMAXCONN`, as defined in **sys/socket.h**, *backlog* is set to `SOMAXCONN`.

For `AF_UNIX` sockets, this value is variable and can be set in the application. For `AF_INET` and `AF_INET6` sockets, the value cannot exceed the maximum number of connections allowed by the installed TCP/IP.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

Returned value

If successful, `listen()` returns 0.

If unsuccessful, `listen()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

The *socket* parameter is not a valid socket descriptor.

EDESTADDRREQ

The socket is not bound to a local address, and the protocol does not support listening on an unbound socket.

EINVAL

An invalid argument was supplied. The socket is not named (a `bind()` has not been done), or the socket is ready to accept connections (a `listen()` has already been done). The socket is already connected.

ENOBUFS

Insufficient system resources are available to complete the call.

ENOTSOCK

The descriptor is for a file, not for a socket.

EOPNOTSUPP

The *socket* parameter is not a socket descriptor that supports the `listen()` call.

listxattr(), llistxattr(), flistxattr() — List extended attribute names

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <sys/xattr.h>

ssize_t listxattr(const char *path, char *list, size_t size);
ssize_t llistxattr(const char *path, char *list, size_t size);
ssize_t flistxattr(int fd, char *list, size_t size);
```

General description

Extended attributes are extensions to the normal attributes that are associated with all `inodes` in the system. They are used as `name:value` pairs that are associated with files and directories to provide more functions to a file system.

`listxattr()` retrieves the list of extended attribute names that are associated with the given path in the file system. The retrieved list is placed in a caller-allocated buffer that is pointed by *list* with size (in bytes) that is specified by *size*. If *size* is specified as zero, only the current size of the list of extended attributes is returned, and the buffer pointed by *list* remains unchanged.

`llistxattr()` is identical to `listxattr()` except that in the case of a symbolic link, the list of names of extended attributes that are associated with the link itself is retrieved by `lremovexattr()`, not the file that it refers to.

`flistxattr()` is identical to `listxattr()` except that only the open file that is referred to by *fd* is interrogated by `flistxattr()` in place of *path*.

Returned value

If successful, the size of the extended attribute name list in bytes is returned.

If unsuccessful, -1 is returned and `errno` is set to one of the following values:

Error Code

Description

ENAMETOOLONG

pathname is longer than `PATH_MAX` characters.

ERANGE

The size of the value buffer is too small to hold the result.

ENOENT

No file is named *pathname*, or *pathname* is an empty string.

llabs() — Calculate absolute value of long long integer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| z/OS UNIX C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | OS/390 V2R10 |

Format

```
#include <stdio.h>

long long llabs(long long int n);
```

Compile requirement: Use of this function requires the long long data type. See [z/OS XL C/C++ Language Reference](#) for information on how to make long long available.

General description

Calculates the absolute value of its long long integer argument *n*. The result is undefined when the argument is equal to `LLONG_MIN`, the smallest available long long integer (-9 223 372 036 854 775 808). The value `LLONG_MIN` is defined in the `limits.h` header file.

Returned value

Returns the absolute value of the long long integer argument *n*.

Related information

- [“stdio.h — Standard input and output” on page 63](#)
- [“stdlib.h — Standard library functions” on page 65](#)

lldiv() — Compute quotient and remainder of integral division for long long type

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| z/OS UNIX C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | OS/390 V2R10 |

Format

```
#include <stdio.h>

long long lldiv(long long numer, long long denom);
```

Compile requirement: Use of this function requires the long long data type. See [z/OS XL C/C++ Language Reference](#) for information on how to make long long available.

General description

Calculates the quotient and remainder of the division of numerator by denominator.

Returned value

Returns a structure of type `lldiv_t`, containing both the quotient `long long quot` and the remainder `long long rem`.

If the value cannot be represented, the returned value is undefined. If *denominator* is 0, a divide by 0 exception is raised.

Example

```
/*
   This example uses the
   lldiv() function to calculate the quotients and
   remainders for a set of two dividends and two divisors.
*/
#define _LONG_LONG 1
#include <stdio.h>
#include <stdlib.h>

int main(void)
```

```

{
    long long num[2] = {45,-45};
    long long den[2] = {7,-7};
    lldiv_t ans; /* lldiv_t is a struct type containing
                  two long long int fields:
                  'quot' stores quotient; 'rem' stores remainder */

    short i,j;

    printf("Results of long division:\n");
    for (i = 0; i < 2; i++)
        for (j = 0; j < 2; j++)
        {
            ans = lldiv(num[i], den[j]);
            printf("Dividend: %6lld Divisor: %6lld", num[i], den[j]);
            printf(" Quotient: %6lld Remainder: %6lld\n", ans.quot,
                  ans.rem);
        }
}

```

Output

```

Results of long division:
Dividend:  45 Divisor:   7 Quotient:   6 Remainder:   3
Dividend:  45 Divisor:  -7 Quotient:  -6 Remainder:   3
Dividend: -45 Divisor:   7 Quotient:  -6 Remainder:  -3
Dividend: -45 Divisor:  -7 Quotient:   6 Remainder:  -3

```

llround(), llroundf(), llroundl() — Round to the nearest integer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```

#define _ISOC99_SOURCE
#include <math.h>

long long int llround(double x);
long long int llroundf(float x);
long long int llroundl(long double x);

```

C++ TR1 C99:

```

#define _TR1_C99
#include <math.h>

long long int llround(float x);
long long int llround(long double x);

```

Compile requirement: Use of this function requires the long long data type. See [z/OS XL C/C++ Language Reference](#) for information on how to make long long available.

General description

The lround() family of functions round x to the nearest integer, rounding halfway cases away from zero, regardless of the current rounding mode.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------|-----|------|
| lround | X | X |
| lroundf | X | X |
| lroundl | X | X |

Returned value

If successful, they return the rounded integer. If the correct value is positive or negative and too large to represent as a long long, a domain error will occur and an unspecified value is returned.

Example

```
/*
 * This program illustrates the use of lround() function
 *
 */
#define _ISOC99_SOURCE
#include <math.h>
#include <_Ieee754.h> /* fpc functions */
#include <stdio.h>

void main() {
    _FP_fpcreg_t    save_rmode;
    long long int   rnd2nearest;
    double          number;

    printf("Illustrates the lround() function\n\n");

    save_rmode.rmode = _RMODE_RZ;
    __fpc_sm(save_rmode.rmode); /* set rounding mode to round to zero */

    number=501.1;
    rnd2nearest = lround(number);
    printf ("lround(%.1f) = %lli\n",number, rnd2nearest);

    number=1.5;
    rnd2nearest = lround(number);
    printf ("lround(%.1f) = %lli\n",number, rnd2nearest);

    number=-2.5;
    rnd2nearest = lround(number);
    printf ("lround(%.1f) = %lli\n",number, rnd2nearest);
}

Output

Illustrates the lround() function

lround(501.1) = 501
lround(1.5) = 2
lround(-2.5) = -3
```

llroundd32(), llroundd64(), llroundd128() — Round to the nearest integer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

long long int llroundd32(_Decimal32 x);
long long int llroundd64(_Decimal64 x);
long long int llroundd128(_Decimal128 x);

long long int llround(_Decimal32 x); /* C++ only */
long long int llround(_Decimal64 x); /* C++ only */
long long int llround(_Decimal128 x); /* C++ only */
```

Compile requirement: Use of this function requires the long long data type. See [z/OS XL C/C++ Language Reference](#) for information on how to make long long available.

General description

The `llround()` family of functions round x to the nearest integer, rounding halfway cases away from zero, regardless of the current rounding mode.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, they return the rounded integer. If the correct value is positive or negative and too large to represent as a long long, a domain error will occur and an unspecified value is returned.

Example

```
/* CELEBL21
   This example illustrates the llroundd32() function.
*/
#pragma strings(readonly)
```

```

#define __STDC_WANT_DEC_FP__
#include <fenv.h>
#include <math.h>
#include <stdio.h>

static void try_rm(int, _Decimal32);

/* pass back printable rounding mode */

static
char *rm_str(int rm)
{
    char *s = "undetermined";

    switch (rm)
    {
        case FE_DEC_TONEAREST :
            s = "FE_DEC_TONEAREST" ; break;
        case FE_DEC_TOWARDZERO :
            s = "FE_DEC_TOWARDZERO" ; break;
        case FE_DEC_UPWARD :
            s = "FE_DEC_UPWARD" ; break;
        case FE_DEC_DOWNWARD :
            s = "FE_DEC_DOWNWARD" ; break;
        case FE_DEC_TONEARESTFROMZERO :
            s = "FE_DEC_TONEARESTFROMZERO" ; break;
        case FE_DEC_TONEARESTTOWARDZERO :
            s = "FE_DEC_TONEARESTTOWARDZERO" ; break;
        case FE_DEC_AWAYFROMZERO :
            s = "FE_DEC_AWAYFROMZERO" ; break;
        case FE_DEC_PREPAREFORSHORTER :
            s = "FE_DEC_PREPAREFORSHORTER" ; break;
    }

    return s;
}

/* Try out one passed-in number with rounding mode */

static void try_rm(int rm, _Decimal32 d32)
{
    long long int ll;

    (void)fe_dec_setround(rm);

    ll = llroundd32(d32);

    printf("llroundd32(%+.2HF) = %+lld - rounding mode = %s\n",
           d32, ll, rm_str(rm));
    return;
}

int main()
{
    try_rm( FE_DEC_TONEAREST, 501.50DF);
    try_rm( FE_DEC_TOWARDZERO, 501.50DF);

lltoa() — Convert long long into a string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R5 |

Format

```
#define _OPEN_SYS_ITOA_EXT
#include <stdlib.h>

char * lltoa(int64_t ll, char * buffer, int radix);
```

Compile requirement: Use of this function requires the long long data type. See [z/OS XL C/C++ Language Reference](#) for information on how to make long long available.

General description

The `lltoa()` function converts the `int64_t ll` into a character string. The string is placed in the buffer passed, which must be large enough to hold the output. The radix values can be OCTAL, DECIMAL, or HEX. When the radix is DECIMAL, `lltoa()` produces the same result as the following statement:

```
(void) sprintf(buffer, "%lld", ll);
```

with `buffer` the returned character string. When the radix is OCTAL, `lltoa()` formats `int64_t ll` into an unsigned octal constant. When the radix is HEX, `lltoa()` formats `int64_t ll` into an unsigned hexadecimal constant. The hexadecimal value will include lower case `abcdef`, as necessary.

Returned value

String pointer (same as `buffer`) will be returned. When passed an invalid radix argument, function will return NULL and set `errno` to `EINVAL`.

Usage notes

1. This is a non-standard function. Even though the prototype given is commonly used by compilers on other platforms, there is no guarantee that this function will behave the same on all platforms, in all cases. You can use this function to help port applications from other platforms, but you should avoid using it when writing new applications, in order to ensure maximum portability.

Example

CELEBL30

```
/* CELEBL30

This example reads an int64_t and formats it to decimal, unsigned
octal, unsigned hexadecimal constants converted to a character
string.

*/

#define _OPEN_SYS_ITOA_EXT
#include <stdio.h>
#include <stdlib.h>

int main ()
{
    int64_t i;
    char buffer [sizeof(int64_t)*8+1];
    printf ("Enter a number: ");
    if (scanf ("%lld",&i) == 1) {
        lltoa (i,buffer,DECIMAL);
        printf ("decimal: %s\n",buffer);
        lltoa (i,buffer,HEX);
        printf ("hexadecimal: %s\n",buffer);
        lltoa (i,buffer,OCTAL);
        printf ("octal: %s\n",buffer);
    }
    return 0;
}
```

Output

If the input is 1234, then the output should be:

```
decimal: 1234
hexadecimal: 4d2
octal: 2322
```

localdtconv() — Date and time formatting convention inquiry

Standards

| Standards / Extensions | C or C++ | Dependencies |
|-------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <locale.h>

struct dtconv *localdtconv(void);
```

General description

Determines the date/time format information of the current locale.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

Returned value

Returns the address of the *dtconv* structure:

```
struct dtconv {
    char *abbrev_month_names[12]; /* Abbreviated month names */
    char *month_names[12];       /* full month names */
    char *abbrev_day_names[7];   /* Abbreviated day names */
    char *day_names[7];          /* full day names */
    char *date_time_format;      /* date and time format */
    char *date_format;           /* date format */
    char *time_format;           /* time format */
    char *am_string;             /* AM string */
    char *pm_string;             /* PM string */
    char *time_format_ampm;      /* long date format */
    char *iso_std8601_2000;      /* ISO 8601:2000 std date format*/
};
```

The *dtconv* structure is an IBM extension that stores values from the LC_TIME category of the current locale. It is initialized by the `setlocale()` function and copied to the user-supplied *dtconv* when `localdtconv()` is called.

The *dtconv* structure can be overwritten by subsequent calls to `localdtconv()` and `setlocale()` with LC_ALL or LC_TIME.

localeconv() – Query numeric conventions

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <locale.h>

struct lconv *localeconv(void);
```

General description

Sets the components of a structure having type `struct lconv` to values appropriate for the current locale. The structure may be overwritten by another call to `localeconv()` or by calling `setlocale()` and passing `LC_ALL`, `LC_MONETARY`, or `LC_NUMERIC`.

For a list of the elements in the `lconv` structure, see [Table 6 on page 37](#).

Pointers to strings with a value of "" indicate that the value is not available in the C locale or is of 0 length. char types with a value of `UCHAR_MAX` indicate that the value is not available in the current locale.

Returned value

Returns a pointer to the structure.

Example

CELEBL06

```
/* CELEBL06

   This example prints out the default decimal point for your locale and
   then the decimal point for the Fr_CA locale.

*/
#include <stdio.h>
#include <locale.h>

int main(void)
{
    char * string;
    struct lconv * mylocale;
    mylocale = localeconv();
    /* Display default decimal point */
    printf( "Default decimal point is a %s\n",
            mylocale->decimal_point );

    if (NULL != (string = setlocale(LC_ALL, "Fr_CA.IBM-1047" )))
    {
        mylocale = localeconv();
        /* A comma is set to be the decimal point
           when the locale is Fr_CA.IBM-1047 */
        printf( "French-speaking Canadian decimal point is a %s\n",
                mylocale->decimal_point );
    }
    else {
        printf("setlocale(LC_ALL, Fr_CA.IBM-1047) returned <NULL>\n");
    }
}
```

```
    return 0;
}
```

Output

```
Default decimal-point is a .
French-speaking Canadian decimal-point is a ,
```

localtime(), localtime64() — Convert time and correct for local time

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```
#include <time.h>

struct tm *localtime(const time_t *timeval);

#define _LARGE_TIME_API
#include <time.h>

struct tm *localtime64(const time64_t *timeval);
```

Compile requirement: Use of `localtime64()` function requires the long long data type. See [z/OS XL C/C++ Language Reference](#) for information on how to make long long available.

General description

The `localtime()` function converts the calendar time pointed to by `timeval` to a broken-down time expressed in local time. Calendar time is usually obtained by a call to the `time()` function.

The `localtime64()` function behaves exactly like `localtime()` except it will break down a `time64_t` value pointing to a calendar time beyond 03:14:07 UTC on January 19, 2038 with a limit of 23:59:59 UTC on December 31, 9999.

Usage notes

1. This function is sensitive to time zone information which is provided by:
 - The TZ environmental variable when POSIX(ON) and TZ is correctly defined, or by the _TZ environmental variable when POSIX(OFF) and _TZ is correctly defined.
 - The LC_TOD category of the current locale if POSIX(OFF) or TZ is not defined.

The time zone external variables tzname, timezone, and daylight declarations remain feature test protected in time.h.
2. The ctime(), localtime(), and mktime() functions now return Coordinated Universal Time (UTC) unless customized locale information is made available, which includes setting the timezone_name variable.
3. In POSIX you can supply the necessary information by using environment variables.
4. In non-POSIX applications, you can supply customized locale information by setting time zone and daylight information in LC_TOD.
5. By customizing the locale, you allow the time functions to preserve both time and date, correctly adjusting for daylight time on a given date.
6. The gmtime() and localtime() functions may use a common, statically allocated structure for the conversion. Each call to one of these functions will alter the result of the previous call.
7. Calendar time returned by the time() function begins at the epoch, which was at 00:00:00 Coordinated Universal Time (UTC), January 1, 1970.
8. The localtime() function converts calendar time (that is, seconds elapsed since the epoch) to broken-down time, expressed as local time, using time zone information provided by the TZ or _TZ environment variable or the LC_TOD category of the current locale:
 - When neither TZ nor _TZ is defined, the current locale is interrogated for time zone information. If neither TZ nor _TZ is defined and LC_TOD time zone information is not present in the current locale, a default value is applied to local time. POSIX programs simply default to Coordinated Universal Time (UTC), while non-POSIX programs establish an offset from UTC based on the setting of the system clock. For more information about customizing a time zone to work with local time, see “Customizing a time zone” in [z/OS XL C/C++ Programming Guide](#).

Returned value

Returns a pointer to a *tm* structure containing the broken-down time, expressed as a local time, and corresponding to the calendar time pointed to by *timeval*. If the calendar time cannot be converted, localtime() returns a NULL pointer. See [“time.h — Time and date” on page 75](#) for a description of the fields of the *tm* structure.

Error Code

Description

EOVERFLOW

The result cannot be represented.

Example

CELEBL07

```
/* CELEBL07

   This example queries the system clock and displays the local time.

*/
#include <time.h>
#include <stdio.h>

int main(void)
{
    struct tm *newtime;
    time_t ltime;
```

```

time(&lttime);
newtime = localtime(&lttime);
printf("The date and time is %s", asctime(newtime));
}

```

Output

This output would occur if the local time is 3:00 p.m. June 16, 2006):

```
The date and time is Fri Jun 16 15:00:00 2006
```

localtime_r(), localtime64_r() — Convert time value to broken-down local time

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 Language Environment | both | OS/390 V2R8 |

Format

```

#define _XOPEN_SOURCE 500
#include <time.h>

struct tm *localtime_r(const time_t *__restrict__ clock,
                      struct tm *__restrict__ result);

```

```

#define _XOPEN_SOURCE 500
#define _XPLATFORM_SOURCE
#include <time.h>

```

```
struct tm *localtime_r(const time_t *__restrict__ clock, struct tm *__restrict__ result);
```

```
#define _LARGE_TIME_API
#include <time.h>
```

```
struct tm *localtime64_r(const time64_t *__restrict__ clock,
                        struct tm *__restrict__ result);
```

Compile requirement: Use of `localtime64_r()` function requires the long long data type. See [z/OS XL C/C++ Language Reference](#) for information on how to make long long available.

General description

The `localtime_r()` function converts the calendar time pointed to by `clock` into a broken-down time that is stored in the structure to which `result` points. The `localtime_r()` function also returns a pointer to that same structure.

Unlike `localtime()`, the reentrant version is not required to set `tzname`.

The `localtime64_r()` function behaves exactly like `localtime_r()` except it will break down a `time64_t` value pointing to a calendar time beyond 03:14:07 Coordinated Universal Time on January 19, 2038 with a limit of 23:59:59 Coordinated Universal Time on December 31, 9999.

Special behavior for `_XPLATFORM_SOURCE`: When `_XPLATFORM_SOURCE` is defined, the structure `tm` includes `tm_gmtoff` and `tm_zone`. The values are available after `localtime_r()` is called.

Returned value

If successful, `localtime_r()` returns a pointer to the structure pointed to by the argument `result`.

If an error is detected, `localtime_r()` returns a null pointer and set `errno` to indicate the error.

Error Code

Description

EOVERFLOW

The result cannot be represented.

lockf() — Record locking on files

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int lockf(int filedes, int function, off_t size);
```

General description

The `lockf()` function allows sections of a file to be locked with advisory-mode locks. Calls to `lockf()` from other processes which attempt to lock the locked file section will either return an error value or block until the section becomes unlocked. All the locks for a process are removed when the process terminates. Record locking with `lockf()` is supported for regular files.

The *filedes* argument is an open file descriptor. The file descriptor must have been opened with a write-only permission (`O_WRONLY`) or with read/write permission (`O_RDWR`) to establish a lock with this function.

The *function* argument is a control value which specifies the action to be taken. The permissible values for *function* are defined in `<unistd.h>` as follows:

| Function | Description |
|----------|---|
| F_ULOCK | unlock locked sections |
| F_LOCK | lock a section for exclusive use |
| F_TLOCK | test and lock a section for exclusive use |
| F_TEST | test a section for locks by other processes |

`F_TEST` detects if a lock by another process is present on the specified section; `F_LOCK` and `F_TLOCK` both lock a section of a file if the section is available; `F_ULOCK` removes locks from a section of the file.

The *size* argument is the number of contiguous bytes to be locked or unlocked. The section to be locked or unlocked starts at the current offset in the file and extends forward for a positive size or backward for a negative size (the preceding bytes up to but not including the current offset). If *size* is 0, the section from the current offset through the largest possible file offset is locked (that is, from the current offset through the present or any future End Of File (EOF)). An area need not be allocated to the file to be locked because locks may exist past the End Of File.

The sections locked with `F_LOCK` or `F_TLOCK` may, in whole or in part, contain or be contained by a previously locked section for the same process. When this occurs, or if adjacent locked sections would occur, the sections are combined into a single locked section. If the request would cause the number of locks to exceed a system-imposed limit, the request will fail.

`F_LOCK` and `F_TLOCK` requests differ only by the action taken if the section is not available. `F_LOCK` blocks the calling process until the section is available. `F_TLOCK` makes the function fail if the section is already locked by another process.

File locks are released on first close by the locking process of any file descriptor for the file.

`F_ULOCK` requests may release (wholly or in part) one or more locked sections controlled by the process. Locked sections will be unlocked starting at the current file offset through *size* bytes or to the End Of File (EOF) if *size* is (`off_t`)0. When all of a locked section is not released (that is, when the beginning or end of the area to be unlocked falls within a locked section), the remaining portions of that section are still

locked by the process. Releasing the center portion of a locked section will cause the remaining locked beginning and end portions to become two separate locked sections. If the request would cause the number of locks in the system to exceed a system-imposed limit, the request will fail.

A potential for deadlock occurs if a process controlling a locked section is blocked by accessing another process's locked section. If the system detects that a deadlock would occur, `lockf()` will fail with an EDEADLK error.

Locks obtained by `lockf()` are controlled by the same facility controlling locks obtained by `fcntl()`.

The interaction between `fcntl()` and `lockf()` locks is unspecified.

Blocking on a section is interrupted by any signal.

Large file support for z/OS UNIX files: Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the [long long data type support](#) enabled and define the `_LARGE_FILES` feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the `_LARGE_FILES` feature test macro as well.

Returned value

If successful, `lockf()` returns 0.

If unsuccessful, existing locks are not changed, `lockf()` returns -1, and sets `errno` to one of the following values:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

| | |
|-------------------------|--|
| EACCES or EAGAIN | The <i>function</i> argument is <code>F_TLOCK</code> or <code>F_TEST</code> and the section is already locked by another process |
| EBADF | The <i>filedes</i> argument is not a valid open file descriptor; or <i>function</i> is <code>F_LOCK</code> or <code>F_TLOCK</code> and <i>filedes</i> is not a valid file descriptor open for writing. |
| EDEADLK | The <i>function</i> argument is <code>F_LOCK</code> and a deadlock is detected. |
| EINTR | A signal was caught during execution of the function. |
| E_OVERFLOW | The offset of the first, or if size is not 0 then the last, byte in the requested section cannot be represented correctly in an object of type <code>off_t</code> . |

log(), logf(), logl() – Calculate natural logarithm

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#include <math.h>

double log(double x);
float log(float x);           /* C++ only */
long double log(long double x); /* C++ only */
float logf(float x);
long double logl(long double x);
```

General description

Calculates the natural logarithm (base e) of x, for x greater than 0.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

Returned value

Returns the computed value.

If x is negative, the function sets errno to EDOM and returns -HUGE_VAL. If x is 0.0, the function returns -HUGE_VAL and sets errno to ERANGE. If the correct value would cause an underflow, 0 is returned and the value ERANGE is stored in errno.

Special behavior for IEEE: If x greater than 0, the function returns the natural logarithm (base e) of x.

If x is negative, the function sets errno to EDOM and returns NaNQ. If x is 0.0, the function returns -HUGE_VAL and errno remains unchanged.

Note: When environment variable _EDC_SUSV3 is set to 2, and if x is 0.0, the function returns -HUGE_VAL and sets errno to ERANGE.

Example

CELEBL08

```
/* CELEBL08

   This example calculates the natural logarithm of 1000.0.

*/
#include <math.h>
#include <stdio.h>

int main(void)
{
    double x = 1000.0, y;
```

```
y = log(x);  
printf("The natural logarithm of %lf is %lf\n", x, y);  
}
```

Output

The natural logarithm of 1000.000000 is 6.907755

logb(), logbf(), logbl() — Unbiased exponent

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|-----------------------------------|
| XPG4.2 C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 for logbf(), logbl() |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1  
#include <math.h>  
  
double logb(double x);
```

C99:

```
#define _ISOC99_SOURCE  
#include <math.h>  
  
float logbf(float x);  
long double logbl(long double x);
```

C++ TR1 C99:

```
#define _TR1_C99  
#include <math.h>  
  
float logb(float x);  
long double logb(long double x);
```

General description

Returns the exponent of its argument *x*, as a signed integer value in floating-point mode. If *x* is subnormal, it is treated as a normalized number.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------|-----|------|
| logb | X | X |
| logbf | X | X |
| logbl | X | X |

Returned value

If successful, `logb()` returns the exponent of `x`.

`logb()` will fail under the following condition: If `x` is equal to 0.0, `logb()` will return `-HUGE_VAL` and set `errno` to `EDOM`.

Example

```

/*
 * This program illustrates the use of logb() function
 *
 */
#define _ISOC99_SOURCE
#include <math.h>
#include <float.h> /* Needed for FLT_RADIX */
#include <stdio.h>

void main() {

    int i;
    union {
        double number;
        unsigned char  uchars [sizeof(double)];
    } dblval;
    double logbx;

    printf("Illustrates the logb() function");

    #ifdef _BFP
        printf(" (IEEE version)\n\n");
    #else
        printf(" (HFP version)\n\n");
    #endif

    /* generate the smallest possible double number */
    for (i=0; i<sizeof(double); i++)
        dblval.uchars[i] = 0;
    dblval.uchars[1] = 0x10;

    logbx = logb(dblval.number);

    printf("x = %g\n",dblval.number);
    printf("logb(x) = %f\n\n", logbx);

    printf("pow(FLT_RADIX, logb(x) ) should equal x\n");
    printf("pow(%d,%f) = %g\n",FLT_RADIX, logbx, pow(FLT_RADIX, logbx));
}

```

Output

Illustrates the logb() function (IEEE version)

x = 2.22507e-308
logb(x) = -1022.000000

pow(FLT_RADIX, logb(x)) should equal x
pow(2,-1022.000000) = 2.22507e-308

logbd32(), logbd64(), logbd128() – Unbiased exponent

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 logbd32(_Decimal32 x);
_Decimal64 logbd64(_Decimal64 x);
_Decimal128 logbd128(_Decimal128 x);

_Decimal32 logb(_Decimal32 x);    /* C++ only */
_Decimal64 logb(_Decimal64 x);    /* C++ only */
_Decimal128 logb(_Decimal128 x);  /* C++ only */
```

General description

Returns the unbiased exponent of its argument *x* as a signed integer value in decimal floating-point mode. For typical numbers, the value returned is the logarithm of $|x|$ rounded down (toward $-\infty$) to the nearest integer value.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, these functions return the unbiased exponent of *x* as a signed integer value in decimal floating-point mode.

These functions will fail under the following condition: If *x* is equal to 0.0, `-HUGE_VAL_D32`, `-HUGE_VAL_D64`, or `-HUGE_VAL_D128` is returned and `errno` is set to `EDOM`.

Example

```
/* CELEBL24
   This program illustrates the use of logbd32() function
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>
#include <stdlib.h>

void main()
{
    _Decimal32 x, logbx;

    printf("Illustrates the logbd32() function\n");

    /* Generate the smallest possible positive _Decimal32 number */
    x = strtod32("0000001.E-101", NULL);
    logbx = logbd32(x);
```

```

printf("x      = %Hg\n" , x      );
printf("logb(x) = %Hf\n\n", logbx);

printf("powd32(10.0, logb32(x)) should equal x\n");
printf("powd32(%Hf, %Hf) = %Hg\n",
       10.0DF, logbx, powd32(10.0DF, logbx));
}

```

__login(), __login_applid() — Create a new security environment for process

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | OS/390 V2R6 |

Format

```
#define _OPEN_SYS
#include <unistd.h>

int __login(int    function_code,
            int    identity_type,
            int    identity_length,
            void   *identity,
            int    pass_length,
            char   *pass,
            int    certificate_length,
            char   *certificate,
            int    option_flags);

int __login_applid(int function_code,
                  int identity_type,
                  int identity_length,
                  void *identity,
                  int pass_length,
                  char *pass,
                  int certificate_length,
                  char *certificate,
                  int option_flags,
                  const char *applid);
```

General description

The __login() function provides a way for a process to change its identity so as to be different than the address space identity and create a new security environment for the process. Once changed the process should not revert back to a previous identity and security environment. The following rules apply:

- Any single-threaded process can issue a __login to change its security environment.

- If the process is in a multiprocessing or multiple user environment and there is no task level security associated with the process, then the new security environment will be associated with the process.
- If the process is in a multiprocessing or multiple user environment and there is task level security associated with the process, then the old security environment will be replaced by the new security environment.

The `__login_applid()` function is equivalent to `__login()` with the added feature that it also allows the application identifier (APPLID) to be supplied that will be passed on to the security product to assist with authentication. This is useful, for example, in situations where a pass ticket is provided and the pass ticket was created with a USERID/APPLID combination. When applid is NULL or a pointer to NULL, no application identifier will be passed on to the security product.

The function has the following parameters:

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

| | |
|-----------------------------|---|
| <i>function_code</i> | Specifies the function. Specify <code>__LOGIN_CREATE</code> , as defined in the <code>unistd.h</code> header file, to create a process level security environment for the caller's process. |
|-----------------------------|---|

| | |
|-----------------------------|--|
| <i>identity_type</i> | Specifies the format of the user identity being provided in <i>*identity</i> . Specify <code>__LOGIN_USERID</code> , as defined in the <code>unistd.h</code> header file. The user ID identity is in the format of a 1-to-8-character userid and is passed as input. |
|-----------------------------|--|

| | |
|-------------------------------|--|
| <i>identity_length</i> | Specifies the length of the <i>identity</i> as defined by <i>identity_type</i> . |
|-------------------------------|--|

| | |
|-------------------------|--|
| <i>*identity</i> | Specifies the user identity as defined by <i>identity_type</i> . |
|-------------------------|--|

| | |
|---------------------------|---|
| <i>pass_length</i> | Specifies the length of the password or PassTicket, or the password phrase defined by <i>pass</i> . |
|---------------------------|---|

| | |
|---------------------|--|
| <i>*pass</i> | Specifies a user password or PassTicket, or a password phrase. |
|---------------------|--|

| | |
|----------------------------------|--|
| <i>certificate_length</i> | Is not used presently and must be set to zero. |
|----------------------------------|--|

| | |
|---------------------------|---|
| <i>certificate</i> | Is not used presently and must point to void. |
|---------------------------|---|

| | |
|----------------------------|---|
| <i>option_flags</i> | Specifies options used to tailor request. Must be set to 0. |
|----------------------------|---|

| | |
|----------------------|--|
| <i>applid</i> | Specifies the application identifier that will be used for authentication with the security product. |
|----------------------|--|

Usage notes

1. The intent of the `__login()` service is to provide a way for a process to change its identity so as to be different than the address space identity. The process should either terminate or select a new user ID, but should not try to revert back to the original identity. The user could issue the `__login()` again with the original user identity, but the task would retain its own security environment and not share the security environment at the address space level.
2. A security product supporting multiprocessing or multiple user environment must be installed and operational.

Returned value

If successful, `__login()` returns 0.

If unsuccessful, `__login()` returns -1 and sets `errno` to one of the following values:

Error Code Description

EACCES

Permission is denied.

EINVAL

A parameter is not valid. For example, length of applid exceeds 8 bytes.

EMVSERR

An MVS environmental error or internal occurred.

EMVSEXPIRE

The password or PassTicket, or a password phrase for the specified resource has expired.

EMVSSAF2ERR

An error occurred in the security product. The userid has been revoked or is unable to use the application.

ENOSYS

The function is not implemented.

EPERM

The operation is not permitted. Calling process may not be authorized in BPX.DAEMON facility class.
The function is not supported in an address space where a load was done from an uncontrolled library.
A required password or PassTicket, or a password phrase was not specified.

ESRCH

The USERID cannot become an OMVS process. The userid provided is not defined to the security product or doesn't have an OMVS segment defined.

|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#include <math.h>

double log10(double x);
float log10(float x);           /* C++ only */
long double log10(long double x); /* C++ only */
float log10f(float x);
long double log10l(long double x);
```

General description

Calculates the base 10 logarithm of the positive value of x .

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

Returned value

Returns the computed value.

If x is negative, the function sets `errno` to `EDOM` and returns `-HUGE_VAL`. If x is 0, the function returns `-HUGE_VAL`, and sets `errno` to `ERANGE`. If the correct value would cause an underflow, 0 is returned and the value `ERANGE` is stored in `errno`.

Special behavior for IEEE: If successful, the function returns the base 10 logarithm of the positive value of x .

If x is negative, the function sets `errno` to `EDOM` and returns `NaNQ`. If x is 0, the function returns `-HUGE_VAL` and `errno` remains unchanged.

Note: When environment variable `_EDC_SUSV3` is set to 2, and if x is 0, the function returns `-HUGE_VAL` and sets `errno` to `ERANGE`.

Example

CELEBL09

```
/* CELEBL09
   This example calculates the base 10 logarithm of 1000.0.
*/
#include <math.h>
#include <stdio.h>

int main(void)
{
```

```
double x = 1000.0, y;

y = log10(x);

printf("The base 10 logarithm of %lf is %lf\n", x, y);
}
```

Output

```
The base 10 logarithm of 1000.000000 is 3.000000
```

log10d32(), log10d64(), log10d128() — Calculate base 10 logarithm

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 log10d32(_Decimal32 x);
_Decimal64 log10d64(_Decimal64 x);
_Decimal128 log10d128(_Decimal128 x);

_Decimal32 log10(_Decimal32 x); /* C++ only */
_Decimal64 log10(_Decimal64 x); /* C++ only */
_Decimal128 log10(_Decimal128 x); /* C++ only */
```

General description

Calculates the base 10 logarithm of the positive value of *x*.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, the function returns the base 10 logarithm of the positive value of *x*.

If *x* is negative, the function sets *errno* to *EDOM* and returns NaNQ.

If *x* is 0, the function returns *-HUGE_VAL_D32*, *-HUGE_VAL_D64*, or *-HUGE_VAL_D128* and *errno* remains unchanged.

Example

```

/* CELEBL23

   This example illustrates the log10d128() function.

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal128 x = 1000.0DL, y;

    y = log10d128(x);

    printf("The base 10 logarithm of %DDf is %DDf\n", x, y);
}

```

log2(), log2f(), log2l() — Calculate the base-2 logarithm

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R5 |

Format

```

#define _ISOC99_SOURCE
#include <math.h>

double log2(double x);
float log2f(float x);
long double log2l(long double x);

```

C++ TR1 C99:

```

#define _TR1_C99
#include <math.h>

float log2(float x);
long double log2(long double x);

```

General description

The log2 functions compute the base-2 logarithm of x.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------|-----|------|
| log2 | X | X |
| log2f | X | X |
| log2l | X | X |

Returned value

The log2 functions return log2 x.
A domain error occurs if x is less than zero. A range error may occur if x is zero.

Special behavior for IEEE: If x is equal to 0, a pole error will occur and errno remains unchanged.

When environment variable _EDC_SUSV3 is set to 2, and if x is equal to 0, the function returns -HUGE_VAL and sets errno to ERANGE.

log2d32(), log2d64(), log2d128() — Calculate the base-2 logarithm

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.11 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 log2d32(_Decimal32 x);
_Decimal64 log2d64(_Decimal64 x);
_Decimal128 log2d128(_Decimal128 x);

_Decimal32 log2(_Decimal32 x); /* C++ only */
_Decimal64 log2(_Decimal64 x); /* C++ only */
_Decimal128 log2(_Decimal128 x); /* C++ only */
```

General description

The log2() functions compute the base-2 logarithm of x.

Notes:

1. These functions work in IEEE decimal floating-point format. See [“IEEE decimal floating-point” on page 97](#) IEEE Decimal Floating-Point for more information.
2. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

The log2 functions return log2 x.
A domain error occurs if x is less than zero.
A range error may occur if x is zero.

Example

```
/* CELEBL28

   This exaxmple illustrates the log2d32() function.

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>
void main(void)
{
    _Decimal32 x, y;

    x = 85.7DF;
    y = log2d32(x);

    printf("log2d32( %Hf ) = %Hf\n", x, y);
}
```

longjmp() — Restore stack environment

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 C11 Single UNIX Specification, Version 3 | both | |

Format

```
#include <setjmp.h>

__noreturn__ void longjmp(jmp_buf env, int value);
```

General description

Restores a stack environment previously saved in *env* by `setjmp()`. The `setjmp()` and `longjmp()` functions provide a way to perform a nonlocal goto. They are often used in signal handlers.

A call to `setjmp()` causes the current stack environment to be saved in *env*. A subsequent call to `longjmp()` restores the saved environment, and returns control to a point in the program corresponding to the `setjmp()` call. Execution resumes as if the `setjmp()` call had just returned the given *value* of the value argument. All variables that are accessible to the function that receives control contain the values they had when `longjmp()` was called. The values of register variables are unpredictable. Nonvolatile *auto* variables that are changed between calls to `setjmp()` and `longjmp()` are also unpredictable.

Note: Ensure that the function that calls `setjmp()` does not return before you call the corresponding `longjmp()` function. Calling `longjmp()` after the function calling `setjmp()` returns causes unpredictable program behavior.

The *value* argument passed to `longjmp()` must be nonzero. If you give a 0 argument for *value*, `longjmp()` substitutes a 1 in its place.

Notes:

1. If `longjmp()` is used to jump back into an XPLink routine, any `alloca()` requests issued by the XPLink routine after the earlier `setjmp()` (or `_setjmp()`, `sigsetjmp()`, `getcontext()`, and so on) was called and before `longjmp()` is called are backed out. All storage obtained by these `alloca()` requests is freed before the XPLink routine is resumed.
2. If `longjmp()` is used to jump back into a non-XPLink routine, `alloca()` requests made after `setjmp()` (and so on) and before `longjmp()` are not backed out.

Special behavior for POSIX: In a POSIX program, the signal mask is *not* saved. Thus, to save and restore a stack environment that includes the current signal mask, use `sigsetjmp()` and `siglongjmp()` instead of `setjmp()` and `longjmp()`. The `sigsetjmp()`—`siglongjmp()` pair, the `setjmp()`—`longjmp()` pair, the `_setjmp()`—`_longjmp()` pair, and the `getcontext()`—`setcontext()` pair cannot be intermixed. A stack environment saved by `setjmp()` can be restored only by `longjmp()`.

Special behavior for C++: If `setjmp()` and `longjmp()` are used to transfer control, the behavior is undefined whether the destruction of automatic C++ objects is done. Additionally, if any automatic objects would be destroyed by a thrown exception transferring control to another (destination) point in the program, then a call to `longjmp()` at the throw point that transfers control to the same (destination) point has undefined behavior. The use of `setjmp()` and `longjmp()` in conjunction with `try()`, `catch()`, and `throw()` is also undefined.

Special behavior for XPG4.2: In a program that was compiled with the feature test macro, `_XOPEN_SOURCE_EXTENDED`, defined, another pair of functions, `_setjmp()`—`_longjmp()` are available. These functions are, on this implementation, functionally identical to `setjmp()`—`longjmp()`. Therefore it is possible, but not recommended, to intermix the `setjmp()`—`longjmp()` pair with the `_setjmp()`—`_longjmp()` pair.

Special behavior for XPLINK-compiled C++: Restrictions concerning `setjmp.h` and `ucontext.h`:

1. All XPLINK programs compiled with the Release 10 or later C compilers that are to run with Language Environment Release 10 or later libraries and use the **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** types must not be compiled with C headers from Language Environment 2.9 or earlier.
2. Non-XPLINK functions compiled with any level of Language Environment headers must not define **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** data items and pass them to XPLINK functions that call `getcontext()`, `longjmp()`, `_longjmp()`, `setjmp()`, `_setjmp()`, `setcontext()`, `sigsetjmp()`, or `swapcontext()` with these passed-in data items.
3. When `__XPLINK__` is defined, the Release 10 and later headers define a larger **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** area that is required by `setjmp()`, `getcontext()`, and related functions when they are called from an XPLINK routine. If `__XPLINK__` is not defined, the Release 10 and later headers define a shorter **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** area. The Language Environment headers before Release 10 also define the shorter version of these data areas. If an XPLINK function calls `setjmp()`, `getcontext()` or similar functions with a short **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** area, a storage overlay or program check may occur when the C library tries to store past the end of the passed-in (too short) data area.

Returned value

`longjmp()` does not use the normal function call and return mechanisms; it returns no values.

Example

This example provides for saving the stack environment at this statement: `if(setjmp(mark) != 0) ...`

When the system first performs the `if` statement, it saves the environment in *mark* and sets the condition to FALSE because `setjmp()` returns a 0 when it saves the environment. The program prints the message: `setjmp has been called`

The subsequent call to function *p* tests for a local error condition, which can cause it to perform the `longjmp()` function. Then, control returns to the original `setjmp()` function using the environment saved in *mark*. This time the condition is TRUE because -1 is the returned value from the `longjmp()` function. The example then performs the statements in the block and prints: `longjmp has been called`

It then performs the *recover* function and leaves the program.

```
/* Illustration of longjmp(). */
#include <stdio.h>
#include <setjmp.h>

jmp_buf mark;

void p(void);
void recover(void);

int main(void)
{
    if (setjmp(mark) != 0)
    {
        printf("longjmp has been called\n");
        recover();
        exit(1);
    }
    printf("setjmp has been called\n");
    :
    p();
    :
}

void p(void)
{
    int error = 0;
    :
    error = 9;
    :
    if (error != 0)
        longjmp(mark, -1);
    :
}

void recover(void)
{
    :
}
```

_longjmp() — Nonlocal goto

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <setjmp.h>

void _longjmp(jmp_buf env, int value);
```

General description

The `_longjmp()` function restores a stack environment previously saved in *env* by `_setjmp()`. The `_setjmp()` and `_longjmp()` functions provide a way to perform a nonlocal *goto*. They are often used in signal handlers.

A call to `_setjmp()` causes the current stack environment to be saved in *env*.

A subsequent call to `_longjmp()` restores the saved environment and returns control to a point in the program corresponding to the `_setjmp()` call. Execution resumes as if the `_setjmp()` call had just returned the given *value* of the value argument. All variables that are accessible to the function that receives control contain the values they had when `_longjmp()` was called. The values of register variables are unpredictable. Nonvolatile *auto* variables that are changed between calls to `_setjmp()` and `_longjmp()` are also unpredictable.

The X/Open standard states that `_longjmp()` and `_setjmp()` are functionally identical to `longjmp()` and `setjmp()`, respectively, with the addition restriction that `_longjmp()` and `_setjmp()` do not manipulate the signal mask. However, on this implementation `longjmp()` and `setjmp()` do not manipulate the signal mask. So on this implementation `_longjmp()` and `_setjmp()` are literally identical to `longjmp()` and `setjmp()`, respectively.

To save and restore a stack environment, including the current signal mask, use `sigsetjmp()` and `siglongjmp()` instead of `_setjmp()` and `_longjmp()`, or `setjmp()` and `longjmp()`.

The `_setjmp()`—`_longjmp()` pair, the `setjmp()`—`longjmp()` pair, the `sigsetjmp()`—`siglongjmp()` pair, and the `getcontext()`—`setcontext()` pair cannot be intermixed. A stack environment saved by `_setjmp()` can be restored only by `_longjmp()`.

Notes:

1. However, on this implementation, since the `_setjmp()`—`_longjmp()` pair are functionally identical to the `setjmp()`—`longjmp()` pair it is possible to intermix them, but it is not recommended.
2. Ensure that the function that calls `_setjmp()` does not return before you call the corresponding `_longjmp()` function. Calling `_longjmp()` after the function calling `_setjmp()` returns causes unpredictable program behavior.
3. If `_longjmp()` is used to jump back into an XPLink routine, any `alloca()` requests issued by the XPLink routine after the earlier `_setjmp()` (or `setjmp()`, `sigsetjmp()`, `getcontext()` and so on) was called and before `_longjmp()` is called are backed out. All storage obtained by these `alloca()` requests is freed before the XPLink routine is resumed.
4. If `_longjmp()` is used to jump back into a non-XPLink routine, `alloca()` requests made after `_setjmp()` (and so on) and before `_longjmp()` are not backed out.

The *value* argument passed to `_longjmp()` must be nonzero. If you give a zero argument for *value*, `_longjmp()` substitutes a 1 in its place.

env

An address for a `jmp_buf` structure

value

The return value from `_setjmp()`

Special behavior for C++: If `_setjmp()` and `_longjmp()` are used to transfer control, the behavior is undefined whether the destruction of automatic C++ objects is done. Additionally, if any automatic objects would be destroyed by a thrown exception transferring control to another (destination) point in the program, then a call to `_longjmp()` at the throw point that transfers control to the same (destination) point has undefined behavior. The use of `_setjmp()` and `_longjmp()` in conjunction with `try()`, `catch()`, and `throw()` is also undefined.

Special behavior for XPLINK-compiled C++: Restrictions concerning `setjmp.h` and `ucontext.h`:

1. All XPLINK programs compiled with the Release 10 or later C compilers that are to run with Language Environment Release 10 or later libraries and use the **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** types must not be compiled with C headers from Language Environment 2.9 or earlier.
2. Non-XPLINK functions compiled with any level of Language Environment headers must not define **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** data items and pass them to XPLINK functions that call `getcontext()`, `longjmp()`, `_longjmp()`, `setjmp()`, `_setjmp()`, `setcontext()`, `sigsetjmp()`, or `swapcontext()` with these passed-in data items.
3. When `__XPLINK__` is defined, the Release 10 and later headers define a larger **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** area that is required by `setjmp()`, `getcontext()`, and related functions when they are called from an XPLINK routine. If `__XPLINK__` is not defined, the Release 10 and later headers define a shorter **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** area. The Language Environment headers before Release 10 also define the shorter version of these data areas. If an XPLINK function calls `setjmp()`, `getcontext()` or similar functions with a short **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** area, a storage overlay or program check may occur when the C library tries to store past the end of the passed-in (too short) data area.

Returned value

`_longjmp()` does not use the normal function call and return mechanisms; it returns no values. When `_longjmp()` completes, program execution continues as if the corresponding invocation of `_setjmp()` had just returned the value specified by *value*.

lrand48() — Pseudo-random number generator

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <stdlib.h>

long int lrand48(void);
```

General description

The drand48(), erand48(), jrand48(), lrand48(), mrand48() and nrand48() functions generate uniformly distributed pseudo-random numbers using a linear congruential algorithm and 48-bit integer arithmetic.

The functions drand48() and erand48() return nonnegative, double-precision, floating-point values, uniformly distributed over the interval [0.0,1.0).

The functions lrand48() and nrand48() return nonnegative, long integers, uniformly distributed over the interval [0,2**31).

The functions mrand48() and jrand48() return signed long integers, uniformly distributed over the interval [-2**31,2**31).

The lrand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, X(i), according to the linear congruential formula:

$$X(n+1) = (aX(n) + c) \bmod (2^{**}48) \quad n \geq 0$$

The initial values of X, a, and c are:

```
X(0) = 1
a    = 5deece66d (base 16)
c    = b          (base 16)
```

C/370 provides storage to save the most recent 48-bit integer value of the sequence, X(i). This storage is shared by the drand48(), lrand48() and mrand48() functions. The value, X(n), in this storage may be reinitialized by calling the lcong48(), seed48() or srand48() function. Likewise, the values of a and c, may be changed by calling the lcong48() function. Thereafter, whenever the seed48() or srand48() function is called to change X(n), the initial values of a and c are also reestablished.

Special behavior for z/OS UNIX Services: You can make the lrand48() function and other functions in the drand48 family thread-specific by setting the environment variable _RAND48 to the value THREAD before calling any function in the drand48 family.

If you do not request thread-specific behavior for the drand48 family, C/370 serializes access to the storage for X(n), a and c by functions in the drand48 family when they are called by a multithreaded application.

If thread-specific behavior is requested, and the lrand48() function is called from thread t, the lrand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, X(t,i), for the thread t. The sequence of values for a thread is generated according to the linear congruential formula:

$$X(t,n+1) = (a(t)X(t,n) + c(t)) \bmod (2^{**}48) \quad n \geq 0$$

The initial values of X(t), a(t) and c(t) for the thread t are:

```
X(t,0) = 1
a(t)   = 5deece66d (base 16)
c(t)   = b          (base 16)
```

C/370 provides storage which is specific to the thread t to save the most recent 48-bit integer value of the sequence, X(t,i), generated by the drand48(), lrand48() or mrand48() function. The value, X(t,n), in this storage may be reinitialized by calling the lcong48(), seed48() or srand48() function from the thread t. Likewise, the values of a(t) and c(t) for thread t may be changed by calling the lcong48() function from the thread. Thereafter, whenever the seed48() or srand48() function is called from the thread t to change X(t,n), the initial values of a(t) and c(t) are also reestablished.

Returned value

lrand48() transforms the generated 48-bit value, $X(n+1)$, to a nonnegative, long integer value on the interval $[0, 2^{31})$ and returns this transformed value.

Special behavior for z/OS UNIX Services: If thread-specific behavior is requested for the drand48 family and lrand48() is called on thread t , lrand48() transforms the generated 48-bit value, $X(t, n+1)$, to a nonnegative, long integer value on the interval $[0, 2^{31})$ and returns this transformed value.

lrint(), lrintf(), lrintl() and llrint(), llrintf(), llrintl() — Round the argument to the nearest integer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _ISOC99_SOURCE
#include <math.h>

long int lrint(double x);
long int lrintf(float x);
long int lrintl(long double x);

long long int llrint(double x);
long long int llrintf(float x);
long long int llrintl(long double x);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

long int lrint(float x);
long int lrint(long double x);
long long int llrint(float x);
long long int llrint(long double x);
```

Compile requirement: The llrint() family of functions requires the long long data type. See [z/OS XL C/C++ Language Reference](#) for information on how to make long long available.

General description

The lrint() and llrint() families of functions round their argument to the nearest integer value according to the current rounding mode. If the rounded value is outside the range of the return type, the numeric result is unspecified. A range error may occur if the magnitude of x is too large.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------|-----|------|
| lrint | X | X |
| lrintf | X | X |
| lrintl | X | X |
| llrint | X | X |
| llrintf | X | X |
| llrintl | X | X |

Returned value

If successful, they return the rounded integer value. If the correct value is positive or negative and too large to represent as a long (lrint() family) or long long (llrint() family), a domain error will occur and an unspecified value is returned.

Example

```

/*
 * This program illustrates the use of lrint() function
 *
 * Note: To get the output shown in this book , this program
 *       should be compiled using IEEE floating point representation
 *
 */
#define _ISOC99_SOURCE
#include <math.h>
#include <stdio.h>
#include <_Ieee754.h> /* save/get fpc functions */

char *RoundStr (_FP_rmode_t rm_type) {
    char *RndStr="undetermined";
    switch (rm_type) {
        case (_RMODE_RN):
            RndStr="round to nearest";
            break;
        case (_RMODE_RZ):
            RndStr="round toward zero";
            break;
        case (_RMODE_RP):
            RndStr="round toward +infinity ";
            break;
        case (_RMODE_RM):
            RndStr="round toward -infinity ";
            break;
    }
    return (RndStr);
}

void main() {
    _FP_fpcreg_t save_rmode, current_rmode;
    long int      rnd2nearest;
    double        number=500.99;

    printf("Illustrates the lrint() function\n");
    __fpc_rd(&current_rmode); /* get current rounding mode */

    rnd2nearest = lrint(number);
    printf ("When rounding direction is %s:\n lrint(%.2f) = %li\n",

```

```

        RoundStr(current_rmode.rmode), number, rnd2nearest);
    save_rmode.rmode = _RMODE_RZ;
    __fpc_sm(save_rmode.rmode); /* set rounding mode to round to zero */

    rnd2nearest = lrint(number);
    printf ("When rounding direction is %s:\n lrint(%.2f) = %li\n",
           RoundStr(save_rmode.rmode), number, rnd2nearest);
}

```

Output

Illustrates the lrint() function
 When rounding direction is round to nearest:
 lrint(500.99) = 501
 When rounding direction is round toward zero:
 lrint(500.99) = 500

lrintd32(), lrintd64(), lrintd128() and llrintd32(), llrintd64(), llrintd128() — Round the argument to the nearest integer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```

#define __STDC_WANT_DEC_FP__
#include <math.h>

long int lrintd32(_Decimal32 x);
long int lrintd64(_Decimal64 x);
long int lrintd128(_Decimal128 x);

long int lrint(_Decimal32 x); /* C++ only */
long int lrint(_Decimal64 x); /* C++ only */
long int lrint(_Decimal128 x); /* C++ only */

long long int llrintd32(_Decimal32 x);
long long int llrintd64(_Decimal64 x);
long long int llrintd128(_Decimal128 x);

long long int llrint(_Decimal32 x); /* C++ only */
long long int llrint(_Decimal64 x); /* C++ only */
long long int llrint(_Decimal128 x); /* C++ only */

```

Compile requirement: Use of this function requires the long long data type. See [z/OS XL C/C++ Language Reference](#) for information on how to make long long available.

General description

The lrint() and llrint() families of functions round their argument to the nearest integer value according to the current rounding mode. If the rounded value is outside the range of the return type, the numeric result is unspecified. A range error may occur if the magnitude of x is too large.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, they return the rounded integer value. If the correct value is positive or negative and too large to represent as a long (lrint() family) or long long (llrint() family), a domain error will occur and an unspecified value is returned.

Example

```
/* CELEBL20

   This example illustrates the lrintd64() and llrintd128() functions.
*/

lround(), lroundf(), lroundl() — Round a decimal floating-point number to its nearest integer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R5 |

Format

```
#define _ISOC99_SOURCE
#include <math.h>

long int lround(double x);
long int lroundf(float x);
long int lroundl(long double x);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

long lround(float x);
long lround(long double x);
```

General description

The lround functions round x to the nearest integer value, rounding halfway cases away from zero, regardless of the current rounding mode.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------|-----|------|
| lround | X | X |
| lroundf | X | X |
| lroundl | X | X |

Returned value

The lround functions return the rounded integer value of x .

If the rounded value is outside the range of the return type, the numeric result is unspecified. A range error may occur if the magnitude of x is too large.

lsearch() — Linear search and update

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <search.h>

void *lsearch(const void *key, void *base, size_t *nelp,
              size_t width,
              int (*compar)(const void *, const void *));
```

General description

The lsearch() function is a linear search routine. It returns a pointer into a table indicating where an entry may be found. If the entry does not occur, it is added at the end of the table. The *key* argument points to the entry to be sought in the table. The *base* argument points to the first element in the table. The *width* argument is the size of an element in bytes. The *nelp* argument points to an integer containing the current number of elements in the table. The integer to which *nelp* points is incremented if the entry is added to the table. The *compar* argument points to a comparison function which the user must supply (strcmp(), for example). It is called with two arguments that point to the elements being compared. The function must return 0 if the elements are equal and nonzero otherwise.

Special behavior for C++: Because C and C++ linkage conventions are incompatible, `lsearch()` cannot receive a C++ function pointer as the comparator argument. If you attempt to pass a C++ function pointer to `lsearch()`, the compiler will flag it as an error. You can pass a C or C++ function to `lsearch()` by declaring it as `extern "C"`.

Returned value

If the searched for entry is found, `lsearch()` returns a pointer to it.

If not found, `lsearch()` returns a pointer to the newly added element. A NULL pointer is returned in case of error.

No errors are defined.

lseek() — Change the offset of a file

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

off_t lseek(int fil-des, off_t offset, int pos);
```

General description

Changes the current file offset to a new position in a z/OS UNIX file. The new position is the given byte *offset* from the position specified by *pos*. After you have used `lseek()` to seek to a new location, the next I/O operation on the file begins at that location.

`lseek()` lets you specify new file offsets past the current end of the file. If data is written at such a point, read operations in the gap between this data and the old end of the file will return bytes containing zeros. (In other words, the gap is assumed to be filled with zeros.)

Seeking past the end of a file, however, does not automatically extend the length of the file. There must be a write operation before the file is actually extended.

Special behavior for POSIX C: For character special files, `lseek()` sets the file offset to the specified value. z/OS UNIX services ignore the file offset value during the read/write processing to character special files.

int *fil-des*;

The file whose current file offset you want to change.

off_t offset;

The amount (positive or negative) the byte offset is to be changed. The sign indicates whether the offset is to be moved forward (positive) or backward (negative).

int pos;

One of the following symbols (defined in the `unistd.h` header file):

SEEK_SET

The start of the file

SEEK_CUR

The current file offset in the file

SEEK_END

The end of the file

Large file support for z/OS UNIX files: Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the [long long data type support](#) enabled and define the `_LARGE_FILES` feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the `_LARGE_FILES` feature test macro as well.

Returned value

If successful, `lseek()` returns the new file offset, measured in bytes from the beginning of the file.

If unsuccessful, `lseek()` returns -1 and sets `errno` to one of the following values:

Error Code**Description****EBADF**

fildev is not a valid open file descriptor.

EINVAL

pos contained something other than one of the three options, or the combination of the *pos* values would have placed the file offset before the beginning of the file.

EOVERFLOW

The resulting file offset would be a value which cannot be represented correctly in an object of type `off_t`.

ESPIPE

fildev is associated with a pipe or FIFO special file.

Example

This fragment positions a file (that has at least 10 bytes) to an offset of 10 bytes before the end of the file.

```
lseek(fildev, -10, SEEK_END);
```

lstat(), lstat64() — Get status of file or symbolic link

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| z/OS UNIX XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

lstat:

```
#define _POSIX1_SOURCE 2
#include <sys/stat.h>

int lstat(const char *__restrict__ pathname, struct stat *__restrict__ buf);
```

lstat64:

```
#define _LARGE_TIME_API
#define _POSIX1_SOURCE 2
#include <sys/stat.h>

int lstat64(const char *__restrict__ pathname, struct stat64 *__restrict__ info);
```

Compile requirement: Use of the `lstat64` function requires the `long long` data type. For more information on how to make the `long long` data type available, see [z/OS XL C/C++ Language Reference](#).

General description

Gets status information about a specified file that is pointed to by the *pathname* argument and places it in the area of memory pointed to by the *buf* argument. You do not need permissions on the file itself, but you must have search permission on all directory components of the *pathname*.

If the named file is a symbolic link, `lstat()` returns information about the symbolic link itself.

The `lstat64()` function behaves exactly like `lstat()` except `lstat64()` uses structure `stat64` instead of `struct stat` to support time beyond 03:14:07 UTC on January 19, 2038.

The information is returned in the following `stat` and `stat64` structures, defined in the `sys/stat.h` header file.

Table 50. Values Returned in `stat` and `stat64` Structures

| Value for <code>stat</code> | Value for <code>stat64</code> | Description |
|-------------------------------|-------------------------------|---|
| <code>mode_t st_mode</code> | <code>mode_t st_mode</code> | A bit string indicating the permissions and privileges of the Symbols are defined in the <code>sys/stat.h</code> header file to refer to bits in a <code>mode_t</code> value; these symbols are listed in “ chmod() — Change the mode of a file or directory ” on page 274. |
| <code>ino_t st_ino</code> | <code>ino_t st_ino</code> | The serial number of the file. |
| <code>dev_t st_dev</code> | <code>dev_t st_dev</code> | The numeric ID of the device containing the file. |
| <code>nlink_t st_nlink</code> | <code>nlink_t st_nlink</code> | The number of links to the file. |

Table 50. Values Returned in stat and stat64 Structures (continued)

| Value for stat | Value for stat64 | Description |
|-----------------|-------------------|--|
| uid_t st_uid | uid_t st_uid | The numeric user ID (UID) of the file's owner. |
| gid_t st_gid | gid_t st_gid | The numeric group ID (GID) of the file's group. |
| off_t st_size | long long st_size | For regular files, the file's size in bytes. For other kinds of files, the value of this field is unspecified. |
| time_t st_atime | time64_t st_atime | The most recent time the file was accessed. |
| time_t st_ctime | time64_t st_ctime | The most recent time the status of the file was changed. |
| time_t st_mtime | time64_t st_mtime | The most recent time the contents of the file were changed. |

Values for `time_t` and `time64_t` are given in terms of seconds that have elapsed since epoch.

If the named file is a symbolic link, `lstat()` updates the time-related fields before putting information in the `stat` structure.

You can examine properties of a `mode_t` value from the `st_mode` field by using a collection of macros defined in the `sys/modes.h` header file. If *mode* is a `mode_t` value, and *genvalue* is an unsigned `int` value from the `stat` structure, then:

S_ISBLK(*mode*)

Is nonzero for block special files.

S_ISCHR(*mode*)

Is nonzero for character special files.

S_ISDIR(*mode*)

Is nonzero for directories.

S_ISEXTL(*mode*,*genvalue*)

Is nonzero for external links.

S_ISFIFO(*mode*)

Is nonzero for pipes and FIFO special files.

S_ISLNK(*mode*)

Is nonzero for symbolic links.

S_ISREG(*mode*)

Is nonzero for regular files.

S_ISSOCK(*mode*)

Is nonzero for sockets.

If `lstat()` successfully determines all this information, it stores it in the area indicated by the *buf* argument.

Large file support for z/OS UNIX files: `lstat64()` automatically supports large z/OS UNIX files for both AMODE 31 and AMODE 64 C/C++ applications, which means there is no need for `_LARGE_FILES` feature test macro to be defined. As for `lstat()`, the automatic support is only for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the long long data type support enabled and define the `_LARGE_FILES` feature test macro before any headers are included to enable `lstat()` to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the `_LARGE_FILES` feature test macro as well.

Returned value

If successful, `lstat()` returns 0.

If unsuccessful, `lstat()` returns -1 and sets `errno` to one of the following values:

Error Code Description

EACCES

The process does not have search permission on some component of the *pathname* prefix.

EINVAL

buf contains a NULL.

EIO

Added for XPG4.2: An I/O error occurred while reading from the file system.

ELOOP

A loop exists in symbolic links. This error is issued if the number of symbolic links encountered during resolution of the *pathname* argument is greater than POSIX_SYMLINK.

ENAMETOOLONG

pathname is longer than **PATH_MAX** characters or some component of *pathname* is longer than **NAME_MAX** characters while **_POSIX_NO_TRUNC** is in effect. For symbolic links, the length of the *pathname* string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values can be determined through `pathconf()`.

ENOENT

There is no file named *pathname*, or *pathname* is an empty string.

ENOTDIR

A component of the *pathname* prefix is not a directory.

EOVERFLOW

The file size in bytes or the number of blocks allocated to the file or the file serial number cannot be represented correctly in the structure pointed to by *buf*.

Note: Starting with z/OS V1.9, environment variable `_EDC_EOVERFLOW` can be used to control behavior of `lstat()` with respect to detecting an EOVERFLOW condition for z/OS UNIX files. By default, `lstat()` will not set EOVERFLOW when the file size can not be represented correctly in structure pointed to by *buf*. When `_EDC_EOVERFLOW` is set to YES, `lstat()` will check for an overflow condition.

Example

CELEBL12

```
/* CELEBL12

   This example provides status information for a file.

*/
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>
#include <time.h>

main() {
    char fn[]="temp.file", ln[]="temp.link";
    struct stat info;
    int fd;

    if ((fd = creat(fn, S_IWUSR)) < 0)
        perror("creat() error");
    else {
        close(fd);
        if (link(fn, ln) != 0)
            perror("link() error");
        else {
            if (lstat(ln, &info) != 0)
                perror("lstat() error");
            else {
                puts("lstat() returned:");
                printf("  inode:   %d\n", (int) info.st_ino);
            }
        }
    }
}
```

```

        printf(" dev id:   %d\n",   (int) info.st_dev);
        printf(" mode:    %08x\n",   info.st_mode);
        printf(" links:   %d\n",   info.st_nlink);
        printf(" uid:     %d\n",   (int) info.st_uid);
        printf(" gid:     %d\n",   (int) info.st_gid);
        printf("created:  %s",      ctime(&info.st_createtime));
    }
    unlink(ln);
}
    unlink(fn);
}
}

```

Output

```

lstat() returned:
inode:   3022
dev id:   1
mode:    03000080
links:    2
uid:      25
gid:      500
created:  Fri Jun 16 15:00:00 2006

```

l64a() — Convert long to base 64 string representation

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

char *l64a(long value);
```

General description

The `l64a()` function converts a long integer into its corresponding base 64 character representation. In this notation, long integers are represented by up to 6 characters, each character representing a digit in base 64 notation. Under AMODE 64, the lower order 32 bits of *value* are used for conversion. The following characters are used to represent digits:

Character

Digit represented

·
0
/
1
0-9
2-11
A-Z
12-37
a-z
38-63

Returned value

`l64a()` returns a pointer to the base 64 representation of *value*. If *value* is zero, `l64a()` returns a pointer to a NULL string.

`l64a()` returns a pointer to a static buffer, which will be overwritten by subsequent calls. Buffers are allocated on a per-thread basis.

There are no `errno` values defined.

ltoa() – Convert long into a string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R5 |

Format

```
#define _OPEN_SYS_ITOA_EXT
#include <stdlib.h>

char * ltoa(long l, char * buffer, int radix);
```

General description

The ltoa() function converts the long *l* into a character string. The string is placed in the buffer passed, which must be large enough to hold the output. The radix values can be OCTAL, DECIMAL, or HEX. When the radix is DECIMAL, ltoa() produces the same result as the following statement:

```
(void) sprintf(buffer, "%ld", l);
```

with buffer the returned character string. When the radix is OCTAL, ltoa() formats long *l* into an unsigned octal constant. When the radix is HEX, ltoa() formats long *l* into an unsigned hexadecimal constant. The hexadecimal value will include lower case abcdef, as necessary

Usage note

This is a non-standard function. Even though the prototype given is commonly used by compilers on other platforms, there is no guarantee that this function will behave the same on all platforms, in all cases. You can use this function to help port applications from other platforms, but you should avoid using it when writing new applications, in order to ensure maximum portability.

Returned value

String pointer (same as buffer) will be returned. When passed an invalid radix argument, function will return NULL and set errno to EINVAL.

Example

CELEBL29

```
/* CELEBL29

   This example reads a long int and formats it to decimal, unsigned
   octal, unsigned hexadecimal constants converted to a character
   string.

*/

#define _OPEN_SYS_ITOA_EXT
#include <stdio.h>
#include <stdlib.h>

int main ()
{
    long i;
    char buffer [sizeof(long)*8+1];
    printf ("Enter a number: ");
    if (scanf ("%ld",&i) == 1) {
        ltoa (i,buffer,DECIMAL);
        printf ("decimal: %s\n",buffer);
        ltoa (i,buffer,HEX);
```

```

    printf ("hexadecimal: %s\n",buffer);
    ltoa (i,buffer,OCTAL);
    printf ("octal: %s\n",buffer);
}
return 0;
}

```

Output

If the input is 1234, then the output should be:

```

decimal: 1234
hexadecimal: 4d2
octal: 2322

```

lutimes() — Change file access and modification times

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```

#define _XPLATFORM_SOURCE 1

#include <sys/time.h>

int lutimes(const char *path, const struct timeval times[2]);

```

General description

The `lutimes()` function changes the access and modification times of a file that is pointed to by the *path* argument to the value of the *times* argument. `lutimes()` behaves the same as `utimes()`, except that when *path* refers to a symbolic link, the link is not dereferenced; instead, the timestamps of the symbolic link are changed.

The *times* argument is an array of two `timeval` structures. The first array member represents the date and time of the last access, and the second member represents the date and time of the last modification. The times in the `timeval` structure are measured in seconds and microseconds since the Epoch, but the actual times that are stored with the file are rounded to the nearest second. The `timeval` members are:

tv_sec

Seconds since 1 January 1970 (Coordinated Universal Time)

tv_usec

Microseconds

If the *times* argument is a NULL pointer, the access and modification times of the file are set to the current time.

Returned value

If successful, `lutimes()` returns 0.
If unsuccessful, `lutimes()` returns -1 and sets `errno` to one of the following values:

Error Code
Description

EACCES
The process does not have search permission on some components of the *path* prefix; or all of the following are true:

- *times* is NULL.
- The effective user ID of the process does not match the owner of the file.
- The process does not have write permission on the file.
- The process does not have appropriate privileges.

ELOOP
A loop exists in symbolic links. This error is issued if more than `POSIX_SYMLINK` symbolic links (defined in the `limits.h` header file) are detected in the resolution of *path*.

ENAMETOOLONG
path is longer than `PATH_MAX` characters or some components of *path* is longer than `NAME_MAX` characters while `_POSIX_NO_TRUNC` is in effect. For symbolic links, the length of the path name string that is substituted for a symbolic link exceeds `PATH_MAX`. The `PATH_MAX` and `NAME_MAX` values can be determined by using `pathconf()`.

ENOTDIR
Some components of the *path* prefix are not a directory.

ENOTENT
No file is named *path*, or the *path* argument is an empty string.

EPERM
times is not NULL. The effective user ID of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges.

EROFS
path is on a read-only file system.

makecontext() – Modify user context

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <ucontext.h>

void makecontext(ucontext_t *ucp, void (*func)(), int argc, ...);
```

General description

The `makecontext()` function modifies the context specified by *ucp*, which has been initialized using `getcontext()`. When this context is resumed using `setcontext()` or `swapcontext()`, program execution continues by calling *func()*, passing it the arguments that follow *argc* in the `makecontext()` call.

The value of *argc* must match the number of integer arguments passed to *func()*, otherwise the behavior is undefined.

The **`uc_link`** member of **`ucontext_t`** is used to determine the context that will be resumed when the context being modified by `makecontext()` returns. If the **`uc_link`** member is not equal to 0, the process continues as if after a call to `setcontext()` with the context pointed to by the **`uc_link`** member. If the **`uc_link`** member is equal to 0, the process exits as if `exit()` were called. The **`uc_link`** member should be initialized before the call to `makecontext()`.

This function is supported only in a POSIX program.

This function is not supported in an AMODE 31 XPLINK environment (for example, one which is in AMODE 31 and in which either the `main()` function was compiled with the XPLINK option, or the XPLINK(ON) runtime option was specified).

The **`<ucontext.h>`** header file defines the **`ucontext_t`** type as a structure that includes the following members:

| | | |
|-------------------------|--------------------------|--|
| <code>mcontext_t</code> | <code>uc_mcontext</code> | A machine-specific representation of the saved context. |
| <code>ucontext_t</code> | <code>*uc_link</code> | Pointer to the context that will be resumed when this context returns. |
| <code>sigset_t</code> | <code>uc_sigmask</code> | The set of signals that are blocked when this context is active. |
| <code>stack_t</code> | <code>uc_stack</code> | The stack used by this context. |

Special behavior for C++

Because C and C++ linkage conventions are incompatible, `makecontext()` cannot receive C++ function pointers. If you attempt to pass a C++ function pointer to `makecontext()`, the compiler will flag it as an error. To use the C++ `makecontext()` function, you must ensure that all functions registered for `makecontext()` have C linkage by declaring them as `extern "C"`. For example:

```
C: void func(int, int);
:
: makecontext(&context, func, 2, arg1, arg2);

C++: extern "C" void func();
:
: makecontext(&context, func, 2, arg1, arg2);
```

AMODE 64 considerations

Storage for the stack must be above the 2GB bar. It may not be storage acquired with the `__malloc24()` or `__malloc31()` functions. The stack must be big enough to allow for the creation of a 1M guard page (aligned on a 1M boundary).

The environment variable `_EDC_CONTEXT_GUARD` can be used to control when the stack is guarded and unguarded. For details on the `_EDC_CONTEXT_GUARD` environment variable, see the "Using Environment Variables" chapter in [z/OS XL C/C++ Programming Guide](#).

Returned value

makecontext() returns no values.

If unsuccessful, makecontext() sets errno to one of the following values:

Error Code

Description

EINVAL

The context being modified is using an alternate stack, and the target function entry point is not a valid Language Environment or C entry point.

The *argc* argument specifies a value less than 0.

ENOMEM

The *ucp* argument does not have enough stack left to complete the operation. Or more than 15 arguments are passed to the target function, and there is not enough storage to hold all of the arguments.

Note: If the target function is in a DLL that has not yet been loaded, then makecontext() cannot determine the size requirement and assumes that the size required is MINSIGSTKSZ. Therefore, in this case, the stack must be at least the size indicated by MINSIGSTKSZ. If the size required by the target function is more than MINSIGSTKSZ, then you must load the DLL before invoking makecontext().

Example

This example creates a context in main with the getcontext() statement, then modifies the context to have its own stack and to invoke the function *func*. It invokes the function with the setcontext() statement. Since the **uc_link** member is set to 0, the process exits when the function returns.

```
/* This example shows the usage of makecontext(). */

#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>
#include <stdio.h>
#include <ucontext.h>
#include <errno.h>

#ifdef _LP64
#define STACK_SIZE 2097152+16384 /* large enough value for AMODE 64 */
#else
#define STACK_SIZE 16384 /* AMODE 31 addressing */
#endif

void func(int);

ucontext_t context, *cp = &context;

int main(void) {
    int value = 1;

    getcontext(cp);
    context.uc_link = 0;
    if ((context.uc_stack.ss_sp = (char *) malloc(STACK_SIZE)) != NULL) {
        context.uc_stack.ss_size = STACK_SIZE;
        context.uc_stack.ss_flags = 0;
        errno = 0;
        makecontext(cp, func, 1, value);
        if (errno != 0) {
            perror("Error reported by makecontext()");
            return -1; /* Error occurred exit */
        }
    }
    else {
        perror("not enough storage for stack");
        abort();
    }
    printf("context has been built\n");
    setcontext(cp);
    perror("returned from setcontext");
    abort();
}
```

```

}

void func(int arg) {

    printf("function called with value %d\n",arg);
    printf("process will exit when function returns\n");
    return;

}

```

Output

```

context has been built
function called with value 1
process will exit when function returns

```

malloc() — Reserve storage block

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```

#include <stdlib.h>

void *malloc(size_t size);

```

General description

Reserves a block of storage of *size* bytes. Unlike the `calloc()` function, the content of the storage allocated is indeterminate. The storage to which the returned value points is always aligned for storage of any type of object. Under IBM z/OS C only, if 4K alignment is required, use the `__4kmalc()` function. (This function is available to C applications in stand-alone System Productivity Facility (SPF) applications.) The library functions specific to the System Programming C (SPC) environment are described in [z/OS XL C/C++ Programming Guide](#).

Special behavior for C++: The C++ keywords `new` and `delete` are not interoperable with `aligned_alloc()`, `calloc()`, `free()`, `malloc()`, `posix_memalign()`, or `realloc()`.

Note: To use the `aligned_alloc()` function, compile the source code with [C11 standard based compilation](#).

Returned value

If successful, malloc() returns a pointer to the reserved space. The storage space to which the returned value points is always suitably aligned for storage of any type of object.

If not enough storage is available, or if size was specified as 0, malloc() returns NULL. If malloc() returns NULL because there is not enough storage or the requested size is 0, it sets errno to one of the following values:

Error Code

Description

ENOMEM

Insufficient memory is available

Example

CELEBM01

```
/* CELEBM01

This example prompts you for the number of array entries you
want and then reserves enough space in storage for the entries.
If &malloc. was successful, the example assigns values
to the entries and prints out each entry; otherwise, it prints
out an error.

*/
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    long * array;      /* start of the array */
    long * index;      /* index variable */
    int i;             /* index variable */
    int num;           /* number of entries of the array */

    printf( "Enter the size of the array\n" );
    scanf( "%i", &num );

    /* allocate num entries */
    if ( (index = array = (long *)malloc( num * sizeof( long ))) != NULL )
    {
        for ( i = 0; i < num; ++i )          /* put values in array */
            *index++ = i;                    /* using pointer notation */

        for ( i = 0; i < num; ++i )          /* print the array out */
            printf( "array[ %i ] = %i\n", i, array[i] );
    }
    else { /* malloc error */
        printf( "Out of storage\n" );
        abort();
    }
}
```

Output

```
Enter the size of the array
array[ 0 ] = 0
array[ 1 ] = 1
array[ 2 ] = 2
array[ 3 ] = 3
array[ 4 ] = 4
```

__malloc24() — Allocate 24-bit storage

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | AMODE 64 |

Format

```
#include <stdlib.h>

void *__malloc24(size_t size);
```

General description

Reserves a block of storage of *size* bytes from "below-the-line" storage (that is, below 16 MB).

Returned value

If successful, __malloc24() returns a pointer to the reserved space. The storage space to which the returned value points is always suitably aligned for storage of any type of object.

If not enough storage is available, or if *size* was specified as 0, __malloc24() returns NULL. If __malloc24() returns NULL because there is not enough storage, it sets errno to one of the following values:

Error Code

Description

ENOMEM

Insufficient memory is available

Related information

__malloc31() – Allocate 31-bit storage

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | AMODE 64 |

Format

```
#include <stdlib.h>

void *__malloc31(size_t size);
```

General description

Reserves a block of storage of *size* bytes from "below-the-bar" storage (that is, below 2 GB).

Returned value

If successful, __malloc31() returns a pointer to the reserved space. The storage space to which the returned value points is always suitably aligned for storage of any type of object.

If not enough storage is available, or if *size* was specified as 0, __malloc31() returns NULL. If __malloc31() returns NULL because there is not enough storage, it sets *errno* to one of the following values:

Error Code

Description

ENOMEM

Insufficient memory is available

__map_init() – Designate a storage area for mapping blocks

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------------------|
| | both | POSIX(ON) OS/390 V2R9 |

Format

```
#define _OPEN_SYS_MAP_EXTENTION
#include <sys/mman.h>

int __map_init(struct _Mmg_init *parmlist);
```

General description

The `__map_init()` function allocates a map area in the private area of the calling address space. This map area is propagated to child address spaces on fork, which is the only way that multiple processes can share a map area. The application can connect and disconnect blocks of storage in the map area, providing a very fast way to connect up to persistent memory. The `__map_init()` function is meant to be used by applications which need more shared memory or mmap storage than will fit in the address space.

The application should set the following values in the `_Mmg_init` structure:

Element

Description

`_Mmg_numblks`

Set to the number of blocks to be contained in the map area.

`_Mmg_megsperblk`

Set to the size in megabytes of each block in the map area.

`_Mmg_token`

Set to an 8 character map token when successful. This map token should be saved and must be used as a parameter on calls to the `__map_service()` function calls.

`_Mmg_res01a`

Reserved, set to 0.

`_Mmg_res01b`

Reserved, set to 0.

`_Mmg_areaaddr`

As input, set to 0 if you want the address assigned or set to the address of storage where you want the map to begin. As output, this field contains the actual address of the map area.

Usage notes

- It is intended that the application call the `__map_init()` service once to create the map area.
- The application then issues fork to create child processes which will inherit a map area initialized to the hidden state.
- The initial process or the child (and grandchildren) process can then use the `__map_service` to connect and disconnect blocks of storage which are persistent until explicitly deleted.
- When the process which created the initial map area terminates, all further activity against the map blocks is terminated. The map blocks are then deleted when the last child process with an active map area terminates.
- There is no explicit call to delete the map area. This is unlike shared memory or other IPC constructs.

Returned value

If successful, `__map_init()` returns NULL.

If unsuccessful, `__map_init()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EEXIST

An attempt was made to create more than one map for the process.

EFAULT

The *parmlist* (*_Mmg_init* structure) has an argument that is not accessible to the caller.

EINVAL

One of the following occurred:

- The number of blocks (*_Mmg_numblks*) was zero or negative.
- The number of megabytes per block (*_Mmg_Megsperblk*) was zero or negative.
- A reserved field contained nonzero data.
- The specified address (*_Mmg_areaaddr*) is not on a megabyte multiple.

EMVSSAF2ERR

An error occurred in the security product. Use the *__errno2()* function to retrieve the reason code to determine the exact reason the error occurred.

ENOMEM

The requested storage at location *_Mmg_areaaddr* or the size requested could not be obtained. The storage is either not available or your Region size is too small to contain the map area. Or, there is insufficient free virtual storage in the address space to satisfy the request.

EPERM

The user is not authorized to use the *__map_init()* function. Callers must be permitted to the BPX.MAP FACILITY class profile to use this service.

Related information

- [“__map_service\(\) — Set memory mapping service” on page 1040](#)

__map_service() — Set memory mapping service

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------------------|
| | both | POSIX(ON) OS/390 V2R9 |

Format

```
#define _OPEN_SYS_MAP_EXTENTION
#include <sys/mman.h>

int __map_service(struct _Mmg_service *parmlist, int count, *_Map_token_t);
```

General description

The *__map_service()* function is used to manipulate the map area created by the *__map_init()* function. The supported functions are defined under *_Mmg_servicetype* below.

Before calling the *__map_service()* service, the application should set values in the *_Mmg_service* structure as follows:

Element

Description

_Mmg_servicetype

Set the type of service being requested for each memory block defined in the array.

Request

Description

_Mmg_newblock

Set for an allocation of a new data block in the mapped area.

_Mmg_conn

Set to request that a data block be connected at the requested location in the map area.

_Mmg_disconn

Set to disconnect a data block from the map area.

_Mmg_free

Set to free the storage backing a data block.

_Mmg_cntl

Set to change the read or write permission settings for a data block.

_Mmg_serviceIflag

Used for `_Mmg_cntl` to indicate read or write and all other bits set to zero. For `_Mmg_disconn` to indicate if the backing storage is to be freed after disconnect. For `_Mmg_newblock` the option of `_Mmg_NoConn` can be set on to bypass the connect to the map area block. The token returned will have to be saved and used for connect services on a later call to make the block accessible. For all other `_Mmg_serviceItype` requests, set all the bits to zero.

_Mmg_serviceOflag

Used for status of the request. When the request has been successfully processed all the bits are set to zero. When processing an list of requests and a failure occurs in `_Mmg_Reqlfail` is set on and further processing on the list is aborted. `_Mmg_servicetype` requests, set all the bits to zero.

_Mmg_token

This is returned as output for a `_Mmg_newblock` request and is used as input for `_Mmg_conn`, and `_Mmg_free`. It is ignored for `_Mmg_disconn` and `_Mmg_cntl`.

_Mmg_res0b

Reserved, set to 0.

_Mmg_blkaddr

For `_Mmg_newblock` and `_Mmg_conn` this is input. It should be set to an address within the map area (on a block multiple) where you want to allocate a block or 0. If 0 is specified, the first available block in the map area is used. On output, this field contains the address within the map area that was assigned to the data block. For `_Mmg_disconn` it is input only and contains the address of the map block to be disconnected. For `_Mmg_cntl` this field is required and specifies the block to be use for the `_Mmg_cntl` option. For `_Mmg_free`, `_Mmg_cntl` and `_Mmg_newblock`, when the option of `_Mmg_NoConn` is set on, this field is ignored.

With *count* reflecting the number of `_Mmg_service` structures included in the array structure supplied on *parmlist* parameter. With *count* a positive integer in the range of 1-1000.

With *_Map_token_t* the 8 character token retrieved from the `_Mmg_token` field in a `_Mmg_service` structure that returned successful from a `__map_init()` function call.

Usage notes

- The `__map_init` and the `__map_service` functions are intended to be used in the following manner:
 - The initial process calls `__map_init` to create a map area large enough for the biggest expected usage.
 - The initial process forks worker processes which inherit the map area at the same virtual address. By having the map area at the same virtual address, storage blocks can be connected to the same block in map areas of different worker processes and pointers can be used to point to data in this or other blocks. This assumes they are always connected at the same location in the map area.
 - As worker processes perform their tasks, they can request new blocks of storage to be created in the map area. Each block has a token associated with it. This token allows other worker processes to connect to the same block. In this respect, the map area acts like shared memory.
 - The worker processes can connect as many blocks to their map area as will fit.

- When the worker process has no further need for a data block, it can disconnect it from the map area. After a delete request for a block, this block is actually freed when the last worker process disconnects for this block.
- When a worker process is completely done with a data block, the storage can be freed. This data is actually freed when the last worker process disconnects from that block.
- Using these services, the application could create multiple gigabytes of storage, of which only certain blocks are mapped into the worker processes at a given time.
- This service is designed to perform the storage connects and disconnects very fast. No data movement occurs.
- Storage blocks are initially connected in write mode. When a block is in write mode, all worker processes which have the block connected, have the block in write mode. If the block access is changed to read-only, then all worker processes which have the block connected, have the block in read-only mode.
- If the initial process or a worker process forks, then the child process inherits a map area initialized to the hidden state.
- Any areas within the map area which do not have a block connected are in the hidden state. Any reference to storage in the hidden state will trigger a SIGSEGV signal.

Returned value

If successful, `__map_service()` returns 0.

If unsuccessful, `__map_service()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EEXIST

A request was made to perform a service on a block but a map is not currently active in the process.

EFAULT

The *parmlist* (`_Mmg_service` structure) argument addresses either could not be accessed or was in read-only storage and could not be updated.

EINVAL

For one of the following reasons:

The block address provided is either not in the map area or it is not on a map block boundary.

A request was made to connect to a block or free the backing storage for a block but the token provided does not match that of any allocated block in the backing store.

A request was made to disconnect from a block but the block is not currently in the map area for this process.

A newblock or connect request was specified for a map area block that is already in use.

A request was made to connect to a block in the backing store that is currently marked to be freed. The connect is not permitted.

The *count* value was not a positive integer in the range of 1-1000.

ENOMEM

A request to create a new block or connect to an existing block was made but there are no unused blocks in the map area to satisfy the request.

maxdesc() — Get socket numbers to extend beyond the default range

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _OPEN_SYS_SOCK_EXT
#include <sys/types.h>
#include <sys/socket.h>

int maxdesc(int *totdesc, int *inetdesc);
```

General description

Bulk mode sockets are not supported. Do not use this function.

Returned value

If successful, `maxdesc()` returns 0.

If unsuccessful, `maxdesc()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EALREADY

Your program called `maxdesc()` after creating a socket, after a call to `setibmssockopt()`, or after a previous call to `maxdesc()`.

EFAULT

Using the `totdesc` parameter as specified results in an attempt to access storage outside of the caller's address space, or storage not modifiable by the caller.

ENOMEM

Your address space has insufficient storage.

mblen() — Calculate length of multibyte character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdlib.h>

int mblen(const char *string, size_t n);
```

General description

Determines the length in bytes of the multibyte character pointed to by *string*. A maximum of *n* bytes is examined.

The behavior of this wide-character function is affected by the `LC_CTYPE` category of the current locale. Changing the `LC_CTYPE` category invalidates the internal shift state: undefined results can occur.

If the current locale supports EBCDIC DBCS characters, then the shift state is updated where applicable. The length returned may be up to 4 (for the shift-out character, 2-byte code, and the shift-in character). If *string* is a NULL pointer, this function resets itself to the initial state.

The function maintains the internal shift state that is altered by subsequent calls.

Returned value

If *string* is NULL, `mblen()` returns:

- Nonzero when DBCS-host code (EBCDIC systems) is used
- Nonzero if multibyte encodings are state-dependent
- Zero otherwise

If *string* is not NULL, `mblen()` returns:

- Zero if *string* points to the NULL character
- The number of bytes comprising the multibyte character
- The value -1 if *string* does not point to a valid multibyte character

Example

```
#include <locale.h>
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    char *mbs = "a"
                "\x0E" /* shift out */
                "\x44\x66" /* <j0158> */
                "\x44\x76" /* <j0159> */
                "\x42\x4e" /* <j0160> */
                "\x0F" /* shift in */
                "b";

    char *loc = setlocale(LC_ALL, "JA_JP.IBM-939");
    int n;

    if (!loc) /* setlocale() failure */
    {
        exit(8);
    }

    printf("We're in the %s locale.\n", loc);

    n = mblen(NULL, MB_CUR_MAX);
    /* n is nonzero, indicating state-dependent encoding; mblen() has */
    /* forced the internal shift state to "initial". */
    /* ===== */
    printf("n = mblen(NULL, MB_CUR_MAX); ==> n = %s\n",
           n ? "NONZERO" : "ZERO");

    n = mblen(mbs, MB_CUR_MAX);
    /* ===== */
    /* n is 1, 'a' is a multibyte character of length 1, internal */
    /* shift state remains at "initial". */
    /* ===== */
    printf("n = mblen(mbs, MB_CUR_MAX); ==> n = %d\n", n);

    n = mblen(mbs + 1, MB_CUR_MAX);
    /* ===== */
    /* n is 3, 'shift out' plus two byte character '<j0158>'. The */
    /* internal state changes to "shift out". */
    /* ===== */
    printf("n = mblen(mbs + 1, MB_CUR_MAX); ==> n = %d\n", n);

    n = mblen(mbs + 4, MB_CUR_MAX);
    /* ===== */
    /* n is 2, two byte character '<j0159>'. The internal shift */
    /* state remains "shift out". */
    /* ===== */
    printf("n = mblen(mbs + 4, MB_CUR_MAX); ==> n = %d\n", n);

    n = mblen(mbs + 6, MB_CUR_MAX);
    /* ===== */
    /* n is 3, two byte character '<j0160>' plus 'shift in'. The */
    /* internal shift state returns to "initial". */
    /* ===== */
    printf("n = mblen(mbs + 6, MB_CUR_MAX); ==> n = %d\n", n);
}
```

```

    n = mblen(mbs + 9, MB_CUR_MAX);
    /*****
    /* n is 1, 'b' is a multibyte character of length 1, internal
    /* shift state remains at "initial".
    /*****/
    printf("n = mblen(mbs + 9, MB_CUR_MAX); ==> n = %d\n", n);

    n = mblen(mbs + 10, MB_CUR_MAX);
    /*****
    /* n is 0 (end of multibyte character string).
    /*****/
    printf("n = mblen(mbs + 10, MB_CUR_MAX); ==> n = %d\n", n);

    return 0;
}
```

Output

```

We're in the JA_JP.IBM-939 locale.
n = mblen(NULL, MB_CUR_MAX); ==> n = NONZERO
n = mblen(mbs, MB_CUR_MAX); ==> n = 1
n = mblen(mbs + 1, MB_CUR_MAX); ==> n = 3
n = mblen(mbs + 4, MB_CUR_MAX); ==> n = 2
n = mblen(mbs + 6, MB_CUR_MAX); ==> n = 3
n = mblen(mbs + 9, MB_CUR_MAX); ==> n = 1
n = mblen(mbs + 10, MB_CUR_MAX); ==> n = 0
```

mbrlen() — Calculate length of multibyte character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C Amendment C99 Single UNIX Specification, Version 3 | both | |

Format

Non-XP4

```
#include <wchar.h>

size_t mbrlen(const char * __restrict__s, size_t n, mbstate_t * __restrict__ps);
```

XP4

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

size_t mbrlen(const char *s, size_t n, mbstate_t *ps);
```

General description

Calculates the number of bytes required to return to the initial shift state. This is equivalent to

```
mbrtowc((wchar_t *)0, s, n, ps != NULL ? ps : &internal);
```

where `&internal` is the address of the internal `mbstate_t` object for the `mbrlen()` function.

`mbrlen()` is a restartable version of `mblen()`. That is, shift state information is passed as one of the arguments, and is updated on exit. With `mbrlen()`, you can switch from one multibyte string to another, provided that you have kept the shift-state information.

The behavior of this wide-character function is affected by the `LC_CTYPE` category of the current locale. If you change the category, undefined results can occur.

Special behavior for XP4

If you define any feature test macro specifying XP4 behavior before the statement in your program source file to include the `wchar` header, then you must also define the `_MSE_PROTOS` feature test macro to make the declaration of the `mbrlen()` function in the `wchar` header available when you compile your program. Please see [Table 2 on page 4](#) for a list of XP4 and other feature test macros.

Returned value

If `s` is a NULL pointer, `mbrlen()` resets the shift state to the initial shift state and returns 0.

If `s` is not a NULL pointer, `mbrlen()` returns the first of the following that applies.

0

If the next `n` or fewer bytes complete the valid multibyte character that corresponds to the NULL wide character.

positive

If the next `n` or fewer bytes complete the valid multibyte character; the value returned is the number of bytes that complete the multibyte character.

-2

If the next `n` bytes form an incomplete (but potentially valid) multibyte character, and all `n` bytes have been processed; it is unspecified whether this can occur when the value of `n` is less than that of the `MB_CUR_MAX` macro.

Note: When a -2 value is returned, and `n` is at least `MB_CUR_MAX`, the string would contain redundant shift-out and shift-in characters. To continue processing the multibyte string, increment the pointer by the value `n`, and call the `mbrtowc()` function.

-1

If an encoding error occurs (when the next `n` or fewer bytes do not contribute to the complete and valid multibyte character), the value of the macro `EILSEQ` is stored in `errno`, but the conversion state remains unchanged.

Example

CELEBM03

```
/* CELEBM03 */
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>

int main(void)
{
    char      mbs[5] = "a";    /* string containing the multibyte char */
    mbstate_t ss      = 0;    /* set shift state to the initial state */
    int       length;

    /* Determine the length in bytes of a multibyte character pointed */
    /* to by mbs.                                                    */

    length = mbrlen(mbs, MB_CUR_MAX, &ss);

    printf("    length: %d \n", length);
    printf("    mbs: \"%s\" \n", mbs);
    printf("MB_CUR_MAX: %d \n", MB_CUR_MAX);
    printf("    ss: %d \n", ss);
}
```

Output

```
    length: 1
    mbs: "a"
MB_CUR_MAX: 4
    ss: 0
```

mbrtoc16() – Convert a multibyte character to a char16_t character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| ISO C Amendment C11 | both | z/OS V2R1 |

Format

```
#include <uchar.h>
```

```
size_t mbrtoc16(char16_t * restrict pc16,
               const char * restrict s,
               size_t n,
               mbstate_t * restrict ps);
```

General description

The `mbrtoc16()` function converts a multibyte character to a wide character of type `char16_t`, and returns the number of bytes of the multibyte character.

If `s` is not a null pointer, the `mbrtoc16()` function inspects at most `n` bytes beginning with the byte pointed to by `s` to determine the number of bytes needed to complete the next multibyte character (including any shift sequences). If the function determines that the next multibyte character is complete and valid, it determines the values of the corresponding wide characters and then, if `pc16` is not a null pointer, stores the value of the first (or only) such character in the object pointed to by `pc16`. Subsequent calls will store successive wide characters without consuming any additional input until all the characters have been stored. If the corresponding wide character is the null wide character, the resulting state described is the initial conversion state.

If `s` is a null pointer, the `mbrtoc16()` function is equivalent to the call `mbrtoc16(NULL, "", 1, ps)`. In this case, the values of the parameters `pc16` and `n` are ignored.

If `ps` is a null pointer, `mbrtoc16()` uses its own internal object to track the shift state. Otherwise `*ps` must be a valid `mbstate_t` object. An `mbstate_t` object `*ps` can be initialized to the initial state by assigning 0 to it, or by calling `mbrtoc16(NULL, NULL, 0, ps)`.

Usage notes

1. To use the `mbrtoc16()` function, compile the source code with [C11 standard based compilation](#).
2. The `mbrtoc16()` function only supports the CCSIDs that are provided by Unicode Services.
3. The result of converting multiple string alternately in one thread by using multiple `mbstate_t` objects (including the internal one) is undefined.

Returned value

The `mbrtoc16()` function returns the first of the following that applies (given the current conversion state):

0

If the next `n` or fewer bytes complete the multibyte character that corresponds to the null wide character (which is the value stored).

between 1 and `n` inclusive

If the next `n` or fewer bytes complete a valid multibyte character (which is the value stored); the value returned is the number of bytes that complete the multibyte character.

-3

If the next character resulting from a previous call has been stored (no byte from the input has been consumed by this call).

-2

If the next `n` bytes contribute to an incomplete (but potentially valid) multibyte character, and all `n` bytes have been processed (no value is stored). When `n` has at least the value of the `MB_CUR_MAX` macro, this case can only occur if `s` points to a sequence of redundant shift sequence (for implementations with state-dependent encodings).

-1

If an encoding error occurs (when the next `n` or fewer bytes do not contribute to a complete and valid multibyte character). The value of the macro `EILSEQ` is stored in `errno`, and the conversion state is unspecified.

Example

```
#include <stdio.h>
#include <stdlib.h>
#include <uchar.h>

int main(void)
{
    char16_t c16;
    char mbs[] = "a" ; /* string containing the multibyte character */
    mbstate_t ss = 0 ; /* set shift state to the initial state */
    int length = 0 ;

    /* Determine the length of the multibyte character pointed to by */
    /* mbs. Store the multibyte character in the char16_t object */
    /* called c16. */

    length = mbrtoc16(&c16, mbs, MB_CUR_MAX, &ss);
    if (length < 0) {
        /* -2 and -3 return value could not happen during converting the 'a' */
        perror("mbrtoc16() fails to convert");
        exit(-1);
    }

    printf(" mbs: \"%s\" \n", mbs);
    printf(" length: %d \n", length);
    printf(" c16: 0x%04hx \n", c16);
}
```

Output:

```
mbs:"a"
length: 1
c16: 0x0061
```

mbrtoc32() – Convert a multibyte character to a char32_t character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| ISO C Amendment C11 | both | z/OS V2R1 |

Format

```
#include <uchar.h>

size_t mbrtoc32(char32_t * restrict pc32,
                const char * restrict s,
                size_t n,
                mbstate_t * restrict ps);
```

General description

The `mbrtoc32()` function converts a multibyte character to a wide character of type `char32_t`, and returns the number of bytes of the multibyte character.

If `s` is not a null pointer, the `mbrtoc32()` function inspects at most `n` bytes beginning with the byte pointed to by `s` to determine the number of bytes needed to complete the next multibyte character (including any shift sequences). If the function determines that the next multibyte character is complete and valid, it determines the values of the corresponding wide characters and then, if `pc32` is not a null pointer, stores the value of the first (or only) such character in the object pointed to by `pc32`. Subsequent calls will store successive wide characters without consuming any additional input until all the characters have been stored. If the corresponding wide character is the null wide character, the resulting state described is the initial conversion state.

If `s` is a null pointer, the `mbrtoc32()` function is equivalent to the call `mbrtoc32(NULL, "", 1, ps)`. In this case, the values of the parameters `pc32` and `n` are ignored.

If `ps` is a null pointer, `mbrtoc32()` uses its own internal object to track the shift state. Otherwise `*ps` must be a valid `mbstate_t` object. An `mbstate_t` object `*ps` can be initialized to the initial state by assigning 0 to it, or by calling `mbrtoc32(NULL, NULL, 0, ps)`.

Usage notes

1. To use the `mbrtoc32()` function, compile the source code with [C11 standard based compilation](#).
2. The `mbrtoc32()` function only supports the CCSIDs that are provided by Unicode Services.
3. The result of converting multiple string alternately in one thread by using multiple `mbstate_t` objects (including the internal one) is undefined.

Returned value

The `mbrtoc32()` function returns the first of the following that applies (given the current conversion state):

0

If the next `n` or fewer bytes complete the multibyte character that corresponds to the null wide character (which is the value stored).

between 1 and `n` inclusive

If the next `n` or fewer bytes complete a valid multibyte character (which is the value stored); the value returned is the number of bytes that complete the multibyte character.

-3

If the next character resulting from a previous call has been stored (no byte from the input has been consumed by this call).

-2

If the next `n` bytes contribute to an incomplete (but potentially valid) multibyte character, and all `n` bytes have been processed (no value is stored). When `n` has at least the value of the `MB_CUR_MAX` macro, this case can only occur if `s` points to a sequence of redundant shift sequence (for implementations with state-dependent encodings).

-1

If an encoding error occurs (when the next `n` or fewer bytes do not contribute to a complete and valid multibyte character). The value of the macro `EILSEQ` is stored in `errno`, and the conversion state is unspecified.

Example

```
#include <stdio.h>
#include <stdlib.h>
#include <uchar.h>
```

```
int main(void)
{
    char32_t c32;
    char mbs[] = "a" ; /* string containing the multibyte character */
    mbstate_t ss = 0 ; /* set shift state to the initial state */
    int length = 0 ;

    /* Determine the length of the multibyte character pointed to by */
    /* mbs. Store the multibyte character in the char32_t object */
    /* called c32. */

    length = mbrtoc32(&c32, mbs, MB_CUR_MAX, &ss);
    if (length < 0) {
        /* -2 and -3 return value could not happen during converting the 'a' */
        perror("mbrtoc32() fails to convert");
        exit(-1);
    }

    printf(" mbs: \"%s\" \n", mbs);
    printf(" length: %d \n", length);
    printf(" c32: 0x%08x \n", c32);
}
```

Output:

```
mbs:"a"
length: 1
c32: 0x00000061
```

mbrtowc() — Convert a multibyte character to a wide character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C Amendment C99 Single UNIX Specification, Version 3 | both | |

Format

Non-XPg4

```
#include <wchar.h>

size_t mbrtowc(wchar_t * __restrict__ pwc, const char * __restrict__ s,
               size_t n, mbstate_t * __restrict__ ps);
```

XPg4

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

size_t mbrtowc(wchar_t *pwc, const char *s, size_t n, mbstate_t *ps);
```

General description

The `mbrtowc()` function is equivalent to `mbrtowc(NULL, "", 1, ps)`.

If `s` is a NULL pointer, the `mbrtowc()` function ignores the `n` and the `pwc`, and resets the shift state, pointed to by `ps`, to the initial shift state.

If `s` is not a NULL pointer, `mbrtowc()` inspects at most `n` bytes, beginning with the byte pointed to by `s`, and the shift state pointed to by `ps`, and determines the number of bytes that is needed to complete the valid multibyte character.

When the multibyte character is completed, `mbrtowc()` determines the value of the corresponding wide character and stores it in the object pointed to by `pwc`, so long as `pwc` is not a NULL pointer. Finally, `mbrtowc()` stores the actual shift state in the object pointed to by `ps`. If `ps` is a NULL pointer, `mbrtowc()` uses its own internal object to track the shift state.

`mbrtowc()` is a restartable version of `mbtowc()`. That is, shift-state information is passed as one of the arguments and is updated on exit. With `mbrtowc()`, you can switch from one multibyte string to another, provided that you have kept the shift-state information.

The behavior of this wide-character function is affected by the `LC_CTYPE` category of the current locale. If you change the category, undefined results may occur.

Special behavior for XPG4

If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the `wchar` header, then you must also define the `_MSE_PROTOS` feature test macro to make the declaration of the `mbrtowc()` function in the `wchar` header available when you compile your program. Please see [Table 2 on page 4](#) for a list of XPG4 and other feature test macros.

Returned value

If `s` is a NULL pointer, `mbrtowc()` resets the shift state to the initial shift state and returns 0.

If `s` is not a NULL pointer, `mbrtowc()` returns one of the following, in the order shown:

0

If the next `n` or fewer bytes complete the valid multibyte character that corresponds to the NULL wide character.

positive integer

If the next `n` or fewer bytes complete the valid multibyte character; the value returned is the number of bytes that complete the multibyte character.

-2

If the next `n` bytes form an incomplete (but potentially valid) multibyte character, and all `n` bytes have been processed. It is unspecified whether this can occur when the value of `n` is less than that of the `MB_CUR_MAX` macro.

Note: When a -2 value is returned, and `n` is at least `MB_CUR_MAX`, the string would contain redundant shift-out and shift-in characters. To continue processing the multibyte string, increment the pointer by the value `n`, and call the `mbrtowc()` function.

-1

If an encoding error occurs (when the next `n` or fewer bytes do not contribute to the complete and valid multibyte character). The value of the macro `EILSEQ` is stored in `errno`, but the conversion state is unchanged.

Example

CELEBM04

```
/* CELEBM04 */
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>
```

```
int main(void)
{
    wchar_t    wc;
    char       mbs[5] = "a";    /* string containing the multibyte char */
    mbstate_t  ss = 0;          /* set shift state to the initial state */
    int        length;

    /* Determine the length of the multibyte character pointed to by
    /* mbs. Store the multibyte character in the wchar_t object
    /* called wc.
    /*
    length = mbrtowc(&wc, mbs, MB_CUR_MAX, &ss);

    printf("    length: %d \n", length);
    printf("    wc: %lc \n", wc);
    printf("    mbs: \"%s\" \n", mbs);
    printf("MB_CUR_MAX: %d \n", MB_CUR_MAX);
    printf("    ss: %d \n", ss);
}
```

mbsinit() — Test state object for initial state

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C Amendment C99 Single UNIX Specification, Version 3 | both | |

Format

Non-XP G4

```
#include <wchar.h>

int mbsinit(const mbstate_t *ps);
```

XP G4

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

int mbsinit(const mbstate_t *ps);
```

General description

If *ps* is not a NULL pointer the mbsinit() function determines whether the pointer to mbstate_t object describes an initial conversion state.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Special behavior for XPG4

If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then you must also define the _MSE_PROTOS feature test macro to make the declaration of the mbsinit() function in the wchar header available when you compile your program. Please see [Table 2 on page 4](#) for a list of XPG4 and other feature test macros.

Returned value

If *ps* is a NULL pointer or if the pointed-to object describes an initial conversion state, mbsinit() returns nonzero.

Otherwise, mbsinit() returns 0.

Example

CELEBM05

```
/* CELEBM05

   This example checks the conversion state to see if it is in the
   initial state.

*/
#include "stdio.h"
#include "wchar.h"
#include "stdlib.h"

main() {
    char    *string = "ABC";
    mbstate_t state = 0;
    wchar_t  wc;
    int      rc;

    rc = mbrtowc(&wc, string, MB_CUR_MAX, &state);
    if (mbsinit(&state))
        printf("In initial conversion state\n");
}
```

mbsrtowcs() — Convert a multibyte string to a wide-character string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment C99 Single UNIX Specification, Version 3 | both | |

Format

Non-XP4

```
#include <wchar.h>

size_t mbsrtowcs(wchar_t *dst, const char **src, size_t len, mbstate_t *ps);
```

XP4

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

size_t mbsrtowcs(wchar_t *dst, const char **src, size_t len, mbstate_t *ps);
```

General description

Converts a sequence of multibyte characters that begins in the conversion state described by *ps* from the array indirectly pointed to by *src*. It converts this sequence into a sequence of corresponding wide characters, that, if *dst* is not a NULL pointer, are then stored into the array pointed to by *dst*. Conversion continues up to and including a terminating NULL character, and the terminating NULL wide character is also stored. Conversion stops earlier in two cases: (1) when a sequence of bytes is reached that does not form a valid multibyte character, or (2) if *dst* is not a NULL pointer, when *len* codes have been stored into the array pointed to by *dst*. Each conversion takes place as if by a call to the `mbtowc()` function.

If *dst* is not a NULL pointer, the pointer object pointed to by *src* is assigned either a NULL pointer (if conversion stopped because a terminating NULL character was reached) or the address just past the last multibyte character converted. If conversion stopped because a terminating NULL character was reached, the resulting state is the initial state.

`mbsrtowcs()` is a restartable version of `mbstowcs()`. That is, shift-state information is passed as one of the arguments and is updated on exit. With `mbsrtowcs()`, you can switch from one multibyte string to another, provided that you have kept the shift-state information.

The behavior of this wide-character function is affected by the `LC_CTYPE` category of the current locale. If you change the category, undefined results can occur.

Special behavior for XP4

If you define any feature test macro specifying XP4 behavior before the statement in your program source file to include the `wchar` header, then you must also define the `_MSE_PROTOS` feature test macro to make the declaration of the `mbsrtowcs()` function in the `wchar` header available when you compile your program. Please see [Table 2 on page 4](#) for a list of XP4 and other feature test macros.

Returned value

If successful, `mbsrtowcs()` returns the number of multibyte characters converted, not including the terminating NULL character, if any.

If the *dst* argument is a null pointer, the *len* argument is ignored and `mbsrtowcs()` returns the required size in wide characters for the destination string.

If the input string contains an invalid multibyte character, `mbsrtowcs()` returns `(size_t)-1` and sets `errno` to one of the following values:

Error Code

Description

EILSEQ

Encoding error (the conversion state is undefined).

Example

CELEBM06

```
/* CELEBM06 */
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>

#define SIZE 10

int main(void)
{
    wchar_t wcs[SIZE];
    char mbs[SIZE]="abcd"; /* string containing the multibyte char */
    char *ptr = mbs; /* pointer to the mbs string */
    int length;

    /* Determine the length of the multibyte string pointed to by */
    /* mbs. Store the multibyte characters in the wchar_t array */
    /* pointed to by wcs. */

    length = mbsrtowcs(wcs, (const char**)&ptr, SIZE, NULL);
    wcs[length] = L'\0';

    printf("    length: %d \n", length);
    printf("    wcs: \"%ls\" \n", wcs);
    printf("    mbs: \"%s\" \n", mbs);
    printf("    &mbs: %p \n", mbs);
    printf("    &ptr: %p \n", ptr);
}
```

mbstowcs() – Convert multibyte characters to wide characters

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdlib.h>

size_t mbstowcs(wchar_t * __restrict__pwc, const char* __restrict__ string, size_t n);
```

General description

Determines the length of the sequence of the multibyte characters that start in the initial shift state and that are pointed to by *string*. It then converts each of the multibyte characters to a `wchar_t`, and stores no more than *n* codes in the array pointed to by *pwc*. The conversion stops if either an invalid multibyte sequence is encountered or if *n* codes have been converted.

Processing continues up to and including the terminating NULL character, and characters that follow it are not processed. The terminating NULL character is converted into a code with the value 0.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

If *pwc* is a NULL pointer, `mbstowcs()` will return the length required to convert the entire array regardless of the value of *n*, but no values are stored.

Returned value

If successful, `mbstowcs()` returns the number of *pwc* array elements modified (or required if *pwc* is NULL) , not counting the terminating 0 code (the `wchar_t` 0 code). Note that, if the return value is *n*, the resulting *wchar_t* array will *not* be NULL-terminated.

If an invalid multibyte character is encountered, `mbstowcs()` returns `(size_t)-1`.

Example

CELEBM07

```
/* CELEBM07

   This example uses &mbstowcs. to convert a multibyte character
   string to a wide character string.

*/
#include <stdio.h>
#include <stdlib.h>

int main()
{
    char      mbsin[8] = "\x50\x0e\x42\xf1\x0f\x50\x00";
    wchar_t   wcsout[5];
    size_t    wcssize;

    printf("mbsin is 0x%.2x 0x%.2x 0x%.2x 0x%.2x 0x%.2x 0x%.2x 0x%.2x\n",
```

```
    mbsin[0], mbsin[1], mbsin[2],
    mbsin[3], mbsin[4], mbsin[5],
    mbsin[6]);

    wcssize = mbstowcs(wcsout, mbsin, 5);

    printf("mbstowcs(wcsout, mbsin, 5); returned %d\n", wcssize);

    printf("wcsout is 0x%.4x 0x%.4x 0x%.4x 0x%.4x\n",
           wcsout[0], wcsout[1],
           wcsout[2], wcsout[3]);
}
```

Output

```
mbsin is 0x50 0x0e 0x42 0xf1 0x0f 0x50 0x00
mbstowcs(wcsout, mbsin, 5); returned 3
wcsout is 0x0050 0x42f1 0x0050 0x0000
```

mbtowc() — Convert multibyte character to wide character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdlib.h>

int mbtowc(wchar_t * __restrict__pwc, const char* __restrict__string, size_t n);
```

General description

Converts a multibyte character to a wide character and returns the number of bytes of the multibyte character. It first determines the length of the multibyte character pointed to by *string*. It then converts the multibyte character to the corresponding wide character and places the wide character in the location pointed to by *pwc*, if *pwc* is not a NULL pointer. A maximum of *n* bytes is examined.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Returned value

If *string* is NULL, mbtowc() returns:

- Nonzero if the multibyte encoding in the current locale (LC_CTYPE) is shift-dependent.
- 0 otherwise.
- The current shift state is set to the initial state.

Otherwise if *string* is not NULL, mbtowc() returns:

- The number of bytes comprising the converted multibyte character, if *n* or fewer bytes form a valid multibyte character.
- 0 if *string* points to the NULL character.
- -1 if *string* does not point to a valid multibyte character, and the next *n* bytes do not form a valid multibyte character.

If the current locale supports EBCDIC DBCS characters, the shift state is updated where applicable. The length returned may be up to 4 characters long (for the shift-out character, 2-byte code, and the shift-in character).

After the function is placed into its initial state, it interprets multibyte characters—pointed to by *string*—accordingly. During the processing of shift-dependent encoded characters, you cannot stop processing one string, then move temporarily to processing another string, and return to the first, because the state would be valid for the second string, not the place where you stopped in the first string.

Example

```
/* This example uses mbtowc() to convert a multibyte character into a wide
   character.
   */
#include <stdio.h>
#include <stdlib.h>

int temp;
char string [6];
wchar_t arr[6];

int main(void)
{ /* Set string to point to a multibyte character. */
  :
    temp = mbtowc(arr, string, MB_CUR_MAX);
    printf("wide-character string: %ls",arr);
  }
```

m_create_layout() – Create and initialize a layout object (bidi data)

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| ISO C XPG4 C99 | both | z/OS V1R2 |

Format

```
#include <sys/layout.h>

LayoutObject m_create_layout(const AttrObject attrobj, const char *modifier);
```

General description

The `m_create_layout()` function is part of the support for handling of bidirectional (Bidi) conversion of data between Visual (MVS) and Implicit (z/OS UNIX) formats. Initial support is for Arabic and Hebrew data.

The `m_create_layout()` function creates a `LayoutObject` associated with the locale identified by *attrobj*. The `LayoutObject` is an opaque object containing all the data and methods necessary to perform the layout operations on context-dependent or directional characters of the locale identified by the *attrobj*.

The memory for the `LayoutObject` is allocated by `m_create_layout()`. The `LayoutObject` created has default layout values. If the *modifier* argument is not NULL, the layout values specified by the *modifier* will overwrite the default layout values associated with the locale. Also, internal states maintained by the layout transformation function across transformations are set to their initial values.

The *attrobj* argument is or may be an amalgam of many opaque objects. A locale object is just one example of the type of object that can be attached to an attribute object. The *attrobj* argument specifies a name that is usually associated with a locale category. If *attrobj* is NULL, the `LayoutObject` created is associated with the current locale as set by the `setlocale()` function.

The *modifier* argument can be used to announce a set of layout values when the `LayoutObject` is created.

A `LayoutObject` created by `m_create_layout()` is deleted by calling the `m_destroy_layout()` function.

For a detailed description of bidirectional layout transformation, see *Bidirectional Language Support in z/OS XL C/C++ Programming Guide*.

Returned value

If successful, `m_create_layout()` returns a `LayoutObject` for use in subsequent calls to `m_*_layout()` functions.

If unsuccessful, `m_create_layout()` returns `(LayoutObject)0` and sets `errno` to one of the following values:

Error Code

Description

EBADF

The attribute object is invalid or the locale associated with the attribute object is not available.

EINVAL

The modifier string has a syntax error or it contains unknown layout values.

ENOMEM

Insufficient storage space is available.

m_destroy_layout() — Destroy a layout object (bidi data)

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| ISO C XPG4 C99 | both | z/OS V1R2 |

Format

```
#include <sys/layout.h>

int m_destroy_layout(const LayoutObject layoutobject);
```

General description

The `m_destroy_layout()` function is part of the support for handling of bidirectional (Bidi) conversion of data between Visual (MVS) and Implicit (z/OS UNIX) formats. Initial support is for Arabic and Hebrew data.

The `m_destroy_layout()` function destroys a `LayoutObject` by deallocating the layout object and all the associated resources previously allocated by the `m_create_layout()` function.

Returned value

If successful, `m_destroy_layout()` returns 0.

If unsuccessful, `m_destroy_layout()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EFAULT

Errors occurred while processing the request.

memccpy() – Copy bytes in memory

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <string.h>

void *memccpy(void *__restrict__ s1, const void *__restrict__ s2, int c, size_t n);
```

General description

The `memccpy()` function copies bytes from memory area `s2` into memory area `s1`, stopping after the first occurrence of byte `c` (converted to an unsigned char) is copied, or after `n` bytes are copied, whichever comes first.

Returned value

If successful, `memccpy()` returns a pointer to the byte after the copy of `c` in `s1`.

If `c` was not found in the first `n` bytes of `s2`, `memccpy()` returns a NULL pointer.

Related information

memchr() – Search buffer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <string.h>

void *memchr(const void *buf, int c, size_t count);
```

General description

The `memchr()` built-in function searches the first *count* bytes pointed to by *buf* for the first occurrence of *c* converted to an unsigned character. The search continues until it finds *c* or examines *count* bytes.

Returned value

If successful, `memchr()` returns a pointer to the location of *c* in *buf*.

If *c* is not within the first *count* bytes of *buf*, `memchr()` returns NULL.

Example

CELEBM11

```
/* CELEBM11

   This example finds the first occurrence of "x" in
   the string that you provide.
   If it is found, the string that starts with that character is
   printed.
   If you compile this code as MYPROG, then it could be invoked
   like this, with exactly one parameter:
       MYPROG skixing

*/
#include <stdio.h>
#include <string.h>

int main(int argc, char ** argv)
{
    char * result;

    if ( argc != 2 )
        printf( "Usage: %s string\n", argv[0] );
    else
    {
        if ((result = (char *)memchr( argv[1], 'x', strlen(argv[1])) ) != NULL)
            printf( "The string starting with x is %s\n", result );
        else
            printf( "The letter x cannot be found in the string\n" );
    }
}
```

Output

```
The string starting with x is xing
```

Related information

memcmp() – Compare bytes

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <string.h>

int memcmp(const void *buf1, const void *buf2, size_t count);
```

General description

The `memcmp()` built-in function compares the first *count* bytes of *buf1* and *buf2*.

The relation is determined by the sign of the difference between the values of the leftmost first pair of bytes that differ. The values depend on EBCDIC encoding. This function is *not* locale sensitive.

Returned value

Indicates the relationship between *buf1* and *buf2* as follows:

Value

Meaning

< 0

The contents of the buffer pointed to by *buf1* less than the contents of the buffer pointed to by *buf2*

= 0

The contents of the buffer pointed to by *buf1* identical to the contents of the buffer pointed to by *buf2*

> 0

The contents of the buffer pointed to by *buf1* greater than the contents of the buffer pointed to by *buf2*

Example

CELEBM12

```
/* CELEBM12

   This example compares first and second arguments passed to
   main to determine which, if either, is greater.

*/
#include <stdio.h>
#include <string.h>

int main(int argc, char ** argv)
{
    int len;
    int result;

    if ( argc != 3 )
    {
        printf( "Usage: %s string1 string2\n", argv[0] );
    }
    else
```

```

{
    /* Determine the length to be used for comparison */
    if (strlen( argv[1] ) < strlen( argv[2] ))
        len = strlen( argv[1] );
    else
        len = strlen( argv[2] );

    result = memcmp( argv[1], argv[2], len );

    printf( "When the first %i characters are compared,\n", len );
    if ( result == 0 )
        printf( "\"%s\" is identical to \"%s\"\n", argv[1], argv[2] );
    else if ( result < 0 )
        printf( "\"%s\" is less than \"%s\"\n", argv[1], argv[2] );
    else
        printf( "\"%s\" is greater than \"%s\"\n", argv[1], argv[2] );
}
}
```

Output

If the program is passed the arguments *firststring* and *secondstring*, you would obtain following:

```

When the first 11 characters are compared,
"firststring" is less than "secondstring"
```

memcpy() – Copy buffer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```

#include <string.h>

void *memcpy(void * __restrict__dest, const void * __restrict__src, size_t count);
```

General description

The memcpy() built-in function copies *count* bytes from the object pointed to by *src* to the object pointed to by *dest*. See [“Built-in functions” on page 96](#) for information about the use of built-in functions. For memcpy(), the source characters may be overlaid if copying takes place between objects that overlap. Use the memmove() function to allow copying between objects that overlap.

Returned value

`memcpy()` returns the value of *dest*.

Example

CELEBM13

```
/* CELEBM13

   This example copies the contents of source to target.

   */
#include <string.h>
#include <stdio.h>

#define MAX_LEN 80

char source[ MAX_LEN ] = "This is the source string";
char target[ MAX_LEN ] = "This is the target string";

int main(void)
{
    printf( "Before memcpy, target is \"%s\\n\", target );
    memcpy( target, source, sizeof(source));
    printf( "After memcpy, target becomes \"%s\\n\", target );
}
```

Output

```
Before memcpy, target is "This is the target string"
After memcpy, target becomes "This is the source string"
```

memmove() – Move buffer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <string.h>

void *memmove(void *dest, const void *src, size_t count);
```

General description

Copies *count* bytes from the object pointed to by *src* to the object pointed to by *dest*. The `memmove()` function allows copying between possibly overlapping objects as if the *count* bytes of the object pointed to by *src* must first be copied into a temporary array before being copied to the object pointed to by *dest*.

Returned value

`memmove()` returns the value of *dest*.

Example

CELEBM14

```
/* CELEBM14

   This example copies the word shiny from position target + 2
   to position target + 8.

*/
#include <string.h>
#include <stdio.h>
#define SIZE    21

char target[SIZE] = "a shiny white sphere";

int main( void )
{
    char * p = target + 8; /* p points at the starting character
                           of the word we want to replace */
    char * source = target + 2; /* start of "shiny" */

    printf( "Before memmove, target is \"%s\"\n", target );
    memmove( p, source, 5 );
    printf( "After memmove, target becomes \"%s\"\n", target );
}
```

Output

```
Before memmove, target is "a shiny white sphere"
After memmove, target becomes "a shiny shiny sphere"
```

memset() — Set buffer to value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <string.h>

void *memset(void *dest, int c, size_t count);
```

General description

The `memset()` built-in function sets the first *count* bytes of *dest* to the value *c* converted to an unsigned int.

Returned value

`memset()` returns the value of *dest*.

Example

CELEBM15

```
/* CELEBM15

   This example sets 10 bytes of the buffer to "A" and
   the next 10 bytes to "B".

*/
#include <string.h>
#include <stdio.h>
#define BUF_SIZE 20
#define HALF_BUF_SIZE BUF_SIZE/2

int main(void)
{
    char buffer[BUF_SIZE + 1];
    char *string;

    memset(buffer, 0, sizeof(buffer));
    string = (char *)memset(buffer, 'A', HALF_BUF_SIZE);
    printf("\nBuffer contents: %s\n", string);
    memset(buffer+HALF_BUF_SIZE, 'B', HALF_BUF_SIZE);
    printf("\nBuffer contents: %s\n", buffer);
}
```

Output

```
Buffer contents: AAAAAAAAAA
Buffer contents: AAAAAAAAAABBBBBBBBBB
```

m_getvalues_layout() — Query layout values of a layout object (bidi data)

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| ISO C XPG4 C99 | both | z/OS V1R2 |

Format

```
#include <sys/layout.h>

int m_getvalues_layout(const LayoutObject layout_object, LayoutValues values,
                      int *index_returned);
```

General description

The `m_getvalues_layout()` function is part of the support for handling of bidirectional (Bidi) conversion of data between Visual (MVS) and Implicit (z/OS UNIX) formats. Initial support is for Arabic and Hebrew data.

The `m_getvalues_layout()` function is used to query the current setting of layout values within a `LayoutObject`. The `layout_object` argument specifies a `LayoutObject` returned by the `m_create_layout()` function. The `values` argument specifies the list of layout values which are to be queried.

Each value element of a `LayoutValueRec` must point to a location where the layout value is stored. For example, if a layout value is of type `T`, the argument must be of type `T*`. The values are queried from the `LayoutObject` and represent its current state.

If the layout value name has **QueryValueSize** OR-ed to it, instead of the value of the layout value, only its size is returned. This option can be used by the caller to determine the amount of memory needed to be allocated for the layout values queried.

It is the user's responsibility to manage the space allocation for the layout values queried.

For a detailed description of bidirectional layout transformation, see [Bidirectional Language Support in z/OS XL C/C++ Programming Guide](#).

Returned value

If successful, `m_getvalues_layout()` returns 0.

If any value cannot be queried, `m_getvalues_layout()` stores into `index_returned` the (zero-based) index of the value causing the error. It returns -1 and sets `errno` to one of the following values:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

EINVAL

The layout value specified by `index_returned` is unknown or its value is invalid or the argument `layout_object` is invalid.

Related information

mkdir() — Make a directory

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <sys/stat.h>

int mkdir(const char *pathname, mode_t mode);
```

General description

Creates a new, empty directory, *pathname*. The file permission bits in *mode* are modified by the file creation mask of the process, and then used to set the file permission bits of the directory being created. For more information on the file creation mask, see [“umask\(\) — Set and retrieve file creation mask” on page 1929](#).

The *mode* argument is created with one of the flags defined in the `sys/stat.h` header file. Any mode flags that are not defined will be turned off, and the function will be allowed to proceed.

Flag**Description****S_IRGRP**

Read permission for the file's group.

S_IROTH

Read permission for users other than the file owner.

S_IRUSR

Read permission for the file owner.

S_IRWXG

Read, write, and search or execute permission for the file's group. `S_IRWXG` is the bitwise inclusive OR of `S_IRGRP`, `S_IWGRP`, and `S_IXGRP`.

S_IRWXO

Read, write, and search or execute permission for users other than the file owner. S_IRWXO is the bitwise inclusive OR of S_IROTH, S_IWOTH, and S_IXOTH.

S_IRWXU

Read, write, and search, or execute, for the file owner; S_IRWXU is the bitwise inclusive OR of S_IRUSR, S_IWUSR, and S_IXUSR.

S_ISGID

Privilege to set group ID (GID) for execution. When this file is run through an exec function, the effective group ID of the process is set to the group ID of the file. The process then has the same authority as the file owner, rather than the authority of the actual invoker.

S_ISUID

Privilege to set the user ID (UID) for execution. When this file is run through an exec function, the effective user ID of the process is set to the owner of the file. The process then has the same authority as the file owner, rather than the authority of the actual invoker.

S_ISVTX

Indicates shared text. Keep loaded as an executable file in storage.

S_IWGRP

Write permission for the file's group.

S_IWOTH

Write permission for users other than the file owner.

S_IWUSR

Write permission for the file owner.

S_IXGRP

Search permission (for a directory) or execute permission (for a file) for the file's group.

S_IXOTH

Search permission for a directory, or execute permission for a file, for users other than the file owner.

S_IXUSR

Search permission (for a directory) or execute permission (for a file) for the file owner.

The owner ID of the new directory is set to the effective user ID of the process. The group ID of the new directory is set to the group ID of the owning directory.

mkdir() sets the access, change, and modification times for the new directory. It also sets the change and modification times for the directory that contains the new directory.

If *pathname* names a symbolic link, mkdir() fails.

Returned value

If successful, mkdir() returns 0.

If unsuccessful, mkdir() does not create a directory, returns -1, and sets errno to one of the following values:

Error Code**Description****EACCES**

The process did not have search permission on some component of *pathname*, or did not have write permission on the parent directory of the directory to be created.

EEXIST

Either the named file refers to a symbolic link, or there is already a file or directory with the given *pathname*.

ELOOP

A loop exists in symbolic links. This error is issued if more than POSIX_SYMLINK_MAX (defined in the limits.h header file) symbolic links are detected in the resolution of *pathname*.

EMLINK

The link count of the parent directory has already reached LINK_MAX (defined in the limits.h header file).

ENAMETOOLONG

pathname is longer than **PATH_MAX** characters or some component of *pathname* is longer than **NAME_MAX** characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the pathname string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values can be determined using pathconf().

ENOENT

Some component of *pathname* does not exist, or *pathname* is an empty string.

ENOSPC

The file system does not have enough space to contain a new directory, or the parent directory cannot be extended.

ENOTDIR

A component of the *pathname* prefix is not a directory.

EROFS

The parent directory of the directory to be created is on a read-only file system.

Example**CELEBM16**

```
/* CELEBM16

   The following example creates a new directory.

*/
#define _POSIX_SOURCE
#include <sys/stat.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
    char new_dir[]="new_dir";

    if (mkdir(new_dir, S_IRWXU|S_IRGRP|S_IXGRP) != 0)
        perror("mkdir() error");
    else if (chdir(new_dir) != 0)
        perror("first chdir() error");
    else if (chdir("..") != 0)
        perror("second chdir() error");
    else if (rmdir(new_dir) != 0)
        perror("rmdir() error");
    else
        puts("success!");
}
```

mkdirat() — Make a directory

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1-2008 Single UNIX Specification, Version 4 | both | |

Format

```
#define _POSIX_C_SOURCE 200809L
#include <fcntl.h>
#include <sys/stat.h>

int mkdirat(int dirfd, const char *pathname, mode_t mode);
```

General description

mkdirat() is equivalent to mkdir() except for the following cases:

- If *pathname* is relative, it is interpreted relative to the directory that is referred to by the file descriptor *dirfd* (rather than relative to the current working directory of the calling process, as is done by mkdir() for a relative path name).
- If *pathname* is relative and *dirfd* is the special value AT_FDCWD, *pathname* is interpreted relative to the current working directory of the calling process (like mkdir()).
- If *pathname* is absolute, *dirfd* is ignored.

Returned value

If successful, mkdirat() returns 0.

If unsuccessful, mkdirat() returns -1 and sets errno to one of the following values:

Error Code

Description

EACCES

The process does not have search permission on some component of *pathname* or does not have write permission on the parent directory of the file or directory to be created.

EBADF

pathname is relative but *dirfd* is not AT_FDCWD or a valid file descriptor.

EEXIST

Either the named file refers to a symbolic link, or there is a file or directory with the given *pathname*.

EFBIG

A request to create a directory is prohibited because the file size limit for the process is set to 0.

ELOOP

A loop exists in symbolic links. This error is issued if more than POSIX_SYMLOOP (defined in the limits.h header file) symbolic links are detected in the resolution of *pathname*.

EMLINK

The link count of the parent directory reaches the maximum number that is defined for the system.

ENAMETOOLONG

pathname is longer than PATH_MAX characters or some component of *pathname* is longer than NAME_MAX characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the *pathname* string that is substituted for a symbolic link exceeds PATH_MAX. The PATH_MAX and NAME_MAX values can be determined by using pathconf().

ENOENT

The named file does not exist, or *pathname* is a relative path name and *dirfd* refers to a directory that is deleted.

ENOSPC

The file system does not have enough space to contain a new file or directory, or the parent directory cannot be extended.

ENOTDIR

A component of the path prefix is not a directory, or *pathname* is relative and *dirfd* is a file descriptor that refers to a file other than a directory.

EROFS

The parent directory of the file or directory to be created is on a read-only file system.

Related information

- [“fcntl.h — POSIX functions for file operations” on page 23](#)

mkfifo() — Make a FIFO special file

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <sys/stat.h>

int mkfifo(const char *pathname, mode_t mode);
```

General description

Sets the access, change, and modification times for the new file. It also sets the change and modification times for the directory that contains the new file.

mkfifo() creates a new FIFO special file, *pathname*. The file permission bits in *mode* are changed by the file creation mask of the process, and then used to set the file permission bits of the FIFO file being created. If *pathname* contains a symbolic link, mkfifo() fails. For more information on the file creation mask, see [“umask\(\) — Set and retrieve file creation mask” on page 1929](#); for information about the file permission bits, see [“chmod\(\) — Change the mode of a file or directory” on page 274](#).

The owner ID of the FIFO file is set to the effective user ID of the process. The group ID of the FIFO file is set to the group ID of the owning directory. *pathname* cannot end in a symbolic link.

Returned value

If successful, mkfifo() returns 0.

If unsuccessful, mkfifo() does not create a FIFO file, returns -1, and sets errno to one of the following values:

Error Code Description

EACCES

The process does not have search permission on some component of *pathname*, or does not have write permission on the parent directory of the file to be created.

EEXIST

Either the named file refers to a symbolic link, or there is already a file or directory with the given *pathname*.

EINTR

A signal is received while this open is blocked waiting for an `open()` for read (if `O_WRONLY` was specified) or for an `open()` for write (if `O_RDONLY` was specified).

ELOOP

A loop exists in symbolic links. This error is issued if more than `POSIX_SYMLLOOP` (defined in the `limits.h` header file) symbolic links are detected in the resolution of *pathname*.

EMLINK

The link count of the parent directory has already reached the maximum defined for the system.

ENAMETOOLONG

pathname is longer than **PATH_MAX** characters or some component of *pathname* is longer than **NAME_MAX** characters while `_POSIX_NO_TRUNC` is in effect. For symbolic links, the length of the *pathname* string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values can be determined using `pathconf()`.

ENOENT

Some component of *pathname* does not exist, or *pathname* is an empty string.

ENOSPC

The file system does not have enough space to contain a new file, or the parent directory cannot be extended.

ENOTDIR

A component of the *pathname* prefix is not a directory.

EROFS

The parent directory of the FIFO file is on a read-only file system.

Example

CELEBM17

```
/* CELEBM17

   This example uses mkfifo() to create a FIFO specail file named
   temp.fifo and then writes and reads from the file before closing it.

*/
#define _POSIX_SOURCE
#include <sys/stat.h>
#include <unistd.h>
#include <fcntl.h>
#include <stdio.h>

main() {
    char fn[]="temp.fifo";
    char out[20]="FIFO's are fun!", in[20];
    int rfd, wfd;

    if (mkfifo(fn, S_IRWXU) != 0)
        perror("mkfifo() error");
    else {
        if ((rfd = open(fn, O_RDONLY|O_NONBLOCK)) < 0)
            perror("open() error for read end");
        else {
            if ((wfd = open(fn, O_WRONLY)) < 0)
                perror("open() error for write end");
            else {
                if (write(wfd, out, strlen(out)+1) == -1)
                    perror("write() error");
            }
        }
    }
}
```

```

        else if (read(rfd, in, sizeof(in)) == -1)
            perror("read() error");
        else printf("read '%s' from the FIFO\n", in);
        close(wfd);
    }
    close(rfd);
}
unlink(fn);
}
}

```

Output

```
read 'FIFO's are fun!' from the FIFO
```

mkfifoat() — Make a FIFO special file

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1-2008 Single UNIX Specification, Version 4 | both | |

Format

```

#define _POSIX_C_SOURCE 200809L
#include <fcntl.h>
#include <sys/stat.h>

int mkfifoat(int dirfd, const char *pathname, mode_t mode);

```

General description

`mkfifoat()` is equivalent to `mkfifo()` except in the case where *pathname* specifies a relative path. In this case the newly created FIFO is created relative to the directory that is associated with the file descriptor *dirfd* instead of the current working directory. If `mkfifoat()` is passed the special value `AT_FDCWD` in the *dirfd* parameter, the current working directory is used and the behavior is identical to a call to `mkfifo()`.

Returned value

If successful, `mkfifoat()` returns 0.

If unsuccessful, `mkfifoat()` returns -1, and sets `errno` to one of the following values:

Error Code

Description

EACCES

The process does not have search permission on some component of *pathname*, or does not have write permission on the parent directory of the file to be created.

EBADF

pathname is relative but *dirfd* is not `AT_FDCWD` or a valid file descriptor.

EEXIST

Either the named file refers to a symbolic link, or there is a file or directory with the given *pathname*.

EFBIG

A request to create a directory is prohibited because the file size limit for the process is set to 0.

EINVAL

The file type that is specified in the *mode* parameter is not valid.

ELOOP

A loop exists in symbolic links. This error is issued if more than `POSIX_SYMLINK` (defined in the `limits.h` header file) symbolic links are detected in the resolution of *pathname*.

EMLINK

The link count of the parent directory reaches the maximum number that is defined for the system.

ENAMETOOLONG

pathname is longer than `PATH_MAX` characters or some component of *pathname* is longer than `NAME_MAX` characters while `_POSIX_NO_TRUNC` is in effect. For symbolic links, the length of the *pathname* string that is substituted for a symbolic link exceeds `PATH_MAX`. The `PATH_MAX` and `NAME_MAX` values can be determined by using `pathconf()`.

ENOENT

The named file does not exist, or *pathname* is a relative path name and *dirfd* refers to a directory that is deleted.

ENOSPC

The file system does not have enough space to contain a new file or directory, or the parent directory cannot be extended.

ENOTDIR

A component of the path prefix is not a directory, or *pathname* is relative and *dirfd* is a file descriptor that refers to a file other than a directory.

EROFS

The parent directory of the file or directory to be created is on a read-only file system.

mknod() — Make a directory or file

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 z/OS UNIX | both | |

Format

_OPEN_SYS

```
#define _OPEN_SYS
#include <sys/stat.h>

int mknod(const char *path, mode_t mode, rdev_t dev_identifier);
```

_XOPEN_SOURCE_EXTENDED 1

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/stat.h>

int mknod(const char *path, mode_t mode, dev_t dev_identifier);
```

General description

Creates a new directory, regular file, character special file, or FIFO special file (named pipe), with the pathname specified in the *path* argument.

The first byte of the *mode* argument determines the file type of the file:

S_IFCHR

Character special file

S_IFFIFO

FIFO special file

S_IFREG

Regular file

S_IFDIR

Directory file

The file permission bits of the new file are initialized with the remaining bits in *mode* and changed by the file creation mask of the process. For more information on these symbols, refer to [“chmod\(\) — Change the mode of a file or directory”](#) on page 274.

dev_identifier applies only to a character special file. It is ignored for the other file types. *dev_identifier* contains a value representing the device major and device minor numbers. The major number is contained in the high-order 16 bits; it identifies a device driver supporting a class of devices, such as interactive terminals. The minor number is contained in the low-order 16 bits of *dev_identifier*; it identifies a specific device within the class referred to by the device major number. With z/OS UNIX services, the device major numbers are:

- 1** Manager pseudoterminal
- 2** Subsidiary pseudoterminal
- 3** /dev/tty
- 4** /dev/null
- 5** /dev/fdn
- 6** Sockets
- 7** OCSRTY
- 8** OCSADMIN

9

"/dev/console"

Device major numbers 1,2 and 7: The device minor numbers range between 0 and one less than the maximum number of pseudoterminal pairs defined by the installation.

Device major numbers 3,4,6,8 and 9: The device minor number is ignored.

Device major number 5: The device minor number value represents the file descriptor to be referred to. For example, device minor 0 refers to file descriptor 0.

When it completes successfully, `mknod()` marks for update the following fields of the file: `st_atime`, `st_ctime`, and `st_mtime`. It also marks for update the `st_ctime` and `st_mtime` fields of the directory that contains the new file.

Returned value

If successful, `mknod()` returns 0.

If unsuccessful, `mknod()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

Search permission is denied on a component of *path*, or write permission is denied on the parent directory of the file to be created.

EEXIST

A file by that name already exists.

ELOOP

A loop exists in symbolic links. This error is issued if more than `POSIX_SYMLLOOP` (defined in the `limits.h` header file) symbolic links are detected in the resolution of *path*.

EMLINK

The link count of the parent directory has already reached the maximum defined for the system.

ENAMETOOLONG

pathname is longer than `PATH_MAX` characters, or some component of *pathname* is longer than `NAME_MAX` characters while `_POSIX_NO_TRUNC` is in effect. For symbolic links, the length of the pathname string substituted for a symbolic link exceeds `PATH_MAX`. The `PATH_MAX` and `NAME_MAX` values can be determined through `pathconf()`.

ENOENT

A component of *path* was not found, or no *path* was specified.

ENOSPC

The file system does not have enough space to contain a new directory, or the parent directory cannot be extended.

ENOTDIR

A component of *path* is not a directory

EPERM

Added for XPG4.2: The invoking process does not have appropriate privileges and the file type is not FIFO-special.

EROFS

The file named in *path* cannot be created, because it would reside on a read-only file system.

Example

CELEBM18

```
/* CELEBM18 */
#include <sys/stat.h>
#include <unistd.h>
#include <stdio.h>
```

```

#define main 0x00010000

main() {
    char fn[]="char  ec";

    if (mknod(fn, S_IFCHR|S_IRUSR|S_IWUSR, main|0x0001) != 0)
        perror("mknod() error");
    else if (unlink(fn) != 0)
        perror("unlink() error");
}

```

mknodat() — Make a directory or file

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1-2008 Single UNIX Specification, Version 4 | both | |

Format

```

#define _POSIX_C_SOURCE 200809L
#include <fcntl.h>
#include <sys/stat.h>

int mknodat(int dirfd, const char *pathname, mode_t mode, dev_t dev);

```

General description

`mknodat()` is equivalent to `mknod()` except for the following cases:

- If *pathname* is relative, it is interpreted relative to the directory that is referred to by the file descriptor *dirfd* (rather than relative to the current working directory of the calling process, as is done by `mknod()` for a relative path name).
- If *pathname* is relative and *dirfd* is the special value `AT_FDCWD`, *pathname* is interpreted relative to the current working directory of the calling process (like `mknod()`).
- If *pathname* is absolute, *dirfd* is ignored.

Returned value

If successful, `mknodat()` returns 0.

If unsuccessful, `mknodat()` returns -1 and sets `errno` to one of the following values:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

EACCES

The process does not have search permission on some component of *pathname* or does not have write permission on the parent directory of the file or directory to be created.

EBADF

pathname is relative but *dirfd* is not `AT_FDCWD` or a valid file descriptor.

EEXIST

Either the named file refers to a symbolic link, or there is a file or directory with the given *pathname*.

EFBIG

A request to create a directory is prohibited because the file size limit for the process is set to 0.

EINVAL

The file type that is specified in the *mode* parameter is not valid.

ELOOP

A loop exists in symbolic links. This error is issued if more than `POSIX_SYMLINK` (defined in the `limits.h` header file) symbolic links are detected in the resolution of *pathname*.

EMLINK

The link count of the parent directory reaches the maximum number that is defined for the system.

ENAMETOOLONG

pathname is longer than `PATH_MAX` characters or some component of *pathname* is longer than `NAME_MAX` characters while `_POSIX_NO_TRUNC` is in effect. For symbolic links, the length of the *pathname* string that is substituted for a symbolic link exceeds `PATH_MAX`. The `PATH_MAX` and `NAME_MAX` values can be determined by using `pathconf()`.

ENOENT

The named file does not exist, or *pathname* is a relative path name and *dirfd* refers to a directory that is deleted.

ENOSPC

The file system does not have enough space to contain a new directory or directory, or the parent directory cannot be extended.

ENOTDIR

A component of the path prefix is not a directory, or *pathname* is relative and *dirfd* is a file descriptor that refers to a file other than a directory.

EPERM

The invoking process does not have appropriate privileges and the file type is not FIFO-special. The operation is not permitted. The requested operation requires a superuser authority.

EROFS

The parent directory of the file or directory to be created is on a read-only file system.

mkstemp() — Make a unique filename

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

int mkstemp(char *template);
```

General description

The `mkstemp()` function replaces the contents of the string pointed to by *template* with a unique file name, and returns a file descriptor for the file open for reading and writing. The function thus prevents any possible race condition between testing whether the file exists and opening it for use. The string in *template* should look like a file name with six trailing 'X's; `mkstemp()` replaces each 'X' with a character from the portable file name character set. The characters are chosen such that the resulting name does not duplicate the name of an existing file. This function is supported only in a POSIX program.

Returned value

If successful, `mkstemp()` returns an open file descriptor.

If no suitable file could be created, `mkstemp()` returns -1.

There are no `errno` values defined.

Related information

- [“stdlib.h — Standard library functions” on page 65](#)
- [“mktemp\(\) — Make a unique file name” on page 1083](#)

mktemp() — Make a unique file name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

char *mktemp(char *template);
```

General description

The `mktemp()` function replaces the contents of the string pointed by *template* by a unique file name and returns *template*. The application must initialize *template* to be a file name with six trailing 'X's; `mktemp()` replaces each 'X' with a single-byte character from the portable file name character set.

This function is supported only in a POSIX program.

Note: The `mktemp()` function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The `mkstemp()` function is preferred for portability and greater reliability.

Returned value

If successful, mktime() returns a pointer to *template*.
If a unique name cannot be created, mktime() sets *template* to a NULL string.
There are no errno values defined.

- [“stdlib.h — Standard library functions” on page 65](#)
- [“mkstemp\(\) — Make a unique filename” on page 1082](#)

mktime(), mktime64() — Convert local time

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```
#include <time.h>

time_t mktime(struct tm *tm_ptr);

#define _LARGE_TIME_API
#include <time.h>

time64_t mktime64 (struct tm *tm_ptr);
```

Compile requirement: Use of mktime64() function requires the long long data type. For more information on how to make long long data type available, see [z/OS XL C/C++ Language Reference](#).

General description

The mktime() function converts broken-down time, expressed as a local time, in the tm structure (described in [Table 16 on page 76](#)) pointed to by *tm_ptr*, to calendar time. Calendar time is the number of seconds since epoch, which was at 00:00:00 Coordinated Universal Time (UTC), January 1, 1970.

The values of the structure members passed to the mktime() function are not restricted to the ranges described in [“time.h — Time and date” on page 75](#). For values that are outside the specified range, the mktime() function will use date arithmetic to adjust the values to produce a valid date and time (see [“Example” on page 1086](#)). The values of *tm_wday* and *tm_yday* are ignored and are assigned their correct values on return.

On the successful completion of the function, all the members of the structure pointed to by *time* are set to represent the specified time since the Epoch with their values forced into the ranges described in [“time.h — Time and date” on page 75](#). The value of *tm_wday* is set after the values of *tm_mon* and *tm_year* are determined. The output value of *tm_isdst* is determined by the mktime() function, independent of the value presented as input to the mktime() function.

If an application uses the `localtime()` function to determine local time, the `localtime()` function will determine if daylight savings applies (assuming DST information is available) and will correctly set the `tm_isdst` flag. If the application wants to determine seconds from Epoch corresponding to a `tm` structure returned by the `localtime()` function, it should not modify the `tm_isdst` flag set by the `localtime()` function.

If an application sets `tm_isdst` to 0 before calling the `mktime()` function, it is asserting that daylight savings does not apply to the input values of the `tm` structure, regardless of the system DST start and end dates. Likewise, if the application has set a value for `tm_isdst` to be greater than 0, it is asserting that the time represented by the `tm` structure has been shifted for daylight savings. Therefore, the `mktime()` function unshifts the time in determining seconds since Epoch.

Setting `tm_isdst` to -1 indicates the `mktime()` function will determine whether daylight savings time applies. If yes, the `mktime()` function returns `tm_isdst` greater than 0. If not, it returns `tm_isdst` of 0 unless DST information is not available on the system, in which case `tm_isdst` of -1 is returned.

Your time zone might not be using DST, perhaps because the `TZ` environment variable does not specify a daylight savings time name or perhaps because `DSTNAME` is unspecified in the current `LC_TOD` locale category. In such a case, if you code `tm_isdst=1` and call the `mktime()` function, `(time_t)-1` is returned to indicate an error.

The `mktime64()` function behaves exactly like the `mktime()` function except it will support a structured date beyond 00:00:00 UTC January 1, 2038 with a limit of 23:59:59 UTC on December 31, 9999.

Returned value

If successful, the `mktime()` function returns a `time_t` representing seconds since the Epoch. The number of seconds corresponds to the broken-down time, expressed as local time, based on the user-supplied `tm` structure pointed to by `tm_ptr`.

If the `mktime()` function cannot convert the broken-down time to a calendar time, it returns `(time_t)-1` to indicate an error, such as time before January 1, 1970 (UTC).

Error Code

Description

EOVERFLOW

The result cannot be represented.

Usage notes

1. The `ctime()`, `localtime()`, and `mktime()` functions now return Coordinated Universal Time (UTC) unless customized locale information is made available, which includes setting the `timezone_name` variable.
2. Applications working with local time may define time zone information by using the `TZ` (POSIX) or `_TZ` (non-POSIX) environment variable or by customizing the `LC_TOD` category of the locale in use.
3. When neither `TZ` nor `_TZ` is defined, the current locale is interrogated for time zone information. If neither `TZ` nor `_TZ` is defined and `LC_TOD` time zone information is not present in the current locale, a default value is applied to local time. POSIX programs simply default to Coordinated Universal Time (UTC), while non-POSIX programs establish an offset from UTC based on the setting of the system clock. For more information about customizing a time zone to work with local time, see “Customizing a time zone” in [z/OS XL C/C++ Programming Guide](#).
4. The `mktime()` functions fails when a result overflows the `time_t` object used to return the number of seconds elapsed from the time in `tm_ptr` back to the start of the standard epoch. In 31-bit, the last year that `mktime()` supports is 2037. In 64-bit, the `time_t` grows from 4 bytes to 8 bytes in length, so that `mktime()` can accommodate dates further into the future. The upper bound in 64-bit is set to the year 9999.

Example

CELEBM19

```
/* CELEBM19

   This example prints the day of the week that is 40 days and
   16 hours from the current date.

*/
#include <stdio.h>
#include <time.h>

char *wday[] = { "Sunday", "Monday", "Tuesday", "Wednesday",
                 "Thursday", "Friday", "Saturday" };

int main(void)
{
    time_t t1, t3;
    struct tm *t2;

    t1 = time(NULL);
    t2 = localtime(&t1);
    t2 -> tm_mday += 40;
    t2 -> tm_hour += 16;
    t3 = mktime(t2);

    printf("40 days and 16 hours from now, it will be a %s \n",
           wday[t2 -> tm_wday]);
}
```

Output

40 days and 16 hours from now, it will be a Sunday

__mlockall() – Lock the address space of a process

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _OPEN_SOURCE_EXTENDED 2
#include <sys/mman.h>

int __mlockall(int flags);
```

General description

The function `__mlockall()` causes all of the pages mapped by the address space of a process to be memory resident until unlocked or until the process exits or execs another process image. The *flags* argument determines whether the pages are to be locked or unlocked.

Flags

Meaning

`_BPX_NONSWAP`

Lock the current pages mapped for this address space.

`_BPX_SWAP`

Unlock the current pages previously locked.

Returned value

If successful, `__mlockall()` returns 0.

If unsuccessful, `__mlockall()` returns -1 and no change is made to the memory state of the address space.

Note: This function will return a `EINVAL` with an `errno2()` of 09300be if the kernel is not available.

Related information

- [“sys/mman.h — Memory management” on page 69](#)

mmap() — Map pages of memory

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 z/OS UNIX | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/mman.h>

void *mmap(void *addr, size_t len, int prot, int flags, int fildes, off_t off);
```

General description

The `mmap()` function establishes a mapping between an address space of a process (for *len* bytes) and a file that is associated with the file descriptor *fildes* at offset *off* for *len* bytes. The format of the call is as follows:

```
pa=mmap(addr, len, prot, flags, fildes, off);
```

The value of *pa* is an unspecified function of the argument *addr* and values of *flags*, further described below. A successful `mmap()` call returns *pa* as its results. The address ranges covered by [*pa*, *pa + len*] and [*off*, *off + len*] must be legitimate for the possible (not necessarily current) address space of a process and the file, respectively.

If the size of the mapped file changes after the call to `mmap()`, the effect of references to portions of the mapped region that correspond to added or removed portions of the file is unspecified.

The *prot* argument determines whether read, write, execute, or some combinations of accesses are permitted to the pages being mapped. The protection options are defined in `<sys/mman.h>`:

PROT_READ

Page can be read.

PROT_WRITE

Page can be written.

PROT_EXEC

Page can be executed.

PROT_NONE

Page cannot be accessed.

Implementations need not enforce all combinations of access permissions. However, write are permitted only when `PROT_WRITE` has been set.

The *flags* argument provides other information about the handling of the mapped pages. The options are defined in `<sys/mman.h>`:

MAP_SHARED

Share changes.

MAP_PRIVATE

Changes are private.

MAP_FIXED

Interpret *addr* exactly.

__MAP_MEGA

Map in megabyte increments.

__MAP_64

Map storage above the 2-gigabyte addressing range.

MAP_ANONYMOUS

The mapping is not backed by any file and the memory contents are initialized to zero. When `MAP_ANONYMOUS` is set, the *fil*des argument must be -1 and the *off* argument must be zero. `MAP_ANONYMOUS` can be used with any of the other `Map_type` options.

MAP_ANON

Synonym for `MAP_ANONYMOUS`.

The `MAP_PRIVATE` and `MAP_SHARED` flags control the visibility of write references to the memory region. Exactly one of these flags must be specified. The mapping type is retained across a *fork*.

If `MAP_SHARED` is set in *flags*, write references to the memory region by the calling process might change the file and are visible in all `MAP_SHARED` mappings of the same portion of the file by any process.

If `MAP_PRIVATE` is set in *flags*, write references to the memory region by the calling process do not change the file and are not visible to any process in other mappings of the same portion of the file.

All changes to the mapped data made by processes that have mapped the memory region using `MAP_SHARED` are shared and are visible to all other processes that have mapped the same file-offset range.

When `MAP_FIXED` is set in the *flags* argument, the implementation is informed that the value of *pa* must be *addr*, exactly. If `MAP_FIXED` is set, `mmap()` might return `(void*) -1` and set `errno` to `EINVAL`. If a `MAP_FIXED` request is successful, the mapping that is established that is by `mmap()` replaces any previous mappings for the process's pages in the range [*pa*, *pa + len*].

When `MAP_FIXED` is not set, the implementation uses *addr* in an unspecified manner to arrive to *pa*. The *pa* so chosen will be an area of the address space, which the implementation deems suitable for a mapping of *len* bytes to the file. All implementation interprets an *addr* value of 0 as granting the implementation complete freedom in selecting *pa*, subject to constraints described below. A nonzero value of *addr* is taken to be a suggestion of a process address near which the mapping should be placed. When the implementation selects a value for *pa*, it never places a mapping at address 0, nor does it replace any extant mapping, nor map into dynamic memory allocation areas.

The *off* argument is constrained to be aligned and sized according to the value returned by `sysconf()` when passed `_SC_PAGESIZE` or `_SC_PAGE_SIZE`. When `MAP_FIXED` is specified, the argument *addr* must also meet these constraints. The implementation performs mapping operations over whole pages. Thus, while the argument *len* need not meet a size or alignment constraint, the implementation includes, in any mapping operation, any partial page specified by the range [*pa*, *pa* + *len*].

The implementation always zero-fills any partial page at the end of a memory region. Further, the implementation never writes out any modified portions of the last page of a file that are beyond the end of the mapped portion of the file. If the mapping established by `mmap()` extends into pages beyond the page containing the last byte of the file, an application references to any of the pages in the mapping that are beyond the last page results in the delivery of a `SIGBUS` or `SIGSEGV` signal.

The `mmap()` function adds an extra reference to the file associated with the file descriptor *fd* is not removed by a subsequent `close()` on that file descriptor. This reference is removed when there are not more mappings to the file.

The `st_atime` field of the mapped file might be marked for update at any time between the `mmap()` call and the corresponding `munmap()` call. The initial read or write reference to a mapped region causes the file's `st_atime` field to be marked for update if it has not already been marked for update.

The `st_ctime` and `st_mtime` fields of a file that is mapped with `MAP_SHARED` and `PROT_WRITE`, will be marked for update at *st*ime point in the interval between a write reference to the mapped region and the next call to `msync()` with `MS_ASYNC` or `MS_SYNC` for that portion of the file by any process. If there is no such call, these fields might be marked for update at any time after a write reference if the underlying file is modified as a result.

If a memory-mapped region is not unmapped before the process terminates, process termination will not automatically write out to disk any modified data in the mapped region. Modified private data in a `MAP_PRIVATE` region will be discarded. If the map region is `MAP_SHARED`, the modified data continue to reside in the cache (if the same file-offset range is being shared) and might ultimately be written out to disk by another process that uses the `msync()` service. However, if no other processes map the same file-offset range as `MAP_SHARED`, the modified data is discarded.

There might be implementation-dependent limits on the number of memory regions that can be mapped (per process or per system). If such a limit is imposed, whether the number of memory regions that can be mapped by a process is decreased by the use of `shmat()` is implementation-dependent.

Specification of the `__MAP_MEGA` option results in the system allocating storage to map the file in megabyte increments. This option should only be used for large files. Any file over half a megabyte in size will likely achieve better performance by using this option. When using this option, `mmaps` and `munmaps` are in megabyte ranges on megabyte boundaries.

When `__MAP_MEGA` is specified, all changes to the mapped data are shared. Modifications to the mapped data are visible to all other processes that map the same file-offset range. That is, `__MAP_MEGA` behaves much like `MAP_SHARED`. `__MAP_MEGA` is mutually exclusive with `MAP_PRIVATE` and `MAP_SHARED`. Specification of `__MAP_MEGA` with either `MAP_PRIVATE` or `MAP_SHARED` will result in the request failing with `errno` set to `EINVAL`.

The `__MAP_MEGA` option might be specified with `MAP_FIXED`.

Map_address parameter: If the map address is not zero and `__MAP_MEGA` has been specified, then for non `MAP_FIXED` requests, the kernel attempts to create the mapping at the `map_address`, truncated to the nearest megabyte boundary. If unsuccessful, it proceeds as if a `map_address` of zero were specified. For `MAP_FIXED` requests, the value of `map_address` must be multiples of the segment size (megabyte multiples). If not, the `mmap` request fails with `errno` set to `EINVAL`.

Map_length parameter: When `__MAP_MEGA` is specified, mapping operations are performed over whole segments (megabyte chunks). If the length is not a multiple of the segment size, the entire trailing portion of the last segment will also be mapped into the user storage.

File_descriptor: The file descriptor identifies the file being mapped. If an attempt is made to map a file that is already mapped but was mapped with a different specification of `__MAP_MEGA`, then the current request fails with `errno` set to `EINVAL-MMapTypeMismatch`. That is, at any point in time a file might be mapped with the `__MAP_MEGA` option or without the `__MAP_MEGA` option but not both ways at the same time.

For a `__MAP_MEGA` mapping, if this is the first map to the file represented by the specified file descriptor then whether the file was opened for read or for write will determine what protection options might be specified for the file by this `mmap` and any future `mmaps` and `mprotects`, by this or any other process mapping to the same file. If the file was opened for read but not write, then only `PROT_READ`, `PROT_EXEC` or `PROT_NONE` are allowed. If the file was opened for write, then any of the protection options will be allowed. Only regular files might be mapped. Note also that remote files accessed through NFS or DFS might not be mapped.

Protect_options: The specification that is made for `Protect_options` has a global effect when the file is mapped with the `__MAP_MEGA` option. The `Protect_option` specified immediately effects all processes currently mapped to the same file-offset range.

Large file support for z/OS UNIX files: Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the [long long data type support](#) enabled and define the `_LARGE_FILES` feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the `_LARGE_FILES` feature test macro as well.

64-bit mapping support: You can enable the 64-bit mapping support in any of the following ways:

- Set the *flags* argument to `__MAP_64`.
- Set the *addr* argument to the value above 64G.
- Set the *len* argument to the value greater than 2G.

If the first mapping of a file uses 64-bit mapping support, then all subsequent mappings of the file must also use 64-bit mapping support until there are no more mappings onto that file. If an attempt is made to map the file without using 64-bit mapping support, an `EINVAL` error is returned. This rule also applies to the 31-bit mapping support.

Usage notes

- The `mmap()` function does not support shared memory objects or typed memory objects.
- When `__MAP_64` is specified, the *addr* argument must be either 0 or a value greater than 64G; otherwise, an `EINVAL` error is returned.
- When `__MAP_64` is specified, it might be combined with `MAP_FIXED` or `MAP_SHARED` or both.
- When both `__MAP_64` and `MAP_FIXED` are specified, the first fullword of the *addr* argument must be nonzero; otherwise, an `EINVAL` error is returned.
- For non-`MAP_FIXED` requests, if *addr* specifies an address that is above 64G, the system attempts to create a mapping at the address that is specified by *addr* and the address must be on a segment boundary. If it is unsuccessful, it proceeds as if an *addr* value of zero were specified, but will attempt to create a mapping above 64G.
- When `MAP_ANONYMOUS` or `MAP_ANON` is specified, the *filides* parameter must be -1 and the *off* parameter must be 0.

Returned value

If successful, `mmap()` returns the address at which the mapping was placed.

If unsuccessful, *mmap()* returns MAP_FAILED and sets *errno* to one of the following values:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

| | |
|-------------------|---|
| EACCESS | The <i>fildev</i> argument is not open for read, regardless of the protection that is specified, or <i>fildev</i> is not open for write and PROT_WRITE was specified for a MAP_SHARED type mapping. |
| EBADF | The <i>fildev</i> argument is not a valid open file descriptor. |
| EINVAL | The <i>addr</i> argument (if MAP_FIXED was specified) or <i>off</i> is not a multiple of the page size as returned by <i>sysconf()</i> , or are considered invalid by the implementation. The value of <i>flags</i> is invalid (neither MAP_PRIVATE nor MAP_SHARED is set). When MAP_ANONYMOUS is specified, the <i>fildev</i> parameter must be -1 and the <i>off</i> parameter must be 0. |
| EMFILE | The number of mapped regions would exceed an implementation-dependent limit (per process or per system). |
| ENODEV | The <i>fildev</i> argument refers to a file whose type is not supported by <i>mmap()</i> . |
| ENOMEM | MAP_FIXED was specified, and the range [<i>addr</i> , <i>addr</i> + range [<i>addr</i> , <i>addr</i> + <i>len</i>], rounding <i>len</i>] exceeds that allowed for the address space for a process; or if MAP_FIXED was not specified and there is insufficient room in the address space to effect the mapping. |
| ENXIO | Address in the range [<i>off</i> , <i>off</i> + <i>len</i>] are invalid for <i>fildev</i> |
| E_OVERFLOW | The file is a regular file and the value of <i>off</i> plus <i>len</i> exceeds the offset maximum that is established in the open file. Note: Starting with z/OS V1.9, environment variable _EDC_E_OVERFLOW can be used to control behavior of <i>mmap()</i> about detecting an E_OVERFLOW condition for z/OS UNIX files. By default, <i>mmap()</i> will not set E_OVERFLOW when the offset maximum is exceeded associated with <i>fildev</i> . When _EDC_E_OVERFLOW is set to YES, <i>mmap()</i> checks for an overflow condition. |

modf(), modff(), modfl() – Extract fractional and integral parts of floating-point value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#include <math.h>

double modf(double x, double *intptr);
float modf(float x, int *intptr);          /* C++ only */
long double modf(long double x, int *intptr); /* C++ only */
float modff(float x, int *intptr);
long double modfl(long double x, int *intptr);
```

General description

Breaks down the floating-point value *x* into fractional and integral parts. The integral part is stored as double, in the object pointed to by *intptr*. Both the fractional and integral parts are given the same sign as *x*.

Restriction: The modff() function does not support the _FP_MODE_VARIABLE feature test macro.

Returned value

Returns the signed fractional portion of *x*.

Example

CELEBM20

```
/* CELEBM20

   This example breaks the floating-point number -14.876 into
   its fractional and integral components.

*/
#include <math.h>
#include <stdio.h>

int main(void)
{
    double x, y, d;

    x = -14.876;
    y = modf(x, &d);

    printf("x = %lf\n", x);
    printf("Integral part = %lf\n", d);
    printf("Fractional part = %lf\n", y);
}
```

Output

```
x = -14.876000
Integral part = -14.000000
Fractional part = -0.876000
```

modfd32(), modfd64(), modfd128() — Extract fractional and integral parts of decimal floating-point value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 modfd32(_Decimal32 x, _Decimal32 *p);
_Decimal64 modfd64(_Decimal64 x, _Decimal64 *x);
_Decimal128 modfd128(_Decimal128 x, _Decimal128 *x);
_Decimal32 modf(_Decimal32 x, _Decimal32 *x); /* C++ only */
_Decimal64 modf(_Decimal64 x, _Decimal64 *x); /* C++ only */
_Decimal128 modf(_Decimal128 x, _Decimal128 *x); /* C++ only */
```

General description

Breaks down the decimal floating-point value *x* into fractional and integral parts. The integral part is stored in the object point to by *p*. Both the fractional and integral parts are given the same sign as *x*.

Note:

- To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

The lround functions return the signed fractional portion of *x*.

If the rounded value is outside the range of the return type, the numeric result is unspecified. A range error may occur if the magnitude of *x* is too large.

Example

```
/* CELEBM24

This example illustrates the modfd128() function.

This example breaks the floating-point number -14.876 into
```

```
    its fractional and integral components.

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal128 x, y, d;

    x = -14.876DL;
    y = modfd128(x, &d);

    printf("Number          = %DDf\n", x);
    printf("Integral part   = %DDf\n", d);
    printf("Fractional part = %DDf\n", y);
}
```

__moservices() - Memory object services

Standards

| Standards / Extensions | C or C++ | Dependencies |
|-------------------------------|----------|--------------|
| AMODE 64 Language Environment | both | z/OS V1.10 |

Format

```
#include <stdlib.h>

int __moservices(int reqtype, size_t mopl len,
                 struct __mopl_s * mopl, void ** moorigin);
```

General description

The __moservices() function allows the caller to perform the following memory object services:

- Create a memory object that is associated with the current Language Environment enclave;
- Free a memory object that was created by using a previous __moservices() call;
- Specify a shared memory dump priority to be used when allocating shared memory.

Argument

Description

reqtype

The request type. Valid values are

__MO_GETSTOR

Use IARV64 REQUEST(GETSTOR) to create a memory object that is associated with the current Language Environment enclave.

__MO_DETACH

Use IARV64 REQUEST(DETACH) to free a memory object that was created by using __moservices().

__MO_SHMDUMPPRIORITY

Set a shared memory dump priority to be associated with shared memory segments on subsequent shmget() calls.

mopllen

The length of the passed mopl structure. If a mopl is not passed, this length must be set to zero.

mopl

Points to a structure describing additional characteristics for the request.

For __MO_GETSTOR and __MO_SHMDUMPPRIORITY requests, this structure is required.

For __MO_DETACH requests, this structure is optional.

moorigin

On __MO_GETSTOR calls, moorigin contains the origin address of the memory object upon return.

On __MO_DETACH calls, moorigin contains the origin address of the memory object to be detached.

The __mopl_s structure is defined in stdlib.h and has the following format:

```
struct __mopl_s {
    unsigned long    __moplrequestsize;
    int             __mopldumppriority;
    unsigned int     __moplgetstorflags;
    long            __moplreserved;
    int             __mopl_iarv64_rc;
    int             __mopl_iarv64_rsn;
};
```

The entire __mopl_s structure must be set to binary zeros before use. The fields are used as follows:

| | |
|---------------------------|---|
| __mopldumppriority | For __MO_GETSTOR, the desired memory object dump priority (1-99). For __MO_SHMDUMPPRIORITY, the desired shared memory dump priority (1-99). |
| __moplrequestsize | For __MO_GETSTOR, the size of the memory object to be created. The size is in 1 MB units when 4 K or 1 MB page frames are requested. The size is in 2 GB units when 2 GB page frames are requested. |

| | |
|---------------------------|---|
| __moplgetstorflags | <p>For __MO_GETSTOR, flags identifying additional characteristics for the memory object to be created. The following flags are defined:</p> <ul style="list-style-type: none"> • __MOPL_PAGEFRAMESIZE1MEG - the memory object is backed by fixed 1 MB page frames. __moservices() returns -1 with errno EMVSERR if the current hardware does not have Large Page support or if large page frames are not available on the system. • __MOPL_PAGEFRAMESIZEMAX - the memory object must be backed by fixed 1 MB page frames. If the request cannot be backed by fixed 1 MB page frames due to unavailability of large page frames, then the request is backed by 4 K page frames. When 4 K page frames are used, the request is successful, but __mopl_iarv64_rc and __mopl_iarv64_rsn contain values to indicate that the memory object is not backed by fixed 1 MB page frames. • __MOPL_PAGEFRAMESIZE_PAGEABLE1MEG - the memory object must be preferentially backed by pageable 1 MB page frames. Pageable 1 MB page frames are backed at first reference. If pageable 1 MB page frames are not available at first reference, pageable 4 K page frames are used. • __MOPL_PAGEFRAMESIZE_2G - the memory object must be backed by 2 GB page frames. __moservices() returns -1 with errno EMVSERR if the current hardware does not have Large Page support or if large page frames are not available on the system. <p>Note: If none of the previous flags are set, the memory object is backed by 4 K page frames. Also, the previous flags are mutually exclusive.</p> <ul style="list-style-type: none"> • __MOPL_EXECUTABLE - the obtained memory object is executable. • __MOPL_NONEXECUTABLE - the obtained memory object is nonexecutable. <p>Note: If neither __MOPL_EXECUTABLE nor __MOPL_NONEXECUTABLE is set, the executable attribute of the memory object obeys the current system defaults. If both __MOPL_EXECUTABLE and __MOPL_NONEXECUTABLE are set, __moservices() returns -1 with errno EINVAL.</p> |
| __mopl_iarv64_rc | The return code from the call to IARV64 |
| __mopl_iarv64_rsn | The reason code from the call to IARV64 |

Constants are available, which identify the dump priorities of memory objects that are obtained by Language Environment:

| | |
|---------------------------------|--|
| __MO_DUMP_PRIORITY_STACK | Dump priority of memory objects to be used as Language Environment stacks. Value is 5. |
| __MO_DUMP_PRIORITY_HEAP | Dump priority of memory objects to be used as Language Environment heaps. Value is 15. |

For the dump priority of memory objects obtained by other programs (such as Java), refer to the corresponding documentation for those programs.

All memory objects that are obtained by __moservices() are unguarded and count toward the address space memlimit. For more information on memory objects and the IARV64 service, see *z/OS MVS Programming: Assembler Services Guide* and the *z/OS MVS Programming: Assembler Services Reference ABE-HSP*, *z/OS MVS Programming: Assembler Services Reference IAR-XCT*.

Returned value

If successful, __moservices() returns 0.

If unsuccessful, __moservices() returns -1 and sets errno to one of the following values:

Error Code

Description

EINVAL

An argument to this function contained an incorrect value. Use __errno2() to obtain more detailed information on the error.

EMVSERR

A z/OS environmental or internal error occurred. Use __errno2() to obtain more detailed information on the error.

If the underlying IARV64 call is unsuccessful, and the mopl argument is specified, then __mopl_iarv64_rc and __mopl_iarv64_rsn contain the return and reason codes that are returned by IARV64.

Example

```
/* CELEBM25

   This example illustrates the __moservices() function.

   This example sets a shared memory dump priority, then
   gets and detaches a memory object.

*/

#include <stdlib.h>
#include <stdio.h>
#include <errno.h>
#include <string.h>

int main(void) {
    __mopl_t mymopl;
    int mos_rv;
    void * mymoptr;

    memset(&mymopl, 0, sizeof(__mopl_t));

    /* Set a shared memory dump priority for subsequent shmget() */
    mymopl.__mopldumppriority = 8;

    mos_rv = __moservices(__MO_SHMDUMPPRIORITY, sizeof(mymopl),
                          &mymopl, &mymoptr);

    if (mos_rv != 0) {
        perror("moservices(SHMDUMPPRIORITY) call failed");
    }

    /* Obtain a 100MB memory object whose dump priority falls
     * between the dump priorities of the Language Environment
     * stacks and heaps.
     */
    mymopl.__mopldumppriority = __MO_DUMP_PRIORITY_STACK + 5;
    mymopl.__moplrequestsize = 100;

    mos_rv = __moservices(__MO_GETSTOR, sizeof(mymopl),
                          &mymopl, &mymoptr);

    if (mos_rv == 0) {
        printf("moservices(GETSTOR) successful, MO addr: %p\n",
              mymoptr);

        /* Free the 100MB memory object.
         */
        mos_rv = __moservices(__MO_DETACH, 0, NULL, &mymoptr);

        if (mos_rv != 0) {
            perror("moservices(DETACH) call failed");
        }
    }
    else {

```

```
        perror("moservices(GETSTOR) call failed");
    }

    return 0;
}
```

mount() — Make a file system available

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

Format 1:

```
#define _OPEN_SYS

#include <sys/stat.h>

int mount(const char *path, char *filesystem, char *filesystype, mtm_t mtm,
          int parmlen, char *parm);
```

Format 2:

```
#define _OPEN_SYS
#define _XPLATFORM_SOURCE

#include <sys/mount.h>
int mount(const char *source, const char *target, const char *filesystemtype, unsigned long
          mountflags, const void *data);
```

General description

mount() supports different input parameters and functions when it is defined under different feature test macros.

Format 1: when only _OPEN_SYS is defined

Adds a file system to z/OS UNIX file system. The same file system cannot be mounted at more than one place in the hierarchical file system.

In order to mount a file system, the caller must be an authorized program, or must be running for a user with appropriate privileges.

path

The mount point directory that the file system is to be mounted to.

filesystem

The name of the file system to be mounted; it must be unique within the system. For a HFS data set, this is a 1-to-44-character MVS data set name specified as all uppercase letters.

This name is terminated with NULL characters.

filesystype

The name for the file system that will perform the mount. This 8-character name must match the TYPE operand on a FILESYSTYPE statement in the BPXPRMxx parmlib member for the file system.

mtm

A flag field that specifies the mount mode and additional mount options:

MTM_RDONLY

Mount the file system as a read-only file system.

MTM_RDWR

Mount the file system as a read/write file system.

MTM_NOSUID

The SETUID and SETGID mode flags will be ignored for programs that reside in this file system.

MTM_SYNCHONLY

The mount must be completed synchronously or fail if it cannot.

parmlen

Length of the *parm* argument. The maximum length is 500 characters. For a HFS data set, this is not specified.

parm

A parameter passed to the physical file system that performs the mount. This parameter may not be required. The form and content of the *parm* are determined by the physical file system. A HFS data set does *not* require a *parm*.

Format 2: when both `_OPEN_SYS` and `_XPLATFORM_SOURCE` are defined

`mount()` attaches the file system that are specified by *source* (which is often a name that refers to a file system, but can also be the path name of a directory or file, or a dummy string) to the location (a directory or file) that is specified by the path name in *target*.

To mount a file system, the caller must be an authorized program, or must run for a user with appropriate privileges.

filesystemtype specifies the name for the file system that performs the mount. This 8-character name must match the TYPE operand on a FILESYSTYPE statement in the BPXPRMxx parmlib member for the file system.

data specifies a parameter that is passed to the file system that performs the mount. This parameter might not be required. The form and content of the data are determined by the file system.

A call to `mount()` performs one of a number of general types of operation, depending on the bits specified in *mountflags*. The choice of which operation to perform is determined by testing the bits set in *mountflags*, with the tests being conducted in the following order:

1. Remount an existing mount: *mountflags* includes MS_REMOUNT.
2. Create a bind mount: *mountflags* includes MS_BIND.
3. Change the propagation type of an existing mount: *mountflags* includes one of MS_PRIVATE or MS_UNBINDABLE.
4. Move an existing mount to a new location: *mountflags* includes MS_MOVE.
5. Create a new mount: *mountflags* includes none of the previous flags.

The following flags can be specified in *mountflags* to modify the behavior of `mount()`:

MS_REC

Used in conjunction with MS_BIND to create a recursive bind mount, and in conjunction with the propagation type flags to recursively change the propagation type of all of the mounts in a subtree.

MS_RDONLY

Mount the file system as a read-only file system.

MS_NOSUID

The SETUID and SETGID mode flags is ignored for programs that reside in this file system.

Remounting an existing mount

An existing mount might be remounted by specifying MS_REMOUNT in *mountflags*. This allows you to change the *mountflags* of an existing mount without having to unmount and remount the filesystem. *target* must be the same value that is specified in the initial `mount()` call.

The *source*, *filesystemtype*, and *data* arguments are ignored.

The *mountflags* argument must match the values that are used in the original `mount()` call, except for those parameters that are deliberately changed. The following *mountflags* can be changed: `MS_NOSUID` and `MS_RDONLY`.

The `MS_REMOUNT` flag can be used with `MS_BIND` to modify only the per-mount-point flags. This is useful for setting or clearing the "read-only" flag on a mount without changing the underlying file system. Specifying *mountflags* as `MS_REMOUNT | MS_BIND | MS_RDONLY` makes access through this mount-point read-only, without affecting other mounts.

Creating a bind mount

If *mountflags* includes `MS_BIND`, perform a bind mount. A bind mount makes a file or a directory subtree visible at another point within the single directory hierarchy.

The *filesystemtype* and *data* arguments are ignored.

The remaining bits (other than `MS_REC`, described below) in the *mountflags* argument are also ignored. (The bind mount has the same mount options as the underlying mount.) However, see the previous discussion of remounting, for a method of making an existing bind mount read-only.

By default, when a directory is bind mounted, only that directory is mounted; if there are any submounts under the directory tree, they are not bind mounted. If the `MS_REC` flag is also specified, then a recursive bind mount operation is performed: all submounts under the source subtree (other than unbindable mounts) are also bind mounted at the corresponding location in the target subtree.

Changing the propagation type of an existing mount

If *mountflags* includes one of `MS_PRIVATE` or `MS_UNBINDABLE`, the propagation type of an existing mount is changed. If more than one of these flags is specified, an error results.

The only other flags that can be specified while changing the propagation type is `MS_REC`.

The *source*, *filesystemtype*, and *data* arguments are ignored.

The meanings of the propagation type flags are as follows:

MS_PRIVATE

Make this mount private. Mount and unmount events do not propagate into or out of this mount.

MS_UNBINDABLE

Make this mount unbindable. This is like a private mount, and in addition this mount cannot be bind mounted. When a recursive bind mount (`mount()` with the `MS_BIND` and `MS_REC` flags) is performed on a directory subtree, any unbindable mounts within the subtree are automatically pruned (i.e., not replicated) when replicating that subtree to produce the target subtree.

By default, changing the propagation type affects only the target mount. If the `MS_REC` flag is also specified in *mountflags*, the propagation type of all mounts under target is also changed.

Moving a mount

mountflags contains the flag `MS_MOVE`, move a subtree: *source* specifies an existing mount and *target* specifies the new location to which that mount is to be relocated. The move is atomic: at no point is the subtree unmounted.

The remaining bits in the *mountflags* argument are ignored, as are the *filesystemtype* and *data* arguments.

Creating a new mount

If none of `MS_REMOUNT`, `MS_BIND`, `MS_MOVE`, `MS_PRIVATE` or `MS_UNBINDABLE` is specified in *mountflags*, `mount()` performs its default action: creating a new mount. *source* specifies the source for the new mount, and *target* specifies the directory at which to create the mount point.

The *filesystemtype* and *data* arguments are employed, and further bits might be specified in *mountflags* to modify the behavior of the call.

Returned value

If successful, `mount()` returns 0.

If the `mount()` is proceeding asynchronously, it returns 1.

If unsuccessful, `mount()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBUSY

The specified file system is unavailable.

EINVAL

A parameter was incorrectly specified.

- When only `_OPEN_SYS` is defined: verify *filesystemtype* and *mtm*.
- When both `_OPEN_SYS` and `_XPLATFORM_SOURCE` are defined: verify *filesystemtype* and *mountflags*. Another possible reason is that the mount point is the root of a file system or the file system is mounted.

EIO

An I/O error occurred.

ELOOP

A loop exists in symbolic links. This error is issued if more than `POSIX_SYMLLOOP` (defined in the `limits.h` header file) symbolic links are detected in the resolution of the path name.

ENAMETOOLONG

When both `_OPEN_SYS` and `_XPLATFORM_SOURCE` are defined: a path name was longer than `PATH_MAX`, or some component of path name is longer than `NAME_MAX` characters.

ENOENT

- When only `_OPEN_SYS` is defined: the mount point does not exist.
- When both `_OPEN_SYS` and `_XPLATFORM_SOURCE` are defined: the specified path name cannot be found.

ENOMEM

There is not enough storage available to save the information that is required for this file system.

ENOTDIR

- When only `_OPEN_SYS` is defined: the mount point is not a directory.
- When both `_OPEN_SYS` and `_XPLATFORM_SOURCE` are defined: the target or a prefix of source is not a directory.

EPERM

Superuser authority is required to issue a mount.

Example

CELEBM21

```
/* CELEBM21

   This example adds a file system to the hierarchical
   file system.

*/
#define _OPEN_SYS
#include <sys/stat.h>
#include <stdio.h>
#include <unistd.h>

main() {
    char mount_point[]="/new_fs";
    char HFS[]="POSIX.NEW.HFS";
    char filesystem[9]="HFS    ";

    setvbuf(stdout, NULL, _IOLBF, 0);
    puts("before mount()");
    system("df -Pk");
    if (mount(mount_point, HFS, filesystem, MTM_RDWR, 0, NULL) != 0)
```

__mount

```
    perror("mount() error");
else {
    puts("After mount()");
    system("df -Pk");
    if (umount(HFS, MTM_UMOUNT) != 0)
        perror("umount() error");
}
}
```

Output

```
before mount()
Filesystem 1024-blocks      Used Available Capacity  Mounted on
POSIX.ROOT.FS  9600      8660       940       90%      /

After mount()
Filesystem 1024-blocks      Used Available Capacity  Mounted on
POSIX.NEW.HFS    200        20       180       10%    /new_fs
POSIX.ROOT.FS  9600      8660       940       90%      /
```

__mount() — Make a file system available

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | OS/390 V2R9 |

Format

```
#define _OPEN_SYS
#include <sys/stat.h>
#include <sys/mntent.h>

int __mount(struct mnt2 *mnte, char *sysname);
```

General description

Adds a file system to the hierarchical file system. The same file system cannot be mounted at more than one place in the hierarchical file system.

In order to mount a file system, the caller must be an authorized program or must be running for a user with appropriate privileges.

Element descriptions

To mount or change the mount of a z/OS UNIX file in a sysplex, the application should set values in *mnte* as follows:

mnt2h_cbid

The mnte2 control block ID. Initialize it to "MNT2".

mnt2h_cblen

The mnt2 size. Initialize it to the size of struct mnt2.

mh2_cursor

Contains the internal cursor. This should be set to 0 initially, and must be left unchanged for subsequent calls.

mnt2h_devno

This element contains the device number, if needed.

mh_bodylen

The mnt2 size of w_mntent2. Must be initialized to the sizeof the w_mntent2 body.

rsvd

This field must be set to all zeros.

mnt2_fstype

The file system type.

mnt2_mode

File system mount mode. A flag field that specifies the mount mode and additional mount options:

mntentfsaunmount

If it is 1 after the file system is mounted, the file system will be unmounted when a system leaves the sysplex. If it is 0, then the setting of mntentfsnoautomove will be used. See mntentfsnoautomove below. This option can be changed after the file is mounted by changing this bit and setting the request bit, mntentnewauto, to 1 before calling __mount(). If changed to 0, also set mntentfsnoautomove to indicate automove or no move.

mntentfsclient

If it is 0, then the file system is a sysplex client. If it is 1, then the file system is not a sysplex client.

Note: Note that mntentfsclient is not an input parameter.

mntentfsnoautomove

If it is 0 after the file system is mounted, it can be moved automatically. If it is 1 after the file system is mounted, it will not be moved automatically. The mode can be reversed after the file is mounted (when mntentfsaunmount is 0) by changing this bit and setting the request bit, mnt2ntnewauto, to 1 before calling __mount().

Note: The setting of this bit only applies if mntentfsaunmount is 0.

mntentfsmodenosec

If it is 1, then the file system will not enforce security checks. If it is 0, then the file system will enforce security checks.

mntentfsmodeexport

If it is 0, then the file system has not been exported by DFS. If it is 1, then the file system has been exported by DFS.

mntentfsmoderonly

If it is 0, then the file system is mounted as read/write. If it is 1, then the file system is mounted as read-only.

mntentfsmodenosuid

If it is 1, then the SETUID and SETGID mode flags will be ignored for programs that reside in this file system. If it is 0 then the SETUID and SETGID mode flags will be enforced for programs that reside in this file system. This information is returned by the function but should not be changed.

mnt2_dev

Device # which stat will return for all files in this file system. Not set on input to __mount().

mnt2_parentdev

st_dev of parent file system. Not set on input to __mount().

mnt2_rootino

The ino of the mount point. Not set on input to __mount().

mnt2_status

status of the file system. The field is not an input parameter. It can be tested on output after a successful request.

mnt2_ddname

The ddname specified on mount. 1 to 8 characters are allowed.

mnt2_fstname

The name of the file system type specified by the FILESYS statement. The name for the file system that will perform the mount. This 8-character name must match the TYPE operand on a FILESYSTYPE statement in the BPXPRMxx parmlib member for the file system. 1 to 8 characters are allowed.

mnt2_fsname

The name of the file system to be mounted; it must be unique within the system. For a HFS data set, this is a 1-to-44-character MVS data set name specified as all uppercase letters. This name is terminated with NULL characters.

mnt2_pathlen

The length of mount point path.

mnt2_mountpoint

The name of the directory where the file system is mounted. 1 to 1023 characters are allowed. Also refers to the mount point directory where the file system will be mounted.

mnt2_parmoffset

Offset of mount parameter *mnt2_parmreturn* from *mnt2_fstype*. Also refers to a parameter passed to the physical file system that performs the mount. This parameter may not be required. The form and content of the parameter are determined by the physical file system. A HFS data set does not require a parameter.

mnt2_parmlen

The length of the mount parameter with size *mnt2_parmreturn*. Also refers to the length of the parameter argument. The maximum length is 1024 characters. A hierarchical file system data set does not require a parameter.

mnt2_sysname

The name of the target system. 1 to 8 characters are allowed. Changing the target system is always supplied as *sysname*. For all other calls, *sysname* must be supplied as NULL or the target name will be changed. When *sysname* is supplied, the *mnt2ntchange* flag must be set off for a mount function call, or the *mnt2ntchange* flag must be set on for a change mount function call. When you specify system on a mount it means mount this file on this system or when you specify system on a change mount it means move the file system from where it is currently mounted to this system.

mnt2_qsystem

The name of the quiesce system. 1 to 8 characters are allowed but the character(s) are padded with blanks and do not contain a NULL terminator. This field is an output only field from *getmntent()*.

mnt2_fromsys

The name of the system from which the file system has moved.

mnt2_flags

The field containing the request flags. A flag field that specifies the change for existing mounted file system:

mnt2ntnewauto

This flag instigates a change of mode which will effect the automove state depending on the value that is set for *mnt2ntfsnoautomove*. See the explanation under *mnt2ntfsnoautomove*.

mnt2ntchange

The request in this *w_mntent* is a change to existing status or mode. This flag must be set on for all change mount requests. The *w_mntent* structure needs to modify either the *mnt2ntfsname* field or the *mnt2ntmountpoint* and *mnt2ndpathlen* fields. When the request is to mount a directory, then this flag must be set to off.

mnt2_status2

The file system status extensions.

mnt2_success

This field is used to return the number of successfully moved file systems when moving a collection of file systems. It is not used in other cases.

parm_point

This field contains the mountpoint parameters to be used when mounting a file system. It is a separate field in the *mnt2* structure but contiguously allocated following the *w_mnt2* body. The *mnt2_parmoffset* field contains the offset to the start of *parm_point*.

mnt2_syslistlength

Length of system list.

mnt2_syslistoffset

Offset of system list.

mnt2_aggnamelength

Length of the aggregate name in *mnt2_aggname*. The length does not include the NULL terminating character, and is only valid if *mnt2_aggnameoffset* has a non-zero value.

mnt2_aggnameoffset

The offset of *mnt2_aggname* from *w_mntent*. If the value is zero, then no aggregate name is returned.

The *mnt3* structure can also be used in place of the *mnt2* structure. The following *mnt3* fields are equivalent to their *mnt2* counterparts, with appropriate changes to the header fields to specify the usage of the *mnt3* structure:

mnt3h_cbid

The *mnt3* control block ID. Initialize it to "MNT3".

mnt3h_cblen

The *mnt3* size. Initialize to the size of struct *mnt3*.

mh3_cursor***mh3_devno******mh_bodylen***

The *mnt3* size of *w_mntent3*. Must be initialized to the sizeof the *w_mntent3* body.

rsvd***mnt3_fstype******mnt3_mode******mnt3_dev******mnt3_parentdev******mnt3_rootino******mnt3_status******mnt3_ddname******mnt3_fsname******mnt3_pathlen******mnt3_mountpoint******mnt3_parmoffset******mnt3_parmlen******mnt3_sysname******mnt3_qsysname******mnt3_fromsys******mnt3_flags******mnt3_status2******mnt3_success***

Returned value

If successful, `__mount()` returns 0.

If the `__mount()` is proceeding asynchronously, it returns 1.

If unsuccessful, `__mount()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBUSY

The specified file system is unavailable.

EINVAL

A parameter was incorrectly specified. Verify *filesystype* and *mtm*. Another possible reason for this error is that the mount point is the root of a file system or that the file system is already mounted.

EIO

An I/O error occurred.

ELOOP

A loop exists in symbolic links. This error is issued if more than `POSIX_SYMLLOOP` (defined in the `limits.h` header file) symbolic links are detected in the resolution of *pathname*.

ENOENT

The mount point does not exist.

ENOMEM

There is not enough storage available to save the information required for this file system.

ENOTDIR

The mount point is not a directory.

EPERM

Appropriate authority is required to issue a mount.

mprotect() — Set protection of memory mapping

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 z/OS UNIX | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/mman.h>
```

```
int mprotect(void *addr, size_t len, int prot);
```

General description

The `mprotect()` function changes the access protections on the mappings specified by the *len* up to the next multiple of the page size as returned by `sysconf()`, to be that specified by *prot*. Legitimate values for *prot* are the same as those permitted for `mprotect()` and are defined in `<sys/mman.h>`:

PROT_READ

page can be read

PROT_WRITE

page can be written

PROT_EXEC

page can be executed

PROT_NONE

page cannot be accessed

The range provided by the `Map_address` and `Map_length` may span regular maps as well as `__MAP_MEGA` maps. `Mprotect` affects `__MAP_MEGA` maps very differently than regular maps. The difference is in the scope of the change. When a change is made to a `__MAP_MEGA` map, the change affects all processes which are currently mapped to the same file-offset range represented by the pages within the provided range. For example, changing a file-offset range (storage pages) that is currently in use with a protection of write to a protection of read, makes the file-offset range read for all processes, not just the current one. In other words, the changes are global. On the other hand, changes to regular maps affect only the process that issues `mprotect`.

When `mprotect()` fails for reasons other than `EINVAL`, the protection on some of the pages in the range `[addr, addr + len)` may have been changed.

Returned value

If successful, `mprotect()` returns 0.

If unsuccessful, `mprotect()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

The *prot* argument specifies a protection that violates the access permission the process has to the underlying memory object.

EAGAIN

The *prot* argument specifies `PROT_WRITE` over a `MAP_PRIVATE` mapping and there are insufficient memory resources to reserve for locking the private page.

EINVAL

The *addr* argument is not a multiple of the page size as returned by `sysconf()`.

ENOMEM

Addresses in the range `[addr, addr + len)` are invalid for the address space of a process, or specify one or more pages

mrnd48() – Pseudo-random number generator

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <stdlib.h>

long int mrnd48(void);
```

General description

The drand48(), erand48(), jrand48(), lrand48(), mrnd48() and nrand48() functions generate uniformly distributed pseudo-random numbers using a linear congruential algorithm and 48-bit integer arithmetic.

The functions drand48() and erand48() return nonnegative, double-precision, floating-point values, uniformly distributed over the interval [0.0,1.0).

The functions lrand48() and nrand48() return nonnegative, long integers, uniformly distributed over the interval [0,2**31).

The functions mrnd48() and jrand48() return signed long integers, uniformly distributed over the interval [-2**31,2**31).

The mrnd48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, X(i), according to the linear congruential formula:

$$X(n+1) = (aX(n) + c) \bmod (2^{**}48) \qquad n \geq 0$$

The initial values of X, a, and c are:

```
X(0) = 1
a    = 5deece66d (base 16)
c    = b          (base 16)
```

C/370 provides storage to save the most recent 48-bit integer value of the sequence, X(i). This storage is shared by the drand48(), lrand48() and mrnd48() functions. The value, X(n), in this storage may be reinitialized by calling the lcong48(), seed48() or srand48() function. Likewise, the values of a and c, may be changed by calling the lcong48() function. Thereafter, whenever the seed48() or srand48() function is called to change X(n), the initial values of a and c are also reestablished.

Special behavior for z/OS UNIX services

You can make the mrnd48() function and other functions in the drand48 family thread-specific by setting the environment variable _RAND48 to the value THREAD before calling any function in the drand48 family.

If you do not request thread-specific behavior for the drand48 family, C/370 serializes access to the storage for X(n), a and c by functions in the drand48 family when they are called by a multithreaded application.

If thread-specific behavior is requested, and the mrnd48() function is called from thread t, the mrnd48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, X(t,i),

for the thread `t`. The sequence of values for a thread is generated according to the linear congruential formula:

$$X(t,n+1) = (a(t)X(t,n) + c(t))\text{mod}(2^{**}48) \qquad n \geq 0$$

The initial values of `X(t)`, `a(t)` and `c(t)` for the thread `t` are:

```
X(t,0) = 1
a(t)   = 5deece66d (base 16)
c(t)   = b          (base 16)
```

`C/370` provides storage which is specific to the thread `t` to save the most recent 48-bit integer value of the sequence, `X(t,i)`, generated by the `drand48()`, `lrand48()` or `mrnd48()` function. The value, `X(t,n)`, in this storage may be reinitialized by calling the `lcong48()`, `seed48()` or `srand48()` function from the thread `t`. Likewise, the values of `a(t)` and `c(t)` for thread `t` may be changed by calling the `lcong48()` function from the thread. Thereafter, whenever the `seed48()` or `srand48()` function is called from the thread `t` to change `X(t,n)`, the initial values of `a(t)` and `c(t)` are also reestablished.

Returned value

`mrnd48()` transforms the generated 48-bit value, `X(n+1)`, to a signed long integer value on the interval `[-2**31,2**31)` and returns this transformed value.

Special behavior for z/OS UNIX Services

If thread-specific behavior is requested for the `drand48` family and the `mrnd48()` function is called on thread `t`, the `mrnd48()` function transforms the generated 48-bit value, `X(t,n+1)`, to a signed long integer value on the interval `[-2**31,2**31)` and returns this transformed value.

m_setvalues_layout() – Set layout values of a layout object (bidi data)

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| ISO C XPG4 C99 | both | z/OS V1R2 |

Format

```
#include <sys/layout.h>

int m_setvalues_layout(LayoutObject layout_object, const LayoutValues values,
                      int *index_returned);
```

General description

The `m_setvalues_layout()` function is part of the support for handling of bidirectional (Bidi) conversion of data between Visual (MVS) and Implicit (z/OS UNIX) formats. Initial support is for Arabic and Hebrew data.

The `m_setvalues_layout()` function is used to change the layout values of a `LayoutObject`. The *layout_object* argument specifies a `LayoutObject` returned by the `m_create_layout()` function. The *values* argument specifies the list of layout values which are to be changed. The values are written into the `LayoutObject` and may affect the behavior of subsequent layout functions.

Note: Some layout values do alter internal states maintained by a `LayoutObject`. The `m_setvalues_layout()` function can be implemented as a macro that evaluates the first argument twice.

Returned value

If successful, `m_setvalues_layout()` sets the requested layout values and returns 0.

If any value cannot be set, `m_setvalues_layout()` does not change any of the layout values. It stores into *index_returned* the (zero-based) index of the value causing the error. It returns -1 and sets `errno` to one of the following values:

Error Code
Description

EINVAL
The layout value specified by *index_returned* is unknown or its value is invalid or the argument *layout_object* is invalid.

Related information

- [“sys/layout.h – Bidirectional conversion of data between Visual and Implicit formats” on page 69](#)

msgctl(), msgctl64() – Message control operations

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

msgctl:

```
#define _XOPEN_SOURCE
#include <sys/msg.h>

int msgctl(int msgid, int cmd, struct msqid_ds *buf);
```

msgctl64:

```
#define _LARGE_TIME_API
#define _XOPEN_SOURCE
#include <sys/msg.h>

int msgctl64(int msgid, int cmd, struct msqid_ds64 * buf);
```

Compile requirement: Use of the `msgctl64()` function requires the `long long` data type. For more information on how to make the `long long` data type available, see [z/OS XL C/C++ Language Reference](#).

General description

The `msgctl()` or `msgctl64()` function provides message control operations as specified by *cmd*. The following values for *cmd*, and the message control operations they specify, are (These symbolic constants are defined by the `<sys/ipc.h>` header):

IPC_STAT

Place the current value of each member of the `msqid_ds` or `msqid_ds64` data structure associated with *msgid* into the structure pointed to by *buf*. The contents of this structure are defined in `<sys/msg.h>`. This command requires read permission.

IPC_SET

Set the value of the following members of the `msqid_ds` or `msqid_ds64` data structure associated with *msgid* to the corresponding value found in the structure pointed to by *buf*:

- `msg_perm.uid`
- `msg_perm.gid`
- `msg_perm.mode`
- `msg_qbytes`

`IPC_SET` can only be executed by a process with the appropriate privileges or that has an effective user ID equal to the value of `msg_perm.cuid` or `msg_perm.uid` in the `msqid_ds` or `msqid_ds64` data structure associated with *msgid*. Only a process with appropriate privileges can raise the value of `msg_qbytes`.

IPC_RMID

Remove the message queue identifier specified by *msgid* from the system and destroy the message queue and `msqid_ds` or `msqid_ds64` data structure associated with it. **IPC_RMID** can only be executed by a process with appropriate privileges or one that has an effective user ID equal to the value of `msg_perm.cuid` or `msg_perm.uid` in the `msqid_ds` or `msqid_ds64` data structure associated with *msgid*.

The `msgctl64()` function behaves exactly like `msgctl()` except `msgctl64()` uses `struct msqid_ds64` instead of `struct msqid_ds` to support time beyond 03:14:07 UTC on January 19, 2038.

Returned value

If successful, `msgctl()` or `msgctl64()` returns 0.

If unsuccessful, `msgctl()` or `msgctl64()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

The argument *cmd* is **IPC_STAT** and the calling process does not have read permission.

EINVAL

The value of *msgid* is not a valid message queue identifier, or the value of *cmd* is not a valid command.

EPERM

The argument *cmd* is **IPC_RMID** or **IPC_SET** and the effective user ID of the calling process is not equal to that of a process with appropriate privileges and it is not equal to the value of *msg_perm.cuid* or *msg_perm.uid* in the data structure associated with *msgid*.

Or the argument *cmd* is **IPC_SET**, an attempt is being made to increase the value of *msg_qbytes*, and the effective user ID of the calling process does not have appropriate privileges.

msgget() – Get message queue

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <sys/msg.h>

int msgget(key_t key, int msgflg);
```

General description

The *msgget()* function returns the message queue identifier associated with the argument *key*.

A message queue identifier, associated message queue and data structure (see <sys/msg.h>) are created for the argument *key* if one of the following is true:

- The argument *key* is equal to **IPC_PRIVATE**
- The argument *key* does not already have a message queue identifier associated with it, and the flag **IPC_CREAT** is on in *msgflg*.

Valid values for the argument *msgflg* include any combination of the following constants defined in <sys/ipc.h> and <sys/modes.h>:

IPC_CREAT

Create a message queue if the *key* specified does not already have an associated ID. **IPC_CREAT** is ignored when **IPC_PRIVATE** is specified

IPC_EXCL

Causes the `msgget()` function to fail if the *key* specified has an associated ID. **IPC_EXCL** is ignored when **IPC_CREAT** is not specified or **IPC_PRIVATE** is specified

IPC_RCVTYPEPID

Creates a message queue that can only be read from `msgrcv()` when `MSG_TYPE` is the process ID of the invoker. This restriction does not apply if the `msgrcv()` invoker has the same effective UID as the message queue creator.

IPC_SNDTYPEPID

Creates a message queue that can only be written to `msgsnd()` when `MSG_TYPE` is the process ID of the invoker. This restriction does not apply if the `msgsnd()` invoker has the same effective UID as the message queue creator.

S_IRUSR

Permits read access when the effective user ID of the caller matches either `msg_perm.cuid` or `msg_perm.uid`

S_IWUSR

Permits write access when the effective user ID of the caller matches either `msg_perm.cuid` or `msg_perm.uid`

S_IRGRP

Permits read access when the effective group ID of the caller matches either `msg_perm.cgid` or `msg_perm.gid`

S_IWGRP

Permits write access when the effective group ID of the caller matches either `msg_perm.cgid` or `msg_perm.gid`

S_IROTH

Permits other read access

S_IWOTH

Permits other write access

When a message set associated with argument *key* already exists, setting **IPC_EXCL** and **IPC_CREAT** in argument *msgflg* will force `msgget()` to fail.

Upon creation, the `msg_ds` data structure associated with the new message queue identifier is initialized as follows:

- The fields `msg_perm.cuid`, `msg_perm.uid`, `msg_perm.cgid`, and `msg_perm.gid` are set equal to the effective user ID and effective group ID, respectively, of the calling process.
- The low-order 9 bits of `msg_perm.mode` are set equal to the low-order 9 bits of *msgflg*.
- The fields `msg_qnum`, `msg_lspid`, `msg_lrpids`, `msg_stime`, and `msg_rtime` are set to zero.
- The field `msg_ctime` is set equal to the current time.
- The field `msg_qbytes` is set equal to the system limit.

Usage notes

1. In a client/server environment, two message queues can be used. One inbound to the server created with **IPC_SNDTYPEPID** and the other outbound from the server created with **IPC_RCVTYPEPID**. This arrangement guarantees that the server knows the process ID of the client and the client is the only process that receives the server's returned message. The server may invoke `msgrcv()` with `PID=0` to see if any messages belong to process IDs that have gone away.
2. Important terms and their descriptions are explained:

Term**Descriptions****PLO**

Perform Lock Operation.

IPC_PLO1

Use PLO serialization (if available) until a select() involving this message queue is detected.

IPC_PLO2

Allow the kernel to use its best judgment with serialization (IPC_PLO1 ignored).

- Message_Flags IPC_PLO1 and IPC_PLO2 are ignored if the PLO instruction is not present on the hardware.
- Performance of the PLO instruction for serialization will vary with the msgrcv type, number of messages on the queue and the number of tasks doing msgsnd() and msgrcv(). Msgrcv() with type<0 and long message queues is expected to be a worse performer. Msgrcv() with type>0 is expected to be an equivalent or good performer. Msgrcv() with type=0 is expected to be a very good performer.
- Message queues created with *Ipc_RcvTypePID*, *Ipc_SndTypePID*, *IPC_PLO1* and *IPC_PLO2* will show these bits and may show the *IPC_PLOINUSE* bit in the S_MODE byte returned with *w_getipc*.
- Message queue PLO serialization is not compatible with select() using message queues. When msgrcv() detects a select() for a message queue, serialization will be changed to use traditional latches.
- Performance runs should be made with *IPC_PLO1* since *IPC_PLO2* may switch to latch serialization and the user would not know when.

Returned value

If successful, msgget() returns a nonnegative integer, namely a message queue identifier.

If unsuccessful, msgget() returns -1 and sets errno to one of the following values:

Error Code**Description****EACCES**

A message queue identifier exists for the argument *key*, but access permission as specified by the low-order 9 bits of *msgflg* could not be granted

EEXIST

A message queue identifier exists for the argument *key*, but both **IPC_CREAT** and **IPC_EXCL** are specified in *msgflg*

EINVAL

The value of argument *msgflg* is not currently supported

ENOENT

A message queue identifier does not exist for the argument *key* and **IPC_CREAT** is not specified.

ENOSPC

A message queue identifier is to be created but the system-imposed limit on the maximum number of allowed message queue identifiers system-wide would be exceeded.

When *msgflg* equals 0, the following applies:

- If a message queue identifier has already been created with *key* earlier, and the calling process of this msgget() has read and/or write permissions to it, then msgget() returns the associated message queue identifier.
- If a message queue identifier has already been created with *key* earlier, and the calling process of this msgget() does not have read and/or write permissions to it, then msgget() returns -1 and sets errno to EACCES.
- If a message queue identifier has not been created with *key* earlier, then msgget() returns -1 and sets errno to ENOENT.

msgrcv() — Message receive operation

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 | both | |

Format

Non-Single UNIX Specification, Version 2

```
#define _XOPEN_SOURCE
#include <sys/msg.h>

int msgrcv(int msgid, void *msgp, size_t msgsz, long int msgtyp, int msgflg);
```

Single UNIX Specification, Version 2

```
#define _XOPEN_SOURCE 500
#include <sys/msg.h>

ssize_t msgrcv(int msgid, void *msgp, size_t msgsz, long int msgtyp, int msgflg);
```

General description

The `msgrcv()` function reads a message from the queue associated with the message queue identifier specified by `msgid` and places it in the user-defined buffer pointed to by `msgp`.

The argument `msgp` points to a user-defined buffer that must contain first a field of type `long int` that will specify the type of the message, and then a data portion that will hold the data bytes of the message. The structure below is an example of what this user-defined buffer should look like:

```
struct message {
    long int  mtype;           //Message type
    char      mtext[n];       //Message text
}
```

The structure member, `mtype`, is the received message's type as specified by the sending process. The structure member, `mtext`, is the text of the message.

The argument `msgsz` specifies the size in bytes of `mtext`. The received message is truncated to `msgsz` bytes if it is larger than `msgsz` and the **MSG_NOERROR** flag was specified in the argument `msgflg`. The truncated portion of the message is lost and no indication of the truncation is given to the calling process.

The argument `msgtyp` specifies the type of message requested, as follows:

- If `msgtyp` is equal to zero, the first message on the queue is received.

- If *msgtyp* is greater than 0, the first message of type, *msgtyp*, is received.
- If *msgtyp* is less than 0, the first message of the lowest type that is less than or equal to the absolute value of *msgtyp* is received.

The argument *msgflg* specifies the action to be taken if a message of the desired type is not on the queue. These are as follows:

- If the **IPC_NOWAIT** flag is on in *msgflg*, the calling process will return immediately with a return value of -1 and errno set to **ENOMSG**.
- If the **IPC_NOWAIT** flag is off in *msgflg* the calling process will suspend execution until one of the following occurs:
 - A message of the desired type is placed on the queue.
 - The message queue identifier, *msgid*, is removed from the system; when this occurs, errno is set to **EIDRM** and a value of -1 is returned.
 - The calling process receives a signal that is to be caught; in this case a message is not received and the calling process resumes execution. A value of -1 is returned and errno is set to **EINTR**.

If successful, the following actions are taken with respect to the data structure, *msgiq_ds*, associated with *msgid*:

1. *msg_qnum* is decremented by 1.
2. *msg_lrpId* is set equal to the process ID of the calling process.
3. *msg_rtime* is set equal to the current time.

Returned value

If successful, *msgrcv()* returns a value equal to the number of bytes actually placed into the *mtext* field of the user-defined buffer pointed to by *msgp*. A value of zero indicates that only the *mtype* field was received from the message queue.

If unsuccessful, *msgrcv()* returns -1 and sets errno to one of the following values:

Error Code Description

E2BIG

The value of *mtext* is greater than *msgsz* and the flag **MSG_NOERROR** was not specified.

EACCES

The calling process does not have read permission to the message queue associated with the message queue identifier *msgid* or the message queue was built with **IPC_RCVTYPEPID** and the **MSG_TYPE** was other than the invoker's process ID (**JRTypeNotPID**).

EIDRM

The message queue identifier, *msgid*, has been removed from the system while the caller of *msgrcv()* was waiting.

EINTR

The function *msgrcv()* was interrupted by a signal before a message could be received.

EINVAL

The value of argument *msgid* is not a valid message queue identifier or the value of *msgsz* is less than zero.

ENOMSG

The flag **IPC_NOWAIT** was specified and the message queue does not contain a message of the desired type.

__msgrcv_timed() — Message receive operation with timeout

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | OS/390 V2R10 |

Format

```
#define _OPEN_SYS_TIMED_EXT 1
#include <time.h>
#include <sys/msg.h>

int __msgrcv_timed(int msgid, void *msgp, size_t msgsz,
                  long int msgtyp, int msgflg, struct timespec *set);
```

General description

Reads a message from the queue associated with the message queue identifier specified by *msgid* and places it in the user-defined buffer pointed to by *msgp*.

The argument *msgp* points to a user-defined buffer that must contain first a field of type long int that will specify the type of the message, and then a data portion that will hold the data bytes of the message. The structure below is an example of what this user-defined buffer should look like:

```
struct message {
    long int  mtype;           //Message type
    char      mtext[n];       //Message text
}
```

The structure member, *mtype*, is the received message's type as specified by the sending process. The structure member, *mtext*, is the text of the message.

The argument *msgsz* specifies the size in bytes of *mtext*. The received message is truncated to *msgsz* bytes if it is larger than *msgsz* and the **MSG_NOERROR** flag was specified in the argument *msgflg*. The truncated portion of the message is lost and no indication of the truncation is given to the calling process.

The argument *msgtyp* specifies the type of message requested, as follows:

- If *msgtyp* is equal to zero, the first message on the queue is received.
- If *msgtyp* is greater than 0, the first message of type, *msgtyp*, is received.
- If *msgtyp* is less than 0, the first message of the lowest type that is less than or equal to the absolute value of *msgtyp* is received.

The argument *msgflg* specifies the action to be taken if a message of the desired type is not on the queue. These are as follows:

- If the **IPC_NOWAIT** flag is on in *msgflg*, the calling process will return immediately with a return value of -1 and *errno* set to ENOMSG.
- If the **IPC_NOWAIT** flag is off in *msgflg* the calling process will suspend execution until one of the following occurs:
 - A message of the desired type is placed on the queue.

- The message queue identifier, *msgid*, is removed from the system; when this occurs, *errno* is set to *EIDRM* and a value of -1 is returned.
- The calling process receives a signal that is to be caught; in this case a message is not received and the calling process resumes execution. A value of -1 is returned and *errno* is set to *EINTR*.

The argument *set* is the *timespec* structure which contains the timeout value.

If successful, the following actions are taken with respect to the data structure, *msqid_ds*, associated with *msgid*:

1. *msg_qnum* is decremented by 1.
2. *msg_lrpid* is set equal to the process ID of the calling process.
3. *msg_rtime* is set equal to the current time.

The variable *set* gives the timeout specification.

- If the `__msgrcv_timed()` function finds that none of the messages specified by *msgid* are received, it waits for the time interval specified in the **timespec** structure referenced by *set*. If the **timespec** structure pointed to by *set* is zero-valued and if none of the messages specified by *msgid* are received, then `__msgrcv_timed()` returns immediately with *EAGAIN*. A **timespec** with the *tv_sec* field set with *INT_MAX*, as defined in `<limits.h>`, will cause the `__msgrcv_timed()` service to wait until a message is received. If *set* is the *NULL* pointer, it will be treated the same as when **timespec** structure was supplied with the *tv_sec* field set with *INT_MAX*.

Returned value

If successful, `__msgrcv_timed()` returns a value equal to the number of bytes actually placed into the *mtext* field of the user-defined buffer pointed to by *msgp*. A value of zero indicates that only the *mtype* field was received from the message queue.

If unsuccessful, `__msgrcv_timed()` returns -1 and sets *errno* to one of the following values:

Error Code Description

E2BIG

The value of *mtext* is greater than *msgsz* and the flag **MSG_NOERROR** was not specified.

EACCES

The calling process does not have read permission to the message queue associated with the message queue identifier *msgid*.

EAGAIN

The operation would result in time requested expired before any messages were received. This would result if the timeout specified expires before a message is posted.

EIDRM

The message queue identifier, *msgid*, has been removed from the system while the caller of `__msgrcv_timed()` was waiting.

EINTR

The function `__msgrcv_timed()` was interrupted by a signal before a message could be received.

EINVAL

The value of argument *msgid* is not a valid message queue identifier or the value of *msgsz* is less than zero.

ENOMSG

The flag **IPC_NOWAIT** was specified and the message queue does not contain a message of the desired type.

- [“sys/msg.h — Message queue structures” on page 69](#)

msgsnd() — Message send operations

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <sys/msg.h>

int msgsnd(int msgid, const void *msgp, size_t msgsz, int msgflg);
```

General description

The `msgsnd()` function is used to send a message to the queue associated with the message queue identifier specified by `msgid`.

The argument `msgp` points to a user-defined buffer that must contain first a field of type `long int` that will specify the type of the message, and then a data portion that will hold the data bytes of the message. The structure below is an example of what this user-defined buffer should look like:

```
struct message {
    long int  mtype;           //Message type
    char      mtext[n];       //Message text
}
```

The structure member, `mtype`, must be a nonzero positive value that can be used by the receiving process for message selection. The structure member, `mtext`, is any text of length, `msgsz`, bytes.

The argument `msgsz` specifies the size in bytes of `mtext`. When only `mtype` is to be sent with no `mtext`, `msgsz` is set to zero. The argument can range from zero to a system-imposed maximum or the maximum number of bytes allowed in the message queue.

The argument `msgflg` specifies the action to be taken if one or more of the following are true:

- Placing the message on the message queue would cause the current number of bytes on the message queue (`msg_cbytes`) to exceed the maximum number of bytes allowed on this queue, as specified in `msg_qbytes`.
- The total number of messages on the queue is equal to the system-imposed limit.

These actions are as follows:

- If the **IPC_NOWAIT** flag is on in `msgflg`, the message will not be sent and the calling process will return immediately. `msgsnd()` will return -1 and set `errno` to `EAGAIN`.
- If the **IPC_NOWAIT** flag is off in `msgflg`, the calling process will suspend execution until one of the following occurs:
 1. The condition responsible for the suspension no longer exists, in which case the message is sent.
 2. The message queue identifier, `msgid`, is removed from the system; when this occurs, `errno` is set to `EIDRM` and a value of -1 is returned.
 3. The calling process receives a signal that is to be caught; in this case a message is not sent and the calling process resumes execution. A value of -1 is returned and error is set to `EINTR`.

If successful, the following actions are taken with respect to the data structure, `msqid_ds`, associated with `msgid`:

1. `msg_qnum` is incremented by 1.
2. `msg_lspid` is set equal to the process ID of the calling process.
3. `msg_stime` is set equal to the current time.

Returned value

If successful, `msgsnd()` returns 0.

If unsuccessful, no message is sent, `msgsnd()` returns -1, and sets `errno` to one of the following values:

Error Code
Description

EACCES
The calling process does not have write permission to the message queue associated with the message queue identifier `msgid` or the message queue was built with `IPC_SNDTYPEPID` and the `MSG_TYPE` was other than the invoker's process ID (`JRTypeNotPID`).

EAGAIN
The message cannot be sent for one of the reasons cited above and `IPC_NOWAIT` was specified.

EIDRM
The message queue identifier, `msgid`, has been removed from the system while the caller of `msgsnd()` was waiting.

EINTR
The function `msgsnd()` was interrupted by a signal before a message could be sent.

EINVAL
The value of argument `msgid` is not a valid message queue identifier, or the value of `mtype` is less than 1; or the value of `msgsz` is less than zero or greater than the system-imposed limit.

ENOMEM
Not enough system storage exists to complete the `msgsnd()` function.

msgxrcv(), msgxrcv64() — Extended message receive operation

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

msgxrcv:

```
#define _OPEN_SYS_IPC_EXTENSIONS
#include <sys/msg.h>
```

```
int msgxrcv(int msgid, void *msgp, size_t msgsz, long int msgtyp, int msgflg);
```

msgxrcv64:

```
#define _LARGE_TIME_API
#define _OPEN_SYS_IPC_EXTENSIONS
#include <sys/msg.h>

int msgxrcv64(int msgid, void *msgp, size_t msgsz, long int msgtyp, int msgflg);
```

Compile requirement: Use of the `msgxrcv64()` function requires the `long long` data type. For more information on how to make the `long long` data type available, see [z/OS XL C/C++ Language Reference](#).

General description

The `msgxrcv()` function reads an extended message from the queue associated with the message queue identifier specified by `msgid` and places it in the user-defined buffer pointed to by `msgp`.

To expose the `msgxrcv()` name, the feature test macro **_OPEN_SYS_IPC_EXTENSIONS** must be defined. Otherwise, the function's name is `__msgxrcv()`.

The argument `msgp` points to a user-defined buffer where the extended message will be received. This buffer must be defined by a data structure of the following format: .

```
struct msgxbuf {
    time_t      mtime;           // Time and date message was sent
    uid_t       muid;           // Sender's effective user ID
    gid_t       mgid;           // Sender's effective group ID
    pid_t       mpid;           // Sender's process ID
    long int     mtype;          // Message type
    char        mtext[n];       // Message text
}
```

The `msgxrcv64()` function behaves exactly like `msgxrcv()` except `msgxrcv64()` supports calendar times beyond 03:14:07 UTC on January 19, 2038. The argument `msgp` points to a user-defined buffer where the extended message will be received. This buffer must be defined by a data structure of the following format:

```
struct msgxbuf64 {
    time64_t     mtime;          // Time and date message was sent
    uid_t        muid;           // Sender's effective user ID
    gid_t        mgid;           // Sender's effective group ID
    pid_t        mpid;           // Sender's process ID
    long int      mtype;          // Message type
    char         mtext[n];       // Message text
}
```

The structure member, `mtype`, is the received message's type as specified by the sending process. The structure member, `mtext`, is the text of the message.

The argument `msgsz` specifies the size in bytes of `mtext`. The received message is truncated to `msgsz` bytes if it is larger than `msgsz` and the **MSG_NOERROR** flag was specified in the argument `msgflg`. The truncated portion of the message is lost and no indication of the truncation is given to the calling process.

The argument `msgtyp` specifies the type of message requested, as follows:

- If `msgtyp` is equal to zero, the first message on the queue is received.
- If `msgtyp` is greater than 0, the first message of type, `msgtyp`, is received.
- If `msgtyp` is less than 0, the first message of the lowest type that is less than or equal to the absolute value of `msgtyp` is received.

The argument `msgflg` specifies the action to be taken if a message of the desired type is not on the queue. These are as follows:

- If the **IPC_NOWAIT** flag is on in `msgflg`, the calling process will return immediately with a return value of -1 and `errno` set to **ENOMSG**.

- If the **IPC_NOWAIT** flag is off in *msgflg* the calling process will suspend execution until one of the following occurs:
 - A message of the desired type is placed on the queue.
 - The message queue identifier, *msgid*, is removed from the system; when this occurs, *errno* is set to **EIDRM** and a value of -1 is returned.
 - The calling process receives a signal that is to be caught; in this case a message is not received and the calling process resumes execution. A value of -1 is returned and *errno* is set to **EINTR**.

If successful, the following actions are taken with respect to the data structure, *msqid_ds*, associated with *msgid*:

1. *msg_qnum* is decremented by 1.
2. *msg_lrpid* is set equal to the process ID of the calling process.
3. *msg_rtime* is set equal to the current time.

Returned value

If successful, *msgxrcv()* or *msgxrcv64()* returns a value equal to the number of bytes actually placed into the *mtext* field of the user-defined buffer pointed to by *msgp*. A value of zero indicates that only the *mtype* field was received from the message queue.

If unsuccessful, *msgxrcv()* returns -1 and sets *errno* to one of the following values:

Error Code

Description

E2BIG

The value of *mtext* is greater than *msgsz* and the flag **MSG_NOERROR** was not specified.

EACCES

The calling process does not have read permission to the message queue associated with the message queue identifier *msgid*.

EIDRM

The message queue identifier, *msgid*, has been removed from the system while the caller of *msgxrcv()* was waiting.

EINTR

The function *msgxrcv()* was interrupted by a signal before a message could be received.

EINVAL

The value of argument *msgid* is not a valid message queue identifier or the value of *msgsz* is less than zero.

ENOMSG

The flag **IPC_NOWAIT** was specified and the message queue does not contain a message of the desired type.

msync() – Synchronize memory with physical storage

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/mman.h>

int msync(void *addr, size_t len, int flags);
```

General description

The `msync()` function writes all modified copies of pages over the range `[addr, addr + len)` to the underlying hardware, or invalidates any copies so that further references to the pages will be obtained by the system from their permanent storage locations.

The `flags` argument is:

MS_ASYNC

Perform asynchronous writes

MS_INVALIDATE

Invalidate mappings

MS_SYNC

Perform synchronous writes

The function synchronizes the file contents to match the current contents to the memory region.

- All write references to the memory region made before the call are visible by subsequent read operations on the file.
- It is unspecified whether writes to the same portion of the file before the call are visible by read references to the memory region.
- It is unspecified whether unmodified pages in the specified range are also written to the underlying hardware.

If `flags` is `MS_ASYNC`, the function may return immediately once all write operations are scheduled; if `flags` is `MS_SYNC`, the function does not return until all write operations are completed.

`MS_INVALIDATE` synchronizes the contents of the memory region to match the current file contents.

- All writes to the mapped portion of the file made before the call are visible by subsequent read references to the mapped memory region.
- It is unspecified whether write references before the call, by any process, to memory regions mapped to the same portion of the file using `MAP_SHARED`, are visible by read references to the region.

If `msync()` causes any write to the file, then the file's `st_ctime` and `st_mtime` fields are marked for update.

Returned value

If successful, `msync()` returns 0.

If unsuccessful, `msync()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

The *addr* argument is not a multiple of the page size as returned by *sysnonf*.

EIO

An I/O error occurred while reading from or writing to the file system.

ENOMEM

Some or all the addresses in the range [*addr*, *addr* + *range*] [*addr*, *addr* + *len*] are invalid for the address space of the process or pages not mapped are specified.

m_transform_layout() — Layout transformation for character strings (bidi data)

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| ISO C XPG4 C99 | both | z/OS V1R2 |

Format

```
#include <sys/layout.h>

int m_transform_layout(LayoutObject layout_object,
                      const char *InpBuf,
                      const size_t InpSize,
                      void *OutBuf,
                      size_t *Outsize,
                      size_t *InpToOut,
                      size_t *OutToInp,
                      unsigned char *Property,
                      size_t *InpBufIndex);
```

General description

The *m_transform_layout()* function is part of the support for handling of bidirectional (Bidi) conversion of data between Visual (MVS) and Implicit (z/OS UNIX) formats. Initial support is for Arabic and Hebrew data.

The *m_transform_layout()* function performs layout transformations (reordering, shaping, cell determination). Alternatively, it may provide additional information needed for layout transformation, such as:

- The expected size of the transformed layout
- The nesting level of different segments in the text
- Cross references between the locations of the corresponding elements before and after the layout transformation.

Both the input text and output text are character strings. The *m_transform_layout()* function transforms the input text in *InpBuf* according to the current layout values in *layout_object*.

Any layout value whose value type is **LayoutTextDescriptor** describes the attributes of the *InpBuf* and *OutBuf* arguments. If the attributes are the same for both *InpBuf* and *OutBuf*, a NULL transformation is performed with respect to that specific layout value.

The *InpBuf* argument specifies the source text to be processed. The *InpBuf* may not be NULL, except when there is a need to reset the internal state.

The *InpSize* argument is the number of bytes within *InpBuf* to be processed by the transformation. Its value will not have changed at the return from the transformation. *InpSize* set to -1 indicates that the text in *InpBuf* is delimited by a NULL code element. If *InpSize* is not set to -1, it is possible to have some NULL elements in the input buffer. This might be used, for example, for a *one shot* transformation of several strings, separated by NULLs.

Outputs of this function may be one or more of the following, depending on the setting of the arguments:

Output Description

OutBuf

Any transformed data is stored in *OutBuf*, converted to **ShapeCharset**.

Outsize

The number of bytes in *OutBuf*.

InpToOut

A cross reference from each *InpBuf* code element to the transformed data. The cross reference relates to the data in *InpBuf*, starting with the first element that *InpBufIndex* points to (and not necessarily starting from the beginning of the *InpBuf*).

OutToInp

A cross reference to each *InpBuf* code element from the transformed data. The cross reference relates to the data in *InpBuf*, starting with the first element that *InpBufIndex* points to (and not necessarily starting from the beginning of the *InpBuf*).

Property

A weighted value that represents specific input string transformation properties with different connotations as explained below. If this argument is not a NULL pointer, it represents an array of values with the same number of elements as the source substring text before the transformation.

Each byte will contain relevant *property* information of the corresponding element in *InpBuf*, starting from the element pointed by *InpBufIndex*.

The four rightmost bits of each *property* byte will contain information for bidirectional environments (when **ActiveDirectional** is True) and they will mean **NestingLevels**. The possible value from 0 to 15 represents the nesting level of the corresponding element in the *InpBuf*, starting from the element pointed by *InpBufIndex*. If **ActiveDirectional** is False, the content of NestingLevels bits will be ignored.

The leftmost bit of each *property* byte will contain a *new cell indicator* for composed character environments. It will be a value of either 1, for an element in *InpBuf* that is transformed to the beginning of a new cell, or 0, for the *zero-length* composing character elements when these are grouped into the same presentation cell with a non-composing character. Here again, each element of *property* pertains to the elements in the *InpBuf*, starting from the element pointed by *InpBufIndex*. (Remember that this is not necessarily the beginning of *InpBuf*.)

If none of the transformation properties is required, the argument *Property* can be NULL.

The use of *property* can be enhanced in the future to pertain to other possible usage in other environments.

InpBufIndex

An offset value to the location of the transformed text. When `m_transform_layout()` is called, *InpBufIndex* contains the offset to the element in *InpBuf* that will be transformed first. (Note that this is not necessarily the first element in *InpBuf*.)

At the return from the transformation, *InpBufIndex* contains the offset to the first element in the *InpBuf* that has not been transformed. If the entire substring has been transformed successfully, *InpBufIndex* will be incremented by the amount defined by *InpSize*.

Each of these output arguments may be NULL to specify that no output is desired for the specific argument, but at least one of them should be set to non-NULL to perform any significant work.

The *layout_object* maintains a directional state that keeps track of directional changes, based on the last segment transformed. The directional state is maintained across calls to the layout transformation functions and allows stream data to be processed with the layout functions. The directional state is reset to its initial state whenever any of the layout values **TypeOfText**, **Orientation** or **ImplicitAlg** is modified by means of a call to *m_setvalues_layout()*.

The *layout_object* argument specifies a LayoutObject returned by the *m_create_layout()* function.

The *OutBuf* argument contains the transformed data. This argument can be specified as a NULL pointer to indicate that no transformed data is required. The encoding of the *OutBuf* argument depends on the **ShapeCharset** layout value defined in *layout_object*. If the **ActiveShapeEditing** layout value is not set (False), the encoding of *OutBuf* is guaranteed to be the same as the codeset of the locale associated with the LayoutObject defined by *layout_object*.

On input, the *OutSize* argument specifies the size of the output buffer in number of bytes. The output buffer should be large enough to contain the transformed result; otherwise, only a partial transformation is performed. If the **ActiveShapeEditing** layout value is set (True), the *OutBuf* should be allocated to contain at least the *InpSize* multiplied by **ShapeCharsetSize**.

OutSize

Upon return, the *OutSize* argument is updated to be the actual number of bytes placed in *OutBuf*.

When the *OutSize* argument is specified as zero, the function calculates the size of an output buffer large enough to contain the transformed text, and the result is returned in this field. The content of the buffers specified by *InpBuf* and *OutBuf*, and the value of *InpBufIndex*, remain unchanged.

If *OutSize* = NULL, the EINVAL error condition is returned.

If the *InpToOut* argument is not a NULL pointer, it points to an array of values with the same number of bytes as *InpBuf*, starting with the one pointed by *InpBufIndex* and up to the end of the substring in the buffer.

On output, the *nth* value in *InpToOut* corresponds to the *nth* byte in *InpBuf*. This value is the index (in units of bytes) in *OutBuf* that identifies the transformed **ShapeCharset** element of the *nth* byte in *InpBuf*.

In the case of multibyte encoding, for each of the bytes of a code element in the *InpBuf*, the index points to the first byte of the transformed code element in the *OutBuf*. *InpToOut* may be specified as NULL if no index array from *InpBuf* to *OutBuf* is desired.

If the *OutToInp* argument is not a NULL pointer, it points to an array of values with the same number of bytes as contained in *OutBuf*. On output, the *nth* value in *OutToInp* corresponds to the *nth* byte in *OutBuf*. This value is the index in *InpBuf*, starting with the byte pointed to by *InpBufIndex*, that identifies the logical code element of the *nth* byte in *OutBuf*.

In the case of multibyte encoding, the index will point, for each of the bytes of a transformed code element in the *OutBuf*, to the first byte of the code element in the *InpBuf*.

OutToInp may be specified as NULL if no index array from *OutBuf* to *InpBuf* is desired.

To perform shaping of a text string without reordering of code elements, the *layout_object* should be set with input and output layout value **TypeOfText** set to TEXT_VISUAL, and both in and out of **Orientation** set to the same value.

Returned value

If successful, *m_transform_layout()* returns 0.

If unsuccessful, *m_transform_layout()* returns -1 and sets *errno* to one of the following values:

Error Code Description

E2BIG

The size of *OutBuf* is not large enough to contain the entire transformed text. The input text state at the end of the uncompleted transformation is saved internally.

EBADF

The layout values are set to a meaningless combination or the layout object is not valid.

EINVAL

Transformation stopped due to an incomplete composite sequence at the end of the input buffer, or *OutSize* contains NULL.

munmap() — Unmap pages of memory

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 z/OS UNIX | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/mman.h>

int munmap(void *addr, size_t len);
```

General description

The `munmap()` function removes the mappings for pages in the range `[addr, addr + len)` rounding the `len` argument up to the next multiple of the page size as returned by `sysconf()`. If `addr` is not the address of a mapping established by a prior call to `mmap()`, the behavior is undefined. After a successful call to `munmap()` and before any subsequent mapping of the unmapped pages, further references to these pages will result in the delivery of a SIGBUS or SIGSEGV signal to the process.

__MAP_MEGA mapping: The `munmap` service removes the mapping for pages in the requested range. The requested range may span multiple maps, and the maps may represent the same or different files. The pages in the range may be part of a regular mapping or may be part of a `__MAP_MEGA` mapping. When unmapping a regular mapping, entire pages are unmapped; when unmapping a `__MAP_MEGA` mapping, entire segments are unmapped.

Map_address: The value of map address must be a multiple of the page size. The specified value does not have to be the start of a mapping. However, if the value specified for `Map_address` falls within a `__MAP_MEGA` map, then the address is rounded down to a megabyte multiple so that an entire segment

__must_stay_clean

is included in the unmap operation. It is not possible to unmap a part of a segment when processing a __MAP_MEGA map.

Map_length: The length can be the size of the whole mapping, or a part of it. If the specified length is not in multiples of the page size, it will be rounded up to a page boundary. If the Map_address plus the Map_length falls within a __MAP_MEGA map, then the length is rounded up to a segment boundary, thus including the entire segment (not necessarily the entire __MAP_MEGA mapping).

Returned value

If successful, munmap() returns 0.

If unsuccessful, munmap() returns -1 and sets errno to one of the following values:

Error Code Description

EINVAL

One of the following error conditions exists:

- The *addr* argument is not a multiple of the page size as returned by *sysconf*.
- Addresses outside the valid range for the address space of a process.
- The *len* argument is 0.

Related information

- [“sys/mman.h — Memory management” on page 69](#)

__must_stay_clean() — Enable or query clean

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | Z/OS V1R8 |

Format

```
#define _OPEN_SYS
#include <unistd.h>

int __must_stay_clean(int request);
```

General description

The __must_stay_clean() function queries or enables the "must stay clean" state for a process. A process that must stay clean is prohibited from doing an exec(), spawn(), or other load of a non-program controlled executable. Only a program controlled executable can enable the must stay clean state. The must stay clean state of a process is propagated to its children created using fork or spawn. Once the must stay clean state is enabled, it cannot be changed. All processes in the address space will be forced to stay clean until they have all terminated. The query support allows a process to determine if it was created in a trusted environment. The BPX.DAEMON class profile must be defined to use the enable function.

Argument**Description****request**

Specify the value `_MSC_QUERY` to query the state. Specify the value `_MSC_ENABLE` to enable "must stay clean" for the process.

Returned value

If successful, `__must_stay_clean()` returns the current "must stay clean" state of the process. The following state values are possible:

_MSC_NOT_ENABLED

The "must stay clean" state is not enabled.

_MSC_ENABLED

The "must stay clean" state is enabled, meaning that it was set using this function, and that it will continue to be enabled even after an `exec()` that causes job step termination.

_MSC_ENABLED_COND

The "must stay clean" state is enabled conditionally, meaning that a prior call to a security service, such as `__passwd()`, implicitly enabled the must stay clean state, and that the state will be reset to "not enabled" at the next `exec()` that causes job step termination. This state value can only be returned using the query request.

If unsuccessful, `__must_stay_clean()` returns `_MSC_FAILED(-1)` and sets `errno` to one of the following values:

Error Code**Description****EINVAL**

A parameter was not valid.

EMVSERR

An MVS environmental error occurred. One possible cause is that a 'dirty' process attempted to enable the must stay clean attribute. Another cause could be that the BPX.DAEMON class profile is not defined.

EMVSSAF2ERR

An error occurred in the security product.

Example

```
/* celeb22.c */
/* This example shows how to use __must_stay_clean() to request */
/* the environment is to "stay clean" until all processes in the */
/* address space are terminated. */
/* Requirements: */
/* 1. The environment must already be clean, noting that the */
/*    program issuing the request must be program-controlled */
/* 2. BPX.DAEMON must be defined */

#define _OPEN_SYS
#include <unistd.h>
#include <errno.h>
#include <stdio.h>
#include <stdlib.h>

int main(void){
    int rc;
    rc = __must_stay_clean(_MSC_ENABLE);    /* Stay Clean! */
    if (rc == _MSC_FAILED){
        perror("could not enable must stay clean");
        printf("errno=%d errno2=%08x\n",errno,__errno2());
        exit(1);
    }
    return 0;
}
```

m_wtransform_layout() – Layout transformation for wide-character strings (bidi data)

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| ISO C XPG4 C99 | both | z/OS V1R2 |

Format

```
#include <sys/layout.h>

int m_wtransform_layout(LayoutObject layout_object,
                        const wchar_t *InpBuf,
                        const size_t InpSize,
                        void *OutBuf,
                        size_t *Outsize,
                        size_t *InpToOut,
                        size_t *OutToInp,
                        unsigned char *Property,
                        size_t *InpBufIndex);
```

General description

The `m_wtransform_layout()` function is part of the support for handling of bidirectional (Bidi) conversion of data between Visual (MVS) and Implicit (z/OS UNIX) formats. Initial support is for Arabic and Hebrew data.

The `m_wtransform_layout()` function performs layout transformations (reordering, shaping, cell determination). Alternatively, it may provide additional information needed for layout transformation, such as:

- The expected size of the transformed layout
- The nesting level of different segments in the text
- Cross references between the locations of the corresponding elements before and after the layout transformation.

Both the input text and output text are wide-character strings. The `m_wtransform_layout()` function transforms the input text in *InpBuf* according to the current layout values in *layout_object*.

Any layout value whose value type is **LayoutTextDescriptor** describes the attributes of the *InpBuf* and *OutBuf* arguments. If the attributes are the same for both *InpBuf* and *OutBuf*, a NULL transformation is performed with respect to that specific layout value.

The *InpBuf* argument specifies the source text to be processed. The *InpBuf* may not be NULL, except when there is a need to reset the internal state.

The *InpSize* argument is the number of characters within *InpBuf* to be processed by the transformation. Its value will not have changed at the return from the transformation. *InpSize* set to -1 indicates that the text in *InpBuf* is delimited by a NULL code element. If *InpSize* is not set to -1, it is possible to have some NULL elements in the input buffer. This might be used, for example, for a *one shot* transformation of several strings, separated by NULLs.

Outputs of this function may be one or more of the following, depending on the setting of the arguments:

Argument Description

OutBuf

Any transformed data is stored in *OutBuf*, converted to **ShapeCharset**.

Outsize

The number of wide characters in *OutBuf*.

InpToOut

A cross reference from each *InpBuf* code element to the transformed data. The cross reference relates to the data in *InpBuf*, starting with the first element that *InpBufIndex* points to (and not necessarily starting from the beginning of the *InpBuf*.)

OutToInp

A cross reference to each *InpBuf* code element from the transformed data. The cross reference relates to the data in *InpBuf*, starting with the first element that *InpBufIndex* points to (and not necessarily starting from the beginning of the *InpBuf*.)

Property

A weighted value that represents specific input string transformation properties with different connotations as explained below. If this argument is not a NULL pointer, it represents an array of values with the same number of elements as the source substring text before the transformation.

Each byte will contain relevant *property* information of the corresponding element in *InpBuf*, starting from the element pointed by *InpBufIndex*.

The four rightmost bits of each *property* byte will contain information for bidirectional environments (when **ActiveDirectional** is True) and they will mean **NestingLevels**. The possible value from 0 to 15 represents the nesting level of the corresponding element in the *InpBuf*, starting from the element pointed by *InpBufIndex*. If **ActiveDirectional** is False, the content of NestingLevels bits will be ignored.

The leftmost bit of each *property* byte will contain a *new cell indicator* for composed character environments. It will be a value of either 1, for an element in *InpBuf* that is transformed to the beginning of a new cell, or 0, for the *zero-length* composing character elements, when these are grouped into the same presentation cell with a non-composing character. Here again, each element of *property* pertains to the elements in the *InpBuf*, starting from the element pointed by *InpBufIndex*. (Remember that this is not necessarily the beginning of *InpBuf*.)

If none of the transformation properties is required, the argument *Property* can be NULL.

The use of *property* can be enhanced in the future to pertain to other possible usage in other environments.

InpBufIndex

An offset value to the location of the transformed text. When `m_wtransform_layout()` is called, *InpBufIndex* contains the offset to the element in *InpBuf* that will be transformed first. (Note that this is not necessarily the first element in *InpBuf*.)

At the return from the transformation, *InpBufIndex* contains the offset to the first element in the *InpBuf* that has not been transformed. If the entire substring has been transformed successfully, *InpBufIndex* will be incremented by the amount defined by *InpSize*.

Each of these output arguments may be NULL to specify that no output is desired for the specific argument, but at least one of them should be set to non-NULL to perform any significant work.

In addition to the possible outputs above, the *layout_object* maintains a directional state across calls to the transform functions. The directional state is reset to its initial state whenever any of the layout values **TypeOfText**, **Orientation** or **ImplicitAlg** is modified by means of a call to `m_setvalues_layout()`.

The *layout_object* argument specifies a `LayoutObject` returned by the `m_create_layout()` function.

The *OutBuf* argument contains the transformed data. This argument can be specified as a NULL pointer to indicate that no transformed data is required. The encoding of the *OutBuf* argument

depends on the **ShapeCharset** layout value defined in *layout_object*. If the **ActiveShapeEditing** layout value is not set (False), the encoding of *OutBuf* is guaranteed to be the same as the codeset of the locale associated with the LayoutObject defined by *layout_object*.

On input, the *OutSize* argument specifies the size of the output buffer in number of wide characters. The output buffer should be large enough to contain the transformed result; otherwise, only a partial transformation is performed. If the **ActiveShapeEditing** layout value is set (True), the *OutBuf* should be allocated to contain at least the *InpSize* multiplied by **ShapeCharsetSize**.

OutSize

Upon return, the *OutSize* argument is updated to be the actual number of code elements placed in *OutBuf*.

When the *OutSize* argument is specified as zero, the function calculates the size of an output buffer large enough to contain the transformed text, and the result is returned in this field. The content of the buffers specified by *InpBuf* and *OutBuf*, and the value of *InpBufIndex*, remain unchanged.

If *OutSize* = NULL, the EINVAL error condition is returned.

If the *InpToOut* argument is not a NULL pointer, it points to an array of values with the same number of wide characters as *InpBuf*, starting with the one pointed by *InpBufIndex* and up to the end of the substring in the buffer.

On output, the *nth* value in *InpToOut* corresponds to the *nth* wide character in *InpBuf*. This value is the index (in units of wide characters) in *OutBuf* that identifies the transformed **ShapeCharset** element of the *nth* wide character in *InpBuf*.

InpToOut may be specified as NULL if no index array from *InpBuf* to *OutBuf* is desired.

If the *OutToInp* argument is not a NULL pointer, it points to an array of values with the same number of wide characters as contained in *OutBuf*. On output, the *nth* value in *OutToInp* corresponds to the *nth* wide character in *OutBuf*. This value is the index in *InpBuf*, starting with the wide character pointed to by *InpBufIndex*, that identifies the logical code element of the *nth* byte in *OutBuf*.

OutToInp may be specified as NULL if no index array from *OutBuf* to *InpBuf* is desired.

To perform shaping of a text string without reordering of code elements, the *layout_object* should be set with input and output layout value **TypeOfText** set to TEXT_VISUAL, and both in and out of **Orientation** set to the same value.

Returned value

If successful, m_wtransform_layout() returns 0.

If unsuccessful, m_wtransform_layout() returns -1 and sets errno to one of the following values:

Error Code

Description

E2BIG

The size of *OutBuf* is not large enough to contain the entire transformed text. The input text state at the end of the uncompleted transformation is saved internally.

EBADF

The layout values are set to a meaningless combination or the layout object is not valid.

EINVAL

Transformation stopped due to an incomplete composite sequence at the end of the input buffer, or *OutSize* contains NULL.

double nan(const char *tagp);
float nanf(const char *tagp);
long double nanl(const char *tagp);
```

General description

In the nan() family of functions, the call nan("n-char-sequence") is equivalent to strtod("NaN(n-charsequence)", (char**) NULL) and the call nan("") is equivalent to strtod("NaN()", (char**) NULL). If tagp does not point to an n-char sequence or an empty string, the call is equivalent to strtod("NaN", (char**) NULL). Calls to nanf() and nanl() are equivalent to the corresponding calls strtod() and strtold().

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------|-----|------|
| nan | X | X |
| nanf | X | X |
| nanl | X | X |

Returned value

If successful, they return a quiet NaN with content indicated by tagp.

Special behavior in hex: The nan() family of functions always return 0.

Example

```
/*
 * This program illustrates the use of the nan() function
 *
 * It calls both nan and strtod with equivalent arguments
 * and displays output of both. Output should be identical.
 */
#define _ISOC99_SOURCE
#include <stdio.h>
#include <stdlib.h> /* needed of strtod */
#include <math.h>
```

```
#define TESTVALS 5
struct {
    const char * str;
} nan_vals[] = {
/*0*/ { "0", },
/*1*/ { "1", },
/*2*/ { "something", }, /* invalid n-char seq. */
/*3*/ { "2147483647", }, /* int max */
/*4*/ { "2147483648", }, /* int max +1 */
},

strods_vals[] = {
/*0*/ { "NAN(0)", },
/*1*/ { "NAN(1)", },
/*2*/ { "NAN", },
/*3*/ { "NAN(2147483647)", },
/*4*/ { "NAN(2147483648)", },
};

void main()
{
    double outnan,
        outstrtod;
    int i;
    char *tagp = (char *)NULL;

    printf("Illustrates the nan() function\n");
    printf("Output for both nan() and strtod() should be identical.\n\n");
    for (i=0; i<TESTVALS; i++) {
        outnan = nan(nan_vals[i].str);
        outstrtod = strtod(strods_vals[i].str, &tagp);

        printf("nan(%s) returned = %g\n",nan_vals[i].str, outnan);
        printf("strtod(%s) returned = %g\n\n",strods_vals[i].str, outstrtod);
    }
}
```

Output

```
Illustrates the nan() function
Output for both nan() and strtod() should be identical.

nan(0) returned = 0
strtod(NAN(0)) returned = 0

nan(1) returned = NaNQ(1)
strtod(NAN(1)) returned = NaNQ(1)

nan(something) returned = NaNQ(1)
strtod(NAN) returned = NaNQ(1)

nan(2147483647) returned = NaNQ(2147483647)
strtod(NAN(2147483647)) returned = NaNQ(2147483647)

nan(2147483648) returned = 0
strtod(NAN(2147483648)) returned = 0
```

nand32(), nand64(), nand128() — Return quiet NaN

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  nand32(const char *tagp);
_Decimal64  nand64(const char *tagp);
_Decimal128 nand128(const char *tagp);
```

General description

In the `nan()` family of functions, the call `nand32("n-char-sequence")` is equivalent to `strtod32("NAN(n-charsequence)", (char**) NULL)` and the call `nand32("")` is equivalent to `strtod32("NAN()", (char**) NULL)`. If `tagp` does not point to an n-char sequence or an empty string, the call is equivalent to `strtod32("NAN", (char**) NULL)`. Calls to `nand64()` and `nand128()` are equivalent to the corresponding calls `strtod64()` and `strtod128()`.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, they return a quiet NaN with content indicated by `tagp`.

Example

```
/* CELEBN05

   This program illustrates the use of the nand32() function.

   It calls both nand32() and strtod32() with equivalent arguments
   and displays output of both. Output should be identical.

*/

#define __STDC_WANT_DEC_FP__

nanosleep() — High-resolution sleep

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| POSIX.1-2001 | both | |
| POSIX.1-2008 | | |

Format

```
#define _XOPEN_SOURCE 500
#include <time.h>

int nanosleep(const struct timespec *req, struct timespec *rem);
```

General description

nanosleep() suspends the execution of the calling thread until one of the following conditions is met:

- At least the time that is specified in **req* elapses.
- The delivery of a signal that triggers the invocation of a handler in the calling thread.
- The delivery of a signal that terminates the process.

If the call is interrupted by a signal handler, nanosleep() returns -1, sets *errno* to EINTR, and writes the remaining time into the structure that is pointed to by *rem* unless *rem* is NULL. The value of **rem* can be used to call nanosleep() again and complete the specified pause.

The structure *timespec* is used to specify intervals of time with nanosecond precision. The value of the nanoseconds field in it must be in the range 0 to 999999999.

Compared to sleep() and usleep(), nanosleep() has the following advantages:

- It provides a higher resolution for specifying the sleep interval; POSIX.1 explicitly specifies that it does not interact with signals.
- It makes the task of resuming a sleep that is interrupted by a signal handler easier.

Returned value

On successful sleeping for the requested interval, `nanosleep()` returns 0.

If the call is interrupted by a signal handler or encounters an error, `nanosleep()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINTR

The pause is interrupted by a signal that is delivered to the thread. The remaining sleep time is written into `*rem` so that the thread can call `nanosleep()` again and continue with the pause.

EINVAL

The value in the `tv_nsec` field is not in the range 0 to 999999999 or the `tv_sec` field is not in the range 0 to 4294967295 for a 64-bit caller.

nearbyint(), nearbyintf(), nearbyintl() — Round the argument to the nearest integer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _ISOC99_SOURCE
#include <math.h>

double nearbyint(double x);
float nearbyintf(float x);
long double nearbyintl(long double x);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

float nearbyint(float x);
long double nearbyint(long double x);
```

General description

The `nearbyint()` family of functions round x to an integer value, in floating-point format, using the current rounding mode without raising the `inexact` floating-point exception.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|-------------------------|-----|------|
| <code>nearbyint</code> | X | X |
| <code>nearbyintf</code> | X | X |
| <code>nearbyinfl</code> | X | X |

Returned value

If successful, they return the rounded integer value. If the correct value causes an overflow, a range error occurs and the value, respectively, of the macro: `+-HUGE_VAL`, `+-HUGE_VALF`, or `+-HUGE_VALL` (with the same sign as x) is returned.

Example

```

/*
 * This program illustrates the use of nearbyint() function
 *
 * Note: to get the results shown in this book , this program
 *       should be compiled using IEEE floating point representation
 *
 */
#define _ISOC99_SOURCE
#include <math.h>
#include <stdio.h>
#include <_Ieee754.h> /* save/get fpc functions */

char *RoundStr (_FP_rmode_t rm_type) {
    char *RndStr="undetermined";
    switch (rm_type) {
        case (_RMODE_RN):
            RndStr="round to nearest";
            break;
        case (_RMODE_RZ):
            RndStr="round toward zero";
            break;
        case (_RMODE_RP):
            RndStr="round toward +infinity ";
            break;
        case (_RMODE_RM):
            RndStr="round toward -infinity ";
            break;
    }
    return (RndStr);
}

void main() {

    _FP_fpcreg_t save_rmode, current_rmode;
    double      rnd2nearest;
    double      number1=1.5,
               number2=-3.92;

    printf("Illustrates the nearbyint() function\n");
    __fpc_rd(&current_rmode); /* get current rounding mode */

    rnd2nearest = nearbyint(number1);
    printf ("When rounding direction is %s:\n nearbyint(%.2f) = %f\n",

```

```

        RoundStr(current_rmode.rmode), number1, rnd2nearest);
save_rmode.rmode = _RMODE_RZ;
__fpc_sm(save_rmode.rmode);    /* set rounding mode to round to zero */

rnd2nearest = nearbyint(number2);
printf ("When rounding direction is %s:\n nearbyint(%.2f) = %f\n",
        RoundStr(save_rmode.rmode), number2, rnd2nearest);
}

```

Output

Illustrates the `nearbyint()` function
 When rounding direction is round to nearest:
`nearbyint(1.50) = 2.000000`
 When rounding direction is round toward zero:
`nearbyint(-3.91) = -3.000000`

nearbyintd32(), nearbyintd64(), nearbyintd128() — Round the argument to the nearest integer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```

#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32  nearbyintd32(_Decimal32 x);
_Decimal64  nearbyintd64(_Decimal64 x);
_Decimal128 nearbyintd128(_Decimal128 x);
_Decimal32  nearbyint(_Decimal32 x);      /* C++ only */
_Decimal64  nearbyint(_Decimal64 x);      /* C++ only */
_Decimal128 nearbyint(_Decimal128 x);     /* C++ only */

```

General description

The `nearbyint()` family of functions round `x` to an integer value, in decimal floating-point format, using the current rounding mode without raising the inexact decimal floating-point exception.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, they return the rounded integer value. If the correct value causes an overflow, a range error occurs and the value, respectively, of the macro: \pm HUGE_VAL_D32, \pm HUGE_VAL_D64, or \pm HUGE_VAL_D128 (with the same sign as x) is returned.

Example

```
/* CELEBN06

   This example illustrates the nearbyintd64() function.
*/

#pragma strings(readonly)

nextafter(), nextafterf(), nextafterl() — Next representable double float

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <math.h>

double nextafter(double x, double y);
```

C99:

```
#define _ISOC99_SOURCE
#include <math.h>

float nextafterf(float x, float y);
long double nextafterl(long double x, long double y);
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

float nextafter(float x, float y);
long double nextafter(long double x, long double y);
```

General description

The nextafter() function computes the next representable double-precision floating-point value following x in the direction of y. Thus, if y is less than x, nextafter() returns the largest representable floating-point number less than x.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|------------|-----|------|
| nextafter | X | X |
| nextafterf | X | X |
| nextafterl | X | X |

Restriction: The nextafterf() function does not support the _FP_MODE_VARIABLE feature test macro.

Returned value

The nextafter() functions return the next representable value following x in the direction of y. They always succeed.

If x is finite and the correct function value overflows, a range error occurs and ±HUGE_VAL, ±HUGE_VALF, and ±HUGE_VALL (with the same sign as x) are returned as appropriate for the return type of the function.

Errno

Descirption

ERANGE

The correct value overflows.

- [“math.h — Floating-point math functions” on page 40](#)

nextafterd32(), nextafterd64(), and nextafterd128() – Next representable decimal floating-point value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 nextafterd32(_Decimal32 x, _Decimal32 y);
_Decimal64 nextafterd64(_Decimal64 x, _Decimal64 y);
_Decimal128 nextafterd128(_Decimal128 x, _Decimal128 y);
_Decimal32 nextafter(_Decimal32 x, _Decimal32 y); /* C++ only */
```

```
_Decimal64 nextafter(_Decimal64 x, _Decimal64 y); /* C++ only */
_Decimal128 nextafter(_Decimal128 x, _Decimal128 y); /* C++ only */
```

General description

The `nextafter()` function computes the next representable decimal floating-point value following `x` in the direction of `y`. Thus, if `y` is less than `x`, `nextafter()` returns the largest representable decimal floating-point number less than `x`.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

The `nextafter()` functions return the next representable value following `x` in the direction of `y`.

| If... | Then... |
|---|---|
| <code>x</code> equals <code>y</code> | <code>copysign(x,y)</code> is returned. |
| <code>x</code> is less than <code>y</code> | the next representable value after <code>x</code> is returned. |
| <code>x</code> is greater than <code>y</code> | the largest representable decimal floating-point number less than <code>x</code> is returned. |
| <code>x</code> or <code>y</code> is a NaN | either <code>x</code> or <code>y</code> is returned. |

Example

```
/* CELEBN07
   This example illustrates the nextafterd128() function.
*/
#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal128 x = 123456789.70DL, dir = 123456790.00DL, z;

    z = nextafterd128(x, dir);

    printf("The next number after %DDf in the direction %DDf\n is %DDf\n",
           x, dir, z);
}
```

C++ TR1 C99:

```
#define _TR1_C99
#include <math.h>

float nexttoward(float x, long double y);
long double nexttoward(long double x, long double y);
```

General description

The nexttoward() family of functions compute the next representable floating-point value following *x* in the direction of *y*.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|-------------|-----|------|
| nexttoward | X | X |
| nexttowardf | X | X |
| nexttowardl | X | X |

Restriction: The nexttowardf() function does not support the _FP_MODE_VARIABLE feature test macro.

Returned value

If successful, they return the next representable value in the specified format after *x* in the direction of *y*.

| If... | Then... |
|-----------------------------------|---|
| <i>x</i> equals <i>y</i> | <i>y</i> (of type <i>x</i>) is returned. |
| <i>x</i> is less than <i>y</i> | the next representable value after <i>x</i> is returned. |
| <i>x</i> is greater than <i>y</i> | the largest representable floating-point number less than <i>x</i> is returned. |

| If... | Then... |
|--|---|
| x is finite and the correct function value would overflow | a range error occurs and +/-HUGE_VAL, +/-HUGE_VALF, or +/-HUGE_VALL (with the same sign as x) is returned by nexttoward(), nexttowardf() or nexttowardl() respectively. |
| x does not equal y and the correct subroutine value is subnormal, 0, or underflows | a range error occurs and either the correct function value (if representable) or 0.0 is returned. |
| x or y is a NaN | a NaN is returned. |

Example

```

/*
 * This program illustrates the use of nexttoward() function
 */
#define _ISOC99_SOURCE
#include <math.h>
#include <stdio.h>

void PrintBytes(char *str, double x)
{
    static union {
        unsigned char bytes[sizeof(double)];
        double val;
    } dbl;

    int i;
    dbl.val = x;

    printf("%s ", str);
    for (i=0; i<sizeof(double); ++i) {
        printf("%02x", dbl.bytes[i]);
    }
    printf("\n");
}

void main() {
    double    nextvalue;
    double    x=1.5;
    long double y=2.0;

    printf("Illustrates the nexttoward() function\n");

    printf("\nTest1 (x<y)    x = %f  y = %Lf\n", x, y);
    PrintBytes("x in hex =", x);
    nextvalue = nexttoward(x, y);
    printf ("nexttoward(x,y) = %f\n", nextvalue);
    PrintBytes("nexttoward(x,y) in hex =", nextvalue);

    x=1.5; y=1.0;
    printf("\nTest2 (x>y)    x = %f  y = %Lf\n", x, y);
    nextvalue = nexttoward(x, y);
    printf ("nexttoward(x,y) = %f\n", nextvalue);
    PrintBytes("nexttoward(x,y) in hex =", nextvalue);
}

```

Output

Illustrates the nexttoward() function

```

Test1 (x<y)    x = 1.500000  y = 2.000000
x in hex = 3ff8000000000000
nexttoward(x,y) = 1.500000
nexttoward(x,y) in hex = 3ff8000000000001

```

```

Test2 (x>y)    x = 1.500000  y = 1.000000
nexttoward(x,y) = 1.500000
nexttoward(x,y) in hex = 3ff7ffffffffffff

```

nexttowardd32(), nexttowardd64(), nexttowardd128() — Calculate the next representable value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 nexttowardd32(_Decimal32 x, _Decimal128 y);
_Decimal64 nexttowardd64(_Decimal64 x, _Decimal128 y);
_Decimal128 nexttowardd128(_Decimal128 x, _Decimal128 y);
_Decimal32 nexttoward(_Decimal32 x, _Decimal128 y); /*C++ only*/
_Decimal64 nexttoward(_Decimal64 x, _Decimal128 y); /*C++ only*/
_Decimal128 nexttoward(_Decimal128 x, _Decimal128 y); /*C++ only*/
```

General description

The nexttoward() family of functions compute the next representable decimal floating-point value following x in the direction of y.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, they return the next representable value in the specified format after x in the direction of y.

| If... | Then... |
|---|---|
| x equals y | y (of type x) is returned. |
| x is less than y | the next representable value after x is returned. |
| x is greater than y | the largest representable decimal floating-point number less than x is returned. |
| x is finite and the correct function value would overflow | a range error occurs and ±HUGE_VAL_D32, ±HUGE_VAL_D64, or ±HUGE_VAL_D128 (with the same sign as x) is returned by nexttowardd32(), nexttowardd64() or nexttowardd128(), respectively. |

| If... | Then... |
|--|---|
| x does not equal y and the correct subroutine value is subnormal, 0, or underflows | a range error occurs and either the correct function value (if representable) or 0.0 is returned. |
| x or y is a NaN | a NaN is returned. |

Example

```
/* CELEBN08

   This example illustrates the nexttowardd32() function.

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

static void try_nt(_Decimal32 x, _Decimal128 y)
{
    _Decimal32 r = nexttowardd32(x, y);
    printf("nexttowardd32(%12.12HG, %12.12DDG) = % 12.12HG\n", x, y, r);
    return;
}

int main(void)
{
    try_nt( 2.000000DF, 2.00000001DL );
    try_nt(-2.000000DF, -2.00000001DL );
    try_nt( 2.000000DF, 2.00000000DL );
    try_nt( 2.000000DF, 1.99999999DL );
    try_nt(-2.000000DF, -1.99999999DL );
    try_nt( 9.999999E+96DF, 9.99999999E+96DL );
    try_nt( 1.000000E-95DF, 0.99999999E-95DL );

    return 0;
}
```

nftw(), nftw64() — Traverse a file tree

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

nftw:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <ftw.h>

int nftw(const char *path,
        int (*fn)(const char *, const struct stat *, int, struct FTW *),
        int fd_limit, int flags);
```

nftw64:

```
#define _LARGE_TIME_API
#define _XOPEN_SOURCE_EXTENDED 1
#include <ftw.h>

int nftw64(const char *path,
           int (*fn)(const char *, const struct stat64 *, int, struct FTW *),
           int fd_limit, int flags);
```

Compile requirement: Use of the `nftw64()` function requires the `long long` data type. For more information on how to make the `long long` data type available, see [z/OS XL C/C++ Language Reference](#).

General description

The `nftw()` function recursively descends the directory hierarchy rooted in *path*. It is similar to `ftw()` except that it takes an additional argument *flags*, which is a bitwise inclusive-OR of zero or more of the following flags:

FTW_CHDIR

If set, `nftw()` will change the current working directory to each directory as it reports files in that directory. If clear, `nftw()` will not change the current working directory.

FTW_DEPTH

If set, `nftw()` will report all files in a directory before reporting the directory itself. If clear, `nftw()` will report any directory before reporting the files in that directory.

FTW_MOUNT

If set, `nftw()` will only report files in the same file system as *path*. If clear, `nftw()` will report all files encountered during the walk.

FTW_PHYS

If set, `nftw()` performs a physical walk and does not follow symbolic links. If clear, `nftw()` will follow links instead of reporting them, and will not report the same file twice.

At each file it encounters, `nftw()` calls the user-supplied function *fn* with four arguments:

- the first argument is the path name of the object.
- the second argument is a pointer to a `stat` buffer containing information on the object.
- the third argument is an integer giving additional information. Its value is one of the following:

FTW_D

for a directory

FTW_DNR

for a directory that cannot be read

FTW_DP

for a directory whose sub-directories have been visited. (This condition will only occur if `FTW_DEPTH` is included in *flags*.)

FTW_F

for a file

FTW_NS

for an object other than a symbolic link on which `stat()` could not be successfully executed. If the object is a symbolic link, and `stat()` failed, it is unspecified whether `nftw()` passes `FTW_SL` or `FTW_NS` to the user-supplied function.

FTW_SL

for a symbolic link

FTW_SLN

for a symbolic link that does not name an existing file. (This condition will only occur if FTW_PHYS is not included in *flags*.)

- the fourth argument is a pointer to an FTW structure. The value of *base* is the offset of the object's filename in the path name passed as the first argument to *fn()*. The value of *level* indicates depth relative to the root of the walk, where the root level is 0.

The argument *fd_limit* limits the directory depth for the search. At most one file descriptor will be used for each directory level.

The *nftw64()* function behaves exactly like *nftw()* except *nftw64()* uses structure *stat64* instead of struct *stat* to support time beyond 03:14:07 UTC on January 19, 2038.

Large file support for z/OS UNIX files: *nftw64()* automatically supports large z/OS UNIX files for both AMODE 31 and AMODE 64 C/C++ applications, which means there is no need for `_LARGE_FILES` feature test macro to be defined. As for *nftw()*, the automatic support is only for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the long long data type support enabled and define the `_LARGE_FILES` feature test macro before any headers are included to enable *nftw()* to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the `_LARGE_FILES` feature test macro as well.

Special behavior for C++: Because C and C++ linkage conventions are incompatible, *nftw()* cannot receive a C++ function pointer as the argument. If you attempt to pass a C++ function pointer to *nftw()*, the compiler will flag it as an error. You can pass a C or C++ function to *nftw()* by declaring it as extern "C".

Returned value

nftw() continues until the first of the following conditions occurs:

- An invocation of *fn()* returns a nonzero value, in which case *nftw()* returns that value.
- The *nftw()* function detects an error other than EACCES (see FTW_DNR and FTW_NS above), in which case *nftw()* returns -1 and sets *errno* to indicate the error.
- The tree is exhausted, in which case *nftw()* returns 0.

If unsuccessful, *nftw()* sets *errno* to one of the following values. All other *errno*s returned by *nftw()* are unchanged.

Error Code**Description****EACCES**

Search permission is denied for any component of *path* or read permission is denied for *path*, or *fn()* returns -1 and does not reset *errno*.

ELOOP

Too many symbolic links were encountered.

EMFILE

OPEN_MAX file descriptors are currently open in the calling process.

ENAMETOOLONG

One of the following error conditions exists:

- Path name resolution of a symbolic link produced an intermediate result whose length exceeds PATH_MAX.
- The length of *path* exceeds PATH_MAX, or a *pathname* component is longer than PATH_MAX.

ENFILE

Too many files are currently open in the system.

ENOENT

A component of *path* does not name an existing file or *path* is an empty string.

ENOTDIR

A component of *path* is not a directory.

The `errno` value might also be set if the function `fn` causes it to be set.

nice() — Change priority of a process

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <unistd.h>

int nice(int increment);
```

General description

`nice()` adds the value of *increment* to the nice value of the calling process. A process's nice value is a nonnegative number for which a more positive value results in a lower CPU priority.

A maximum nice value of $2 \cdot \{NZERO\} - 1$ and a minimum value of zero are imposed by the system. Requests for values above or below these limits result in the nice value being set to the corresponding limit. Only a process with appropriate privileges can lower the nice value.

The changing of a process's nice value has the equivalent effect on a process's scheduling priority value, since they both represent the process's relative CPU priority. For example, increasing one's nice value to its maximum value of $(2 \cdot NZERO) - 1$ has the equivalent effect of setting one's scheduling priority value to its maximum value (19), and will be reflected on the `nice()`, `getpriority()`, and `setpriority()` functions.

Returned value

If successful, `nice()` return the new nice value minus (NZERO).

If unsuccessful, `nice()` returns -1 and sets `errno` to one of the following values:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

ENOSYS

The system does not support this function.

EPERM

The value of *increment* was negative and the calling process does not have the appropriate privileges.

Because `nice()` can return the value -1 on successful completion, it is necessary to set the external variable `errno` to 0 before a call to `nice()`. If `nice()` returns -1, then `errno` can be checked to see if an error occurred or if the value is a legitimate nice value.

nlist() — Get entries from a name list

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <nlist.h>

int nlist(const char *loadname, struct nlist *np);
```

General description

The `nlist()` function allows a program to examine the name list in the executable file named by the *loadname* parameter. It selectively extracts a list of values and places them in the array of `nlist` structures pointed to by the *np* parameter.

The name list specified by the *np* parameter consists of an array of structures containing names of variables, types and values. The list is terminated with an element that has a NULL string in the name structure member. Each variable name is looked up in the name list of the executable file. If the name is found, the type and the value of the name is copied into the `nlist` structure field. If the name is not found, both the type and value entry will be set to zero.

All entries are set to zero if the specified executable file cannot be read or it does not contain a valid name list.

Notes:

1. The only variable type that will be supported by this version of `nlist()` is external function.
2. `nlist()` will extract the offset of the external functions from *loadname*.
3. The type returned in `nlist` structure will always be 2 to indicate function if the function name is found in *loadname*.
4. *loadname* must be a linear format load module containing `main()`.
5. *loadname* cannot be a dll (dynamic link library) or a fetchable load module.

Returned value

If successful, `nlist()` returns 0. The offset and type of functions if found will be returned in the `nlist` structure.

If unsuccessful, `nlist()` returns -1.

Related information

- [“nlist.h — nlist\(\) fucntion” on page 52](#)

nl_langinfo() — Retrieve locale information

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#include <langinfo.h>

char *nl_langinfo(nl_item item);
```

General description

Retrieves from the current locale the string that describes the requested information specified by *item*.
For a list of macros that define the constants used to identify the information queried in the current locale, see [Table 4 on page 32](#).

Returned value

If successful, nl_langinfo() returns a pointer to a NULL-terminated string containing information concerning the active language or cultural area. The active language or cultural area is determined by the most recent setlocale() call. The array pointed to by the returned value is modified by subsequent calls to the function. The array shall not be modified by the user's program.
If the item is not valid, nl_langinfo() returns a pointer to an empty string.

Example

CELEBN01

```
/* CELEBN01

   This example retrieves the current codeset name using the
   &nl1. function.

*/
#include "langinfo.h"
#include "locale.h"
#include "stdio.h"

main() {
    char *codeset;
    setlocale(LC_ALL, "");
    codeset = nl_langinfo(CODESET);
    printf("codeset is %s\n", codeset);
}
```

nrand48() — Pseudo-random number generator

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <stdlib.h>

long int nrand48(unsigned short int x16v[3]);
```

General description

The drand48(), erand48(), jrand48(), lrand48(), mrand48() and nrand48() functions generate uniformly distributed pseudo-random numbers using a linear congruential algorithm and 48-bit integer arithmetic.

The functions drand48() and erand48() return nonnegative, double-precision, floating-point values, uniformly distributed over the interval [0.0,1.0).

The functions lrand48() and nrand48() return nonnegative, long integers, uniformly distributed over the interval [0,2**31).

The functions mrand48() and jrand48() return signed long integers, uniformly distributed over the interval [-2**31,2**31).

The nrand48() function generates the next 48-bit integer value in a sequence of 48-bit integer values, X(i), according to the linear congruential formula:

$$X(n+1) = (aX(n) + c) \bmod (2^{**}48) \quad n \geq 0$$

The nrand48() function uses storage provided by the argument array, x16v[3], to save the most recent 48-bit integer value in the sequence, X(i). The nrand48() function uses x16v[0] for the low-order (rightmost) 16 bits, x16v[1] for the middle-order 16 bits, and x16v[2] for the high-order 16 bits of this value.

The initial values of a, and c are:

```
a  = 5deece66d (base 16)
c  = b          (base 16)
```

The values a and c, may be changed by calling the lcong48() function. The initial values of a and c are restored if either the seed48() or srand48() function is called.

Special behavior for z/OS UNIX Services: You can make the nrand48() function and other functions in the drand48 family thread-specific by setting the environment variable _RAND48 to the value THREAD before calling any function in the drand48 family.

If you do not request thread-specific behavior for the drand48 family, C/370 serializes access to the storage for X(n), a and c by functions in the drand48 family when they are called by a multithreaded application.

If thread-specific behavior is requested and the `rand48()` function is called from thread `t`, the `rand48()` function generates the next 48-bit integer value in a sequence of 48-bit integer values, $X(t,i)$, for the thread according to the linear congruential formula:

$$X(t,n+1) = (a(t)X(t,n) + c(t)) \bmod (2^{**}48) \qquad n \geq 0$$

The `rand48()` function uses storage provided by the argument array, `x16v[3]`, to save the most recent 48-bit integer value in the sequence, $X(t,i)$. The `rand48()` function uses `x16v[0]` for the low-order (rightmost) 16 bits, `x16v[1]` for the middle-order 16 bits, and `x16v[2]` for the high-order 16 bits of this value.

The initial values of `a(t)` and `c(t)` on the thread `t` are:

$$\begin{aligned} a(t) &= 5\text{deece66d} \quad (\text{base } 16) \\ c(t) &= b \quad (\text{base } 16) \end{aligned}$$

The values `a(t)` and `c(t)` may be changed by calling the `lcong48()` function from the thread `t`. The initial values of `a(t)` and `c(t)` are restored if either the `seed48()` or `srand48()` function is called from the thread.

Returned value

`rand48()` saves the generated 48-bit value, $X(n+1)$, in storage provided by the argument array, `x16v[3]`. `rand48()` transforms the generated 48-bit value to a nonnegative, long integer value on the interval $[0, 2^{**}31)$ and returns this transformed value.

Special behavior for z/OS UNIX Services: If thread-specific behavior is requested for the `drand48` family and `rand48()` is called on thread `t`, `rand48()` saves the generated 48-bit value, $X(t,n+1)$, in storage provided by the argument array, `x16v[3]`. `rand48()` transforms the generated 48-bit value to a nonnegative, long integer value on the interval $[0, 2^{**}31)$ and returns this transformed value.

ntohl() — Translate a long integer into host byte order

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

XPG4.2:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <arpa/inet.h>
```

```
in_addr_t ntohl(in_addr_t netlong);
```

SUSV3:

```
#define _POSIX_C_SOURCE 200112L
#include <arpa/inet.h>

uint32_t ntohl(uint32_t netlong);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <netinet/in.h>
#include <arpa/inet.h>

unsigned long ntohl(unsigned long a);
```

General description

The `ntohl()` function translates a long integer from network byte order to host byte order.

Parameter

Description

a

The unsigned long integer to be put into host byte order.

in_addr_t *netlong*

Is typed to the unsigned long integer to be put into host byte order.

Notes:

1. For MVS, host byte order and network byte order are the same.
2. Since this function is implemented as a macro, you need one of the feature test macros and the `inet` header file.

Returned value

`ntohl()` returns the translated long integer.

ntohs() — Translate an unsigned short integer into host byte order

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

XPG4.2:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <arpa/inet.h>

in_port_t ntohs(in_port_t netshort);
```

SUSV3:

```
#define _POSIX_C_SOURCE 200112L
#include <arpa/inet.h>

uint16_t ntohs(uint16_t netshort);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <arpa/inet.h>
#include <netinet/in.h>

unsigned short ntohs(unsigned short a);
```

General description

The `ntohs()` function translates a short integer from network byte order to host byte order.

Parameter

Description

a

The unsigned short integer to be put into host byte order.

in_port_t *netshort*

Is typed to the unsigned short integer to be put into host byte order.

Notes:

1. For MVS, host byte order and network byte order are the same.
2. Since this function is implemented as a macro, you need one of the feature test macros and the `inet` header file.

Returned value

`ntohs()` returns the translated short integer.

open() — Open a file

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <fcntl.h>

int open(const char *pathname, int options, ...);
```

General description

Opens a file and returns a number called a *file descriptor*.

The *pathname* argument must be a z/OS UNIX file name. You can use this file descriptor to refer to the file in subsequent I/O operations, for example, `read()` or `write()`. Each file opened by a process gets a new file descriptor.

Restriction: Using this function with FIFOs, POSIX terminals, and character special files requires IBM z/OS C programs running POSIX(ON).

The argument *pathname* is a string giving the name of the file you want to open. The integer *options* specifies options for the open operation by taking the bitwise inclusive-OR of symbols defined in the `fcntl.h` header file. The options indicate whether the file should be accessed for reading, writing, reading and writing, and so on.

An additional argument (`. . .`) is required if the `O_CREAT` option is specified in *options*. This argument may be called the *mode* and has the `mode_t` type. It specifies file permission bits to be used when a file is created. All the file permission bits are set to the bits of *mode*, except for those set in the file-mode creation mask of the process. Here is a list of symbols that can be used for a mode.

S_IRGRP

Read permission for the file's group.

S_IROTH

Read permission for users other than the file owner.

S_IRUSR

Read permission for the file owner.

S_IRWXG

Read, write, and search or execute permission for the file's group. `S_IRWXG` is the bitwise inclusive-OR of `S_IRGRP`, `S_IWGRP`, and `S_IXGRP`.

S_IRWXO

Read, write, and search or execute permission for users other than the file owner. `S_IRWXO` is the bitwise inclusive-OR of `S_IROTH`, `S_IWOTH`, and `S_IXOTH`.

S_IRWXU

Read, write, and search, or execute, for the file owner; `S_IRWXU` is the bitwise inclusive-OR of `S_IRUSR`, `S_IWUSR`, and `S_IXUSR`.

S_ISGID

Privilege to set group ID (GID) for execution. When this file is run through an exec function, the effective group ID of the process is set to the group ID of the file, so that the process has the same authority as the file owner rather than the authority of the actual invoker.

S_ISUID

Privilege to set the user ID (UID) for execution. When this file is run through an exec function, the effective user ID of the process is set to the owner of the file, so that the process has the same authority as the file owner rather than the authority of the actual invoker.

S_ISVTX

Indicates shared text. Keep loaded as an executable file in storage.

S_IWGRP

Write permission for the file's group.

S_IWOTH

Write permission for users other than the file owner.

S_IWUSR

Write permission for the file owner.

S_IXGRP

Search permission (for a directory) or execute permission (for a file) for the file's group.

S_IXOTH

Search permission for a directory, or execute permission for a file, for users other than the file owner.

S_IXUSR

Search permission (for a directory) or execute permission (for a file) for the file owner.

Most open operations position a *file offset* (an indicator showing where the next read or write will take place in the file) at the beginning of the file; however, there are options that can change this position. One of the following must be specified in the *options* argument of the `open()` operation:

O_RDONLY

Open for reading only

O_WRONLY

Open for writing only

O_RDWR

Open for both reading and writing

One or more of the following can also be specified in *options*:

O_APPEND

Positions the file offset at the end of the file before each write operation.

O_CLOEXEC

Enable the close-on-exec flag for the new file descriptor. Specifying this flag permits a program to avoid additional `fcntl()` `F_SETFD` operations to set the `FD_CLOEXEC` flag. This flag is defined by the `_XPLATFORM_SOURCE` feature test macro.

O_CREAT

Indicates that the call to `open()` has a *mode* argument.

If the file being opened already exists `O_CREAT` has no effect except when `O_EXCL` is also specified; see `O_EXCL` following.

If the file being opened does not exist it is created. The user ID is set to the effective ID of the process, and its group ID is set to the group ID of its directory. File permission bits are set according to *mode*.

If `O_CREAT` is specified and the file did not previously exist a successful `open()` sets the access time, change time, and modification time for the file. It also updates the change time and modification time fields in the parent directory.

O_DIRECT

Try to minimize cache effects of the I/O to and from this file. This flag is defined by the `_XPLATFORM_SOURCE` feature test macro.

O_DIRECTORY

If *pathname* is not a directory, cause the open to fail. This flag is defined by the `_XPLATFORM_SOURCE` feature test macro.

O_EXCL

If both `O_EXCL` and `O_CREAT` are specified `open()` fails if the file already exists. If both `O_EXCL` and `O_CREAT` are specified and *pathname* names a symbolic link `open()` fails regardless of the contents of the symbolic link.

The check for the existence of the file and the creation of the file if it does not exist is atomic with respect to other threads executing `open()` naming the same filename in the same directory with `O_EXCL` and `O_CREAT` set.

O_NOCTTY

If *pathname* specifies a terminal `open()` does not make the terminal the controlling terminal of the process (and the session). If `O_NOCTTY` is not specified the terminal becomes the controlling terminal if the following conditions are true:

- The process is a session leader.
- There is no controlling terminal for the session.
- The terminal is not already a controlling terminal for another session.

O_NOFOLLOW

If the trailing component (i.e., base name) of *pathname* is a symbolic link, the open fails with the error `ELOOP`. This flag is defined by the `_XPLATFORM_SOURCE` feature test macro.

O_NONBLOCK

Has different meanings depending on the situation.

- When you are opening a FIFO special file with `O_RDONLY` or `O_WRONLY`:

If `O_NONBLOCK` is specified a read-only `open()` returns immediately. A write-only `open()` returns with an error if no other process has the FIFO open for reading.

If `O_NONBLOCK` is not specified a read-only `open()` blocks until another process opens the FIFO for writing. A write-only `open()` blocks until another process opens the FIFO for reading.

- When you are opening a character special file that supports a nonblocking `open()`, `O_NONBLOCK` controls whether subsequent reads and writes can block.

O_PATH

Obtain a file descriptor either to indicate a location in the file system tree or to perform operations that act at the file descriptor level. This flag is defined by the `_XPLATFORM_SOURCE` feature test macro.

O_TRUNC

If the file is successfully opened with `O_RDWR` or `O_WRONLY`, this will truncate the file to zero length if the file exists and is a regular file. The mode and owner of the file are unchanged. This option should not be used with `O_RDONLY`. `O_TRUNC` has no effect on FIFO special files or directories.

If `O_TRUNC` is specified and the file previously existed a successful `open()` updates the change time and modification time for the file.

O_SYNC

Force synchronous update. If this flag is 1 every `write()` operation on the file is written to permanent storage. That is, the file system buffers are forced to permanent storage. Also see `fsync()`.

The program is assured that all data for the file has been written to permanent storage on return from a function which performs a synchronous update,

If *pathname* refers to a STREAM file, *oflag* can be constructed from `O_NONBLOCK` OR-ed with either `O_RDONLY`, `O_WRONLY` or `O_RDWR`. Other flag values are not applicable to STREAMS devices and have no

effect on them. The value `O_NONBLOCK` affects the operation of STREAMS drivers and certain functions applied to file descriptors associated with STREAMS files. For STREAMS drivers, the implementation of `O_NONBLOCK` is device-specific.

Note: z/OS UNIX services do not supply any STREAMS devices or pseudodevices. It is impossible for `open()` to return a valid STREAMS file descriptor.

The largest value that can be represented correctly in an object of type `off_t` is established as the offset maximum in the open file description.

Large file support for z/OS UNIX files: Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the [long long data type support](#) enabled and define the `_LARGE_FILES` feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the `_LARGE_FILES` feature test macro as well.

Returned value

If successful, `open()` returns a file descriptor.

If unsuccessful, `open()` returns -1 and sets `errno` to one of the following values:

Error Code Description

EACCES

Access is denied. Possible reasons include:

- The process does not have search permission on a component in *pathname*.
- The file exists, but the process does not have permission to open the file in the way specified by the flags.
- The file does not exist, and the process does not have write permission on the directory where the file is to be created.
- `O_TRUNC` was specified, but the process does not have write permission on the file.

EBUSY

The process attempted to open a file that is in use.

EEXIST

`O_CREAT` and `O_EXCL` were specified, and either the named file refers to a symbolic link, or the named file already exists.

EINTR

`open()` was interrupted by a signal.

EINVAL

The *options* parameter does not specify a valid combination of the `O_RDONLY`, `O_WRONLY` and `O_TRUNC` bits.

EIO

The *pathname* argument names a STREAMS file and a hang-up or error occurred during the `open()`.

EISDIR

pathname is a directory, and *options* specifies write or read/write access.

ELOOP

A loop exists in symbolic links. This error is issued if the number of symbolic links detected in the resolution of *pathname* is greater than `POSIX_SYMLINK_MAX`.

EMFILE

The process has reached the maximum number of file descriptors it can have open.

ENAMETOOLONG

pathname is longer than `PATH_MAX` characters, or some component of *pathname* is longer than `NAME_MAX` characters while `_POSIX_NO_TRUNC` is in effect. For symbolic links, the length of the

pathname string substituted for a symbolic link exceeds `PATH_MAX`. The `PATH_MAX` and `NAME_MAX` values can be determined using `pathconf()`.

ENFILE

The system has reached the maximum number of file descriptors it can have open.

ENOENT

Typical causes:

- `O_CREAT` is not specified, and the named file does not exist.
- `O_CREAT` is specified, and either the prefix of *pathname* does not exist or the *pathname* argument is an empty string.

ENOMEM

The *pathname* argument names a STREAMS file and the system is unable to allocate resources.

ENOSPC

The directory or file system intended to hold a new file has insufficient space.

ENOSR

The *pathname* argument names a STREAMS-based file and the system is unable to allocate a STREAM.

ENOSYS

For main pseudoterminals, subsidiary initialization did not complete.

ENOTDIR

A component of *pathname* is not a directory.

ENXIO

`O_NONBLOCK` and `O_WRONLY` were specified and the named file is a FIFO, but no process has the file open for reading. For a pseudoterminal, the requested minor number exceeds the maximum number supported by the installation.

EPERM

For subsidiary pseudoterminals, permission to open is denied for one of these reasons:

- It is the first open of the subsidiary after the main pseudoterminal was opened, and the user ID associated with the two opening processes is not the same.
- There was an internal error in the security system after the main pseudoterminal was opened.
- The attempt to open the subsidiary used a different pathname than earlier opens used.

EROFS

pathname is on a read-only file system, and one or more of the options `O_WRONLY`, `O_RDWR`, `O_TRUNC`, or `O_CREAT` (if the file does not exist) was specified.

Example

The following opens an output file for appending:

```
int fd;
fd = open("outfile", O_WRONLY | O_APPEND);
```

The following statement creates a new file with read/write/execute permissions for the creating user. If the file already exists, `open()` fails.

```
fd = open("newfile", O_WRONLY | O_CREAT | O_EXCL, S_IRWXU);
```

openat() — Open a file relative to a directory file descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1-2008 Single UNIX Specification, Version 4 | both | |

Format

```
#define _POSIX_C_SOURCE 200809L
#include <fcntl.h>

int openat(int dirfd, const char *pathname, int flags, ...);
```

General description

`openat()` opens a file by using the specified directory file descriptor as the starting location for the path search. It operates in the same way as `open()` except for the following differences.

- If *pathname* is absolute, *dirfd* is ignored.
- If *pathname* is relative and *dirfd* is the special value `AT_FDCWD`, *pathname* is interpreted relative to the current working directory of the calling process.
- If *pathname* is relative, it is interpreted relative to the directory referred to by the file descriptor *dirfd* (rather than relative to the current working directory of the calling process, as is done by `open()` for a relative *pathname*).
- If *pathname* is relative and *dirfd* is not a valid file descriptor, an error (EBADF) is returned.

Returned value

If successful, `openat()` returns a new file descriptor.

If unsuccessful, `openat()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

Access is denied. Possible reasons include:

- The process does not have search permission on a component in *pathname*.
- The file exists, but the process does not have permission to open the file in the way specified by the flags.
- The file does not exist, and the process does not have write permission on the directory where the file is to be created.

- O_TRUNC was specified, but the process does not have write permission on the file.

EBUSY

The process attempted to open a file that is in use.

EEXIST

O_CREAT and O_EXCL were specified, and either the named file refers to a symbolic link, or the named file already exists.

EINTR

open() was interrupted by a signal.

EINVAL

The *options* parameter does not specify a valid combination of the O_RDONLY, O_WRONLY and O_TRUNC bits.

EIO

The *pathname* argument names a STREAMS file and a hang-up or error occurred during the open().

EISDIR

pathname is a directory, and *options* specifies write or read/write access.

ELOOP

A loop exists in symbolic links. This error is issued if the number of symbolic links detected in the resolution of *pathname* is greater than POSIX_SYMLINK_MAX.

EMFILE

The process has reached the maximum number of file descriptors it can have open.

ENAMETOOLONG

pathname is longer than PATH_MAX characters, or some component of *pathname* is longer than NAME_MAX characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the pathname string substituted for a symbolic link exceeds PATH_MAX. The PATH_MAX and NAME_MAX values can be determined using pathconf().

ENFILE

The system has reached the maximum number of file descriptors it can have open.

ENOENT

Typical causes:

- O_CREAT is not specified, and the named file does not exist.
- O_CREAT is specified, and either the prefix of *pathname* does not exist or the *pathname* argument is an empty string.

ENOMEM

The *pathname* argument names a STREAMS file and the system is unable to allocate resources.

ENOSPC

The directory or file system intended to hold a new file has insufficient space.

ENOSR

The *pathname* argument names a STREAMS-based file and the system is unable to allocate a STREAM.

ENOSYS

For main pseudoterminals, subsidiary initialization did not complete.

ENOTDIR

A component of *pathname* is not a directory.

ENXIO

O_NONBLOCK and O_WRONLY were specified and the named file is a FIFO, but no process has the file open for reading. For a pseudoterminal, the requested minor number exceeds the maximum number supported by the installation.

EPERM

For subsidiary pseudoterminals, permission to open is denied for one of these reasons:

- It is the first open of the subsidiary after the main pseudoterminal was opened, and the user ID associated with the two opening processes is not the same.
- There was an internal error in the security system after the main pseudoterminal was opened.
- The attempt to open the subsidiary used a different pathname than earlier opens used.

EROFS

pathname is on a read-only file system, and one or more of the options `O_WRONLY`, `O_RDWR`, `O_TRUNC`, or `O_CREAT` (if the file does not exist) was specified.

EBADF

dirfd is not a valid file descriptor.

ENOTDIR

pathname is relative and *dirfd* is a file descriptor referring to a file other than a directory.

openat2() — Open a file with more extensions

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#define POSIX_SOURCE          /* Definition of O_* and S_* constants */
#include <fcntl.h>

long openat2(int dirfd, const char *pathname, struct open_how *how, size_t size);
```

Compile requirement: This function must be used under the [extended language level](#).

General description

`openat2()` is an extension of `openat()` and provides a superset of its functions. For `openat()`, the *flags* and *mode* parameters are passed as separate integer fields, where in `openat2()` they are passed as an `open_how` structure.

`openat2()` opens the file that is specified by *pathname*. If the specified file does not exist, it might optionally be (if `O_CREAT` is specified in *how.flags*) created.

As with `openat()`, if *pathname* is relative, it is interpreted relative to the directory that is referred to by the file descriptor *dirfd* (or the current working directory of the calling process, if *dirfd* is the special value `AT_FDCWD`). If *pathname* is absolute, *dirfd* is ignored (unless *how.resolve* contains `RESOLVE_IN_ROOT`, in which case *pathname* is resolved relative to *dirfd*).

Rather than taking a single *flags* argument, an extensible structure (*how*) is passed to allow for future extensions. The *size* argument must be specified as `sizeof(struct open_how)`.

The *how* argument specifies how *pathname* is opened and acts as a superset of the *flags* and *mode* arguments to `openat()`. This argument is a pointer to a structure of the following form:

```
struct open_how {
    uint64_t flags;        /* O_* flags */
    uint64_t mode;         /* Mode for O_CREAT */
    uint64_t resolve;      /* RESOLVE_* flags */
    /* ... */
};
```

Any future extensions to `openat2()` will be implemented as new fields that are appended to the previous structure. The fields of the `open_how` structure are as follows:

flags

Specifies the file creation and file status flags to use when opening the file. All of the `O_*` flags defined for `openat()` are valid `openat2()` flag values.

mode

Specifies the mode for the new file, with identical semantics to the *mode* argument of `openat()`.

resolve

A bit-mask of flags that modify how all components of *pathname* are resolved (a component is a substring that is delimited by '/'). The primary use case for these flags is to allow trusted programs to restrict how untrusted paths (or paths inside untrusted directories) are resolved. The full list of resolve flags is as follows:

RESOLVE_BENEATH

Do not permit the path resolution to succeed if any component of the resolution is not a descendant of the directory that is indicated by *dirfd*. This causes absolute symbolic links (and absolute values of *pathname*) to be rejected.

This flag disables magic-link resolution. Therefore, to ensure that magic links are not resolved, the caller must specify `RESOLVE_NO_MAGICLINKS`.

RESOLVE_IN_ROOT

Treat the directory that is referred to by *dirfd* as the root directory while resolving *pathname*. Absolute symbolic links are interpreted relative to *dirfd*. If a prefix component of *pathname* equates to *dirfd*, an immediately following component likewise equates to *dirfd* (just as `/. .` is traditionally equivalent to `/`). If *pathname* is an absolute path, it is also interpreted relative to *dirfd*.

The effect of this flag is as though the calling process uses `chroot()` to (temporarily) modify its root directory (to the directory that is referred to by *dirfd*). However, unlike `chroot()` (which changes the file system root permanently for a process), `RESOLVE_IN_ROOT` allows a program to restrict path resolution on a per-open basis.

This flag disables magic-link resolution. Therefore, to ensure that magic links are not resolved, the caller must specify `RESOLVE_NO_MAGICLINKS`.

RESOLVE_NO_MAGICLINKS

Disallows all magic-link resolution during path resolution.

Magic links are symbolic link-like objects that are found in `proc()`; examples include `/proc/[pid]/exe` and `/proc/[pid]/fd/*`.

Unknowingly opening magic links can be risky for some applications. Examples of such risks include the following:

- If the process opening a path name is a controlling process that has no controlling terminal (see `credentials(7)`), opening a magic link inside `/proc/[pid]/fd` that happens to refer to a terminal causes the process to acquire a controlling terminal.
- In a containerized environment, a magic link inside `/proc` might refer to an object outside the container, and thus might provide a means to escape from the container.

Because of such risks, an application might prefer to disable magic link resolution by using the `RESOLVE_NO_MAGICLINKS` flag.

If the trailing component (base name) of *pathname* is a magic link, *how.resolve* contains `RESOLVE_NO_MAGICLINKS`, and *how.flags* contains both `O_PATH` and `O_NOFOLLOW`, an `O_PATH` file descriptor that references the magic link is returned.

RESOLVE_NO_SYMLINKS

Disallows resolution of symbolic links during *pathname* resolution. This option implies `RESOLVE_NO_MAGICLINKS`.

If the trailing component (base name) of *pathname* is a symbolic link, *how.resolve* contains `RESOLVE_NO_SYMLINKS` and *how.flags* contains both `O_PATH` and `O_NOFOLLOW`, an `O_PATH` file descriptor that references the symbolic link is returned.

Note: The effect of the `RESOLVE_NO_SYMLINKS` flag, which affects the treatment of symbolic links in all the components of *pathname*, differs from the effect of the `O_NOFOLLOW` file creation flag (in *how.flags*), which affects the handling of symbolic links only in the final component of *pathname*.

Applications that employ the `RESOLVE_NO_SYMLINKS` flag are encouraged to make its use configurable (unless it is used for a specific security purpose), as symbolic links are widely used by users. Setting this flag indiscriminately (for purposes that are not related to security) for all uses of `openat2()` might result in spurious errors on previously functional systems. This might occur if, for example, a system *pathname* that is used by an application is modified (for example, in a new distribution release) so that a path name component contains a symbolic link.

RESOLVE_NO_XDEV

Disallows traversal of mount points during path resolution (including all bind mounts). *pathname* must either be on the same mount as the directory referred to by *dirfd*, or on the same mount as the current working directory if *dirfd* is specified as `AT_FDCWD`.

Applications that employ the `RESOLVE_NO_XDEV` flag are encouraged to make its use configurable (unless it is used for a specific security purpose), as bind mounts are widely used by users. Setting this flag indiscriminately (for purposes that are not related to security) for all uses of `openat2()` might result in spurious errors on previously functional systems. This might occur if, for example, a system path name that is used by an application is modified (for example, in a new distribution release) so that a path name component contains a bind mount.

RESOLVE_CACHED

Makes the open operation fail unless all path components present in the kernel's lookup cache. If any revalidation or I/O is needed to satisfy the lookup, `openat2()` fails with the error `EAGAIN`. This is useful in providing a fast path open that can be performed without resorting to thread offload, or other mechanisms that an application might use to offload slower operations.

If any bits other than those that are listed previously are set in *how.resolve*, an error is returned.

Returned value

If successful, `openat2()` returns a new file descriptor.

If unsuccessful, `openat2()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCESS

Access is denied. Possible reasons include:

- The process does not have search permission on a component in *pathname*.
- The file exists, but the process does not have permission to open the file in the way specified by the flags.
- The file does not exist, and the process does not have write permission on the directory where the file is to be created.

- O_TRUNC was specified, but the process does not have write permission on the file.

EBUSY

The process attempted to open a file that is in use.

EEXIST

O_CREAT and O_EXCL were specified, and either the named file refers to a symbolic link, or the named file already exists.

EINTR

open() was interrupted by a signal.

EINVAL

The *options* parameter does not specify a valid combination of the O_RDONLY, O_WRONLY and O_TRUNC bits.

An unknown flag or invalid value is specified in *how*, or *mode* is nonzero, but *how.flags* does not contain O_CREAT or O_TMPFILE.

EIO

The *pathname* argument names a STREAMS file and a hang-up or error occurred during the open().

EISDIR

pathname is a directory, and *options* specifies write or read/write access.

ELOOP

- A loop exists in symbolic links. This error is issued if the number of symbolic links detected in the resolution of *pathname* is greater than POSIX_SYMLINK.
- *how.resolve* contains RESOLVE_NO_SYMLINKS, and one of the path components is a symbolic link (or magic link).
- *how.resolve* contains RESOLVE_NO_MAGICLINKS, and one of the path components is a magic link.

EMFILE

The process has reached the maximum number of file descriptors it can have open.

ENAMETOOLONG

pathname is longer than PATH_MAX characters, or some component of *pathname* is longer than NAME_MAX characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the pathname string substituted for a symbolic link exceeds PATH_MAX. The PATH_MAX and NAME_MAX values can be determined using pathconf().

ENFILE

The system has reached the maximum number of file descriptors it can have open.

ENOENT

Typical causes:

- O_CREAT is not specified, and the named file does not exist.
- O_CREAT is specified, and either the prefix of *pathname* does not exist or the *pathname* argument is an empty string.

ENOMEM

The *pathname* argument names a STREAMS file and the system is unable to allocate resources.

ENOSPC

The directory or file system intended to hold a new file has insufficient space.

ENOSR

The *pathname* argument names a STREAMS-based file and the system is unable to allocate a STREAM.

ENOSYS

For main pseudoterminals, subsidiary initialization did not complete.

ENOTDIR

A component of *pathname* is not a directory.

pathname is relative and *dirfd* is a file descriptor referring to a file other than a directory.

ENXIO

O_NONBLOCK and O_WRONLY were specified and the named file is a FIFO, but no process has the file open for reading. For a pseudoterminal, the requested minor number exceeds the maximum number supported by the installation.

EPERM

For subsidiary pseudoterminals, permission to open is denied for one of these reasons:

- It is the first open of the subsidiary after the main pseudoterminal was opened, and the user ID associated with the two opening processes is not the same.
- There was an internal error in the security system after the main pseudoterminal was opened.
- The attempt to open the subsidiary used a different pathname than earlier opens used.

EROFS

pathname is on a read-only file system, and one or more of the options O_WRONLY, O_RDWR, O_TRUNC, or O_CREAT (if the file does not exist) was specified.

EBADF

dirfd is not a valid file descriptor.

E2BIG

Unsupported flag is specified in the *resolve* field.

EAGAIN

RESOLVE_CACHED is set, and the open operation cannot be performed by using only cached information. The caller must retry without RESOLVE_CACHED set in *how.resolve*.

EXDEV

- *how.resolve* contains either RESOLVE_IN_ROOT or RESOLVE_BENEATH, and an escape from the root during path resolution is detected.
- *how.resolve* contains RESOLVE_NO_XDEV, and a path component crosses a mount point.

opendir() — Open a directory

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <dirent.h>
```

```
DIR *opendir(const char *dirname);
```

General description

Opens a directory so that it can be read with `readdir()` or `__readdir2()`. *dirname* is a string giving the name of the directory you want to open. The first `readdir()` or `__readdir2()` call reads the first entry in the directory.

Returned value

If successful, `opendir()` returns a pointer to a DIR object. This object describes the directory and is used in subsequent operations on the directory, in the same way that FILE objects are used in file I/O operations.

If unsuccessful, `opendir()` returns a NULL pointer and sets `errno` to one of the following values:

Error Code

Description

EACCES

The process does not have permission to search some component of *dirname*, or it does not have read permission on the directory itself.

ELOOP

A loop exists in the symbolic links. This error is issued if more than POSIX_SYMLLOOP (defined in the limits.h header file) symbolic links are encountered during resolution of the *dirname* argument.

EMFILE

The process has too many other file descriptors already open.

ENAMETOOLONG

dirname is longer than **PATH_MAX** characters, or some component of *dirname* is longer than **NAME_MAX** characters while `_POSIX_NO_TRUNC` is in effect. For symbolic links, the length of the pathname string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values can be determined using `pathconf()`.

ENFILE

The entire system has too many other file descriptors already open.

ENOENT

The directory *dirname* does not exist.

ENOMEM

There is not enough storage available to open the directory.

ENOTDIR

Some component of the *dirname* pathname is not a directory.

Example

CELEB001

```
/* CELEB001
   This example opens a directory.
*/
#define _POSIX_SOURCE
#include <dirent.h>
#include <errno.h>
#include <sys/stat.h>
#include <sys/types.h>
#undef _POSIX_SOURCE
#include <stdio.h>

void traverse(char *fn, int indent) {
    DIR *dir;
    struct dirent *entry;
    int count;
    char path[1025];
```

```

struct stat info;

for (count=0; count<indent; count++) printf(" ");
printf("%s\n", fn);

if ((dir = opendir(fn)) == NULL)
    perror("opendir() error");
else {
    while ((entry = readdir(dir)) != NULL) {
        if (entry->d_name[0] != '.') {
            strcpy(path, fn);
            strcat(path, "/");
            strcat(path, entry->d_name);
            if (stat(path, &info) != 0)
                fprintf(stderr, "stat() error on %s: %s\n", path,
                    strerror(errno));
            else if (S_ISDIR(info.st_mode))
                traverse(path, indent+1);
        }
    }
    closedir(dir);
}
}

main() {
    puts("Directory structure:");
    traverse("/etc", 0);
}

```

Output

```

Directory structure:
/etc
/etc/samples
/etc/samples/IBM
/etc/IBM

```

__opendir2() — Open a directory

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | OS/390 V2R6 |

Format

```
#define _OPEN_SYS_DIR_EXT
#include <dirent.h>

DIR *__opendir2(const char *dirname, size_t bufsize);
```

General description

Opens a directory so that it can be read with `readdir()` or `__readdir2()`. The first `readdir()` or `__readdir2()` call reads the first entry in the directory.

dirname is a string giving the name of the directory you want to open. *bufsize* is the size (in bytes) of the internal work buffer used by `readdir()` or `__readdir2()` to hold directory entries. The larger the buffer, the less overhead there will be when reading through large numbers of directory entries. This buffer will exist until the directory is closed. If the specified buffer size is too small, it is ignored. A minimum-size buffer is used instead.

`__opendir2()` is the same as `opendir()`, except that the buffer size can be specified as a parameter.

Returned value

If successful, `__opendir2()` returns a pointer to a `DIR` object. This object describes the directory and is used in subsequent operations on the directory, in the same way that `FILE` objects are used in file I/O operations.

If unsuccessful, `__opendir2()` returns a `NULL` pointer and sets `errno` to one of the following values:

Error Code

Description

EACCES

The process does not have permission to search some component of *dirname*, or it does not have read permission on the directory itself.

ELOOP

A loop exists in the symbolic links. This error is issued if more than `POSIX_SYMLLOOP` (defined in the `limits.h` header file) symbolic links are encountered during resolution of the *dirname* argument.

EMFILE

The process has too many other file descriptors already open.

ENAMETOOLONG

dirname is longer than `PATH_MAX` characters, or some component of *dirname* is longer than `NAME_MAX` characters while `_POSIX_NO_TRUNC` is in effect. For symbolic links, the length of the pathname string substituted for a symbolic link exceeds `PATH_MAX`. The `PATH_MAX` and `NAME_MAX` values can be determined using `pathconf()`.

ENFILE

The entire system has too many other file descriptors already open.

ENOENT

The directory *dirname* does not exist.

ENOMEM

There is not enough storage available to open the directory using a buffer that is length *bufsize* bytes long.

ENOTDIR

Some component of the *dirname* pathname is not a directory.

openlog() — Open the system control log

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <syslog.h>

void openlog(const char *ident, int logopt, int facility);
```

General description

The `openlog()` function optionally opens a connection to the logging facility, and sets process attributes that affect subsequent calls to the `syslog()` function. The argument *ident* is a string that is prefixed to every message. *logopt* is a bit field indicating logging options. Current values of *logopt* are:

LOG_CONS

Write messages to the system console if they cannot be sent to the logging facility. This option is safe to use in processes that have no controlling terminal, since the `syslog()` function forks before opening the console.

LOG_NDELAY

Open the connection to the logging facility immediately. Normally the open is delayed until the first message is logged. This is useful for programs that need to manage the order in which file descriptors are allocated..

LOG_NOWAIT

Do not wait for child processes that have been forked to log messages onto the console. This option should be used by processes that enable notification of child termination using `SIGCHLD`, since the `syslog()` function may otherwise block waiting for a child whose exit status has already been collected.

LOG_ODELAY

Delay open until `syslog()` is called.

LOG_PID

Log the processID with each message. This is useful for identifying specific processes. In the message header, the processID is surrounded by square brackets. The code point values for the square brackets are taken from code page IBM-1047. The value for the left square bracket is 0xAD. The value for the right square bracket is 0xBD.

The *facility* argument encodes a default facility to be assigned to all messages that do not have an explicit facility already encoded. The initial default facility is as follows:

LOG_USER

Message generated by random processes. This is the default facility identifier if none is specified.

Returned value

openlog() returns no values.

No errors are defined.

__open_stat(), __open_stat64() — Open a file and get file status information

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | OS/390 V2R6 |

Format

__open_stat:

```
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/stat.h>

int __open_stat(const char *pathname, int options, mode_t mode,
                struct stat *info);
```

__open_stat64:

```
#define _LARGE_TIME_API
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/stat.h>

int __open_stat64(const char *pathname, int options, mode_t mode,
                  struct stat64 *info);
```

Compile requirement: Use of the __open_stat64() function requires the long long data type. For more information on how to make the long long data type available, see [z/OS XL C/C++ Language Reference](#).

General description

Opens a file and returns a number called a *file descriptor*. __open_stat() also returns information about the opened file. __open_stat() is a combination of open() and fstat().

The __open_stat64() function behaves exactly like __open_stat() except __open_stat64() uses structure stat64 instead of struct stat to support time beyond 03:14:07 UTC on January 19, 2038.

The parameters are:

Parameters

Description

pathname

This parameter is a NULL-terminated character string containing the hierarchical file system (HFS) path name of the file to be opened.

pathname can begin with or without a slash.

- A path name beginning with a slash is an absolute path name. The slash refers to the root directory, and the search for the file starts at the root directory.
- A path name not beginning with a slash is a relative path name. The search for the file begins at the working directory.

See [“open\(\) — Open a file” on page 1157](#) for more information about the *pathname* parameter and the types of files that can be opened.

options

An integer containing option bits for the open operation. These options are the same as those in the *options* parameter passed to `open()`. These bits are defined in `fcntl.h`. For a list of these option bits and their meaning, see [“open\(\) — Open a file” on page 1157](#).

mode

mode is the same as the optional third parameter for `open()`, which is used when a new file is being created. For `__open_stat()`, the *mode* parameter is always required. If a new file is not being created, *mode* is ignored, and might be set to 0. When `__open_stat()` creates a file, the flag bits in *mode* specify the file permissions and other characteristics for the new file. The flag bits in *mode* are defined in `sys/modes.h`. For more information about the *mode* parameter, see [“open\(\) — Open a file” on page 1157](#).

info

The *info* parameter points to an area of memory where the system will store information about the file that is opened. This parameter is the same as the *info* parameter in `fstat()` or `stat()`. If the file is successfully opened, the system returns file status information in a `stat` structure, as defined in `sys/stat.h`. The elements of this structure are described in [“stat\(\), stat64\(\) — Get file information” on page 1706](#).

Returned value

If successful, `__open_stat()` returns a file descriptor.

If unsuccessful, `__open_stat()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCESS

Access to the file was denied. One of the following errors occurred:

- The calling process does not have permission to search one of the directories specified in the *pathname* parameter.
- The calling process does not have permission to open the file in the way specified by the *options* parameter.
- The file does not exist, and the calling process does not have permission to write into files in the directory the file would have been created in.
- The truncate option was specified, but the process does not have write permission for the file.

EAGAIN

Resources were temporarily unavailable.

EBUSY

pathname specifies a main pseudoterminal that is either already in use or for which the corresponding subsidiary is open.

EEXIST

The exclusive create option was specified, but the file already exists.

Use `__errno2()` to determine the exact reason the error occurred.

EFBIG

A request to create a new file is prohibited because the file size limit for the process is set to 0.

EINTR

The `__open_stat()` operation was interrupted by a signal.

EINVAL

The *options* parameter does not specify a valid combination of the `O_RDONLY`, `O_WRONLY` and `O_TRUNC` bits, or the file type specified in the *mode* parameter is not valid.

Use `__errno2()` to determine the exact reason the error occurred.

EISDIR

The file specified by *pathname* is a directory and the *options* parameter specifies write or read/write access.

Use `__errno2()` to determine the exact reason the error occurred.

ELOOP

A loop exists in symbolic links encountered during resolution of the *pathname* parameter. This error is issued if more than 8 symbolic links are detected in the resolution of *pathname*.

EMFILE

The process has reached the maximum number of file descriptors it can have open.

ENAMETOOLONG

pathname is longer than 1023 characters, or a component of *pathname* is longer than 255 characters. (The system does not support filename truncation.)

ENODEV

Typical causes of this error are:

- An attempt was made to open a character special file for a device not supported by the system.
- An attempt was made to open a character special file for a device that is not yet initialized.

Use `__errno2()` to determine the exact reason the error occurred.

ENOENT

Typical causes of this error are:

- The request did not specify that the file was to be created, but the file named by *pathname* was not found.
- The request asked for the file to be created, but some component of *pathname* was not found, or the *pathname* parameter was blank.

Use `__errno2()` to determine the exact reason the error occurred.

ENOSPC

The directory or file system intended to hold a new file has insufficient space.

ENOTDIR

A component of *pathname* is not a directory.

ENXIO

The `__open_stat()` request specified write-only and non-block for a FIFO special file, but no process has the file open for reading. For pseudo terminals, this `errno` can mean that the minor number associated with *pathname* is too big.

EPERM

The caller is not permitted to open the specified subsidiary pseudoterminal or the corresponding main is not yet open. `EPERM` is also returned if the subsidiary is closed with `HUPCL` set and an attempt is made to reopen it.

EROFS

The *pathname* parameter names a file on a read-only file system, but options that would allow the file to be altered were specified: write-only, read/write, truncate, or `--` for a new file `-- create`.

Use `__errno2()` to determine the exact reason the error occurred.

__osname() — Get true operating system name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | OS/390 V2R10 |

Format

```
#define _POSIX_SOURCE
#include <sys/utsname.h>

int __osname(struct utsname *name);
```

General description

The `__osname()` function retrieves information identifying the true operating system you are running on. The argument *name* points to a memory area where a structure describing the true operating system the process is running on can be stored.

The information about the true operating system is returned in a `utsname` structure, which has the following elements:

char *sysname;

The true name of the implementation of the operating system.

char *nodename;

The node name of this particular machine. The node name is set by the `SYSNAME sysparm` (specified at IPL), and usually differentiates machines running at a single location.

char *release;

The true current release level of the implementation.

char *version;

The true current version level of the release.

char *machine;

The name of the hardware type the system is running on.

Each of the `utsname` structure elements is a normal C string, terminated with a NULL character.

The values returned by the `__osname()` function are not intended to be used for comparison purposes in order to determine a level of functionality provided by the operating system. This is because the version and release values are not guaranteed to be equal to or greater than the previous implementation.

[Table 51 on page 1177](#) lists the true operating system information returned by the `__osname()` function.

Table 51. Operating system information returned by the `__osname()` function

| Operating system | Sysname | Release | Version |
|------------------|---------|---------|---------|
| z/OS 3.2 | z/OS | 02.00 | 03 |
| z/OS 3.1 | z/OS | 01.00 | 03 |
| z/OS 2.5 | z/OS | 05.00 | 02 |

Returned value

If successful, the `__osname()` function returns a non-negative value.

If unsuccessful, the `__osname()` function returns -1 and an `errno` might be set to indicate the reason for the failure.

Example

CELEB002

```

/*
 * This example gets information about the system you are running on.
 */
#define _POSIX_SOURCE
#include <sys/utsname.h>
#include <stdio.h>
main() {
    struct utsname uts;
    if (__osname(&uts) < 0)
        perror("__osname() error");
    else {
        printf("Sysname: %s\n", uts.sysname);
        printf("Nodename: %s\n", uts.nodename);
        printf("Release: %s\n", uts.release);
        printf("Version: %s\n", uts.version);
        printf("Machine: %s\n", uts.machine);
    }
}

```

Output

```

Sysname:  z/OS
Nodename: SY1
Release:  02.00
Version:  03
Machine:  8561

```

- [“sys/utsname.h — Operating system name” on page 73](#)
- [“uname\(\) — Display current operating system name” on page 1935](#)

`__passwd()`, `__passwd_applid()` — Verify or change user password

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <pwd.h>
```

```
int __passwd(const char *username, const char *oldpass, const char *newpass);
int __passwd_applid(const char *username, const char *oldpass,
                   const char *newpass, const char *applid);
```

General description

The `__passwd()` function verifies or changes the *username* password or the password phrase. The *username* is a NULL-terminated character string of 1 to 8 bytes. The *oldpass* is the current password or password phrase for user *username*, and is a NULL-terminated character string of a password or a password phrase. When *newpass* is NULL, then *oldpass* represents the password or password phrase to be verified, and no password or password phrase change is performed. Otherwise, *newpass* is a NULL-terminated character string of a password or a password phrase. Other installation-dependent restrictions on passwords or password phrases may apply, both in terms of length and content. Length restrictions may be imposed by the security product.

The `__passwd_applid()` function is equivalent to `__passwd()` with the added feature that it also allows the application identifier (APPLID) to be supplied that will be passed on to the security product to assist with authentication. When *applid* is NULL or a pointer to NULL, no application identifier will be passed on to the security product.

The function has the following parameters:

| | |
|------------------|--------------------|
| Parameter | Description |
|------------------|--------------------|

applid

Specifies the application identifier that will be used for authentication with the security product.

If the BPX.DAEMON facility class profile is defined, then all modules within the address space must be loaded from a controlled library. This includes all modules in the application and runtime libraries. See also "Checking Which Module is not Defined to Program Control" in [z/OS UNIX System Services Planning](#).

Returned value

If successful, `__passwd()` returns 0. When *newpass* is NULL, the password or the password phrase has been verified. When *newpass* is not NULL, the new password or password phrase has been set.

If a user specifies password for *oldpass* and new password phrase for *newpass* or password phrase for *oldpass* and new password for *newpass*, then `__passwd()` returns -1 and sets *errno* to EMVSPASSWORD and the current password or password phrase is not changed.

If unsuccessful, `__passwd()` returns -1 and sets *errno* to one of the following values:

| | |
|-------------------|--------------------|
| Error Code | Description |
|-------------------|--------------------|

EACCES

The *oldpass* is not authorized.

EINVAL

The *username*, *oldpass*, *newpass*, or *applid* argument is invalid.

EMVSERR

The specified function is not supported in an address space where a load was done from an uncontrolled library.

EMVSEXPIRE

The *oldpass* has expired and no *newpass* has been provided.

EMVSPASSWORD

The *newpass* is not valid, or does not meet the installation-exit requirements.

EMVSSAF2ERR

Internal processing error.

EMVSSAFEXTRERR

An internal SAF/RACF extract error has occurred. A possible reason is that the *username* access has been revoked. *errno2* contains the BPX1PWD reason code. For more information, see [z/OS UNIX System Services Programming: Assembler Callable Services Reference](#).

ESRCH

The *username* provided is not defined to the security product or does not have an OMVS segment defined.

For more information, refer to [z/OS UNIX System Services Messages and Codes](#) and [z/OS UNIX System Services Programming: Assembler Callable Services Reference](#).

Related information

- [“pwd.h — Access user database through password structure” on page 56](#)

pathconf() — Determine configurable path name variables

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1a XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

long pathconf(const char *pathname, int varcode);
```

General description

Lets an application determine the value of a configuration variable, *varcode*, associated with a particular file or directory, *pathname*.

The *varcode* argument may be any one of the following symbols, defined in the *unistd.h* header file, each standing for a configuration variable:

_PC_LINK_MAX

Represents LINK_MAX, the maximum number of links the file can have. If *pathname* is a directory, *pathconf()* returns the maximum number of links that can be established to the directory itself.

_PC_MAX_CANON

Represents MAX_CANON, the maximum number of bytes in a terminal canonical input line. *pathname* must refer to a character special file for a terminal.

_PC_MAX_INPUT

Represents MAX_INPUT, the maximum number of bytes for which space is available in a terminal input queue. That is, it refers to the maximum number of bytes that a portable application can have the user enter before the application actually reads the input. *pathname* must refer to a character special file for a terminal.

_PC_NAME_MAX

Represents NAME_MAX, the maximum number of characters in a file name (not including any terminating NULL at the end if the file name is stored as a string). This symbol refers only to the file name itself, that is, the last component of the file's path name. pathconf() returns the maximum length of file names.

_PC_PATH_MAX

Represents PATH_MAX, the maximum number of characters in a complete path name (not including any terminating NULL at the end if the path name is stored as a string). pathconf() returns the maximum length of a relative path name.

_PC_PIPE_BUF

Represents PIPE_BUF, the maximum number of bytes that can be written “atomically” to a pipe. If more than this number of bytes is written to a pipe, the operation may take more than one physical write operation and physical read operation to read the data on the other end of the pipe. If *pathname* is a FIFO special file, pathconf() returns the value for the file itself. If *pathname* is a directory, pathconf() returns the value for any FIFOs that exist or that can be created under the directory. If *pathname* is any other kind of file, an errno of EINVAL will be returned, indicating an invalid path name was specified.

_PC_CHOWN_RESTRICTED

Represents _POSIX_CHOWN_RESTRICTED defined in the unistd.h header file, and restricts use of chown() to a process with appropriate privileges. It also changes the group ID of a file to the effective group ID of the process or to one of its supplementary group IDs. If *pathname* is a directory, pathconf() returns the value for any kind of file under the directory, but not for subdirectories of the directory.

_PC_NO_TRUNC

Represents _POSIX_NO_TRUNC defined in the unistd.h header file, and generates an error if a file name is longer than NAME_MAX. If *pathname* refers to a directory, the value returned by pathconf() applies to all files under that directory.

_PC_VDISABLE

Represents _POSIX_VDISABLE defined in the unistd.h header file. This symbol indicates that terminal special characters can be disabled using this character value, if it is defined; see the callable service tcsetattr() for details. *pathname* must refer to a character special file for a terminal.

_PC_ACL

Returns 1 if an access control mechanism is supported by the security product.

_PC_ACL_ENTRIES_MAX

Returns the maximum number of ACL entries in an ACL for a file or directory that supports ACLs.

Returned value

If successful, pathconf() return the value of the variable requested in *varcode*.

If unsuccessful, pathconf() returns -1. If a particular variable has no limit, such as PATH_MAX, pathconf() returns -1 but does not change errno.

If pathconf() cannot determine an appropriate value, it sets errno to one of the following values:

Error Code**Description****EACCES**

The process does not have search permission on some component of the *pathname*.

EINVAL

varcode is not a valid variable code, or the given variable cannot be associated with the specified file.

- If *varcode* refers to MAX_CANON, MAX_INPUT, or _POSIX_VDISABLE, and *pathname* does not refer to a character special file, pathconf() returns -1 and sets errno to EINVAL.
- If *varcode* refers to NAME_MAX, PATH_MAX, or POSIX_NO_TRUNC, and *pathname* does not refer to a directory, pathconf() returns the requested information.

- If *varcode* refers to PC_PIPE_BUF and *pathname* refers to a pipe or a FIFO, the value returned applies to the referenced object itself. If *pathname* refers to a directory, the value returned applies to any FIFOs that exist or can be created within the directory. If *pathname* refers to any other type of file, the function sets *errno* to EINVAL.

ELOOP

A loop exists in symbolic links. This error is issued if more than POSIX_SYMLINKS symbolic links are detected in the resolution of *pathname*.

ENAMETOOLONG

pathname is longer than PATH_MAX characters, or some component of *pathname* is longer than NAME_MAX while _POSIX_NO_TRUNC is in effect.

For symbolic links, the length of the path name string substituted for a symbolic link exceeds PATH_MAX.

ENOENT

There is no file named *pathname*, or the *pathname* argument is an empty string.

ENOTDIR

Some component of the *pathname* is not a directory.

Example**CELEBP01**

```
/* CELEBP01

   This example determines the maximum number of characters in a file name.

*/
#define _POSIX_SOURCE
#include <errno.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
    long result;

    errno = 0;
    puts("examining NAME_MAX limit for root filesystem");
    if ((result = pathconf("/", _PC_NAME_MAX)) == -1)
        if (errno == 0)
            puts("There is no limit to NAME_MAX.");
        else perror("pathconf() error");
    else
        printf("NAME_MAX is %ld\n", result);
}
```

Output:

```
examining NAME_MAX limit for root file system
NAME_MAX is 255
```

pause() — Suspend a process pending a signal

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 POSIX.4a XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

int pause(void);
```

General description

Suspends execution of the calling thread. The thread does not resume execution until a signal is delivered, executing a signal handler or ending the thread. Some signals can be blocked by the process's *thread*. See [“sigprocmask\(\) — Examine or change a thread”](#) on page 1643 for details.

If an incoming unblocked signal ends the thread, `pause()` never returns to the caller. If an incoming signal is handled by a signal handler, `pause()` returns after the signal handler returns.

Returned value

If `pause()` returns, it always returns -1 and sets `errno` to `EINTR`, indicating that a signal was received and handled successfully.

Example

CELEBP02

```
/* CELEBP02

   This example suspends execution and determines the
   current time.

*/
#define _POSIX_SOURCE
#include <unistd.h>
#include <signal.h>
#include <stdio.h>
#include <time.h>

void catcher(int signum) {
    puts("inside catcher...");
}

void timestamp() {
    time_t t;
    time(&t);
    printf("the time is %s", ctime(&t));
}

main() {
    struct sigaction sigact;

    sigemptyset(&sigact.sa_mask);
    sigact.sa_flags = 0;
    sigact.sa_handler = catcher;
    sigaction(SIGALRM, &sigact, NULL);
```

```

alarm(10);
printf("before pause... ");
timestamp();
pause();
printf("after pause... ");
timestamp();
}

```

Output:

```

before pause... the time is Fri Jun 16 09:42:29 2006
inside catcher...

after pause... the time is Fri Jun 16 09:42:39 2006

```

pclose() — Close a pipe stream to or from a process

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```

#define _XOPEN_SOURCE
#include <stdio.h>

int pclose(FILE *stream);

```

General description

The `pclose()` function closes a stream that was opened by `popen()`, waits for the command specified as an argument in `popen()` to terminate, and returns the status of the process that was running the shell command. However, if a call caused the termination status to be unavailable to `pclose()`, then `pclose()` returns `-1` with `errno` set to `ECHILD` to report this situation; this can happen if the application calls one of the following functions:

- `wait()`
- `waitid()`
- `waitpid()` with a *pid* argument less than or equal to the process ID of the shell command

perror

- any other function that could do one of the above

In any case, `pclose()` will not return before the child process created by `popen()` has terminated.

If the shell command cannot be executed, the child termination status returned by `pclose()` will be as if the shell command terminated using `exit(127)` or `_exit(127)`.

The `pclose()` function will not affect the termination status of any child of the calling process other than the one created by `popen()` for the associated stream.

If the argument *stream* to `pclose()` is not a pointer to a stream created by `popen()`, the termination status returned will be -1.

Threading Behavior: The `pclose()` function can be executed from any thread within the parent process.

Returned value

If successful, `pclose()` returns the termination status of the shell command.

If unsuccessful, `pclose()` returns -1 and sets `errno` to one of the following values:

Error Code Description

ECHILD

The status of the child process could not be obtained.

Related information

- [“stdio.h — Standard input and output” on page 63](#)
- [“popen\(\) — Initiate a pipe stream to or from a process” on page 1200](#)
- [“waitpid\(\) — Wait for a specific child process to end” on page 1981](#)

perror() — Print error message

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```
#include <stdio.h>

void perror(const char *string);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

void perror_unlocked(const char *string);
```

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdio.h>
```

```
void perror(const char *string);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <stdio.h>

void perror(const char *string);
```

General description

Prints an error message to `stderr`. If *string* is not NULL and it does not point to a NULL character, the *string* pointed to by *string* is printed to the standard error stream, followed by a colon and a space. The message associated with the value in `errno` is then printed followed with the `errno2` value in parenthesis and a newline character. The content of the message is the same as the content of a string returned by `strerror()` with the argument `errno`.

The `perror()` string shown as: EDC5121I Invalid argument. (`errno2=0x0C0F8402`).

To produce accurate results, you should ensure that `perror()` is called immediately after a library function returns with an error; otherwise, subsequent calls may alter the `errno` value.

If the error is associated with the `stderr` file, a call to `perror()` is not valid.

There is an environment variable `_EDC_ADD_ERRNO2`, which when set to 0, will remove the append of the current `errno2` value at the end of the `perror()` string shown.

The `perror()` function will not change the orientation of the `stderr` stream.

`perror_unlocked()` is functionally equivalent to `perror()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

`perror()` returns no values.

Example

CELEBP03

```
/* CELEBP03

This example tries to open a stream.
If the fopen() function fails, the example prints a message and ends
the program.

*/
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    FILE *fh;

    if ((fh = fopen("myfile.dat", "r")) == NULL)
    {
        perror("Could not open data file");
        abort();
    }
}
```

The following example tries to open a stream socket. If the socket fails, the example prints a message and ends the program.

```
#include <stdio.h>
#include <stdlib.h>
```

__pid_affinity

```
#include <sys/socket>

int main(void)
{
    int s;

    if ((s = socket (AF_INET,SOCK_STREAM,0)) <0)
    {
        perror("Could not open socket");
        exit(-1);
    }
}
```

__pid_affinity() — Add or delete process affinity

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | OS/390 V2R6 |

Format

```
#define _OPEN_SYS
#include <unistd.h>

int __pid_affinity(int    function_code,
                  pid_t   target_pid,
                  pid_t   signal_pid,
                  int      signal);
```

General description

The `__pid_affinity()` function adds or deletes an entry in a process's affinity list. When a process terminates, each process in its affinity list is notified (sent a signal) of the termination. The `__pid_affinity()` function provides the ability to dynamically create or break an association between two processes that is similar to the notification mechanism between parent and child processes without the processes being related.

The *function_code* can be set to one of the following symbolics, as defined in the `unistd.h` header file:

__PAF_ADD_PID

Add the process and signal specified by *signal_pid* and *signal* to the affinity list of the process specified by *target_pid*.

__PAF_DELETE_PID

Delete the process and signal specified by *signal_pid* and *signal* from the affinity list of the process specified by *target_pid*.

The *target_pid* identifies the process whose affinity list will be altered.

The *signal_pid* identifies the process that upon termination of the *target_pid* will be sent *signal* signal.

The *signal* identifies the signal that the *signal_pid* process will receive when the *target_pid* process terminates.

Usage notes

1. Either the *Target_Pid* or *Signal_Pid* must contain the PID of the caller's process.

2. The __pid affinity service is limited to adding and deleting entries in the caller's affinity list, or adding and deleting entries that contain the caller's PID (*Signal_Pid*) in other processes affinity list.
3. When the PAF_DELETE_PID# function is specified the *Signal* is ignored. It is not validated and may contain any value.
4. An entry is only deleted (PAF_DELETE_PID# specified) when the *Signal_Pid* matches an entry in the *Target_Pid* process's affinity list.
5. Entries with duplicate PIDs are not allowed in an affinity list. If adding an entry (PAF_ADD_PID# specified) and an entry with a PID that matches the *Signal_Pid* is found the entry is reused. This may result in the loss of a specific signal.
6. No permission is required when adding the caller's PID to another process's affinity list. All processes have permission to send a signal to themselves (raise()).
7. The PIDs specified by the *Target_Pid* and *Signal_Pid* parameters must be greater than 1. Specifying a PID equal to or less than 1 will result in a error.

Returned value

If successful, __pid_affinity() returns 0.

If unsuccessful, __pid_affinity() returns -1 and sets errno to one of the following values:

Error Code

Description

EINVAL

One or more of the following conditions were detected:

- The value specified by *Function_code* is not supported.
- The value specified by *Signal* is not a supported signal.
- *Target_Pid* does not contain a value greater than 1.
- *Signal_Pid* does not contain a value greater than 1.
- The *Signal_Pid* or *Target_Pid* does not specify the caller PID.

EMVSERR

A MVS environmental or internal error has occurred.

EMVSSAF2ERR

An internal SAF/RACF error has occurred.

EPERM

The caller does not have permission to send the signal to the *Signal_Pid* process.

ESRCH

One or more of the following conditions were detected:

- No process corresponding to *Target_Pid* was found.
- No process corresponding to *Signal_Pid* was found.

Related information

pipe() — Create an unnamed pipe

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

int pipe(int fdinfo[2]);
```

General description

Creates a *pipe*, an I/O channel that a process can use to communicate with another process (in the same process or another process), or in some cases with itself. Data is written into one end of the pipe and read from the other. *fdinfo*[2] points to a memory area where *pipe*() can store two file descriptors. *pipe*() stores a file descriptor for the input end of the pipe in *fdinfo*[1], and stores a file descriptor for the output end of the pipe in *fdinfo*[0]. Thus, processes can read from *fdinfo*[0] and write to *fdinfo*[1]. Data written to *fdinfo*[1] is read from *fdinfo*[0] on a first-in-first-out (FIFO) basis.

When *pipe*() creates a pipe, the *O_NONBLOCK* and *FD_CLOEXEC* flags are turned off on both ends of the pipe. You can turn these flags on with *fcntl*(). See “[fcntl\(\) — Control open file descriptors](#)” on page 483 for details.

If *pipe*() successfully creates a pipe, it updates the access, change, and modification times for the pipe.

It is unspecified whether *fdinfo*[0] is also open for writing and whether *fdinfo*[1] is also open for reading. z/OS UNIX pipes are not STREAMS-based.

Returned value

If successful, *pipe*() returns 0.

If unsuccessful, *pipe*() returns -1 and sets *errno* to one of the following values:

Error Code

Description

EMFILE

Opening the pipe would exceed the limit on the number of file descriptors the process can have open. This limit is given by *OPEN_MAX*, defined in the *limits.h* header file.

ENFILE

Opening the pipe would exceed the number of files that the system can have open simultaneously.

ENOMEM

Opening the pipe requires more space than is available.

Example

CELEBP04

```
/* CELEBP04
   This example creates an I/O channel.
```

The output shows the data written into one end and read from the other.

```

*/
#define _POSIX_SOURCE
#include <unistd.h>
#include <stdio.h>

void reverse(char *s) {
    char *first, *last, temp;

    first = s;
    last = s+strlen(s)-1;
    while (first != last) {
        temp = *first;
        *(first++) = *last;
        *(last--) = temp;
    }
}

main() {
    char original[]="This is the original string";
    char buf[80];
    int p1[2], p2[2];

    if (pipe(p1) != 0)
        perror("first pipe() failed");
    else if (pipe(p2) != 0)
        perror("second pipe() failed");
    else if (fork() == 0) {
        close(p1[1]);
        close(p2[0]);
        if (read(p1[0], buf, sizeof(buf)) == -1)
            perror("read() error in parent");
        else {
            reverse(buf);
            if (write(p2[1], buf, strlen(buf)+1) == -1)
                perror("write() error in child");
        }
        exit(0);
    }
    else {
        close(p1[0]);
        close(p2[1]);
        printf("parent is writing '%s' to pipe 1\n", original);
        if (write(p1[1], original, strlen(original)+1) == -1)
            perror("write() error in parent");
        else if (read(p2[0], buf, sizeof(buf)) == -1)
            perror("read() error in parent");
        else printf("parent read '%s' from pipe 2\n", buf);
    }
}

```

Output:

```

parent is writing 'This is the original string' to pipe 1
parent read 'gnirts lanigiro eht si sihT' from pipe 2

```

pipe2() – Create a pipe

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#define _POSIX_SOURCE          /* Definition of 0_* constants */
#include <fcntl.h>              /* Definition of 0_* constants */
#include <unistd.h>

int pipe2(int pipefd[2], int flags);
```

General description

`pipe2()` creates a pipe, which is a unidirectional data channel that can be used for interprocess communication. The array *pipefd* is used to return two file descriptors that refer to the ends of the pipe. *pipefd*[0] refers to the read end of the pipe. *pipefd*[1] refers to the write end of the pipe. Data that is written to the write end of the pipe is buffered by the kernel until it is read from the read end of the pipe.

If *flags* is 0, `pipe2()` is the same as `pipe()`. The following values can be bitwise ORed in *flags* to obtain different behavior:

O_CLOEXEC

Set the close-on-exec (FD_CLOEXEC) flag on the two new file descriptors.

O_DIRECT

Create a pipe that performs I/O in "packet" mode. Each write to the pipe is dealt with as a separate packet. Read one packet at a time from the pipe.

Notes:

- The maximum number of bytes that can be written atomically when writing to a pipe can be determined by using `pathconf()`.
- If a read specifies a buffer size that is smaller than the next packet, the requested number of bytes are read, and the excess bytes in the packet are discarded. Specifying a buffer size of PIPE_BUF are sufficient to read the largest possible packets.
- Zero-length packets are not supported. (A read that specifies a buffer size of zero is a no-op, and returns 0.)

O_NONBLOCK

Set the O_NONBLOCK file status flag on the open file descriptions that are referred to by the new file descriptors. Using this flag saves extra calls to `fcntl()` to achieve the same result.

Returned value

If successful, `pipe2()` returns 0.

If unsuccessful, `pipe2()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EFAULT

pipefd is invalid.

EINVAL

Invalid value in *flags*.

EMFILE

The process reaches the maximum number of file descriptors that it can have open.

ENFILE

The maximum number of file descriptors that can be open is reached.

pivot_root() — Change root mount

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <unistd.h>

int pivot_root(const char *new_root, const char *put_old);
```

General description

`pivot_root()` changes the root mount in the mount namespace of the calling process. It moves the root mount to the directory `put_old` and makes `new_root` the new root mount. The caller must be an authorized program or must run for a user with appropriate privileges.

`pivot_root()` changes the root directory and the current working directory of each process or thread in the same mount namespace to `new_root` if they point to the old root directory. `pivot_root()` does not change the caller's current working directory (unless it is on the old root directory), and thus it must be followed by a `chdir("/")` call.

Restriction:

- `new_root` and `put_old` must be directories.
- `new_root` and `put_old` must not be on the same mount as the current root.
- `put_old` must be at or underneath `new_root`; that is, adding some nonnegative number of `"/.."` prefixes to the path name that is pointed to by `put_old` must yield the same directory as `new_root`.
- `new_root` must be a path to a mount point but can't be `"/"`. A path that is not a mount point can be converted into one by bind mounting the path onto itself.
- The current root directory must be a mount point.

Returned value

If successful, `pivot_root()` returns 0.

If unsuccessful, `pivot_root()` returns -1 and sets `errno` to one of the following values:

Error Code
Description

EBUSY
new_root or put_old is on the current root mount.

EINVAL

- new_root is not a mount point.
- put_old is not at or underneath new_root.
- The current root directory is not a mount point.

ENOTDIR
new_root or put_old is not a directory.

EPERM
The calling process has no authority.

__poe() — Port of entry information

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R5 |

Format

```
#define _OPEN_SYS
#include <sys/socket.h>

int __poe(__poe_t *poe);
```

General description

The __poe() function allows the application to specify what port of entry (POE) information the system should use in determining various levels of permission checking. The attributes for the port of entry are used by services that perform user ID security authorization (examples are: setuid(), __login(), __passwd()).

Argument poe is the address of a __poe_t structure which is used to control the port of entry operation. The __poe_t structure is defined in <sys/socket.h>. For proper behavior the user should ensure that this structure has been initialized to zeros before it is populated. The elements of the __poe_t structure are as follows:

__poe_options

Port of entry options. There are scope and action options. The combination defines the behavior of the function.

The scope option values are:

_POE_SCOPE_THREAD
 _POE_SCOPE_PROCESS
 _POE_SCOPE_SOCKET

Scope options _POE_SCOPE_THREAD, _POE_SCOPE_PROCESS, and _POE_SCOPE_SOCKET are mutually exclusive. One must be specified.

Note: As of z/OS V1R12, scope options _POE_THREAD and _POE_PROCESS have been deprecated and replaced with new names. The old names remain for compatibility and must be used when the target operating system release is prior to z/OS V1R12.

The action option values are:

_POE_ACTION_READ
 _POE_ACTION_WRITE
 _POE_ACTION_SETGET

Action options _POE_ACTION_READ, _POE_ACTION_WRITE, and _POE_ACTION_SETGET are mutually exclusive. These are optional.

__poe_entry_type

Port of entry type. The types are:

_POE_SOCKET

Entry is a file descriptor for a socket.

_POE_FILE

Entry is a file descriptor for a non-socket file. Supported file types are character special, FIFO, regular, symbolic link, and directory.

__poe_entry_len

Port of entry length. The lengths are:

_POE_SOCKET_LEN

Length of a file descriptor for a socket.

_POE_FILE_LEN

Length of a file descriptor for a non-socket file.

__poe_entry_ptr

Address of port of entry.

__poe_poeattr

Port of entry attributes. This element is an IocPoeAttr structure as defined in <termios.h>.

The following table summarizes the port of entry operation according to scope and action:

| Options | | POE Data | | Description |
|---------|--------|-------------------------------|--|--|
| Scope | Action | Source | Destination | |
| Socket | Read | Socket or file descriptor | POE data in struct __poe_cb_s | POE data is extracted from the file/socket descriptor supplied by the caller and returned to the caller via the struct __poe_cb_s. |
| | Write | n/a | n/a | Request fails with EINVAL |
| | SetGet | n/a | n/a | Request fails with EINVAL |
| | None | n/a | n/a | Request fails with EINVAL |
| Process | Read | Process level (OAPB) | POE data in struct __poe_cb_s | Process level POE data is copied from the OAPB and is returned to the caller via the struct __poe_cb_s. |
| | Write | POE data in struct __poe_cb_s | Process level (OAPB) | POE data received from the caller via the struct __poe_cb_s is copied to the process level POE data in the OAPB. |
| | SetGet | Socket or file descriptor | Process level (OAPB) and POE data in struct __poe_cb_s | POE data is extracted from the file/socket descriptor supplied by the caller. The data is copied to the process level POE data in the OAPB and returned to the caller via the struct __poe_cb_s. |
| | None | Socket or file descriptor | Process level (OAPB) | POE data is extracted from the file/socket descriptor supplied by the caller and copied to the process level POE data in the OAPB. |

| | None | Socket or file descriptor | Thread level (OTCB) | POE data is extracted from the file/socket descriptor supplied by the caller and copied to the thread level POE data in the OTCB. |

The ability to register port of entry is a privileged operation. An installation has two ways of allowing an application to use this service:

1. For the highest level of security, the installation defines the BPX.POE FACILITY class profile. For an application to use this service the user ID it runs under must be given read access to this profile. See [z/OS UNIX System Services Planning](#) for more information on setting up this profile.
2. For a lower security arrangement, you can assign the user ID under which the application is run a UID of 0 so that it operates as a superuser.

For more detailed information on the usage of this function see [z/OS Planning for Multilevel Security and the Common Criteria](#) and [z/OS UNIX System Services Programming: Assembler Callable Services Reference](#).

Returned value

If successful, __poe() returns 0.

If unsuccessful, __poe() returns -1 and sets errno to one of the following values:

EINVAL

The __poe_cb_t structure is not correct. Use __errno2() for more details.

EPERM

The calling process does not have the appropriate privileges to read or write the POE attributes.

EFAULT

A bad address was received. Either the *poeebp* parameter or the *__poe_entry_ptr* field in the *__poeb_t* structure is not a valid address.

poll() — Monitor activity on file descriptors and message queues

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format**Sockets:**

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <poll.h>

int poll(struct pollfd fds[], nfds_t nmsgsfds, int timeout);
```

Message queues and sockets:

```
#define _XOPEN_SOURCE_EXTENDED 1
#define _OPEN_MSGQ_EXT
#include <sys/types.h>
#include <sys/time.h>
#include <sys/msg.h>
#include <poll.h>

int poll(void *listptr, nmsgsfds_t nmsgsfds, int timeout);
```

_OPEN_MSGQ_EXT must be defined if message queues are to be monitored.

General description

The *poll()* function provides applications with a mechanism for multiplexing input/output over the following set of file descriptors:

- regular files
- terminal and pseudoterminal devices
- STREAMS-based files
- sockets
- message queues.
- FIFOs
- pipes

For each member of the array(s) pointed to by *listptr*, *poll()* examines the given file descriptor or message queue for the event(s) specified in the member. The number of *pollmsg* structures and the number

of pollfd structures in the arrays are specified by *nmsgsfds*. The poll() function identifies those file descriptors on which an application can read or write data, or on which an error event has occurred.

listptr

A pointer to an array of pollfd structures, pollmsg structures, or to a pollist structure. Each structure specifies a file descriptor or message queue identifier and the events of interest for this file or message queue. The type of parameter to pass depends on whether you want to monitor file and socket descriptors, message queue identifiers, or both. To monitor socket descriptors only, set the high-order halfword of *nmsgsfds* to 0, the low-order halfword to the number of pollfd structures to be provided, and pass a pointer to an array of pollfd structures. To monitor message queues only, set the low-order halfword of *nmsgsfds* to 0, the high-order halfword to the number of pollmsg structures to be provided, and pass a pointer to an array of pollmsg structures. To monitor both, set *nmsgsfds* as described below, and pass a pointer to a pollist structure. If a pollist structure is to be used, a structure similar to the following should be defined in a user program. The pollfd structure must precede the pollmsg structure.

```
struct pollist {
    struct pollfd fds[3];
    struct pollmsg msgids[2];
} list;
```

nmsgsfds

The number of pollmsg structures and the number of pollfd structures pointed to by *listptr*.

This parameter is divided into two parts. The first half (the high-order 16 bits) gives the number of pollmsg structures containing message queue identifiers. This number must not exceed the value 32767. The second half (the low-order 16 bits) gives the number of pollfd structures containing file descriptors to check. If either half of the *nmsgsfds* parameter is equal to a value of 0, the corresponding pollmsg structures or pollfd structures is assumed not to be present.

timeout

The amount of time, in milliseconds, to wait for an event to occur.

If none of the defined events have occurred on any selected descriptor, poll() waits at least *timeout* milliseconds for an event to occur on any of the selected descriptors. If the value of *timeout* is 0, poll() returns immediately. If the value of *timeout* is -1, poll() blocks until a requested event occurs or until the call is interrupted.

The above processing also applies to message queues.

Each pollfd or pollmsg structure contains the following fields:

- fd/msgid - open file descriptor or message queue identifier
- events - requested events
- revents - returned events

The events and revents fields are bitmasks constructed by OR-ing a combination of the following event flags:

POLLERR

An error or exceptional condition has occurred. This flag is only valid in the revents bitmask; it is ignored in the events bitmask.

POLLHUP

The device has been disconnected. This event and POLLOUT are mutually exclusive, a stream can never be writable if a hang-up has occurred. However, this event and POLLIN, POLLRDNORM, POLLRDBAND or POLLPRI are not mutually exclusive. This flag is only valid in the revents bitmask. It is ignored in the events member.

POLLIN

Same as POLLRDNORM

POLLNVAL

The specified fd/msgid value is invalid. This flag is only valid in the revents bitmask; it is ignored in the events bitmask.

POLLOUT

Same as POLLWRNORM

POLLPRI

Out-of-band data may be received without blocking.

POLLRDBAND

Data from a nonzero priority band may be read without blocking. For STREAMS, this flag is set in revents even if the message is of zero length.

POLLRDNORM

Normal data may be read without blocking.

POLLWRBAND

Priority data (priority band greater than 0) may be written.

POLLWRNORM

Normal data may be written without blocking.

Note: Poll bits are supported as follows.

Regular Files

Always poll() true for reading and writing. This means that all poll() read and write bits are supported. They will never return with POLLERR or POLLHUP.

FIFOs / PIPEs

Do not have the concept of out-of-band data or priority band data. They support POLLIN, POLLRDNORM, POLLOUT, and POLLWRNORM. They ignore POLLPRI, POLLRDBAND, and POLLWRBAND. They never return POLLERR.

TTYs / OCS

Same support as FIFOs and PIPEs, except that TTYs may return POLLERR.

Sockets

Have the concept of out-of-band data. They support POLLIN, POLLRDNORM, POLLOUT, POLLWRNORM, and POLLPRI for out-of-band data. They ignore POLLRDBAND and POLLWRBAND. They may return POLLERR, and never return POLLHUP.

If the value of fd/msgid is less than 0, events is ignored and revents is set to 0 in that entry on return from poll().

In each pollfd structure, poll() clears the revents member except that where the application requested a report on a condition by setting one of the bits of events listed above, poll() sets the corresponding bit in revents if the requested condition is true. In addition, poll() sets the **POLLERR** flag in revents if the condition is true, even if the application did not set the corresponding bit in events.

The poll() function is not affected by the **O_NONBLOCK** flag.

A file descriptor for a socket that is listening for connections will indicate that it is ready for reading, once connections are available. A file descriptor for a socket that is connecting asynchronously will indicate that it is ready for writing, once a connection has been established.

The following macros are provided to manipulate the *nmsgsfds* parameter and the return value from poll():

Macro**Description****_SET_FDS_MSGS(*nmsgsfds*, *nmsgs*, *nfds*)**

Sets the high-order halfword of *nmsgsfds* to *nmsgs*, and sets the low-order halfword of *nmsgsfds* to *nfds*.

_NFDS(*n*)

If the return value *n* from poll() is nonnegative, returns the number of socket descriptors that meet the read, write, and exception criteria.

_NMSGs(*n*)

If the return value *n* from poll() is nonnegative, returns the number of message queues that meet the read, write, and exception criteria.

Returned value

If successful, `poll()` returns a nonnegative value.

A positive value indicates the total number of events that were found to be ready among the message queues and the total number of events that were found to be ready among the file descriptors. The return value is similar to `nmsgsfds` in that the high-order 16 bits of the return value give the number associated with message queues, and the low-order 16 bits give the number associated with file descriptors. Should the number associated with message queues be greater than 32767, only 32767 will be reported. This is to ensure that the return value does not appear to be negative. Should the number associated with file descriptors be greater than 65535, only 65535 will be reported.

If the call timed out and no file descriptors have been selected, `poll()` returns 0.

If unsuccessful, `poll()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EAGAIN

The allocation of internal data structures failed, but a subsequent request may succeed.

EINTR

A signal was caught during `poll()`.

EINVAL

One of the parameters specified a value that was not correct. Consult the reason code to determine the exact reason the error occurred. The following reason codes can accompany this return code.

- JRWAITFOREVER
- JRINVALIDDNFDS
- JRNOFDSTOOMANYQIDS

EIO

One of the descriptors in the select mask has become inoperative and it is being repeatedly included in a select even though other operations against this descriptor have been failing with EIO. A socket descriptor, for example, can become inoperative if TCP/IP is shut down. A failure from select can not tell you which descriptor has failed so generally select will succeed and these descriptors will be reported to you as being ready for whatever event they were being selected for. Subsequently when the descriptor is used on a receive or other operation you will receive the EIO failure and can react to the problem with the individual descriptor. In general you would `close()` the descriptor and remove it from the next select mask. If the individual descriptor's failing return code is ignored though and an inoperative descriptor is repeatedly selected on and used, even though each time it is used that call fails with EIO, eventually the select call itself will fail with EIO.

popen() — Initiate a pipe stream to or from a process

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _XOPEN_SOURCE
#include <stdio.h>

FILE *popen(const char *command, const char *mode);
```

General description

The `popen()` function executes the command specified by the string *command*. It creates a pipe between the calling program and the executed command, and returns a pointer to a stream that can be used to either read from or write to the pipe.

The environment of the executed command will be as if a child process were created within the `popen()` call using `fork()`, and the child invoked the `sh` utility using the call:

```
exec1("/bin/sh", "sh", "-c", command, (char *)0);
```

The `popen()` function ensures that any streams from previous `popen()` calls that remain open in the parent process are closed in the child process.

The *mode* argument to `popen()` is a string that specifies I/O mode:

1. If *mode* is **r**, file descriptor **STDOUT_FILENO** will be the writable end of the pipe when the child process is started. The file descriptor *fileno(stream)* in the calling process, where *stream* is the stream pointer returned by `popen()`, will be the readable end of the pipe.
2. If *mode* is **w**, file descriptor **STDIN_FILENO** will be the readable end of the pipe when the child process is started. The file descriptor *fileno(stream)* in the calling process, where *stream* is the stream pointer returned by `popen()`, will be the writable end of the pipe.
3. If *mode* is any other value, a NULL pointer is returned and `errno` is set to `EINVAL`.

After `popen()`, both the parent and the child process will be capable of executing independently before either terminates.

Because open files are shared, a mode *r* command can be used as an input filter and a mode *w* command as an output filter.

Buffered reading before opening an input filter (that is, before `popen()`) may leave the standard input of that filter mispositioned. Similar problems with an output filter may be prevented by buffer flushing with `fflush()`.

A stream opened with `popen()` should be closed by `pclose()`.

The behavior of `popen()` is specified for values of *mode* of *r* and *w*. *mode* values of *rb* and *wb* are supported but are not portable.

If the shell command cannot be executed, the child termination status returned by `pclose()` will be as if the shell command terminated using `exit(127)` or `_exit(127)`.

If the application calls `waitpid()` with a *pid* argument greater than 0, and it still has a stream that was created with `popen()` open, it must ensure that *pid* does not refer to the process started by `popen()`

The stream returned by `popen()` will be designated as byte-oriented.

Special behavior for file tagging and conversion: When the FILETAG(AUTOTAG) runtime option is specified, the pipe opened for communication between the parent and child process by `popen()` will be tagged with the writer's program CCSID upon first I/O. For example, if `popen(some_command, "r")` were specified, then the stream returned by the `popen()` would be tagged in the child process' program CCSID.

Returned value

If successful, `popen()` returns a pointer to an open stream that can be used to read or write to a pipe.

If unsuccessful, `popen()` returns a NULL pointer and sets `errno` to one of the following values:

Error Code

Description

EINVAL

The *mode* argument is invalid.

`popen()` may also set `errno` values as described by `spawn()`, `fork()`, or `pipe()`.

posix_memalign() — Reserve aligned storage block

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|--------------|
| Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _UNIX03_SOURCE
#include <stdlib.h>

int posix_memalign(void **memptr, size_t alignment, size_t size);
```

General description

The `posix_memalign()` function reserves a block of storage and returns a pointer to the reserved storage in *memptr*. The alignment of the storage is specified by *alignment*, whose value must be a

power of two and a multiple of `sizeof(void *)`. The size of the storage is specified by *size*. If successful completion, the value pointed to by *memptr* must be a multiple of *alignment*.

This function is supported only in a POSIX program.

Special behavior for C++ : The C++ keywords `new` and `delete` are not interoperable with `aligned_alloc()`, `calloc()`, `free()`, `malloc()`, `posix_memalign()`, or `realloc()`.

Returned value

If successful, `posix_memalign()` returns 0; otherwise, it returns an error number and the contents of *memptr* must either be left unmodified or be set to a null pointer.

If *size* was specified to 0, `posix_memalign()` returns zero and sets *memptr* to a null pointer.

Error Code

Description

EINVAL

The value of the alignment parameter is not a power of two or a multiple of `sizeof(void *)`.

ENOMEM

There is insufficient memory available with the requested alignment.

Example

```
#define _UNIX03_SOURCE
#include <stdio.h>
#include <stdlib.h>
#include <errno.h>

int main(void)
{
    void *p;
    size_t alignment,size;
    int ret;

    ret = 0;
    alignment = 32;
    size = 64;
    ret = posix_memalign(&p,alignment,size);
    if(!ret){
        printf("Address of aligned storage is %p\n",p);
        return 0;
    }
    else{
        printf("posix_memalign() failed with errno = %d\n",errno);
        return -1;
    }
}
```

Output:

```
Address of aligned storage is 22C7ED20
```

posix_openpt() — Open a pseudo-terminal device

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|--------------|
| Single UNIX Specification, Version 3 | both | z/OS V1.9 |

Format

```
#define _XOPEN_SOURCE 600
#include <stdlib.h>
#include <fcntl.h>

int posix_openpt(int oflag);
```

General description

The `posix_openpt()` function establishes a connection between a main device for a pseudo-terminal and a file descriptor. The file descriptor is used by other I/O functions that refer to that pseudo-terminal.

The file status flags and file access modes of the open file description are set according to the value of `oflag`.

Values for `oflag` are constructed by a bitwise-inclusive OR of flags from the following list, defined in `<fcntl.h>`:

O_RDWR

Open for reading and writing.

O_NOCTTY

If set `posix_openpt()` will not cause the terminal device to become the controlling terminal for the process.

The behavior of other values for the `oflag` argument is unspecified.

Argument

Description

oflag

The value of the file status flags and file access modes of the open file description.

Returned value

Upon successful completion, the `posix_openpt()` function opens a main pseudo-terminal device and returns a non-negative integer representing the lowest numbered unused file descriptor. Otherwise, -1 is returned and `errno` set to indicate the error.

Error Code

Description

EMFILE

{OPEN_MAX} file descriptors are currently open in the calling process.

ENFILE

The maximum allowable number of files is currently open in the system.

EINVAL

The value of `oflag` is not valid.

EAGAIN

Out of pseudo-terminal resources.

Example

CELEBP71

```
/* CELEBP71

This example demonstrates how to use posix_openpt() to open a
main psuedo-terminal device.

Expected output:
The main psuedo-terminal id is [first available descriptor]

*/
#define _XOPEN_SOURCE 600
#include <stdlib.h>
#include <fcntl.h>
#include <stdio.h>

void main() {
    int fd;

    fd = posix_openpt(O_RDWR | O_NOCTTY);
    if (fd == -1)
        perror("Error opening a terminal.\n");
    else
        printf("The main psuedo-terminal id is %d\n",fd);
}
```

pow(), powf(), powl() – Raise to power

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#include <math.h>

double pow(double x, double y);
double pow(double x, int y);           /* C++ only */
float pow(float x, int y);             /* C++ only */
float pow(float x, float y);           /* C++ only */
long double pow(long double x, int y); /* C++ only */
long double pow(long double x, long double y); /* C++ only */
float powf(float x, float y);
long double powl(long double x, long double y);
```

General description

The pow(), powf(), and powl() functions calculate the value of x to the power of y.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See “IEEE binary floating-point” on page 97 for more information about IEEE Binary Floating-Point.

Restriction: The powf() function does not support the _FP_MODE_VARIABLE feature test macro.

Returned value

If successful, the `pow()`, `powf()`, and `powl()` functions return the value of x to the power of y .

If y is 0, the function returns 1.

If x is negative and y is non-integral, the function sets `errno` to `EDOM` and returns `-HUGE_VAL`. If the correct value is outside the range of representable values, $\pm\text{HUGE_VAL}$ is returned according to the sign of the value, and the value of `ERANGE` is stored in `errno`.

Special behavior for IEEE: If x is negative or 0, then the y parameter must be an integer. If y is 0, the function returns 1.0 for all x parameters.

If an overflow occurs, the function returns `HUGE_VAL` and sets `errno` to `ERANGE`.

If both x and y are negative, the function returns `NaNQ` and sets `errno` to `EDOM`.

If x is 0 and y is negative, the function returns `HUGE_VAL` and does not modify `errno`, but `powf` sets `errno` to `ERANGE`.

Note: When environment variable `_EDC_SUSV3` is set to 2, and if x is 0 and y is negative, the function returns `-HUGE_VAL` and sets `errno` to `ERANGE`.

Example

CELEBP05

```
/* CELEBP05

   This example calculates the value of 2**3.

*/
#include <math.h>
#include <stdio.h>

int main(void)
{
    double x, y, z;

    x = 2.0;
    y = 3.0;
    z = pow(x,y);

    printf("%lf to the power of %lf is %lf\n", x, y, z);
}
```

Output:

```
2.000000 to the power of 3.000000 is 8.000000
```

[powd32\(\), powd64\(\), powd128\(\) — Raise to power](#)

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 powd32(_Decimal32 x, _Decimal32 y);
_Decimal64 powd64(_Decimal64 x, _Decimal64 y);
_Decimal128 powd128(_Decimal128 x, _Decimal128 y);

_Decimal32 pow(_Decimal32 x, _Decimal32 y); /* C++ only */
_Decimal64 pow(_Decimal64 x, _Decimal64 y); /* C++ only */
_Decimal128 pow(_Decimal128 x, _Decimal128 y); /* C++ only */
```

General description

The powd32(), powd64(), and powd128() functions calculate the value of x to the power of y .

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, the powd32(), powd64(), and powd128() functions return the value of x to the power of y .

If x is negative or 0, then the y parameter must be an integer. If y is 0, the function returns 1.0 for all x parameters.

If an overflow occurs, the function returns HUGE_VAL_D32, HUGE_VAL_D64, or HUGE_VAL_D128 and sets `errno` to `ERANGE`.

If x is negative and y is not an integer, the function returns NaNQ and sets `errno` to `EDOM`.

If x is 0 and y is negative, the function returns HUGE_VAL_D32, HUGE_VAL_D64, or HUGE_VAL_D128 but does not modify `errno`.

Example

```
/* CELEBP59

   This example illustrates the powd64() function
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal64 x, y, z;

    x = 2.0DD;
    y = 3.0DD;
    z = powd64(x, y);

    printf("%Df to the power of %Df is %Df\n", x, y, z);
}
```

Related information

__pow_i() — Raise to a power (R**I)

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | z/OS V1R7 |

Format

```
#include <math.h>

double __pow_i(double x, int y);
```

General description

The `__pow_i()` function calculates the value of x to the power of y and is a C interface to the Language Environment Math Service CEESDXPI. Information about the Language Environment math service CEESDXPI can be found in the following publications:

- [z/OS Language Environment Programming Guide](#)
- [z/OS Language Environment Programming Reference](#)
- [z/OS Language Environment Concepts Guide](#)

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------------------|-----|------|
| <code>__pow_i</code> | X | X |

Returned value

If successful, `__pow_i()` returns the value of x to the power of y .

| If... | Then... |
|------------------------------------|--|
| x is not equal to 0 and y is 0 | 1 is returned. |
| x is 0 and y is positive | 0 is returned. |
| x and y are 0 | 0 is returned and <code>errno</code> is set to <code>EDOM</code> . |
| x is 0 and y is negative | $\pm\text{HUGE_VAL}$ is returned and <code>errno</code> is set to <code>EDOM</code> . |
| x and y cause an overflow | <code>HUGE_VAL</code> is returned. |

Related information

__pow_ii() – Raise to a power (I**I)

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | z/OS V1R7 |

Format

```
#include <math.h>

int __pow_ii(int x, int y);
```

General description

The __pow_ii() function calculates the value of x to the power of y and is a C interface to the LE Math Service CEESIXPI. Information about the LE Math Service CEESIXPI can be found in the following publications:

- [z/OS Language Environment Programming Guide](#)
- [z/OS Language Environment Programming Reference](#)
- [z/OS Language Environment Concepts Guide](#)

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------|-----|------|
| __pow_ii | X | X |

Returned value

If successful, __pow_ii() returns the value of x to the power of y.

| If... | Then... |
|---|---|
| x is not equal to 0 and y is 0 | 1 is returned. |
| x is 0 and y is positive | 0 is returned. |
| x is 0 and y is negative | INT_MAX is returned and errno is set to EDOM. |
| x and y are 0 | 0 is returned and errno is set to EDOM. |
| x is 1 and y is negative | 1 is returned. |
| x is -1 and y is negative | ±1 is returned. |
| x is greater than 1 and y is negative | 0 is returned and errno is set to EDOM. |
| x is less than -1 and y is negative | 0 is returned and errno is set to EDOM. |
| The values of x and y cause an overflow and x is less than 0 or y is odd. | errno is set to ERANGE and the function returns INT_MIN |
| The values of x and y cause an overflow and x is greater than 0 or y is even. | errno is set to ERANGE and the function returns INT_MAX |

prctl() — Operate on a process or thread

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <sys/prctl.h>
```

```
int prctl(int option, unsigned long arg2, unsigned long arg3, unsigned long arg4, unsigned long arg5);
```

General description

`prctl()` manipulates various aspects of the behavior of a calling thread or process.

`prctl()` is called with a first argument that describes what to do (with values that are defined in `<sys/prctl.h>`), and further arguments that depend on the first one. The first argument can be:

PR_SET_CHILD_SUBREAPER

If `arg2` is nonzero, set the "child subreaper" attribute of the calling process; if `arg2` is zero, unset the attribute.

When a process becomes orphaned (that is, its immediate parent terminates), that process is reparented to the nearest living ancestor subreaper. Then, calls to `getppid()` in the orphaned process return the PID of the subreaper process, and when the orphan terminates, it is the subreaper process that receives a `SIGCHLD` signal. The setting of the "child subreaper" attribute is not inherited by the children that are created by `fork()` and `clone()`. The setting is preserved across `execve()`.

Establishing a subreaper process is useful in session management frameworks where a hierarchical group of processes is managed by a subreaper process, which needs to be informed when one of the processes (for example, a double-forked daemon) terminates (so that it can restart that process).

PR_GET_CHILD_SUBREAPER

Return the "child subreaper" setting of the caller in the location that is pointed to by `(int *) arg2`.

PR_SET_DUMPABLE

Set the state of the "dumpable" attribute, which determines whether core dumps are produced for the calling process upon delivery of a signal whose default behavior is to produce a core dump. `arg2` must be either 0 (process is not dumpable) or 1 (process is dumpable). Normally, the "dumpable" attribute is set to 1. However, it is reset to value 0 in the following circumstances:

- The process's effective user or group ID is changed.
- The process's file system user or group ID is changed.
- The process calls `execve()` to execute a set-user-ID or set-group-ID program, resulting in a change of either the effective user ID or the effective group ID.

As a security measure, the ownership is made `root:root` if the process's "dumpable" attribute is set to a value other than 1.

PR_GET_DUMPABLE

Return the current state of the calling process's dumpable attribute as the function result.

PR_SET_NAME

Set the name of the calling thread by using the value in the location that is pointed to by (char *) *arg2*. The name can be a null-terminated string with the max length of 16 characters. If the length of the string, including the terminating null byte, exceeds 16 bytes, the string is truncated.

PR_GET_NAME

Return the name of the calling thread in the buffer that is pointed to by (char *) *arg2*. The name can be a string with the max length of 16 characters. The returned string is null-terminated if it is shorter than that.

PR_SET_NO_NEW_PRIVS

Set the calling thread's no_new_privs attribute to the value in *arg2*. With no_new_privs set to 1, `execve()` promises not to grant privileges to do anything that cannot be done without the `execve()` call. Once set, the no_new_privs attribute cannot be unset. The setting of this attribute is inherited by the children that are created by `fork()` and `clone()` and preserved across `execve()`.

PR_GET_NO_NEW_PRIVS

Return the value of the no_new_privs attribute for the calling thread as the function result. A value of 0 indicates the regular `execve(2)` behavior. A value of 1 indicates `execve()` operates in the privilege-restricting mode.

PR_SET_PDEATHSIG

Set the parent-death signal of the calling process to *arg2* (0 to clear). This is the signal that the calling process gets when its parent dies.

Warning: The "parent" in this case is considered to be the thread that created this process. The signal is sent when that thread terminates (for example, by calling `pthread_exit()`), rather than after all of the threads in the parent process terminate. The parent-death signal is sent upon subsequent termination of the parent thread and also upon termination of each subreaper process to which the caller is then reparented. If the parent thread and all ancestor subreapers are terminated by the time of the `PR_SET_PDEATHSIG` operation, no parent-death signal is sent to the caller.

The parent-death signal setting is cleared for the child of a `fork()`. It is also cleared when executing a set-user-ID or set-group-ID binary; otherwise, this value is preserved across `execve()`. The parent-death signal setting is also cleared upon changes to any of the following thread credentials: effective user ID, effective group ID, file system user ID, or file system group ID.

PR_GET_PDEATHSIG

Return the current value of the parent process death signal in the location that is pointed to by (int *) *arg2*.

Returned value

If successful, `PR_GET_DUMPABLE` and `PR_GET_NO_NEW_PRIVS` return the nonnegative values that are described previously. All other option values return 0.

If unsuccessful, `prctl()` returns -1 and sets `errno` to one of the following values:

Error Code**Description****EFAULT**

arg2 is an invalid address.

EINVAL

option is `PR_SET_PDEATHSIG` or `PR_GET_Name` and *arg2* is not a valid signal number.

prlimit() — Get or set the hard and soft resource limits of a specified process

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#define _XPLATFORM_SOURCE
#include <sys/resource.h>

int prlimit(pid_t pid, int resource, const struct rlimit *new_limit, struct rlimit *old_limit);
```

General description

`prlimit()` gets or sets resource limits for the specified process. A resource limit is a pair of values; one specifies the current (soft) limit and the other the maximum (hard) limit.

The *pid* argument specifies the process whose resource limits are to be set or retrieved. If *pid* is equal to 0, the resource limits are set or retrieved for the calling process.

The caller must have either of the following privileges for changing other process resource limit:

- The caller has superuser level authority.
- The real, effective, and saved set user IDs of the target process match the real user ID of the caller and the real, effective, and saved set group IDs of the target process must match the real group ID of the caller.

The soft limit might be modified to any value that is less than or equal to the hard limit. For certain resource values (RLIMIT_CPU, RLIMIT_NOFILE, RLIMIT_AS), the soft limit cannot be set lower than the existing usage.

The hard limit might be lowered to any value that is greater than or equal to the soft limit. The hard limit can be raised only by a process that has superuser authority. Both the soft limit and hard limit can be changed by a `prlimit()` call.

The value of RLIM_INFINITY that is defined in `<sys/resource.h>` is considered to be larger than any other limit value. If a call to `prlimit()` returns RLIM_INFINITY for a resource, it means that the implementation does not enforce limits on that resource. Specifying RLIM_INFINITY as any resource limit values on a successful call to `prlimit()` inhibits enforcement of that resource limit.

The *resource* argument specifies which resource to set the hard and/or soft limits for. The valid values of *resource* are:

RLIMIT_AS

The maximum address space size for the process in bytes. If the limit is exceeded, `malloc()` and `mmap()` fail with an `errno` of ENOMEM. Automatic stack growth fails.

RLIMIT_CORE

The maximum size of a dump of memory in bytes that is allowed for the process. A value of 0 prevents file creation. Dump file creation stops at this limit.

RLIMIT_CPU

The maximum amount of CPU time in seconds that is allowed for the process. If the limit is exceeded, a SIGXCPU signal is sent to the process, and the process is granted a small CPU time extension to allow for signal generation and delivery. If the extension is used up, the process is terminated with a SIGKILL signal. An attempt to set the CPU limit lower than that already used results in an EINVAL `errno`.

RLIMIT_DATA

The maximum size of the break value for the process in bytes. This resource has a hard and soft limit value of RLIM_INFINITY. A call to `prlimit()` to set this resource to any value other than RLIM_INFINITY fails with an `errno` of EINVAL.

RLIMIT_FSIZE

The maximum file size in bytes that is allowed for the process. A value of 0 prevents file creation. If the size is exceeded, a SIGXFSZ signal is sent to the process. If the process is blocking, catching, or ignoring SIGXFSZ, continued attempts to increase the size of a file beyond the limit fail with an `errno` of EFBIG.

RLIMIT_MEMLIMIT

The maximum amount of usable storage above the 2-gigabyte bar (in 1-megabyte segments) that can be allocated. Any attempt to extend the usable amount of virtual storage above the 2-gigabyte bar fails.

RLIMIT_NOFILE

The maximum number of open file descriptors that is allowed for the process. This number is one greater than the maximum value that might be assigned to a new descriptor. That is, it is one-based. Any function that attempts to create a new file descriptor beyond the limit fails with an EMFILE `errno`. An attempt to set the open file descriptors limit lower than that already used results in an EINVAL `errno`.

Restriction: This value cannot exceed 524288.

RLIMIT_STACK

The maximum size of the stack for a process in bytes. In z/OS UNIX System Services, the stack is a per-thread resource. This resource has a hard and soft limit value of RLIM_INFINITY. A call to `prlimit()` to set this resource to any value other than RLIM_INFINITY fails with an `errno` of EINVAL.

The *rlp* argument points to a `rlimit` structure. This structure contains the following members:

rlim_cur

The current (soft) limit

rlim_max

The maximum (hard) limit

- If the *new_limit* argument is not NULL, the `rlimit` structure to which it points is used to set new values for the soft and hard limits for *resource*.
- If the *old_limit* argument is not NULL, a successful call to `prlimit()` places the previous soft and hard limits for *resource* in the `rlimit` structure that is pointed to by *old_limit*.
- If the *new_limit* and *old_limit* arguments are all NULL, no operation are taken.
- If both the *new_limit* and *old_limit* arguments are not NULL, get operation is performed first.

The resource limit values are propagated across `exec` and `fork`.

Special behavior for z/OS UNIX System Services:

An exception exists for `exec` processing in daemon support. If a daemon process withvokes `exec` after it invokes `setuid()`, the RLIMIT_CPU, RLIMIT_AS, RLIMIT_CORE, RLIMIT_FSIZE, and RLIMIT_NOFILE limit values are set based on the limit values that are specified in the kernel parmlib member BPXPRMxx.

For processes that are not the only process within an address space, the RLIMIT_CPU and RLIMIT_AS limits are shared with all the processes within the address space. For RLIMIT_CPU, when the soft limit is exceeded, action is taken on the first process within the address space. If the action is termination, all processes within the address space are terminated.

In addition to the RLIMIT_CORE limit values, the dump file defaults are set by SYSMDUMP defaults. Refer to [z/OS MVS Initialization and Tuning Reference](#) for information on setting up SYSMDUMP defaults by using the IEADMR00 parmlib member.

Dumps of memory are taken in 4160-byte increments. Therefore, RLIMIT_CORE values affect the size of memory dumps in 4160-byte increments. For example, if the RLIMIT_CORE soft limit value is 4000, the

dump contains no data. If the RLIMIT_CORE soft limit value is 8000, the maximum size of a memory dump is 4160 bytes.

When setting RLIMIT_NOFILE, the hard limit cannot exceed the system-defined limit of 524288.

Returned value

If successful, `prlimit()` returns 0.

If unsuccessful, `prlimit()` returns -1 and sets `errno` to one of the following values:

Error Code Description

EINVAL

An invalid resource is specified, or the soft limit to set exceeds the hard limit to set, the soft limit to set is below the current usage, or the resource does not allow any value other than RLIM_INFINITY.

EMVSSAF2ERR

A Security product internal error occurs. See the `Reason_code` parameter for the exact reason for the error.

EPERM

The limit that is specified to `prlimit()` raises the maximum limit value, and the calling process does not have appropriate privileges.

pread() — Read from a file or socket without file pointer change

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 | both | OS/390 V2R10 |

Format

```
#define _XOPEN_SOURCE 500
#include <unistd.h>

ssize_t pread(int fildev, void *buf, size_t nbyte, off_t offset);
```

General description

The `pread()` function performs the same action as `read()`, except that it reads from a given position in the file without changing the file pointer.

The first three arguments to `pread()` are the same as `read()`, with the addition of a fourth argument *offset* for the desired position inside the file.

An error result is returned for any attempt to perform a `pread()` on a file that is incapable of a seek action.

For regular files, no data transfer will occur past the offset maximum established in the open file description associated with *fildev*.

Returned value

If successful, `pread()` returns a non-negative integer indicating the number of bytes actually read.

If unsuccessful, `pread()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EAGAIN

`O_NONBLOCK` is set to 1, but data was not available for reading.

EBADF

fildev is not a valid file or socket descriptor.

ECONNRESET

A connection was forcibly closed by a peer.

EFAULT

Using the *buf* and *nbyte* parameters would result in an attempt to access memory outside the caller's address space.

EINTR

`pread()` was interrupted by a signal that was caught before any data was available.

EINVAL

nbyte contains a value that is less than 0, or the request is invalid or not supported, or the STREAM or multiplexer referenced by *fildev* is linked (directly or indirectly) downstream from a multiplexer.

The *offset* argument is invalid. The value is negative.

EIO

The process is in a background process group and is attempting to read from its controlling terminal, and either the process is ignoring or blocking the SIGTTIN signal or the process group of the process is orphaned. For sockets, an I/O error occurred.

ENOBUFS

Insufficient system resources are available to complete the call.

ENOTCONN

A receive was attempted on a connection-oriented socket that is not connected.

ENXIO

A request was outside the capabilities of the device.

EOVERFLOW

The file is a regular file and an attempt was made to read or write at or beyond the offset maximum associated with the file.

ESPIPE

fildev is associated with a pipe or FIFO.

ETIMEDOUT

The connection timed out during connection establishment, or due to a transmission timeout on active connection.

EWOULDBLOCK

socket is in nonblocking mode and data is not available to read, or the `SO_RCVTIMEO` timeout value was reached before data was available.

- [“read\(\) — Read from a file or socket” on page 1380](#)

printf() — Format and write data

The information for this function is included in [“fprintf\(\), printf\(\), sprintf\(\) — Format and write data”](#) on page 593.

pselect() - Monitor activity on files or sockets and message queues

The information for this function is included in [“select\(\), pselect\(\) — Monitor activity on files or sockets and message queues”](#) on page 1472.

psignal() — Print signal description

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1-2008 Single UNIX Specification, Version 4 | both | |

Format

```
#define _POSIX_C_SOURCE 200809L
#include <signal.h>

void psignal(int sig, const char *s);
```

General description

`psignal()` displays a message on `stderr`, which consists of the string `s`, a colon, a space, a string that describes the signal number `sig`, and a trailing newline. If the string `s` is `NULL` or empty, the colon and space are omitted. If `sig` is invalid, the message that is displayed indicates an unknown signal.

`psignal()` does not change the orientation of the `stderr` stream.

`psignal_unlocked()` is functionally equivalent to `psignal()` with the exception that it is not thread-safe. `psignal_unlocked()` can safely be used in a multithreaded application only when it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

`psignal()` returns no values.

Error Code

Description

No errors are defined.

pthread_atfork() - Register fork handlers

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|---------------------|
| Single UNIX Specification, Version 3 | both | z/OS V1R9 POSIX(ON) |

Format

```
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_atfork(void (*prepare)(void), void (*parent)(void),
void (*child)(void));
```

General description

The *pthread_atfork()* function registers fork handlers to be called before and after *fork()*, in the context of the thread that called *fork()*. Fork handler functions may be named for execution at the following three points in thread processing:

- The *prepare* handler is called before *fork()* processing commences.
- The *parent* handler is called after *fork()* processing completes in the parent process.
- The *child* handler is called after *fork()* processing completes in the child process.

If any argument to *pthread_atfork()* is NULL, the call does not register a handler to be invoked at the point corresponding to that argument.

The order of calls to *pthread_atfork()* is significant. The *parent* and *child* fork handlers are called in the order in which they were established by calls to *pthread_atfork()*. The *prepare* fork handlers are called in the opposite order.

The intended purpose of *pthread_atfork()* is to provide a mechanism for maintaining the consistency of mutex locks between parent and child processes. The handlers are expected to be straightforward programs, designed simply to manage the synchronization variables and must return to ensure that all registered handlers are called. Historically, the prepare handler acquired needed mutex locks, and the parent and child handlers released them. Unfortunately, this usage is not practical on the z/OS platform and is not guaranteed to be portable in the current UNIX standards. When the parent process is multi-threaded (invoked *pthread_create()* at least once), the child process can only safely call async-signal-safe functions before it invokes an *exec()* family function. This restriction was added to the POSIX.1 standard in 1996. Because functions such as *pthread_mutex_lock()* and *pthread_mutex_unlock()* are not async-signal-safe, unpredictable results may occur if they are used in a child handler.

Special behavior for IBM z/OS C: The C Library *pthread_atfork()* function has the following restrictions:

- Any fork handler registered by a fetched module that has been released is removed from the list at the time of release. See [“fetch\(\) — Get a load module”](#) on page 516, [“fetchep\(\) — Share writable static”](#) on page 526, and [“release\(\) — Delete a load module”](#) on page 1424 for details about fetching and releasing modules.
- Any handler registered in an explicitly loaded DLL (using *dllload()* or *dlopen()*) that has been freed (using *dllfree()* or *dlclose()*) is removed from the list, except when the DLL has also been implicitly loaded.
- Use of non-C subroutines or functions as fork handlers will result in undefined behavior.

Special behavior for IBM z/OS C/C++:

- All of the behaviors listed under "Special Behavior for IBM z/OS C."
- The *pthread_atfork()* function cannot receive C++ function pointers compiled as 31-bit non-XPLINK objects, because C and C++ linkage conventions are incompatible in that environment. If you attempt

to pass a C++ function pointer to `pthread_atfork()`, the compiler will flag it as an error. In C++, you must ensure that all handlers registered for use by `pthread_atfork()` have C linkage by declaring them as `extern "C"`.

Returned value

If successful, `pthread_atfork()` returns zero; otherwise, it returns an error number.

Error Code

Description

ENOMEM

Insufficient table space exists to record the fork handler addresses.

Example

CELEBP60

```
/* CELEBP60 */
/* Example using SUSv3 pthread_atfork() interface */

#define _UNIX03_THREADS 1

pthread_attr_destroy() — Destroy the thread attributes object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_attr_destroy(pthread_attr_t *attr);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_attr_destroy(pthread_attr_t *attr);
```

General description

Removes the definition of the thread attributes object. An error results if a thread attributes object is used after it has been destroyed.

attr is a pointer to a thread attribute object initialized by pthread_attr_init().

You can use a thread attribute object to manage the characteristics of threads in your application. It defines the set of values to be used for the thread during its creation. By establishing a thread attribute object, you can create many threads with the same set of characteristics, without defining those characteristics for each thread. You can define more than one thread attribute object.

If a thread attribute object is shared between threads, the application must provide the necessary synchronization because a thread attribute object is defined in the application's storage.

Returned value

If successful, pthread_attr_destroy() returns 0.

If unsuccessful, pthread_attr_destroy() returns -1.

There are no documented errno values. Use perror() or strerror() to determine the cause of the error.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_attr_destroy() returns an error number to indicate the error.

Example

CELEBP06

```
/* CELEBP06 */
#define _OPEN_THREADS
#include <stdio.h>
#include <pthread.h>

void *thread1(void *arg) {
    pthread_exit(NULL);
}

int main()
{
    pthread_t      thid;
    pthread_attr_t attr;

    if (pthread_attr_init(&attr) == -1) {
        perror("error in pthread_attr_init");
        exit(1);
    }

    if (pthread_create(&thid, &attr, thread1, NULL) == -1) {
        perror("error in pthread_create");
        exit(2);
    }

    if (pthread_detach(&thid) == -1) {
        perror("error in pthread_detach");
        exit(4);
    }

    if (pthread_attr_destroy(&attr) == -1) {
        perror("error in pthread_attr_destroy");
        exit(5);
    }
    exit(0);
}
```

pthread_attr_getdetachstate() — Get the detach state attribute

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_attr_getdetachstate(pthread_attr_t *attr);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>
int pthread_attr_getdetachstate(const pthread_attr_t *attr,
                               int *detachstate);
```

General description

Returns the current value of the detachstate attribute for the thread attribute object, *attr*, that is created by pthread_attr_init(). The detachstate attribute values are:

0

Undetached. An undetached thread will keep its resources after termination.

1

Detached. A detached thread will have its resources automatically freed by the system at termination. Thus, you cannot get the thread's termination status (or wait for the thread to terminate) by using pthread_join().

You can use a thread attribute object to manage the characteristics of threads in your application. It defines the set of values to be used for the thread during its creation. By establishing a thread attribute object, you can create many threads with the same set of characteristics, without defining those characteristics for each thread. You can define more than one thread attribute object.

Returned value

If successful, pthread_attr_getdetachstate() returns the detachstate (0 or 1).

If unsuccessful, pthread_attr_getdetachstate() returns -1.

There are no documented errno values. Use perror() or strerror() to determine the cause of the error.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_attr_getdetachstate() returns an error number to indicate the error.

Example

CELEBP07

```
/* CELEBP07 */
#define _OPEN_THREADS
#include <stdio.h>
#include <pthread.h>
```

```

int main()
{
    pthread_attr_t attr;
    char          typ[12];

    if (pthread_attr_init(&attr) == -1) {
        perror("error in pthread_attr_init");
        exit(1);
    }

    switch(pthread_attr_getdetachstate(&attr)) {
        default:
            perror("error in pthread_attr_getdetachstate()");
            exit(2);
        case 0:
            strcpy(typ, "undetached");
            break;
        case 1:
            strcpy(typ, "detached");
    }
    printf("The detach state is %s.\n", typ);

    if (pthread_attr_destroy(&attr) == -1) {
        perror("error in pthread_attr_destroy");
        exit(2);
    }
    exit(0);
}

```

CELEBP61

```

/* CELEBP61 */
/* Example using SUSv3 pthread_attr_getdetachstate() interface */

#define _UNIX03_THREADS 1
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <pthread.h>
#include <errno.h>

int main(void)
{
    pthread_attr_t attr;
    int          rc, newstate, foundstate;
    char          state[12];

    if (pthread_attr_init(&attr) == -1) {
        perror("error in pthread_attr_init");
        exit(1);
    }

    newstate = PTHREAD_CREATE_DETACHED;
    pthread_attr_setdetachstate(&attr, newstate);

    rc = pthread_attr_getdetachstate(&attr, &foundstate);
    switch(foundstate) {
        case PTHREAD_CREATE_JOINABLE:
            strcpy(state, "joinable");
            break;
        case PTHREAD_CREATE_DETACHED:
            strcpy(state, "detached");
            break;
        default:
            printf("pthread_attr_getdetachstate returned: %d\n", rc);
            printf("Error: %d, Errno_Jr: %08x\n", errno, __errno2());
            exit(2);
    }

    printf("Threads created with this attribute object are %s.\n", state);

    if (pthread_attr_destroy(&attr) == -1) {
        perror("error in pthread_attr_destroy");
        exit(3);
    }

    exit(0);
}

```

pthread_attr_getguardsize() - Get guardsize attribute

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|---------------------|
| Single UNIX Specification, Version 3 | both | z/OS V1R9 POSIX(ON) |

Format

```
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_attr_getguardsize(const pthread_attr_t *__restrict__ attr,
                             size_t ** __restrict__ guardsize);
```

General description

pthread_attr_getguardsize() gets the guardsize attribute from *attr* and stores it into *guardsize*.

attr is a pointer to a thread attribute object initialized by *pthread_attr_init()*.

The retrieved guardsize always matches the size stored by *pthread_attr_setguardsize()*, despite internal adjustments for rounding to multiples of the PAGESIZE system variable.

Returned value

If successful, *pthread_attr_getguardsize()* returns 0; otherwise it returns an error number.

Error Number

Description

EINVAL

The value specified by *attr* does not refer to an initialized thread attribute object.

Example

```
/* CELEBP62 */
/* Example using SUSv3 pthread_attr_getguardsize() interface */

#define _XOPEN_SOURCE 600

#include <stdio.h>
#include <stdlib.h>
#include <pthread.h>
#include <limits.h>
#include <errno.h>

int main(void)
{
    pthread_attr_t attr;
    int rc;
    size_t guardsize;

    if (pthread_attr_init(&attr) == -1) {
        perror("error in pthread_attr_init");
```

```

    exit(1);
}

printf("Set guardsize to value of PAGESIZE.\n");
rc = pthread_attr_setguardsize(&attr, PAGESIZE);
if (rc != 0) {
    printf("pthread_attr_setguardsize returned: %d\n", rc);
    printf("Error: %d, Errno_Jr: %08x\n", errno, __errno2());
    exit(2);
} else {
    printf("Set guardsize is %d\n", PAGESIZE);
}

rc = pthread_attr_getguardsize(&attr, &guardsize);
if (rc != 0) {
    printf("pthread_attr_getguardsize returned: %d\n", rc);
    printf("Error: %d, Errno_Jr: %08x\n", errno, __errno2());
    exit(3);
} else {
    printf("Retrieved guardsize is %d\n", guardsize);
}

rc = pthread_attr_destroy(&attr);
if (rc != 0) {
    perror("error in pthread_attr_destroy");
    exit(4);
}

exit(0);
}

```

pthread_attr_getschedparam() - Get scheduling parameter attributes

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|---------------------|
| Single UNIX Specification, Version 3 | both | z/OS V1R9 POSIX(ON) |

Format

```

#define _UNIX03_THREADS
#include <pthread.h>
#include <sched.h>

int pthread_attr_getschedparam(const pthread_attr_t *__restrict__ attr,
                               struct sched_param *__restrict__ param);

```

General description

pthread_attr_getschedparam() gets the scheduling priority attribute from *attr* and stores it into *param*. *attr* is a pointer to a thread attribute object initialized by *pthread_attr_init()*.

param points to a user-defined scheduling parameter object into which pthread_attr_getschedparam() copies the thread scheduling priority attribute.

Returned value

If successful, pthread_attr_getschedparam() returns 0; otherwise it returns an error number.

Error Number

Description

EINVAL

The value specified by attr does not refer to an initialized thread attribute object.

Example

```
/* CELEBP63 */
/* Example using SUSv3 pthread_attr_getschedparam() interface */

#define _UNIX03_THREADS 1
#include <stdio.h>
#include <stdlib.h>
#include <pthread.h>
#include <errno.h>

int main(void)
{
    pthread_attr_t attr;
    int rc;
    struct sched_param param;

    param.sched_priority = 999;

    if (pthread_attr_init(&attr) == -1) {
        perror("error in pthread_attr_init");
        exit(1);
    }

    rc = pthread_attr_setschedparam(&attr, &param);
    if (rc != 0) {
        printf("pthread_attr_setschedparam returned: %d\n", rc);
        printf("Error: %d, Errno_Jr: %08x\n", errno, __errno2());
        exit(2);
    } else {
        printf("Set schedpriority to %d\n", param.sched_priority);
    }

    param.sched_priority = 0;

    rc = pthread_attr_getschedparam(&attr, &param);
    if (rc != 0) {
        printf("pthread_attr_getschedparam returned: %d\n", rc);
        printf("Error: %d, Errno_Jr: %08x\n", errno, __errno2());
        exit(3);
    } else {
        printf("Retrieved schedpriority of %d\n", param.sched_priority);
    }

    rc = pthread_attr_destroy(&attr);
    if (rc != 0) {
        perror("error in pthread_attr_destroy");
        exit(4);
    }

    exit(0);
}
```

pthread_attr_getstack() - Get stack attribute

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|---------------------|
| Single UNIX Specification, Version 3 | both | z/OS V1R9 POSIX(ON) |

Format

```
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_attr_getstack(const pthread_attr_t *__restrict__ attr,
    void ** __restrict__ addr, size_t * __restrict__ size);
```

General description

The *pthread_attr_getstack()* function gets both the base (lowest addressable) storage address and size of the initial stack segment from a thread attribute structure and stores them into *addr* and *size* respectively.

attr is a pointer to a thread attribute object initialized by *pthread_attr_init()*.

addr is a pointer to the user-defined location where this function will place the base address of the initial stack segment.

size points to the user-defined location where this function will store the size of the initial stack segment.

Note: An XPLINK application uses two stacks, an upward-growing stack and a downward-growing stack. The "size" argument refers to the size of the downward-growing stack.

Returned value

If successful, *pthread_attr_getstack()* returns 0; otherwise it returns an error number.

Error Number

Description

EINVAL

The value specified by *attr* does not refer to an initialized thread attribute object.

Example

```
/* CELEBP69 */
/* Example using SUSv3 pthread_attr_getstack() interface */

#define _UNIX03_THREADS 1

#include <stdio.h>
#include <stdlib.h>
#include <pthread.h>
#include <limits.h>
#include <errno.h>

int main(void)
{
    pthread_attr_t attr;
    int rc;

    void *mystack;
    size_t mystacksize = 2 * PTHREAD_STACK_MIN;

    if (pthread_attr_init(&attr) == -1) {
        perror("error in pthread_attr_init");
        exit(1);
    }
}
```

```

/* Get a big enough stack and align it on 4K boundary. */
mystack = malloc(PTHREAD_STACK_MIN * 3);
if (mystack != NULL) {
    printf("Using PTHREAD_STACK_MIN to align stackaddr %x.\n", mystack);
    mystack = (void *)((((long)mystack + (PTHREAD_STACK_MIN - 1)) /
        PTHREAD_STACK_MIN) * PTHREAD_STACK_MIN);
} else {
    perror("Unable to acquire storage.");
    exit(2);
}

printf("Setting stackaddr to %x\n", mystack);
printf("Setting stacksize to %x\n", mystacksize);
rc = pthread_attr_setstack(&attr, mystack, mystacksize);
if (rc != 0) {
    printf("pthread_attr_setstack returned: %d\n", rc);
    printf("Error: %d, Errno_Jr: %08x\n", errno, __errno2());
    exit(3);
} else {
    printf("Set stackaddr to %x\n", mystack);
    printf("Set stacksize to %x\n", mystacksize);
}

rc = pthread_attr_destroy(&attr);
if (rc != 0) {
    perror("error in pthread_attr_destroy");
    printf("Returned: %d, Error: %d\n", rc, errno);
    printf("Errno_Jr: %x\n", __errno2());
    exit(4);
}

exit(0);
}

```

pthread_attr_getstackaddr() - Get stackaddr attribute

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|---------------------|
| Single UNIX Specification, Version 3 | both | z/OS V1R9 POSIX(ON) |

Format

```

#define _UNIX03_THREADS
#include <pthread.h>

int pthread_attr_getstackaddr(const pthread_attr_t *__restrict__ attr,
    void ** __restrict__ addr);

```

General description

The `pthread_attr_getstackaddr()` function gets the `stackaddr` attribute from `attr` and stores it into `addr`. The `stackaddr` attribute holds the storage location of the created thread's initial stack segment.

`attr` is a pointer to a thread attribute object initialized by `pthread_attr_init()`.

Note: The `pthread_attr_getstackaddr()` function is provided for historical reasons and is marked obsolescent in the Single UNIX Specification, Version 3 (SUSv3). New applications should use the newer function `pthread_attr_getstack()`, which provides functionality compatible with the SUSv3 standard.

Returned value

If successful, `pthread_attr_getstackaddr()` returns 0; otherwise it returns an error number.

Error Number

Description

EINVAL

The value specified by `attr` does not refer to an initialized thread attribute object.

Example

```
/* CELEBP64 */
/* Example using SUSv3 pthread_attr_getstackaddr() interface */

#define _UNIX03_THREADS 1

#include <stdio.h>
#include <stdlib.h>
#include <pthread.h>
#include <limits.h>
#include <errno.h>

int main(void)
{
    pthread_attr_t attr;
    int rc;
    void *stackaddr;
    void *mystack;

    if (pthread_attr_init(&attr) == -1) {
        perror("error in pthread_attr_init");
        exit(1);
    }

    /* Get a big enough stack and align it on 4K boundary. */
    mystack = malloc(PTHREAD_STACK_MIN * 2);
    if (mystack != NULL) {
        printf("Using PTHREAD_STACK_MIN to align stackaddr %x.\n", mystack);
        mystack = (void *)((((long)mystack + (PTHREAD_STACK_MIN - 1)) /
                               PTHREAD_STACK_MIN) * PTHREAD_STACK_MIN);
    } else {
        perror("Unable to acquire storage.");
        exit(2);
    }

    printf("Setting stackaddr to %x\n", mystack);
    rc = pthread_attr_setstackaddr(&attr, mystack);
    if (rc != 0) {
        printf("pthread_attr_setstackaddr returned: %d\n", rc);
        printf("Error: %d, Errno_Jr: %08x\n", errno, __errno2());
        exit(3);
    } else {
        printf("Set stackaddr to %x\n", mystack);
    }

    rc = pthread_attr_getstackaddr(&attr, &stackaddr);
    if (rc != 0) {
        printf("pthread_attr_getstackaddr returned: %d\n", rc);
        printf("Error: %d, Errno_Jr: %08x\n", errno, __errno2());
        exit(4);
    } else {
        printf("Retrieved stackaddr is %x\n", stackaddr);
    }

    rc = pthread_attr_destroy(&attr);
    if (rc != 0) {
        perror("error in pthread_attr_destroy");
        printf("Returned: %d, Error: %d\n", rc, errno);
        printf("Errno_Jr: %x\n", __errno2());
        exit(5);
    }
}
```

```
    exit(0);
}
```

pthread_attr_getstacksize() — Get the thread attribute stacksize object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_attr_getstacksize(pthread_attr_t *attr, size_t *stacksize);
```

SUSV3

```
#define _UNIX03_THREADS
#include <pthread.h>
int pthread_attr_getstacksize(const pthread_attr_t * __restrict__ attr,
                             size_t * __restrict__ stacksize);
```

General description

Gets the value, in bytes, of the `stacksize` attribute for the thread attribute object, `attr`, that is created by `pthread_attr_init()`. This function returns the value in the variable pointed to by `stacksize`.

You can use a thread attribute object to manage the characteristics of threads in your application. It defines the set of values to be used for the thread during its creation. By establishing a thread attribute object, you can create many threads with the same set of characteristics, without defining those characteristics for each thread. You can define more than one thread attribute object.

Note: An XPLINK application uses two stacks, an upward-growing stack and a downward-growing stack. The “stacksize” refers to the size of the downward-growing stack.

Returned value

If successful, `pthread_attr_getstacksize()` returns 0 and stores the `stacksize` attribute value in `stacksize`.

If unsuccessful, `pthread_attr_getstacksize()` returns -1.

There are no documented `errno` values. Use `perror()` or `strerror()` to determine the cause of the error.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_attr_getstacksize() returns an error number to indicate the error.

Example

CELEBP08

```
/* CELEBP08 */
#define _OPEN_THREADS
#include <stdio.h>
#include <pthread.h>

int main()
{
    pthread_attr_t attr;
    size_t size;

    if (pthread_attr_init(&attr) == -1) {
        perror("error in pthread_attr_init");
        exit(1);
    }

    if (pthread_attr_getstacksize(&attr, &size) == -1) {
        perror("error in pthread_attr_getstackstate()");
        exit(2);
    }
    printf("The stack size is %d.\n", (int) size);

    if (pthread_attr_destroy(&attr) == -1) {
        perror("error in pthread_attr_destroy");
        exit(2);
    }
    exit(0);
}
```

Output:

The stack size is 524288.

pthread_attr_getsynctype_np() — Get thread sync type

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | POSIX(ON) |

Format

```
#define _OPEN_SYS
#include <pthread.h>

int pthread_attr_getsynctype_np(pthread_attr_t *attr);
```

General description

The `pthread_attr_getsynctype_np` function returns the current synctype setting of the *attr* thread attribute object.

The *synctype* can be set to one of the following symbolics, as defined in the `pthread.h` header file:

__PTATSYNCHRONOUS

Can only create as many threads as TCBs available (or as many threads are available, depending on which number is smaller).

__PTATASYNCHRONOUS

Allows threads to be queued, that is, can create more threads than TCBs are available up to limit of how many threads are available. The queued threads will be released as TCBs become available.

Returned value

If successful, `pthread_attr_getsynctype_np()` returns the synctype value of the thread attribute object.

If unsuccessful, `pthread_attr_getsynctype_np()` returns -1.

There are no documented `errno` values. Use `perror()` or `strerror()` to determine cause of the error.

Related information

- [“pthread.h — Thread interfaces” on page 53](#)
- [“pthread_attr_init\(\) — Initialize a thread attribute object” on page 1233](#)

pthread_attr_getweight_np() — Get weight of thread attribute object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#define _OPEN_SYS
#include <pthread.h>

int pthread_attr_getweight_np(pthread_attr_t *attr);
```

General description

Obtains the current weight of the thread setting of the thread attributes object, *attr*. The symbols for weight are defined in the `pthread.h` include file. The following weights are supported:

__MEDIUM_WEIGHT

The executing task can be reused when the thread exits.

__HEAVY_WEIGHT

When this exits, the associated MVS task can no longer request threads to process.

You can use a thread attribute object to manage the characteristics of threads in your application. It defines the set of values to be used for the thread during its creation. By establishing a thread

attribute object, you can create many threads with the same set of characteristics, without defining those characteristics for each and every thread. You can define more than one thread attribute object.

Returned value

If successful, `pthread_attr_getweight_np()` returns the value of the weight of the thread attribute.

If unsuccessful, `pthread_attr_getweight_np()` returns -1.

There are no documented `errno` values. Use `perror()` or `strerror()` to determine the cause of the error.

Example

CELEBP09

```
/* CELEBP08 */
#define _OPEN_THREADS
#define _OPEN_SYS          /* Needed to identify __HEAVY_WEIGHT AND
                           __MEDIUM_WEIGHT */
#include <stdio.h>
#include <pthread.h>

int main()
{
    pthread_attr_t attr;
    char          weight[12];

    if (pthread_attr_init(&attr) == -1) {
        perror("error in pthread_attr_init");
        exit(1);
    }

    switch(pthread_attr_getweight_np(&attr)) {
        default:
            perror("error in pthread_attr_getweight_np()");
            exit(2);
        case __HEAVY_WEIGHT:
            strcpy(weight, "heavy");
            break;
        case __MEDIUM_WEIGHT:
            strcpy(weight, "medium");
    }
    printf("The thread weight is %s.\n", weight);

    if (pthread_attr_destroy(&attr) == -1) {
        perror("error in pthread_attr_destroy");
        exit(2);
    }
    exit(0);
}
```

Output:

```
The thread weight is heavy.
```

pthread_attr_init() – Initialize a thread attribute object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_attr_init(pthread_attr_t *attr);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_attr_init(pthread_attr_t *attr);
```

General description

Initializes *attr* with the default thread attributes, whose defaults are:

stacksize

Inherited from the STACK runtime option

detachstate

Undetached

synch

Synchronous

weight

Heavy

Using a thread attribute object, you can manage the characteristics of threads in your application. It defines the set of values to be used for the thread during its creation. By establishing a thread attribute object, you can create many threads with the same set of characteristics, without defining those characteristics for each thread. You can define more than one thread attribute object. All threads are of equal priority.

If a thread attribute object is shared between threads, the application must provide the necessary synchronization because a thread attribute object is defined in the application's storage.

Note: An XPLINK application uses two stacks, an upward-growing stack and a downward-growing stack. "stacksize" always refers to the size of the upward-growing stack. The size of the downward-growing stack is inherited from the THREADSTACK runtime option.

Returned value

If successful, pthread_attr_init() returns 0.

If unsuccessful, pthread_attr_init() returns -1 and sets errno to one of the following values:

Error Code

Description

ENOMEM

Not enough memory is available to create the thread attribute object.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_attr_init() returns an error number to indicate the error.

Example

CELEBP10

```
/* CELEBP10 */
#define _OPEN_THREADS
#include <stdio.h>
#include <pthread.h>

void *thread1(void *arg)
{
    printf("hello from the thread\n");
    pthread_exit(NULL);
}

int main()
{
    int rc, stat;
    pthread_attr_t attr;
    pthread_t thid;

    rc = pthread_attr_init(&attr);
    if (rc == -1) {
        perror("error in pthread_attr_init");
        exit(1);
    }

    rc = pthread_create(&thid, &attr, thread1, NULL);
    if (rc == -1) {
        perror("error in pthread_create");
        exit(2);
    }

    rc = pthread_join(thid, (void *)&stat);
    exit(0);
}
```

Related information

pthread_attr_setdetachstate() — Set the detach state attribute

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_attr_setdetachstate(pthread_attr_t *attr, int *detachstate);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>
int pthread_attr_setdetachstate(pthread_attr_t *attr, int detachstate);
```

General description

Alters the current *detachstate* setting of a thread attributes object, which can be set to *PTHREAD_CREATE_JOINABLE* or *PTHREAD_CREATE_DETACHED*.

0

Causes all the threads created with *attr* to be in an undetached state. An undetached thread will keep its resources after termination.

1

Causes all the threads created with *attr* to be in a detached state. A detached thread will have its resources automatically freed by the system at termination. Thus, you cannot get the thread's termination status, or wait for the thread to terminate by using `pthread_join()`.

You can use a thread attribute object to manage the characteristics of threads in your application. It defines the set of values to be used for the thread during its creation. By establishing a thread attribute object, you can create many threads with the same set of characteristics, without defining those characteristics for each thread. You can define more than one thread attribute object.

Returned value

If successful, `pthread_attr_setdetachstate()` returns 0.

If unsuccessful, `pthread_attr_setdetachstate()` returns -1.

Error Code

Description

EINVAL

The value of *detachstate* was not valid or the value specified by *attr* does not refer to an initialized thread attribute object.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, `pthread_attr_setdetachstate()` returns an error number to indicate the error.

Example**CELEBP11**

```
/* CELEBP11 */
#define _OPEN_THREADS
#include <stdio.h>
#include <pthread.h>

void **stat;
void *thread1(void *arg)
{
    printf("hello from the thread\n");
    pthread_exit((void *)0);
}

int main()
{
    int          ds, rc;
    size_t       s1;
    pthread_attr_t attr;
    pthread_t     thid;

    rc = pthread_attr_init(&attr);
    if (rc == -1) {
        perror("error in pthread_attr_init");
        exit(1);
    }
}
```

```

ds = 0;
rc = pthread_attr_setdetachstate(&attr, &ds);
if (rc == -1) {
    perror("error in pthread_attr_setdetachstate");
    exit(2);
}

rc = pthread_create(&thid, &attr, thread1, NULL);
if (rc == -1) {
    perror("error in pthread_create");
    exit(3);
}

rc = pthread_join(thid, stat);
exit(0);
}

```

pthread_attr_setguardsize() - Set guardsize attribute

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|---------------------|
| Single UNIX Specification, Version 3 | both | z/OS V1R9 POSIX(ON) |

Format

```

#define _UNIX03_THREADS
#include <pthread.h>

int pthread_attr_setguardsize(pthread_attr_t *attr, size_t guardsize);

```

General description

pthread_attr_setguardsize() sets the guardsize attribute in *attr* using the value of *guardsize*.

attr is a pointer to a thread attribute object initialized by *pthread_attr_init()*.

This function stores the guardsize attribute in the thread attribute object for subsequent calls to *pthread_attr_getguardsize()*, but no further action is taken. The guardsize attribute is ignored during thread creation.

Note:

The Single UNIX Specification, Version 3 expects a guard area of at least *guardsize* bytes, but permits the rounding of *guardsize* to a multiple of the system variable, *PAGESIZE*. Stack management in z/OS UNIX sets a guard area of *PAGESIZE* in 31-bit applications and of (*PAGESIZE* * *PAGESIZE*) bytes in AMODE64. These values are the default for the guard size attribute. Requests for larger guard areas will fail with *EINVAL*.

A zero *guardsize* requests that no guard area be provided. However, z/OS UNIX stack management requires a guard area. Therefore, this request cannot be satisfied, although *pthread_attr_setguardsize()* will tolerate a *guardsize* of zero.

Returned value

If successful, `pthread_attr_setguardsize()` returns 0; otherwise, it returns an error number.

Error Code

Description

EINVAL

The parameter *guardsize* is not valid or the value specified by *attr* does not refer to an initialized thread attribute object.

Example

```
/* CELEBP66 */
/* Example using SUSv3 pthread_attr_setguardsize() interface */

#define _XOPEN_SOURCE 600

#include <stdio.h>
#include <stdlib.h>
#include <pthread.h>
#include <limits.h>
#include <errno.h>

int main(void)
{
    pthread_attr_t attr;
    int rc;

    if (pthread_attr_init(&attr) == -1) {
        perror("error in pthread_attr_init");
        exit(1);
    }

    printf("Set guardsize to value of PAGESIZE.\n");
    rc = pthread_attr_setguardsize(&attr, PAGESIZE);
    if (rc != 0) {
        printf("pthread_attr_setguardsize returned: %d\n", rc);
        printf("Error: %d, Errno_Jr: %08x\n", errno, __errno2());
        exit(2);
    } else {
        printf("Set guardsize is %d\n", PAGESIZE);
    }

    rc = pthread_attr_destroy(&attr);
    if (rc != 0) {
        perror("error in pthread_attr_destroy");
        exit(3);
    }

    exit(0);
}
```

pthread_attr_setschedparam() - Set scheduling parameter attributes

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|---------------------|
| Single UNIX Specification, Version 3 | both | z/OS V1R9 POSIX(ON) |

Format

```
#define _UNIX03_THREADS
#include <pthread.h>
#include <sched.h>

int pthread_attr_setschedparam(pthread_attr_t *__restrict__ attr,
                               const struct sched_param *__restrict__ param);
```

General description

pthread_attr_setschedparam() sets the scheduling priority attribute in *attr* using the value from *param*.

attr is a pointer to a thread attribute object initialized by *pthread_attr_init()*.

param points to a user-defined scheduling parameter object used by *pthread_attr_setschedparam()* as the source of the thread scheduling priority attribute to set in *attr*. The scheduling priority member of a *sched_param* structure is declared as an int.

If successful, the *sched_priority* from *param* is available for subsequent calls to the *pthread_getschedparam()* function. However, z/OS UNIX takes no other action based on the value of the scheduling priority stored in *attr*.

Returned value

If successful, *pthread_attr_setschedparam()* returns 0; otherwise, it returns an error number.

Error Code

Description

EINVAL

The value specified by *attr* does not refer to an initialized thread attribute object.

Example

```
/* CELEBP67 */
/* Example using SUSv3 pthread_attr_setschedparam() interface */

#define _UNIX03_THREADS 1
#include <stdio.h>
#include <stdlib.h>
#include <pthread.h>
#include <errno.h>

int main(void)
{
    pthread_attr_t attr;
    int rc;
    struct sched_param param;

    param.sched_priority = 999;

    if (pthread_attr_init(&attr) == -1) {
        perror("error in pthread_attr_init");
        exit(1);
    }
```

```

rc = pthread_attr_setschedparam(&attr, &param);
if (rc != 0) {
    printf("pthread_attr_setschedparam returned: %d\n", rc);
    printf("Error: %d, Errno_Jr: %08x\n", errno, __errno2());
    exit(2);
} else {
    printf("Set schedpriority to %d\n", param.sched_priority);
}

rc = pthread_attr_destroy(&attr);
if (rc != 0) {
    perror("error in pthread_attr_destroy");
    exit(3);
}

exit(0);
}

```

pthread_attr_setstack() - Set stack attribute

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|---------------------|
| Single UNIX Specification, Version 3 | both | z/OS V1R9 POSIX(ON) |

Format

```

#define _UNIX03_THREADS
#include <pthread.h>

int pthread_attr_setstack(pthread_attr_t *attr, void *addr, size_t size);

```

General description

The *pthread_attr_setstack()* function sets the *stackaddr* and *stacksize* attributes in *attr* from the values of *addr* and *size* respectively.

When a thread is created, the *stackaddr* attribute locates the base (lowest addressable byte) of the created thread's initial stack segment. The *stacksize* attribute is the size, in bytes, of the initial stack segment allocated for the thread.

attr is a pointer to a thread attribute object initialized by *pthread_attr_init()*.

addr is the memory location to use for the initial stack segment and must be aligned appropriately to be used as a stack. For 31-bit applications, stack alignment is on a 4K boundary; in AMODE64, the alignment is on a one megabyte boundary.

size must be at least as large as *PTHREAD_STACK_MIN*. This constant is defined in the *<limits.h>* header.

The minimum stacksize in 31-bit is 4096 (4K) and in 64-bit 1048576 (1M). In addition, the system will allocate an equivalent-sized guardpage. There is no specified maximum stacksize. If more storage

is requested than the system can satisfy at pthread creation, then pthread_create() will fail and return EINVAL.

Usage notes

1. An XPLINK application uses two stacks, an upward-growing stack and a downward-growing stack. The "size" argument refers to the size of the downward-growing stack.
2. The Language Environment storage report tolerates but does not maintain statistics on application-managed stacks. Also, the runtime storage option, suboption for dsa initialization does not support application-managed stacks.

Returned value

If successful, *pthread_attr_setstack()* returns 0; otherwise, it returns an error number.

Error Code

Description

EINVAL

Can be one of the following error conditions:

- size is less than PTHREAD_STACK_MIN
- addr does not have proper alignment to be used as a stack
- (addr + size) lacks proper alignment
- attr does not refer to an initialized thread attribute object.

Example

```
/* CELEBP65 */
/* Example using SUSv3 pthread_attr_setstack() interface */

#define _UNIX03_THREADS 1

#include <stdio.h>
#include <stdlib.h>
#include <pthread.h>
#include <limits.h>
#include <errno.h>

int main(void)
{
    pthread_attr_t attr;
    int rc;

    void * stackaddr;
    void * mystack;

    size_t stacksize;
    size_t mystacksize = 2 * PTHREAD_STACK_MIN;

    if (pthread_attr_init(&attr) == -1) {
        perror("error in pthread_attr_init");
        exit(1);
    }

    /* Get a big enough stack and align it on 4K boundary. */
    mystack = malloc(PTHREAD_STACK_MIN * 3);
    if (mystack != NULL) {
        printf("Using PTHREAD_STACK_MIN to align stackaddr %x.\n", mystack);
        mystack = (void *)((((long)mystack + (PTHREAD_STACK_MIN - 1)) /
                           PTHREAD_STACK_MIN) * PTHREAD_STACK_MIN);
    } else {
        perror("Unable to acquire storage.");
        exit(2);
    }

    printf("Setting stackaddr to %x\n", mystack);
    printf("Setting stacksize to %x\n", mystacksize);
    rc = pthread_attr_setstack(&attr, mystack, mystacksize);
    if (rc != 0) {
```

```

    printf("pthread_attr_setstack returned: %d\n", rc);
    printf("Error: %d, Errno_Jr: %08x\n", errno, __errno2());
    exit(3);
} else {
    printf("Set stackaddr to %x\n", mystack);
    printf("Set stacksize to %x\n", mystacksize);
}

rc = pthread_attr_getstack(&attr, &stackaddr, &stacksize);
if (rc != 0) {
    printf("pthread_attr_getstack returned: %d\n", rc);
    printf("Error: %d, Errno_Jr: %08x\n", errno, __errno2());
    exit(4);
} else {
    printf("Retrieved stackaddr is %x\n", mystack);
    printf("Retrieved stacksize is %x\n", mystacksize);
}

rc = pthread_attr_destroy(&attr);
if (rc != 0) {
    perror("error in pthread_attr_destroy");
    printf("Returned: %d, Error: %d\n", rc, errno);
    printf("Errno_Jr: %x\n", __errno2());
    exit(5);
}

exit(0);
}

```

pthread_attr_setstackaddr() - Set stackaddr attribute

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|---------------------|
| Single UNIX Specification, Version 3 | both | z/OS V1R9 POSIX(ON) |

Format

```

#define _UNIX03_THREADS
#include <pthread.h>

int pthread_attr_setstackaddr(pthread_attr_t *attr, void *addr);

```

General description

The *pthread_attr_setstackaddr()* function sets the stackaddr attribute in *attr* using the value of *addr*.

attr is a pointer to a thread attribute object initialized by *pthread_attr_init()*.

addr is the lowest addressable byte of the memory designated for use as the initial stack segment. It must have at least PTHREAD_STACK_MIN storage allocated. The PTHREAD_STACK_MIN constant is defined in <limits.h>. The *addr* value must also be aligned with the stack frame size, a multiple of 4K in 31-bit applications and one megabyte in AMODE 64.

The thread must have permission to read and write to all pages within the stack referenced by *addr*.

A stacksize is required at pthread creation. If the value is not present in the thread attribute object, the stacksize will default to PTHREAD_STACK_MIN. Subsequent calls to *pthread_attr_setstacksize()* can overwrite the stacksize prior to pthread creation.

Usage notes

1. The *pthread_attr_setstackaddr()* function is provided for historical reasons. It is marked obsolescent in the Single UNIX Specification, Version 3 (SUSv3). New applications should use the newer function *pthread_attr_setstack()*, which provides functionality compatible with the SUSv3 standard.
2. An attribute object with the stackaddr attribute set may not be used more than once, unless it is destroyed and reinitialized, or its stackaddr attribute changed. For more details, see "Thread stack attributes" in the z/OS X/L C/C++ Programming Guide.
3. An XPLINK application uses two stacks, an upward-growing stack and a downward-growing stack. The variable *addr* always refers to lowest addressable byte of the downward-growing stack.
4. The Language Environment storage report tolerates but does not maintain statistics on application-managed stacks. Also, the runtime storage option, suboption for dsa initialization does not support application-managed stacks.

Returned value

If successful, *pthread_attr_setstackaddr()* returns 0; otherwise, it returns an error number.

Error Code

Description

EINVAL

The value of *addr* does not have proper alignment to be used as a stack or the value specified by *attr* does not refer to an initialized thread attribute object.

Example

```
/* CELEBP68 */
/* Example using SUSv3 pthread_attr_setstackaddr() interface */

#define _UNIX03_THREADS 1

#include <stdio.h>
#include <stdlib.h>
#include <pthread.h>
#include <limits.h>
#include <errno.h>

int main(void)
{
    pthread_attr_t attr;
    int rc;
    void *mystack;

    if (pthread_attr_init(&attr) == -1) {
        perror("error in pthread_attr_init");
        exit(1);
    }

    /* Get a big enough stack and align it on 4K boundary. */
    mystack = malloc(PTHREAD_STACK_MIN * 2);
    if (mystack != NULL) {
        printf("Using PTHREAD_STACK_MIN to align stackaddr %x.\n", mystack);
        mystack = (void *)((((long)mystack + (PTHREAD_STACK_MIN - 1)) /
                           PTHREAD_STACK_MIN) * PTHREAD_STACK_MIN);
    } else {
        perror("Unable to acquire storage.");
        exit(2);
    }

    printf("Setting stackaddr to %x\n", mystack);
    rc = pthread_attr_setstackaddr(&attr, mystack);
```

```

    if (rc != 0) {
        printf("pthread_attr_setstackaddr returned: %d\n", rc);
        printf("Error: %d, Errno_Jr: %08x\n", errno, __errno2());
        exit(3);
    } else {
        printf("Set stackaddr to %x\n", mystack);
    }

    rc = pthread_attr_destroy(&attr);
    if (rc != 0) {
        perror("error in pthread_attr_destroy");
        printf("Returned: %d, Error: %d\n", rc, errno);
        printf("Errno_Jr: %x\n", __errno2());
        exit(4);
    }

    exit(0);
}

```

pthread_attr_setstacksize() — Set the stacksize attribute object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```

#define _OPEN_THREADS
#include <pthread.h>

int pthread_attr_setstacksize(pthread_attr_t *attr, size_t stacksize);

```

SUSV3:

```

#define _UNIX03_THREADS
#include <pthread.h>

int pthread_attr_setstacksize(pthread_attr_t *attr, size_t stacksize);

```

General description

Sets the stacksize, in bytes, for the thread attribute object, *attr*. *stacksize* is the initial stack size. Other stack characteristics, like stack increment size, are inherited from the STACK64/THREADSTACK64 runtime option.

You can use a thread attribute object to manage the characteristics of threads in your application. It defines the set of values to be used for the thread during its creation. By establishing a thread attribute object, you can create many threads with the same set of characteristics, without defining those characteristics for each thread. You can define more than one thread attribute object.

Usage notes

1. An XPLINK application uses two stacks, an upward-growing stack and a downward-growing stack. The "stacksize" refers to the size of the downward-growing stack.
2. When using Single UNIX Specification, Version thread support, the minimum stacksize in 31-bit is 4096 (4K) and in 64-bit 1048576 (1M). In addition, the system will allocate an equivalent-sized guardpage. There is no specified maximum stacksize. If more storage is requested than the system can satisfy at pthread creation, then pthread_create() will fail and return EINVAL.

Returned value

If successful, pthread_attr_setstacksize() returns 0.

If unsuccessful, pthread_attr_setstacksize() returns -1.

Error Code

Description

EINVAL

The value of stacksize is less than PTHREAD_STACK_MIN, or the value specified by attr does not refer to an initialized thread attribute object.

Special behavior for Single UNIX Specification, Version 3:

If unsuccessful, pthread_attr_setstacksize() returns an error number to indicate the error.

Example

CELEBP12

```
/* CELEBP12 */
#define _OPEN_THREADS
#include <stdio.h>
#include <pthread.h>

void *thread1(void *arg)
{
    printf("hello from the thread\n");
    pthread_exit(NULL);
}

int main()
{
    int          rc, stat;
    size_t       s1;
    pthread_attr_t attr;
    pthread_t     thid;

    rc = pthread_attr_init(&attr);
    if (rc == -1) {
        perror("error in pthread_attr_init");
        exit(1);
    }

    s1 = 4096;
    rc = pthread_attr_setstacksize(&attr, s1);
    if (rc == -1) {
        perror("error in pthread_attr_setstacksize");
        exit(2);
    }

    rc = pthread_create(&thid, &attr, thread1, NULL);
    if (rc == -1) {
        perror("error in pthread_create");
        exit(3);
    }

    rc = pthread_join(thid, (void *)&stat);
    exit(0);
}
```

pthread_attr_setsynctype_np() — Set thread sync type

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | POSIX(ON) |

Format

```
#define _OPEN_SYS
#include <pthread.h>

int pthread_attr_setsynctype_np(pthread_attr_t *attr, int synctype);
```

General description

The `pthread_attr_setsynctype_np` function allows you to alter the `synctype` setting of the `attr` thread attribute object.

The `synctype` can be set to one of the following symbolics, as defined in the `pthread.h` header file:

__PTATSYNCHRONOUS

Can only create as many threads as TCBs available (or as many threads are available, depending on which number is smaller).

__PTATASYNCHRONOUS

Allows threads to be queued, that is, can create more threads than TCBs are available up to limit of how many threads are available. The queued threads will be released as TCBs become available. While threads are on the queue, they can still be affected by other pthread functions.

Returned value

If successful, `pthread_attr_setsynctype_np()` returns 0.

If unsuccessful, `pthread_attr_setsynctype_np()` returns -1.

There are no documented `errno` values. Use `perror()` or `strerror()` to determine cause of the error.

pthread_attr_setweight_np() – Set weight of thread attribute object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#define _OPEN_SYS
#include <pthread.h>

int pthread_attr_setweight_np(pthread_attr_t *attr, int threadweight);
```

General description

Alter the current weight of the thread setting of the thread attribute object, *attr*.

threadweight can be set to one of the following two symbols for the weight of the thread, as defined in the pthread.h header file.

__LIGHT_WEIGHT

Not supported.

__MEDIUM_WEIGHT

Each thread runs on a task. Upon exiting, if another thread is not queued to run, the task waits for some other thread to issue a pthread_create(), and the thread then runs on that task. The thread is assumed to cleanup all resources it used.

__HEAVY_WEIGHT

The task is attached on pthread_create() and terminates upon a pthread_exit(). Full MVS EOT resource cleanup occurs when exiting. When this exits, the associated MVS task can no longer request threads to process.

You can use a thread attribute object to manage the characteristics of threads in your application. It defines the set of values to be used for the thread during its creation. By establishing a thread attribute object, you can create many threads with the same set of characteristics, without defining those characteristics for each thread. You can define more than one thread attribute object.

Returned value

If successful, pthread_attr_setweight_np() returns 0.

If unsuccessful, pthread_attr_setweight_np() returns -1.

There are no documented errno values. Use perror() or strerror() to determine the cause of the error.

Example

CELEBP13

```
/* CELEBP13 */
#define _OPEN_THREADS
#define _OPEN_SYS /* Needed to identify __MEDIUM_WEIGHT */
#include <stdio.h>
#include <pthread.h>

void *thread1(void *arg)
{
    printf("hello from the thread\n");
```

```

    pthread_exit((void *)0);
}

int main()
{
    int          rc, stat;
    pthread_attr_t attr;
    pthread_t     thid;

    rc = pthread_attr_init(&attr);
    if (rc == -1) {
        perror("error in pthread_attr_init");
        exit(1);
    }

    rc = pthread_attr_setweight_np(&attr, __MEDIUM_WEIGHT);
    if (rc == -1) {
        perror("error in pthread_attr_setweight_np");
        exit(2);
    }

    rc = pthread_create(&thid, &attr, thread1, NULL);
    if (rc == -1) {
        perror("error in pthread_create");
        exit(3);
    }

    rc = pthread_join(thid, (void *)&stat);
    exit(0);
}

```

pthread_cancel() — Cancel a thread

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```

#define _OPEN_THREADS
#include <pthread.h>

int pthread_cancel(pthread_t thread);

```

SUSV3:

```

#define _UNIX03_THREADS
#include <pthread.h>

int pthread_cancel(pthread_t thread);

```

General description

Requests that a thread be canceled. The thread to be canceled controls when this cancelation request is acted on through the cancelability state and type.

The cancelability states can be:

PTHREAD_INTR_DISABLE

The thread cannot be canceled.

PTHREAD_INTR_ENABLE

The thread can be canceled, but it is subject to type.

The cancelability types can be:

PTHREAD_INTR_CONTROLLED

The thread can be canceled, but only at specific points of execution:

- When waiting on a condition variable, which is `pthread_cond_wait()` or `pthread_cond_timedwait()`
- When waiting for the end of another thread, which is `pthread_join()`
- While waiting for an asynchronous signal, which is `sigwait()`
- Testing specifically for a cancel request, which is `pthread_testintr()`
- When suspended because of POSIX functions or one of the following C standard functions: `close()`, `fcntl()`, `open()`, `pause()`, `read()`, `tcdrain()`, `tcsetattr()`, `sigsuspend()`, `sigwait()`, `sleep()`, `wait()`, or `write()`

PTHREAD_INTR_ASYNCHRONOUS

The thread can be canceled at any time.

A thread that is joined on a thread that is canceled has a status of -1 returned to it. For more information, refer to “[pthread_join\(\) — Wait for a thread to end](#)” on page 1287.

pthread_t is the data type used to uniquely identify a thread. It is returned by `pthread_create()` and used by the application in function calls that require a thread identifier.

Note: A thread in mutex wait will not be interrupted by a signal, and therefore not canceled.

Special behavior for C++: Destructors for automatic objects on the stack will be run when a thread is canceled. The stack is unwound and the destructors are run in reverse order.

Special behavior for SUSv3 : Single UNIX Standard, Version 3 defines new symbols for cancelability state and type. These are equivalent to the symbols described above and must be used when compiling in the SUSv3 namespace. The symbols for state are `PTHREAD_CANCEL_ENABLE` and `PTHREAD_CANCEL_DISABLE`. Symbols for type are `PTHREAD_CANCEL_DEFERRED` and `PTHREAD_CANCEL_ASYNCHRONOUS`.

Returned value

If successful, `pthread_cancel()` returns 0. Success indicates that the `pthread_cancel()` request has been issued. The thread to be canceled may still execute because of its interruptibility state.

If unsuccessful, `pthread_create()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

The specified thread is not valid.

ESRCH

The specified thread does not refer to a currently existing thread.

Special behavior for Single UNIX Specification, Version 3:

If unsuccessful, `pthread_cancel()` returns an error number to indicate the error.

Example

CELEBP14

```
/* CELEBP14 */
#define _OPEN_THREADS
```

```

#include <errno.h>
#include <pthread.h>
#include <stdio.h>
#include <string.h>
#include <unistd.h>

int  thstatus;

void * thread(void *arg)
{
    puts("thread has started. now sleeping");
    while (1)
        sleep(1);
}

main(int argc, char *argv[])
{
    pthread_t      thid;
    void           *status;

    if ( pthread_create(&thid, NULL, thread, NULL) != 0) {
        perror("pthread_create failed");
        exit(2);
    }

    if ( pthread_cancel(thid) == -1 ) {
        perror("pthread_cancel failed");
        exit(3);
    }

    if ( pthread_join(thid, &status)== -1 ) {
        perror("pthread_join failed");
        exit(4);
    }

    if ( status == (int *)-1 )
        puts("thread was cancelled");
    else
        puts("thread was not cancelled");

    exit(0);
}

```

Output:

```

thread has started. now sleeping
thread was canceled

```

pthread_cleanup_pop() – Remove a cleanup handler

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

void pthread_cleanup_pop(int execute);
```

General description

Removes the specified *routine* in the last executed `pthread_cleanup_push()` statement from the top of the calling thread's cleanup stack.

The *execute* parameter specifies whether the cleanup routine that is popped should be run or just discarded. If the value is nonzero, the cleanup routine is executed.

`pthread_cleanup_push()` and `pthread_cleanup_pop()` must appear in pairs in the program within the same lexical scope, or undefined behavior will result.

When the thread ends, all pushed but not yet popped cleanup routines are popped from the cleanup stack and executed in last-in-first-out (LIFO) order. This occurs when the thread:

- Calls `pthread_exit()`
- Does a return from the start routine (that gets controls as a result of a `pthread_create()`)
- Is canceled because of a `pthread_cancel()`

Returned value

`pthread_cleanup_pop()` returns no values.

This function is used as a statement.

If an error occurs while a `pthread_cleanup_pop()` statement is being processed, a termination condition is raised.

There are no documented `errno` values. Use `perror()` or `strerror()` to determine the cause of an error.

Example

CELEBP15

```
/* CELEBP15 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>

int iteration;

void noise_maker(void *arg) {
    printf("hello from noise_maker in iteration %d!\n", iteration);
}

void *thread(void *arg) {
    pthread_cleanup_push(noise_maker, NULL);
    pthread_cleanup_pop(iteration == 1 ? 0 : 1);
}
```

```

main() {
    pthread_t thid;
    void * ret;

    for (iteration=1; iteration<=2; iteration++) {

        if (pthread_create(&thid, NULL, thread, NULL) != 0) {
            perror("pthread_create() error");
            exit(1);
        }

        if (pthread_join(thid, &ret) != 0){
            perror("pthread_join() error");
            exit(2);
        }
        /*
        if (pthread_detach(&thid) != 0) {
            perror("pthread_detach() error");
            exit(3);
        }
        */
    }
}

```

Output:

```
hello from noise_maker in iteration 2!
```

Related information

- [“pthread.h — Thread interfaces” on page 53](#)
- [“pthread_cancel\(\) — Cancel a thread” on page 1247](#)
- [“pthread_cleanup_push\(\) — Establish a cleanup handler” on page 1251](#)
- [“pthread_exit\(\) — Exit a thread” on page 1279](#)

pthread_cleanup_push() — Establish a cleanup handler

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```

#define _OPEN_THREADS
#include <pthread.h>

void pthread_cleanup_push(void (*routine)(void *arg), void *arg);

```

General description

Pushes the specified *routine* onto the calling thread's cleanup stack. The cleanup handler is executed as a result of a `pthread_cleanup_pop()`, with a nonzero value for the *execute* parameter.

When the thread ends, all pushed but not yet popped cleanup routines are popped from the cleanup stack and executed in last-in-first-out (LIFO) order. This occurs when the thread:

- Calls `pthread_exit()`
- Does a return from the start routine
- Is canceled because of a `pthread_cancel()`

pthread_cleanup_push() and pthread_cleanup_pop() must appear in pairs and within the same lexical scope, or undefined behavior will result.

Special behavior for C++: Because C and C++ linkage conventions are incompatible, pthread_cleanup_push() cannot receive a C++ function pointer as the start routine function pointer. If you attempt to pass a C++ function pointer to pthread_cleanup_push(), the compiler will flag it as an error. You can pass a C or C++ function to pthread_cleanup_push() by declaring it as extern "C".

Returned value

pthread_cleanup_push() returns no values.

This function is used as a statement.

If an error occurs while a pthread_cleanup_push() statement is being processed, a termination condition is raised.

There are no documented errno values. Use perror() or strerror() to determine the cause of an error.

Example

CELEBP16

```
/* CELEBP16 */
#define _OPEN_THREADS

#include <pthread.h>
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>

int footprint=0;

void *thread(void *arg) {
    char *storage;

    if ((storage = (char*) malloc(80)) == NULL) {
        perror("malloc() failed");
        exit(6);
    }

    /* Plan to release storage even if thread doesn't exit normally */
    pthread_cleanup_push(free, storage);

    puts("thread has obtained storage and is waiting to be cancelled");
    footprint++;
    while (1)
        sleep(1);

    pthread_cleanup_pop(1);
}

main() {
    pthread_t thid;

    if (pthread_create(&thid, NULL, thread, NULL) != 0) {
        perror("pthread_create() error");
        exit(1);
    }

    while (footprint == 0)
        sleep(1);

    puts("IPT is cancelling thread");

    if (pthread_cancel(thid) != 0) {
        perror("pthread_cancel() error");
        exit(3);
    }

    if (pthread_join(thid, NULL) != 0) {
        perror("pthread_join() error");
        exit(4);
    }
}
```

```
}
}
```

Output:

```
thread has obtained storage and is waiting to be canceled
IPT is canceling thread
```

pthread_cond_broadcast() — Broadcast a condition

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_cond_broadcast(pthread_cond_t *cond);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_cond_broadcast(pthread_cond_t *cond);
```

General description

Unblock all threads that are blocked on the specified condition variable, *cond*. If more than one thread is blocked, the order in which the threads are unblocked is unspecified.

pthread_cond_broadcast() has no effect if there are no threads currently blocked on *cond*.

Returned value

If successful, pthread_cond_broadcast() returns 0.

If unsuccessful, pthread_cond_broadcast() returns -1 and sets errno to one of the following values:

Error Code**Description****EINVAL**

The value specified by *cond* does not refer to an initialized condition variable.

Special behavior for Single UNIX Specification, Version 3:

If unsuccessful, pthread_cond_broadcast() returns an error number to indicate the error.

Example

CELEBP17

```
/* CELEBP17 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>

main() {
    pthread_cond_t cond;

    if (pthread_cond_init(&cond, NULL) != 0) {
        perror("pthread_cond_init() error");
        exit(1);
    }

    if (pthread_cond_broadcast(&cond) != 0) {
        perror("pthread_cond_broadcast() error");
        exit(2);
    }

    if (pthread_cond_destroy(&cond) != 0) {
        perror("pthread_cond_destroy() error");
        exit(3);
    }
}
```

pthread_cond_destroy() – Destroy the condition variable object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_cond_destroy(pthread_cond_t *cond);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_cond_destroy(pthread_cond_t *cond);
```

General description

Destroys the condition variable object specified by *cond*.

A condition variable object identifies a condition variable. Condition variables are used in conjunction with mutexes to protect shared resources.

Returned value

If successful, pthread_cond_destroy() returns 0.

If unsuccessful, pthread_cond_destroy() returns -1 and sets errno to one of the following values:

Error Code Description

EBUSY

An attempt was made to destroy the object referenced by *cond* while it is referenced by another thread.

EINVAL

The value specified by *cond* is not valid.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_cond_destroy() returns an error number to indicate the error.

Example

CELEBP18

```

/* CELEBP18 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>

main() {
    pthread_cond_t cond;

    if (pthread_cond_init(&cond, NULL) != 0) {
        perror("pthread_cond_init() error");
        exit(1);
    }

    if (pthread_cond_destroy(&cond) != 0) {
        perror("pthread_cond_destroy() error");
        exit(2);
    }
}

```

int pthread_cond_init(pthread_cond_t *cond, pthread_condattr_t *attr);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>
int pthread_cond_init(pthread_cond_t * __restrict__ cond,
                     pthread_condattr_t * __restrict__ attr);
```

General description

Initializes the condition variable referenced by *cond* with attributes referenced by *attr*. If *attr* is NULL, the default condition variable attributes are used.

Returned value

If successful, pthread_cond_init() returns 0.

If unsuccessful, pthread_cond_init() returns -1 and sets errno to one of the following values:

Error Code

Description

ENOMEM

There is not enough memory to initialize the condition variable.

EAGAIN

The system lacked the necessary resources (other than memory) to initialize another condition variable.

EBUSY

The implementation has detected an attempt to reinitialize the object referenced by cond, a previously initialized, but not yet destroyed, condition variable.

EINVAL

The value specified by attr is invalid.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_cond_init() returns an error number to indicate the error.

Usage notes

The _OPEN_SYS_MUTEX_EXT feature switch can be optionally included. If the feature is set, then significantly larger pthread_cond_t objects will be defined. The feature is used for the management of mutex and condition variables in shared memory. If the feature switch is set in the define of the condition variables in shared memory, then the same feature switch must be set in the define of the mutex associated with the condition variables.

If the supplied extended pthread_cond_t object is not in shared memory, pthread_cond_init() will treat the object as a non-shared object, since it is not accessible to any other process.

If the _OPEN_SYS_MUTEX_EXT feature switch is set, a shared condition variable is tied to the specified mutex for the life of the condition variable and mutex the very first time a pthread_cond_wait() or pthread_cond_timedwait() is issued. No other mutex can be associated with the specified condition variable or vice versa until the condition variable or mutex is destroyed.

It is recommended that you define and initialize pthread_cond_t objects in the same compile unit. If you pass a pthread_cond_t object around to be initialized, make sure the initialization code has been compiled with the same _OPEN_SYS_MUTEX_EXT feature setting as the code that defines the object.

The following sequence may cause storage overlay with unpredictable results:

1. Declare or define a `pthread_cond_t` object (in shared storage) without `#define` of the `_OPEN_SYS_MUTEX_EXT` feature. The created `pthread_cond_t` object is standard size (i.e. small) without the `_OPEN_SYS_MUTEX_EXT` feature defined.
2. Pass the `pthread_cond_t` object to another code unit, which was compiled with the `_OPEN_SYS_MUTEX_EXT` feature defined, to be initialized as a shared object. The `pthread_cond_t` initialization generally involves the following steps:
 - a. `pthread_condattr_init()`
 - b. `pthread_condattr_setpshared()`. This step sets the attribute of the `pthread_cond_t` as `PTHREAD_PROCESS_SHARED` and designates the object to be of extended size.
 - c. `pthread_cond_init()`. This step initializes the passed-in (small) `pthread_cond_t` object as if it is an extended object, causing storage overlay.

Example

CELEBP19

```

/* CELEBP19 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>

main() {
    pthread_cond_t cond;

    if (pthread_cond_init(&cond, NULL) != 0) {
        perror("pthread_cond_init() error");
        exit(1);
    }

    if (pthread_cond_destroy(&cond) != 0) {
        perror("pthread_cond_destroy() error");
        exit(2);
    }
}

```

pthread_cond_signal() — Signal a condition

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```

#define _OPEN_THREADS
#include <pthread.h>

```

```
int pthread_cond_signal(pthread_cond_t *cond);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_cond_signal(pthread_cond_t *cond);
```

General description

Unblock at least one thread that is blocked on the specified condition variable, *cond*. If more than one thread is blocked, the order in which the threads are unblocked is unspecified.

pthread_cond_signal() will have no effect if there are no threads currently blocked on *cond*.

Returned value

If successful, pthread_cond_signal() returns 0.

If unsuccessful, pthread_cond_signal() returns -1 and sets errno to one of the following values:

Error Code**Description****EINVAL**

The value specified by *cond* does not refer to an initialized condition variable.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_cond_signal() returns an error number to indicate the error.

Example**CELEBP20**

```
/* CELEBP20 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>

main() {
    pthread_cond_t cond;

    if (pthread_cond_init(&cond, NULL) != 0) {
        perror("pthread_cond_init() error");
        exit(1);
    }

    if (pthread_cond_signal(&cond) != 0) {
        perror("pthread_cond_broadcast() error");
        exit(2);
    }

    if (pthread_cond_destroy(&cond) != 0) {
        perror("pthread_cond_destroy() error");
        exit(3);
    }
}
```

pthread_cond_timedwait(), pthread_cond_timedwait64() – Wait on a condition variable

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

pthread_cond_timedwait:

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_cond_timedwait(pthread_cond_t *cond, pthread_mutex_t *mutex,
                           const struct timespec *abstime);
```

pthread_cond_timedwait64:

```
#define _LARGE_TIME_API
#define _OPEN_THREADS
#include <pthread.h>

int pthread_cond_timedwait64(pthread_cond_t *cond, pthread_mutex_t *mutex,
                              const struct timespec64 *abstime);
```

SUSV3:

pthread_cond_timedwait:

```
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_cond_timedwait(pthread_cond_t * __restrict__ cond,
                           pthread_mutex_t * __restrict__ mutex,
                           const struct timespec * __restrict__ abstime);
```

pthread_cond_timedwait64:

```
#define _LARGE_TIME_API
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_cond_timedwait64(pthread_cond_t * __restrict__ cond,
                              pthread_mutex_t * __restrict__ mutex,
                              const struct timespec64 * __restrict__ abstime);
```

Compile requirement: Use of the pthread_cond_timedwait64 function requires the long long data type. For more information on how to make the long long data type available, see [z/OS XL C/C++ Language Reference](#).

General description

Allows a thread to wait on a condition variable until satisfied or until a specified time occurs. pthread_cond_timedwait() is the same as pthread_cond_wait() except it returns an error if the absolute time, specified by *abstime*, satisfies one of these conditions:

- Passes before *cond* is signaled or broadcasted.
- Has already been passed at the time of the call.

When such timeouts occur, pthread_cond_timedwait() reacquires the mutex, referenced by *mutex* (created by pthread_mutex_init()).

The two elements within the struct *timespec* are defined as follows:

tv_sec

The time to wait for the condition signal. It is expressed in seconds from midnight, January 1, 1970 UTC. The value specified must be greater than or equal to current calendar time expressed in seconds since midnight, January 1, 1970 UTC and less than 2,147,483,648 seconds.

tv_nsec

The time in nanoseconds to be added to tv_sec to determine when to stop waiting. The value specified must be greater than or equal to zero (0) and less than 1,000,000,000 (1,000 million).

The pthread_cond_timedwait64() function behaves exactly like pthread_cond_timedwait() except that pthread_cond_timedwait64() supports time beyond 03:14:07 UTC on January 19, 2038.

Returned value

If successful, pthread_cond_timedwait() returns 0.

If unsuccessful, pthread_cond_timedwait() returns -1 and sets errno to one of the following values:

Error Code

Description

EAGAIN

For a private condition variable, the time specified by *abstime* has passed.

EINVAL

Can be one of the following error conditions:

- The value specified by *cond* is not valid.
- The value specified by *mutex* is not valid.
- The value specified by *abstime* (tv_sec) is not valid.
- The value specified by *abstime* (tv_nsec) is not valid.
- Different mutexes were specified for concurrent operations on the same condition variable.

ETIMEDOUT

For a shared condition variable, the time specified by *abstime* has passed.

Note: In SUSV3, pthread_cond_timedwait() also returns ETIMEDOUT for a private condition variable, when the time specified by *abstime* has passed.

EPERM

The mutex was not owned by the current thread at the time of the call.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_cond_timedwait() returns an error number to indicate the error.

Usage notes

If the condition variable is shared (PTHREAD_PROCESS_SHARED), the mutex must also be shared, with the _OPEN_SYS_MUTEX_EXT feature defined when the mutex was created and initialized.

If the condition variable is private (PTHREAD_PROCESS_PRIVATE), the mutex must also be private.

If the condition variable is shared, all calls to pthread_cond_wait() or pthread_cond_timedwait() for a given condition variable must use the same mutex for the life of the process, or until both the condition variable and mutex are destroyed (using pthread_cond_destroy() and pthread_mutex_destroy()).

Example

CELEBP21

```

/* CELEBP21 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>
#include <time.h>
#include <errno.h>

main() {
    pthread_cond_t cond;
    pthread_mutex_t mutex;
    time_t T;
    struct timespec t;

    if (pthread_mutex_init(&mutex, NULL) != 0) {
        perror("pthread_mutex_init() error");
        exit(1);
    }

    if (pthread_cond_init(&cond, NULL) != 0) {
        perror("pthread_cond_init() error");
        exit(2);
    }

    if (pthread_mutex_lock(&mutex) != 0) {
        perror("pthread_mutex_lock() error");
        exit(3);
    }

    time(&T);
    t.tv_sec = T + 2;
    t.tv_nsec = 0;
    printf("starting timedwait at %s", ctime(&T));
    if (pthread_cond_timedwait(&cond, &mutex, &t) != 0)
        if (errno == EAGAIN)
            puts("wait timed out");
        else {
            perror("pthread_cond_timedwait() error");
            exit(4);
        }

    time(&T);
    printf("timedwait over at %s", ctime(&T));
}

```

Output:

```

starting timedwait at Fri Jun 16 10:44:00 2006
wait timed out
timedwait over at Fri Jun 16 10:44:02 2006

```

pthread_cond_wait() — Wait on a condition variable

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_cond_wait(pthread_cond_t *cond, pthread_mutex_t *mutex);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>
int pthread_cond_wait(pthread_cond_t * __restrict__ cond,
                     pthread_mutex_t * __restrict__ mutex);
```

General description

Blocks on a condition variable. It must be called with *mutex* locked by the calling thread, or undefined behavior will result. A mutex is locked using `pthread_mutex_lock()`.

cond is a condition variable that is shared by threads. To change it, a thread must hold the *mutex* associated with the condition variable. The `pthread_cond_wait()` function releases this *mutex* before suspending the thread and obtains it again before returning.

The `pthread_cond_wait()` function waits until a `pthread_cond_broadcast()` or a `pthread_cond_signal()` is received. For more information on these functions, refer to “[pthread_cond_broadcast\(\) — Broadcast a condition](#)” on page 1253 and to “[pthread_cond_signal\(\) — Signal a condition](#)” on page 1257.

Returned value

If successful, `pthread_cond_wait()` returns 0.

If unsuccessful, `pthread_cond_wait()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

Different mutexes were specified for concurrent operations on the same condition variable.

EPERM

The mutex was not owned by the current thread at the time of the call.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, `pthread_cond_wait()` returns an error number to indicate the error.

Usage notes

If the condition variable is shared (`PTHREAD_PROCESS_SHARED`), the mutex must also be shared, with the `_OPEN_SYS_MUTEX_EXT` feature defined when the mutex was created and initialized.

If the condition variable is private (`PTHREAD_PROCESS_PRIVATE`), the mutex must also be private.

If the condition variable is shared, all calls to `pthread_cond_wait()` or `pthread_cond_timedwait()` for a given condition variable must use the same mutex for the life of the process, or until both the condition variable and mutex are destroyed (using `pthread_cond_destroy()` and `pthread_mutex_destroy()`).

Example

CELEBP22

```

/* CELEBP22 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>
#include <time.h>
#include <unistd.h>

pthread_cond_t cond;
pthread_mutex_t mutex;

int footprint = 0;

void *thread(void *arg) {
    time_t T;

    if (pthread_mutex_lock(&mutex) != 0) {
        perror("pthread_mutex_lock() error");
        exit(6);
    }
    time(&T);
    printf("starting wait at %s", ctime(&T));
    footprint++;

    if (pthread_cond_wait(&cond, &mutex) != 0) {
        perror("pthread_cond_timedwait() error");
        exit(7);
    }
    time(&T);
    printf("wait over at %s", ctime(&T));
}

main() {
    pthread_t thid;
    time_t T;
    struct timespec t;

    if (pthread_mutex_init(&mutex, NULL) != 0) {
        perror("pthread_mutex_init() error");
        exit(1);
    }

    if (pthread_cond_init(&cond, NULL) != 0) {
        perror("pthread_cond_init() error");
        exit(2);
    }

    if (pthread_create(&thid, NULL, thread, NULL) != 0) {
        perror("pthread_create() error");
        exit(3);
    }

    while (footprint == 0)
        sleep(1);

    puts("IPT is about ready to release the thread");
    sleep(2);

    if (pthread_cond_signal(&cond) != 0) {
        perror("pthread_cond_signal() error");
        exit(4);
    }

    if (pthread_join(thid, NULL) != 0) {
        perror("pthread_join() error");
        exit(5);
    }
}

```

Output:

```
starting wait at Fri Jun 16 10:54:06 2006
IPT is about ready to release the thread
wait over at Fri Jun 16 10:54:09 2006
```

pthread_condattr_destroy() — Destroy condition variable attribute object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_condattr_destroy(pthread_condattr_t *attr);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_condattr_destroy(pthread_condattr_t *attr);
```

General description

Destroys a condition attribute object. Condition-variable attribute objects are similar to mutex attribute objects because you can use them to manage the characteristics of condition variables in your application. They define the set of values to be used for the condition variable during its creation.

pthread_condattr_init() is used to define a condition variable attribute object. pthread_condattr_destroy() is used to remove the definition of the condition variable attribute object. These functions are provided for portability purposes.

You can define a condition variable without using these functions by supplying a NULL parameter during the pthread_cond_init() call. For more details, refer to [“pthread_cond_init\(\) — Initialize a condition variable” on page 1255](#).

Returned value

If successful, pthread_condattr_destroy() returns 0.

If unsuccessful, pthread_condattr_destroy() returns -1 and sets errno to one of the following values:

Error Code**Description**

EINVAL

The value specified by *attr* is not valid.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, `pthread_condattr_destroy()` returns an error number to indicate the error.

Example**CELEBP23**

```
/* CELEBP23 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>

main() {
    pthread_condattr_t cond;

    if (pthread_condattr_init(&cond) != 0) {
        perror("pthread_condattr_init() error");
        exit(1);
    }

    if (pthread_condattr_destroy(&cond) != 0) {
        perror("pthread_condattr_destroy() error");
        exit(2);
    }
}
```

pthread_condattr_getkind_np() — Get kind attribute from a condition variable attribute object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#define _OPEN_SYS
#include <pthread.h>

int pthread_condattr_getkind_np(pthread_condattr_t *attr, int *kind);
```

General description

Gets the attribute *kind* for the condition variable attribute object *attr*. Condition variable attribute objects are similar to mutex attribute objects. You can use them to manage the characteristics of condition variables in your application. They define the set of values for the condition variable during its creation.

The valid values for the attribute *kind* are:

__COND_DEFAULT

No defined attributes.

__COND_NODEBUG

State changes to this condition variable will *not* be reported to the debug interface, even though it is present.

Returned value

If successful, pthread_condattr_getkind_np() returns 0.

If unsuccessful, pthread_condattr_getkind_np() returns -1 and sets errno to one of the following values:

Error Code**Description****EINVAL**

The value specified for *attr* is not valid.

Example**CELEBP24**

```

/* CELEBP24 */
#pragma runopts(TEST(ALL))

#ifdef _OPEN_THREADS
#define _OPEN_THREADS
#define _OPEN_SYS          /* Needed to identify __COND_NODEBUG and
                           __COND_DEFAULT */
#endif

#include <stdio.h>
#include <pthread.h>

pthread_condattr_t attr;

int kind;

main() {
    if (pthread_condattr_init(&attr) == -1) {
        perror("pthread_condattr_init()");
        exit(1);
    }

    if (pthread_condattr_setkind_np(&attr, __COND_NODEBUG) == -1) {
        perror("pthread_condattr_setkind_np()");
        exit(1);
    }

    if (pthread_condattr_getkind_np(&attr, &kind) == -1) {
        exit(1);
    }

    switch(kind) {
        case __COND_DEFAULT:
            printf("\ncondition variable will have no defined attributes");
            break;

        case __COND_NODEBUG:
            printf("\ncondition variable will have nodebug attribute");
            break;

        default:
            printf("\nattribute kind value returned by \
pthread_condattr_getkind_np() unrecognized");
    }

    exit(0);
}

```

pthread_condattr_getpshared() — Get the process-shared condition variable attribute

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| Language Environment Extension Single UNIX Specification, Version 3 | both | z/OS V1R2 |

Format

```
#define _OPEN_THREADS
#define _OPEN_SYS_MUTEX_EXT
#include <pthread.h>

int pthread_condattr_getpshared(const pthread_condattr_t *attr,
                               int *pshared);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>
int pthread_condattr_getpshared(const pthread_condattr_t * __restrict_attr,
                               int * __restrict_pshared);
```

General description

Gets the attribute *pshared* for the condition variable attribute object *attr*. By using *attr*, you can determine its process-shared value for a condition variable.

Valid values for the attribute *pshared* are:

Value

Description

PTHREAD_PROCESS_SHARED

Permits a condition variable to be operated upon by any thread that has access to the memory where the condition variable is allocated; even if the condition variable is allocated in memory that is shared by multiple processes.

PTHREAD_PROCESS_PRIVATE

A condition variable can only be operated upon by threads created within the same process as the thread that initialized the condition variable. If threads of differing processes attempt to operate on such a condition variable, only the process to initialize the condition variable will succeed. When a new process is created by the parent process it will receive a different copy of the private condition variable which can only be used to serialize between threads in the child process.

Note: This is the default value of *pshared*

Returned value

If successful, 0 is returned. If unsuccessful, -1 is returned and the errno value is set. The following is the value of errno:

| Value | Description |
|-------|-------------|
|-------|-------------|

EINVAL
The value specified for *attr* is not valid.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_condattr_getpshared() returns an error number to indicate the error.

int pthread_condattr_init(pthread_condattr_t *attr);
```

General description

Establishes the default values for the condition variables that will be created. A condition attribute (*condattr*) object contains various condition variable characteristics. You can set up a template of these characteristics and then create a set of condition variables with similar characteristics.

Condition variable attribute objects are similar to mutex attribute objects. You can use them to manage the characteristics of condition variables in your application. They define the set of values to be used for the condition variable during its creation. For a valid condition variable attribute, refer to "pthread_condattr_setkind_np() -- Set Kind Attribute from a Condition Variable Attribute Object and pthread_condattr_setpshared() --Set the Process-Shared Condition Variable Attribute

pthread_condattr_init() is used to define a condition variable attribute object. pthread_condattr_destroy() is used to remove the definition of the condition variable attribute object. These functions are provided for portability purposes.

You can define a condition variable without using these functions by supplying a NULL parameter during the pthread_cond_init() call. For more details, refer to [“pthread_cond_init\(\) — Initialize a condition variable”](#) on page 1255.

Returned value

If successful, pthread_condattr_init() returns 0.

If unsuccessful, pthread_condattr_init() returns -1 and sets errno to one of the following values:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

| | |
|---------------|--|
| ENOMEM | There is not enough memory to initialize the condition variable attributes object. |
|---------------|--|

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_condattr_init() returns an error number to indicate the error.

Example

CELEBP25

```
/* CELEBP25 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>

main() {
    pthread_condattr_t cond;

    if (pthread_condattr_init(&cond) != 0) {
        perror("pthread_condattr_init() error");
        exit(1);
    }

    if (pthread_condattr_destroy(&cond) != 0) {
        perror("pthread_condattr_destroy() error");
        exit(2);
    }
}
```

pthread_condattr_setclock() – Sets the clock selection condition variable attribute

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1j Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE 600
#include <pthread.h>
int pthread_condattr_setclock(pthread_condattr_t *attr, clockid_t clock_id);
```

General description

The `pthread_condattr_setclock()` function sets the clock attribute in an initialized attributes object referenced by `attr`.

The `clockid_t` attribute is the clock ID of the clock that is used to measure the timeout service of `pthread_cond_timedwait()`. The default value of the clock attribute shall refer to the system clock.

The valid values for the attribute `clockid_t` are:

CLOCK_REALTIME

The system real-time clock

CLOCK_MONOTONIC

The system monotonic clock

Returned value

If successful, `pthread_condattr_setclock()` returns 0.

If unsuccessful, `pthread_condattr_setclock()` returns an error number to indicate the error.

Error Code

Description

EINVAL

The value specified by `clock_id` does not refer to a known clock.

pthread_condattr_setkind_np() – Set kind attribute from a condition variable attribute object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#define _OPEN_SYS
#include <pthread.h>

int pthread_condattr_setkind_np(pthread_condattr_t *attr, int kind);
```

General description

Sets the attribute *kind* for the condition variable attribute object *attr*. Condition variable attribute objects are similar to mutex attribute objects. You can use them to manage the characteristics of condition variables in your application. They define the set of values to be used for the condition variable during its creation.

The valid values for the attribute *kind* are:

__COND_DEFAULT

No defined attributes.

__COND_NODEBUG

State changes to this condition variable will *not* be reported to the debug interface, even though it is present.

Returned value

If successful, pthread_condattr_setkind_np() returns 0.

If unsuccessful, pthread_condattr_setkind_np() returns -1 and sets errno to one of the following values:

Error Code

Description

EINVAL

The value specified for *attr* or *kind* is not valid.

Example

CELEBP26

```
/* CELEBP26 */
#pragma runopts(TEST(ALL))

#ifdef _OPEN_THREADS
#define _OPEN_THREADS
#define _OPEN_SYS /* Needed to identify __COND_NODEBUG and
                  __COND_DEFAULT */
#endif

#include <stdio.h>
#include <pthread.h>

pthread_condattr_t attr;

int kind;

main() {
    if (pthread_condattr_init(&attr) == -1) {
        perror("pthread_condattr_init()");
        exit(1);
    }

    if (pthread_condattr_setkind_np(&attr, __COND_NODEBUG) == -1) {
        perror("pthread_condattr_setkind_np()");
        exit(1);
    }

    if (pthread_condattr_getkind_np(&attr, &kind) == -1) {
        exit(1);
    }

    switch(kind) {
```

```
case __COND_DEFAULT:
    printf("\ncondition variable will have no defined attributes");
    break;

case __COND_NODEBUG:
    printf("\ncondition variable will have nodebug attribute");
    break;

default:
    printf("\nattribute kind value returned by \
pthread_condattr_getkind_np() unrecognized");
}

exit(0);
}
```

Related information

pthread_condattr_setpshared() – Set the process-shared condition variable attribute

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| Language Environment Extension Single UNIX Specification, Version 3 | both | z/OS V1R2 |

Format

```
#define _OPEN_THREADS
#define _OPEN_SYS_MUTEX_EXT
#include <pthread.h>

int pthread_condattr_setpshared(pthread_condattr_t *attr,
                                int pshared);
```

SUSV3:

```
#define _UNIX03_THREADS
#define _OPEN_SYS_MUTEX_EXT
#include <pthread.h>

int pthread_condattr_setpshared(pthread_condattr_t *attr,
                                int pshared);
```

General description

Sets the attribute *pshared* for the condition variable attribute object *attr*.

A condition variable attribute object (*attr*) allows you to manage the characteristics of condition variables in your application by defining a set of values to be used for a condition variable during its creation. By establishing a condition variable attribute object, you can create many condition variables with the same set of characteristics, without needing to define the characteristics for each and every condition variable. By using *attr*, you can define its process-shared value for a condition variable.

Valid values for the attribute *pshared* are:

Value**Description****PTHREAD_PROCESS_SHARED**

Permits a condition variable to be operated upon by any thread that has access to the memory where the condition variable is allocated; even if the condition variable is allocated in memory that is shared by multiple processes.

PTHREAD_PROCESS_PRIVATE

A condition variable can only be operated upon by threads created within the same process as the thread that initialized the condition variable. If threads of differing processes attempt to operate on such a condition variable, only the process to initialize the condition variable will succeed. When a new process is created by the parent process it will receive a different copy of the private condition variable which can only be used to serialize between threads in the child process.

Note: This is the default value of *pshared*.

Returned value

If successful, 0 is returned. If unsuccessful, -1 is returned and the *errno* value is set. The following is the value of *errno*:

Value**Description****EINVAL**

The value specified for *attr* is not valid.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, `pthread_condattr_setpshared()` returns an error number to indicate the error.

Usage notes

It is recommended that you define and initialize `pthread_cond_t` objects in the same compile unit. If you pass a `pthread_cond_t` object around to be initialized, make sure the initialization code has been compiled with the same `_OPEN_SYS_MUTEX_EXT` feature setting as the code that defines the object.

The following sequence may cause storage overlay with unpredictable results:

1. Declare or define a `pthread_cond_t` object (in shared storage) without `#define` of the `_OPEN_SYS_MUTEX_EXT` feature. The created `pthread_cond_t` object is standard size (i.e. small) without the `_OPEN_SYS_MUTEX_EXT` feature defined.
2. Pass the `pthread_cond_t` object to another code unit, which was compiled with the `_OPEN_SYS_MUTEX_EXT` feature defined, to be initialized as a shared object. The `pthread_cond_t` initialization generally involves the following steps:
 - a. `pthread_condattr_init()`
 - b. `pthread_condattr_setpshared()`. This step sets the attribute of the `pthread_cond_t` as `PTHREAD_PROCESS_SHARED` and designates the object to be of extended size.
 - c. `pthread_cond_init()`. This step initializes the passed-in (small) `pthread_cond_t` object as if it is an extended object, causing storage overlay.

pthread_create() — Create a thread

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_create(pthread_t *thread, pthread_attr_t *attr,
                  void *(*start_routine) (void *arg), void *arg);
```

SUSV3

```
#define _UNIX03_THREADS
#include <pthread.h>
int pthread_create(pthread_t * __restrict_thread,
                  const pthread_attr_t *attr,
                  void *(*start_routine) (void *arg),
                  void * __restrict_arg);
```

General description

Creates a new thread within a process, with attributes defined by the thread attribute object, *attr*, that is created by `pthread_attr_init()`.

If *attr* is NULL, the default attributes are used. See [“pthread_attr_init\(\) — Initialize a thread attribute object”](#) on page 1233 for a description of the thread attributes and their defaults. If the attributes specified by *attr* are changed later, the thread's attributes are not affected.

pthread_t is the data type used to uniquely identify a thread. It is returned by `pthread_create()` and used by the application in function calls that require a thread identifier.

The thread is created running *start_routine*, with *arg* as the only argument. If `pthread_create()` completes successfully, *thread* will contain the ID of the created thread. If it fails, no new thread is created, and the contents of the location referenced by *thread* are undefined.

System default for the thread limit in a process is set by MAXTHREADS in the BPXPRMxx parmlib member.

The maximum number of threads is dependent upon the size of the private area below 16M.

`pthread_create()` inspects this address space before creating a new thread. A realistic limit is 200 to 400 threads.

Special behavior for C++: Because C and C++ linkage conventions are incompatible, `pthread_create()` cannot receive a C++ function pointer as the start routine function pointer. If you attempt to pass a C++ function pointer to `pthread_create()`, the compiler will flag it as an error. You can pass a C or C++ function to `pthread_create()` by declaring it as extern "C".

The started thread provides a boundary with respect to the scope of try-throw-catch processing. A throw done in the start routine or a function called by the start routine causes stack unwinding up to and including the start routine (or until caught). The stack unwinding will not go beyond the start routine back into the thread creator. If the exception is not caught, `terminate()` is called.

The exception stack (for try-throw-catch) are thread-based. The throw of a condition, or re-throw of a condition by a thread does not affect exception processing on another thread, unless the condition is not caught.

Returned value

If successful, `pthread_create()` returns 0.

If unsuccessful, `pthread_create()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EAGAIN

The system lacks the necessary resources to create another thread.

EINVAL

The value specified by *thread* is null.

ELEMULTITHREADFORK

`pthread_create()` was invoked from a child process created by calling `fork()` from a multi-threaded process. This child process is restricted from becoming multi-threaded.

ENOMEM

There is not enough memory to create the thread.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, `pthread_create()` returns an error number to indicate the error.

Example

CELEBP27

```
/* CELEBP27 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdlib.h>
#include <stdio.h>
void *thread(void *arg) {
    char *ret;
    printf("thread() entered with argument '%s'\n", arg);
    if ((ret = (char*) malloc(20)) == NULL) {
        perror("malloc() error");
        exit(2);
    }
    strcpy(ret, "This is a test");
    pthread_exit(ret);
}

main() {
    pthread_t thid;
    void *ret;

    if (pthread_create(&thid, NULL, thread, "thread 1") != 0) {
        perror("pthread_create() error");
        exit(1);
    }

    if (pthread_join(thid, &ret) != 0) {
        perror("pthread_create() error");
        exit(3);
    }

    printf("thread exited with '%s'\n", ret);
}
```

Output:

```
thread() entered with argument 'thread 1'
thread exited with 'This is a test'
```

Related information

pthread_detach() — Detach a thread

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_detach(pthread_t *thread);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>
int pthread_detach(pthread_t thread);
```

General description

Allows storage for the thread whose thread ID is in the location *thread* to be reclaimed when that thread ends. This storage is reclaimed on process exit, regardless of whether the thread was detached, and may include storage for *thread*'s return value. If *thread* has not ended, pthread_detach() will not cause it to end.

pthread_t is the data type used to uniquely identify a thread. It is returned by pthread_create() and used by the application in function calls that require a thread identifier.

Returned value

If successful, pthread_detach() returns 0.

If unsuccessful, pthread_detach() returns -1 and sets errno to one of the following values:

Error Code

Description

EINVAL

The value specified by *thread* is not valid.

ESRCH

A value specified by *thread* refers to a thread that is already detached.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_detach() returns an error number to indicate the error.

Example

CELEBP28

```

/* CELEBP28 */
#define _OPEN_SYS
#define _OPEN_THREADS
#include <pthread.h>
#include <stdlib.h>
#include <stdio.h>

void *thread(void *arg) {
    char *ret;
    printf("thread() entered with argument '%s'\n", arg);
    if ((ret = (char*) malloc(20)) == NULL) {
        perror("malloc() error");
        exit(2);
    }
    strcpy(ret, "This is a test");
    pthread_exit(ret);
}

main() {
    pthread_t thid;
    void *ret;

    if (pthread_create(&thid, NULL, thread, "thread 1") != 0) {
        perror("pthread_create() error");
        exit(1);
    }

    if (pthread_join_d4_np(thid, &ret) != 0) {
        perror("pthread_create() error");
        exit(3);
    }

    printf("thread exited with '%s'\n", ret);

    if (pthread_detach(&thid) != 0) {
        perror("pthread_detach() error");
        exit(4);
    }
}

```

Output:

```

thread() entered with argument 'thread 1'
thread exited with 'This is a test'

```

Related information

- [“pthread.h — Thread interfaces” on page 53](#)
- [“pthread_join\(\) — Wait for a thread to end” on page 1287](#)

pthread_equal() — Compare thread IDs

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```

#define _OPEN_THREADS
#include <pthread.h>

```

```
int pthread_equal(pthread_t t1, pthread_t t2);
```

General description

Compares the thread IDs of *t1* and *t2*.

pthread_t is the data type used to uniquely identify a thread. It is returned by `pthread_create()` and used by the application in function calls that require a thread identifier.

Returned value

If *t1* and *t2* are equal, `pthread_equal()` returns a positive value. Otherwise, the value 0 is returned. If *t1* or *t2* are not valid thread IDs, the behavior is undefined.

If unsuccessful, `pthread_equal()` returns -1.

There are no documented `errno` values. Use `perror()` or `strerror()` to determine the cause of the error.

Example

CELEBP29

```
/* CELEBP29 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>

pthread_t thid, IPT;

void *thread(void *arg) {
    if (pthread_equal(IPT, thid))
        puts("the thread is the IPT...?");
    else
        puts("the thread is not the IPT");
}

main() {
    IPT = pthread_self();

    if (pthread_create(&thid, NULL, thread, NULL) != 0) {
        perror("pthread_create() error");
        exit(1);
    }

    if (pthread_join(thid, NULL) != 0) {
        perror("pthread_create() error");
        exit(3);
    }
}
```

Output:

```
the thread is not the IPT
```

Related information

- [“pthread.h — Thread interfaces” on page 53](#)
- [“pthread_create\(\) — Create a thread” on page 1274](#)
- [“pthread_self\(\) — Get the caller” on page 1334](#)

pthread_exit() — Exit a thread

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

void pthread_exit(void *status);
```

General description

Ends the calling thread and makes *status* available to any thread that calls `pthread_join()` with the ending thread's thread ID.

As part of `pthread_exit()` processing, cleanup and destructor routines may be run:

- For details on the cleanup routines, refer to [“pthread_cleanup_pop\(\) — Remove a cleanup handler”](#) on page 1250 and [“pthread_cleanup_push\(\) — Establish a cleanup handler”](#) on page 1251.
- For details on the destructor routine, refer to [“pthread_key_create\(\) — Create thread-specific data key”](#) on page 1290.

Special behavior for C++: Destructors for automatic objects on the stack will be run when a thread is canceled. The stack is unwound and the destructors are run in reverse order.

Returned value

`pthread_exit()` cannot return to its caller.

There are no documented `errno` values. Use `perror()` or `strerror()` to determine the cause of the error.

Example

CELEBP30

```
/* CELEBP30 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdlib.h>
#include <stdio.h>

void *thread(void *arg) {
    char *ret;

    if ((ret = (char*) malloc(20)) == NULL) {
        perror("malloc() error");
        exit(2);
    }
    strcpy(ret, "This is a test");
    pthread_exit(ret);
}

main() {
    pthread_t thid;
    void *ret;

    if (pthread_create(&thid, NULL, thread, NULL) != 0) {
        perror("pthread_create() error");
        exit(1);
    }
}
```

```

    if (pthread_join(thid, &ret) != 0) {
        perror("pthread_create() error");
        exit(3);
    }

    printf("thread exited with '%s'\n", ret);
}

```

Output:

```
thread exited with 'This is a test'
```

pthread_getconcurrency() — Get the level of concurrency

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|---------------------|
| Single UNIX Specification, Version 3 | both | z/OS V1R7 POSIX(ON) |

Format

```

#define _OPEN_THREADS 2
#include <pthread.h>

int pthread_getconcurrency(void);

```

General description

pthread_getconcurrency() returns the value set by a previous call to pthread_setconcurrency(), or 0 if pthread_setconcurrency() was not previously called.

Returned value

If successful, pthread_getconcurrency() returns the concurrency level set by a previous call to pthread_setconcurrency(); otherwise, 0.

Related information

- "Thread Cancellation" in the *z/OS XL C/C++ Programming Guide*
- [“pthread.h — Thread interfaces” on page 53](#)
- [“pthread_setconcurrency\(\) — Set the level of concurrency” on page 1336](#)

pthread_getspecific() – Get the thread-specific value for a key

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_getspecific(pthread_key_t key, void **value);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>
void *pthread_getspecific(pthread_key_t key);
```

General description

Returns the thread-specific data associated with the specified *key* for the current thread. If no thread-specific data has been set for *key*, the NULL value is returned in *value*.

Many multithreaded applications require storage shared among threads, where each thread has its own unique value. A thread-specific data key is an identifier, created by a thread, for which each thread in the process can set a unique key *value*.

pthread_key_t is a storage area where the system places the key identifier. To create a key, a thread uses *pthread_key_create()*. This returns the key identifier into the storage area of type *pthread_key_t*. At this point, each of the threads in the application has the use of that key, and can set its own unique value by using *pthread_setspecific()*. A thread can get its own unique value using *pthread_getspecific()*.

Returned value

When unsuccessful, *pthread_getspecific()* sets *errno* to one of the following values:

Error Code

Description

EINVAL

The value for *key* is not valid.

Note: In SUSV3, if the key is invalid, *pthread_getspecific()* returns NULL but does not set or return an *errno* value.

Example

CELEBP31

```
/* CELEBP31 */
#ifdef _OPEN_THREADS
#define _OPEN_THREADS
#endif

#include <stdio.h>
#include <stdlib.h>
#include <errno.h>
#include <pthread.h>
```

```

#define threads 3
#define BUFFSZ 48
pthread_key_t key;

void *threadfunc(void *parm)
{
    int status;
    void *value;
    int threadnum;
    int tnum;
    void *getvalue;
    char Buffer[BUFFSZ];

    tnum = parm;
    threadnum = *tnum;

    printf("Thread %d executing\n", threadnum);

    if (!(value = malloc(sizeof(Buffer))))
        printf("Thread %d could not allocate storage, errno = %d\n",
               threadnum, errno);
    status = pthread_setspecific(key, (void *) value);
    if (status < 0) {
        printf("pthread_setspecific failed, thread %d, errno %d",
               threadnum, errno);
        pthread_exit((void *)12);
    }
    printf("Thread %d setspecific value: %d\n", threadnum, value);

    getvalue = 0;
    status = pthread_getspecific(key, &getvalue);
    if (status < 0) {

pthread_getspecific_d8_np() – Get the thread-specific value for a key

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| POSIX.4a, draft 8 | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

void *pthread_getspecific_d8_np(pthread_key_t key);
```

General description

Returns the thread-specific data associated with the specified *key* for the current thread. If no thread-specific data has been set for *key*, the NULL value is returned.

Many multithreaded applications require storage shared among threads, where each thread has its own unique value. A thread-specific data key is an identifier, created by a thread, for which each thread in the process can set a unique key *value*.

pthread_key_t is a storage area where the system places the key identifier. To create a key, a thread uses `pthread_key_create()`. This returns the key identifier into the storage area of type *pthread_key_t*. At this point, each of the threads in the application has the use of that key, and can set its own unique value by using `pthread_setspecific()`. A thread can get its own unique value using `pthread_getspecific_d8_np()` or `pthread_getspecific()`.

The only difference between `pthread_getspecific_d8_np()` and `pthread_getspecific()` is the syntax of the function.

Returned value

When successful, `pthread_getspecific_d8_np()` returns the thread-specific data value associated with *key*.

When unsuccessful, `pthread_getspecific_d8_np()` returns NULL and sets `errno` to one of the following values:

Error Code

Description

EINVAL

The value for *key* is not valid.

Example

```
#ifndef _OPEN_THREADS
#define _OPEN_THREADS
#endif

#include <stdio.h>
#include <stdlib.h>
#include <errno.h>
#include <pthread.h>

#define threads 3
#define BUFFSZ 48
pthread_key_t key;

void *threadfunc(void *);
void destr_fn(void *);

main() {
    int status;
    int i;
    int threadparm[threads];
    pthread_t threadid[threads];
    int thread_stat[threads];

    if ((status = pthread_key_create(&key, destr_fn)) < 0) {
        printf("pthread_key_create failed, errno=%d", errno);
        exit(1);
    }

    /* create 3 threads, pass each its number */
    for (i=0; i<threads; i++) {
        threadparm[i] = i+1;
        status = pthread_create(&threadid[i],
                                NULL,
                                threadfunc,
                                (void *)&threadparm[i]);
        if (status < 0) {
            printf("pthread_create failed, errno=%d", errno);
            exit(2);
        }
    }
}
```

```

    }
}

for ( i=0; i<threads; i++) {
    status = pthread_join( threadid[i], (void *)&thread_stat[i]);
    if ( status < 0) {
        printf("pthread_join failed, thread %d, errno=%d\n", i+1, errno);
    }

    if (thread_stat[i] != 0) {
        printf("bad thread status, thread %d, status=%d\n", i+1,
            thread_stat[i]);
    }
}

exit(0);
}

void *threadfunc(void *parm) {
    int      status;
    int      *void;
    int      threadnum;
    int      *tnum;
    void      *getvalue;
    char      Buffer[BUFSZ];

    tnum = parm;
    threadnum = *tnum;

    printf("Thread %d executing\n", threadnum);

    if (!(value = malloc(sizeof(Buffer))))
        printf("Thread %d could not allocate storage, errno = %d\n",
            threadnum, errno);

    status = pthread_setspecific(key, (void *) value);
    if ( status < 0) {
        printf("pthread_setspecific failed, thread %d, errno %d",
            threadnum, errno);

pthread_join() – Wait for a thread to end

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_join(pthread_t thread, void **status);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_join(pthread_t thread, void **status);
```

General description

Allows the calling thread to wait for the ending of the target *thread*.

pthread_t is the data type used to uniquely identify a thread. It is returned by `pthread_create()` and used by the application in function calls that require a thread identifier.

status contains a pointer to the *status* argument passed by the ending thread as part of `pthread_exit()`. If the ending thread terminated with a return, *status* contains a pointer to the return value. If the thread was canceled, *status* can be set to -1.

Returned value

If successful, `pthread_join()` returns 0.

If unsuccessful, `pthread_join()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EDEADLK

A deadlock has been detected. This can occur if the target is directly or indirectly joined to the current thread.

EINVAL

The value specified by *thread* is not valid.

ESRCH

The value specified by *thread* does not refer to an undetached thread.

Notes:

1. When `pthread_join()` returns successfully, the target thread has been detached.
2. Multiple threads cannot use `pthread_join()` to wait for the same target thread to end. If a thread issues `pthread_join()` for a target thread after another thread has successfully issued `pthread_join()` for the same target thread, the second `pthread_join()` will be unsuccessful.
3. If the thread calling `pthread_join()` is canceled, the target thread is not detached.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, `pthread_join()` returns an error number to indicate the error.

Example

CELEBP32

```
/* CELEBP32 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdlib.h>
#include <stdio.h>

void *thread(void *arg) {
    char *ret;
    printf("thread() entered with argument '%s'\n", arg);
    if ((ret = (char*) malloc(20)) == NULL) {
        perror("malloc() error");
        exit(2);
    }
    strcpy(ret, "This is a test");
    pthread_exit(ret);
}

main() {
    pthread_t thid;
    void *ret;

    if (pthread_create(&thid, NULL, thread, "thread 1") != 0) {
        perror("pthread_create() error");
        exit(1);
    }

    if (pthread_join(thid, &ret) != 0) {
        perror("pthread_create() error");
        exit(3);
    }

    printf("thread exited with '%s'\n", ret);
}
```

Output:

```
thread() entered with argument 'thread 1'
thread exited with 'This is a test'
```

pthread_join_d4_np() — Wait for a thread to end

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | POSIX(ON) |

Format

```
#define _OPEN_SYS
#define _OPEN_SYS
#include <pthread.h>

int pthread_join_d4_np(pthread_t thread, void **status);
```

General description

Allows the calling thread to wait for the ending of the target *thread*.

pthread_t is the data type used to uniquely identify a thread. It is returned by `pthread_create()` and used by the application in function calls that require a thread identifier.

status contains a pointer to the *status* argument passed by the ending thread as part of `pthread_exit()`. If the ending thread ended by a return, *status* contains a pointer to the return value. If the thread was canceled, *status* can be set to -1.

Returned value

If successful, `pthread_join_d4_np()` returns 0.

If unsuccessful, `pthread_join_d4_np()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EDEADLK

A deadlock has been detected. This can occur if the target is directly or indirectly joined to the current thread.

EINVAL

The value specified by *thread* is not valid.

ESRCH

The value specified by *thread* does not refer to an undetached thread.

Notes:

1. When `pthread_join_d4_np()` returns successfully, the target thread has not been detached.
2. Multiple threads can use `pthread_join_d4_np()` to wait for the same target thread to end.

Example

CELEBP33

```
/* CELEBP33 */
#define _OPEN_SYS
#define _OPEN_THREADS
#include <pthread.h>
#include <stdlib.h>
#include <stdio.h>

void *thread(void *arg) {
    char *ret;
    printf("thread() entered with argument '%s'\n", arg);
    if ((ret = (char*) malloc(20)) == NULL) {
        perror("malloc() error");
        exit(2);
    }
    strcpy(ret, "This is a test");
    pthread_exit(ret);
}

main() {
    pthread_t thid;
    void *ret;

    if (pthread_create(&thid, NULL, thread, "thread 1") != 0) {
        perror("pthread_create() error");
        exit(1);
    }

    if (pthread_join_d4_np(thid, &ret) != 0) {
        perror("pthread_create() error");
        exit(3);
    }

    printf("thread exited with '%s'\n", ret);
}
```

```
    if (pthread_detach(&thid) != 0) {  
        perror("pthread_detach() error");  
        exit(4);  
    }  
}
```

Output:

```
thread() entered with argument 'thread 1'  
thread exited with 'This is a test'
```

pthread_key_create() — Create thread-specific data key

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS  
#include <pthread.h>  
  
int pthread_key_create(pthread_key_t *key, void (*destructor)(void *));
```

SUSV3:

```
#define _UNIX03_THREADS  
#include <pthread.h>  
  
int pthread_key_create(pthread_key_t *key, void (*destructor)(void *));
```

General description

Creates a key identifier, associated with *key*, and returns the key identifier into the storage area of type *pthread_key_t*. At this point, each of the threads in the application has the use of that key, and can set its own unique value by use of *pthread_setspecific()*. A thread can get its own unique value using *pthread_getspecific()*.

The *destructor* routine may be called when the thread ends. It is called when a non-NULL value has been set for the key for this thread, using *pthread_setspecific()*, and the thread:

- Calls *pthread_exit()*
- Does a return from the start routine
- Is canceled because of a *pthread_cancel()* request.

When called, the destructor routine is passed the value bound to the key by the use of *pthread_setspecific()*.

Special behavior for C++: Because C and C++ linkage conventions are incompatible, *pthread_key_create()* cannot receive a C++ function pointer as the start routine function pointer. If you

attempt to pass a C++ function pointer to `pthread_key_create()`, the compiler will flag it as an error. You can pass a C or C++ function to `pthread_key_create()` by declaring it as extern "C".

Returned value

If successful, `pthread_key_create()` returns 0 and stores the newly created key identifier in *key*.

If unsuccessful, `pthread_key_create()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EAGAIN

There were not enough system resources to create another thread-specific data key, or the limit is exceeded for the total number of keys per process.

ENOMEM

There is not enough memory to create *key*.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, `pthread_key_create()` returns an error number to indicate the error.

Example

CELEBP34

```
/* CELEBP34 */
#ifndef _OPEN_THREADS
#define _OPEN_THREADS
#endif

#include <stdio.h>
#include <stdlib.h>
#include <errno.h>
#include <pthread.h>

#define threads 3

```

General description

`pthread_key_delete()` deletes thread-specific data keys created with `pthread_key_create()`. The thread-specific data values associated with *key* do not need to be NULL when the *key* is deleted. The application is responsible for freeing any storage or cleaning up data structures referring to thread-specific data associated with the deleted *key* in any thread. After *key* has been deleted, passing it to any function taking a thread-specific data key results in undefined behavior.

`pthread_key_delete()` can be called from destructor functions. Calling `pthread_key_delete()` will not cause any destructor functions to be invoked. Any destructor function associated with *key* when it was created will not be called on thread exit after *key* has been deleted.

Returned value

If successful, `pthread_key_delete()` returns 0. Upon failure, `pthread_key_delete()` returns an error number to indicate the error:

Error Code

Description

EINVAL

The key value is invalid.

pthread_kill() — Send a signal to a thread

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#include <pthread.h>
#include <signal.h>

int pthread_kill(pthread_t thread, int sig);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <signal.h>

int pthread_kill(pthread_t thread, int sig);
```

General description

Directs a signal *sig* to the thread *thread*. The value of *sig* must be either 0 or one of the symbols defined in `signal.h`. (See [Table 57 on page 1606](#) for a list of signals.) If *sig* is 0, `pthread_kill()` performs error checking but does not send a signal.

pthread_t is the data type used to uniquely identify a thread. It is returned by `pthread_create()` and used by the application in function calls that require a thread identifier.

Special behavior for C++: If a thread is sent a signal using `pthread_kill()` and that thread does not handle the signal, then destructors for local objects may not be executed.

Usage notes

1. The SIGTHSTOP and SIGTHCONT signals can be issued by this function. *pthread_kill()* is the only function that can issue SIGTHSTOP or SIGTHCONT.

Returned value

If successful, `pthread_kill()` returns 0.

If unsuccessful, `pthread_kill()` returns -1 sends no signal, and sets `errno` to one of the following values:

Error Code**Description****EINVAL**

One of the following error conditions exists:

- The thread ID specified by *thread* is not valid.
- The value of *sig* is incorrect or is not the number of a supported signal.

ESRCH

No thread could be found corresponding to that specified by the given thread ID.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, `pthread_kill()` returns an error number to indicate the error.

Example**CELEBP35**

```
/* CELEBP35 */
#define _OPEN_THREADS

#include <errno.h>
#include <pthread.h>
#include <signal.h>
#include <stdio.h>
#include <unistd.h>

void          *threadfunc(void *parm)
{
    int          threadnum;
    int          *tnum;
    sigset_t      set;

    tnum = parm;
    threadnum = *tnum;

    printf("Thread %d executing\n", threadnum);
```

```

sigemptyset(&set);
if(sigaddset(&set, SIGUSR1) == -1) {
    perror("Sigaddset error");
    pthread_exit((void *)1);
}

if(sigwait(&set) != SIGUSR1) {
    perror("Sigwait error");
    pthread_exit((void *)2);
}

pthread_exit((void *)0);
}

main() {
    int          status;
    int          threadparm = 1;
    pthread_t    threadid;
    int          thread_stat;

    status = pthread_create( &threadid,
                           NULL,
                           threadfunc,
                           (void *)&threadparm);

    if ( status < 0 ) {
        perror("pthread_create failed");
        exit(1);
    }

    sleep(5);

    status = pthread_kill( threadid, SIGUSR1);
    if ( status < 0 )
        perror("pthread_kill failed");

    status = pthread_join( threadid, (void *)&thread_stat);
    if ( status < 0 )
        perror("pthread_join failed");

    exit(0);
}

```

pthread_mutex_destroy() – Delete a mutex object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_mutex_destroy(pthread_mutex_t *mutex);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_mutex_destroy(pthread_mutex_t *mutex);
```

General description

Deletes a mutex object, which identifies a mutex. Mutexes are used to protect shared resources. *mutex* is set to an invalid value, but can be reinitialized using `pthread_mutex_init()`.

Returned value

If successful, `pthread_mutex_destroy()` returns 0.

If unsuccessful, `pthread_mutex_destroy()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBUSY

A request has detected an attempt to destroy the object referenced by *mutex* while it was locked or referenced by another thread (for example, while being used in a `pthread_cond_wait()` or `pthread_cond_timedwait()` function).

EINVAL

The value specified by *mutex* is not valid.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, `pthread_mutex_destroy()` returns an error number to indicate the error.

Example

CELEBP36

```
/* CELEBP36 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>

main() {
    pthread_mutex_t mutex;

    if (pthread_mutex_init(&mutex, NULL) != 0) {
        perror("pthread_mutex_init() error");
        exit(1);
    }
}
```

```

    if (pthread_mutex_destroy(&mutex) != 0) {
        perror("pthread_mutex_destroy() error");
        exit(2);
    }
}

```

pthread_mutex_init() — Initialize a mutex object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```

#define _OPEN_THREADS
#include <pthread.h>

int pthread_mutex_init(pthread_mutex_t *mutex, pthread_mutexattr_t *attr);

```

SUSV3:

```

#define _UNIX03_THREADS
#include <pthread.h>
int pthread_mutex_init(pthread_mutex_t * __restrict__ mutex,
                      const pthread_mutexattr_t * __restrict__ attr);

```

General description

Creates a mutex, referenced by *mutex*, with attributes specified by *attr*. If *attr* is NULL, the default mutex attribute (NONRECURSIVE) is used.

Returned value

If successful, pthread_mutex_init() returns 0, and the state of the mutex becomes initialized and unlocked.

If unsuccessful, pthread_mutex_init() returns -1 and sets errno to one of the following values:

Error Code

Description

EAGAIN

The system lacked the necessary resources (other than memory) to initialize another mutex.

EBUSY

detected an attempt to re-initialize the object referenced by *mutex*, a previously initialized, but not yet destroyed, mutex.

EINVAL

The value specified by *attr* is not valid.

ENOMEM

There is not enough memory to acquire a lock. This errno will only occur in the private path.

EPERM

The caller does not have the privilege to perform the operation.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, `pthread_mutex_init()` returns an error number to indicate the error.

Usage notes

The `_OPEN_SYS_MUTEX_EXT` feature switch can be optionally included. If the feature is set, then significantly larger `pthread_mutex_t` objects will be defined. The feature is used for the management of mutex and condition variables in shared memory.

If the supplied extended `pthread_mutex_t` object is not in shared memory, `pthread_mutex_init()` will treat the object as a non-shared object, since it is not accessible to any other process.

It is recommended that you define and initialize the `pthread_mutex_t` objects in the same compile unit. If you pass a `pthread_mutex_t` object around to be initialized, make sure the initialization code has been compiled with the same `_OPEN_SYS_MUTEX_EXT` feature setting as the code that defines the object.

The following sequence may cause storage overlay with unpredictable results:

1. Declare or define a `pthread_mutex_t` object (in shared storage) without `#define` of the `_OPEN_SYS_MUTEX_EXT` feature. The created `pthread_mutex_t` object is standard size (i.e. small) without the `_OPEN_SYS_MUTEX_EXT` feature defined.
2. Pass the `pthread_mutex_t` object to another code unit, which was compiled with the `_OPEN_SYS_MUTEX_EXT` feature defined, to be initialized as a shared object. The `pthread_mutex_t` initialization generally involves the following steps:
 - a. `pthread_mutexattr_init()`
 - b. `pthread_mutexattr_setpshared()`. Shared `pthread_mutex_t` objects can be small or of extended size. The presence of the `_OPEN_SYS_MUTEX_EXT` feature declares it to be of extended size.
 - c. `pthread_mutex_init()`. This step initializes the passed-in (small) `pthread_mutex_t` object as if it is an extended object, causing storage overlay.

Example**CELEBP37**

```
/* CELEBP37 */
#ifndef _OPEN_THREADS
#define _OPEN_THREADS
#endif

#include <pthread.h>

main() {
    pthread_mutexattr_t    attr;
    pthread_mutex_t        mut;

    if (pthread_mutexattr_init(&attr) == -1) {
        perror("mutexattr_init error");
        exit(1);
    }

    if (pthread_mutex_init(&mut, &attr) == -1) {
        perror("mutex_init error");
        exit(2);
    }
}
```

```
    exit(0);
}
```

pthread_mutex_lock() — Wait for a lock on a mutex object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_mutex_lock(pthread_mutex_t *mutex);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_mutex_lock(pthread_mutex_t *mutex);
```

General description

Locks a mutex object, which identifies a mutex. Mutexes are used to protect shared resources. If the mutex is already locked by another thread, the thread waits for the mutex to become available. The thread that has locked a mutex becomes its current owner and remains the owner until the same thread has unlocked it.

When the mutex has the attribute of recursive, the use of the lock may be different. When this kind of mutex is locked multiple times by the same thread, then a count is incremented and no waiting thread is posted. The owning thread must call `pthread_mutex_unlock()` the same number of times to decrement the count to zero.

The mutex types are described below:

PTHREAD_MUTEX_NORMAL

A normal type mutex does not detect deadlock. That is, a thread attempting to relock this mutex without first unlocking it will deadlock. The mutex is either in a locked or unlocked state for a thread.

PTHREAD_MUTEX_ERRORCHECK

An errorcheck type mutex provides error checking. That is, a thread attempting to relock this mutex without first unlocking it will return with an error. The mutex is either in a locked or unlocked state for a thread. If a thread attempts to relock a mutex that it has already locked, it will return with an error. If a thread attempts to unlock a mutex that is unlocked, it will return with an error.

PTHREAD_MUTEX_RECURSIVE

A recursive type mutex permits a thread to lock many times. That is, a thread attempting to relock this mutex without first unlocking will succeed. This type of mutex must be unlocked the same number of times it is locked before the mutex will be returned to an unlocked state.

PTHREAD_MUTEX_DEFAULT

The default type mutex is mapped to a normal type mutex which does not detect deadlock. That is, a thread attempting to relock this mutex without first unlocking it will deadlock. The mutex is either in a locked or unlocked state for a thread. The normal mutex is the default type mutex.

Returned value

If successful, pthread_mutex_lock() returns 0.

If unsuccessful, pthread_mutex_lock() returns -1 and sets errno to one of the following values:

Error Code**Description****EAGAIN**

The mutex could not be acquired because the maximum number of recursive locks for mutex has been exceeded. This errno will only occur in the shared path.

EDEADLK

The current thread already owns the mutex, and the mutex has a *kind* attribute of `__MUTEX_NONRECURSIVE`.

EINVAL

The value specified by *mutex* is not valid.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_mutex_lock() returns an error number to indicate the error.

Usage notes

If the `_OPEN_SYS_MUTEX_EXT` feature switch is set, all shared (extended) mutex locks are released when the thread ends, whether normally or abnormally. If the thread ends normally (i.e. pthread_exit() or pthread_cancel()), the first waiter of the mutex lock will be resumed. If the thread ends abnormally, the processes of the mutex waiters for this mutex lock will be terminated.

Example**CELEBP38**

```
/* CELEBP38 */
#ifndef _OPEN_THREADS
#define _OPEN_THREADS
#endif

#include <pthread.h>
#include <stdio.h>

main() {
    pthread_mutex_t mut;

    if (pthread_mutex_init(&mut, NULL) != 0) {
        perror("mutex_lock");
        exit(1);
    }

    if (pthread_mutex_lock(&mut) != 0) {
        perror("mutex_lock");
    }
}
```

```

    exit(2);
}

puts("the mutex has been locked");
exit(0);
}

```

pthread_mutex_trylock() — Attempt to lock a mutex object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```

#define _OPEN_THREADS
#include <pthread.h>

int pthread_mutex_trylock(pthread_mutex_t *mutex);

```

SUSV3:

```

#define _UNIX03_THREADS
#include <pthread.h>

int pthread_mutex_trylock(pthread_mutex_t *mutex);

```

General description

Locks a mutex object, which identifies a mutex. Mutexes are used to protect shared resources. If `pthread_mutex_trylock()` is locked, it returns immediately.

For recursive mutexes, `pthread_mutex_trylock()` will effectively add to the count of the number of times `pthread_mutex_unlock()` must be called by the thread to release the mutex. (That is, it has the same behavior as a `pthread_mutex_lock()`.)

Returned value

If successful, `pthread_mutex_trylock()` returns 0.

If unsuccessful, `pthread_mutex_trylock()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EAGAIN

The mutex could not be acquired because the maximum number of recursive locks for mutex has been exceeded. This `errno` will only occur in the shared path.

EBUSY

mutex could not be acquired because it was already locked.

EINVAL

The value specified by *mutex* is not valid.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, `pthread_mutex_trylock()` returns an error number to indicate the error.

Usage notes

1. If the `_OPEN_SYS_MUTEX_EXT` feature switch is set, all shared (extended) mutex locks are released when the thread ends, whether normally or abnormally. If the thread ends normally (i.e. `pthread_exit()` or `pthread_cancel()`), the first waiter of the mutex lock will be resumed. If the thread ends abnormally, the processes of the mutex waiters for this mutex lock will be terminated.

Example**CELEBP40**

```

/* CELEBP40 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>
#include <errno.h>

pthread_mutex_t mutex;

void *thread(void *arg) {
    if (pthread_mutex_trylock(&mutex) != 0)
        if (errno == EBUSY)
            puts("thread was denied access to the mutex");
        else {
            perror("pthread_mutex_trylock() error");
            exit(1);
        }
    else puts("thread was granted the mutex");
}

main() {
    pthread_t thid;

    if (pthread_mutex_init(&mutex, NULL) != 0) {
        perror("pthread_mutex_init() error");
        exit(2);
    }

    if (pthread_create(&thid, NULL, thread, NULL) != 0) {
        perror("pthread_create() error");
        exit(3);
    }

    if (pthread_mutex_trylock(&mutex) != 0)
        if (errno == EBUSY)
            puts("IPT was denied access to the mutex");
        else {
            perror("pthread_mutex_trylock() error");
            exit(4);
        }
    else puts("IPT was granted the mutex");

    if (pthread_join(thid, NULL) != 0) {
        perror("pthread_join() error");
        exit(5);
    }
}

```

Output:

```

IPT was granted the mutex
thread was denied access to the mutex

```

Related information

pthread_mutex_unlock() — Unlock a mutex object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_mutex_unlock(pthread_mutex_t *mutex);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_mutex_unlock(pthread_mutex_t *mutex);
```

General description

Releases a mutex object. If one or more threads are waiting to lock the mutex, pthread_mutex_unlock() causes one of those threads to return from pthread_mutex_lock() with the mutex object acquired. If no threads are waiting for the mutex, the mutex unlocks with no current owner.

When the mutex has the attribute of recursive the use of the lock may be different. When this kind of mutex is locked multiple times by the same thread, then unlock will decrement the count and no waiting thread is posted to continue running with the lock. If the count is decremented to zero, then the mutex is released and if any thread is waiting it is posted.

Returned value

If successful, pthread_mutex_unlock() returns 0.

If unsuccessful, pthread_mutex_unlock() returns -1 and sets errno to one of the following values:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

EINVAL
The value specified by *mutex* is not valid.

EPERM
The current thread does not own the *mutex*.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_mutex_unlock() returns an error number to indicate the error.

Example

CELEBP41

```

/* CELEBP41 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>
#include <errno.h>

pthread_mutex_t mutex;

void *thread(void *arg) {
    if (pthread_mutex_lock(&mutex) != 0) {
        perror("pthread_mutex_lock() error");
        exit(1);
    }

    puts("thread was granted the mutex");

    if (pthread_mutex_unlock(&mutex) != 0) {
        perror("pthread_mutex_unlock() error");
        exit(2);
    }
}

main() {
    pthread_t thid;

    if (pthread_mutex_init(&mutex, NULL) != 0) {
        perror("pthread_mutex_init() error");
        exit(3);
    }

    if (pthread_create(&thid, NULL, thread, NULL) != 0) {
        perror("pthread_create() error");
        exit(4);
    }

    if (pthread_mutex_lock(&mutex) != 0) {
        perror("pthread_mutex_lock() error");
        exit(5);
    }

    puts("IPT was granted the mutex");

    if (pthread_mutex_unlock(&mutex) != 0) {
        perror("pthread_mutex_unlock() error");
        exit(6);
    }

    if (pthread_join(thid, NULL) != 0) {
        perror("pthread_mutex_lock() error");
        exit(7);
    }
}

```

Output:

```

IPT was granted the mutex
thread was granted the mutex

```

pthread_mutexattr_destroy() – Destroy a mutex attribute object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#define _OPEN_SYS
#include <pthread.h>

int pthread_mutexattr_destroy(pthread_mutexattr_t *attr);
```

SUSV3:

```
#define _UNIX03_THREADS
#define _OPEN_SYS
#include <pthread.h>

int pthread_mutexattr_destroy(pthread_mutexattr_t *attr);
```

General description

Destroys an initialized mutex attribute object. With a mutex attribute object, you can manage the characteristics of mutexes in your application. It defines the set of values to be used for the mutex during its creation. By establishing a mutex attribute object, you can create many mutexes with the same set of characteristics, without defining those characteristics for each mutex. `pthread_mutexattr_init()` is used to define a mutex attribute object.

Returned value

If successful, `pthread_mutexattr_destroy()` returns 0.

If unsuccessful, `pthread_mutexattr_destroy()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

The value specified for *attr* is not valid.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, `pthread_mutexattr_destroy()` returns an error number to indicate the error.

Example

CELEBP42

```
/* CELEBP42 */
#define _OPEN_THREADS
#define _OPEN_SYS      /* Needed to identify __MUTEX_RECURSIVE */
#include <pthread.h>
#include <stdio.h>

main() {
    pthread_mutexattr_t attr;
    pthread_mutex_t mutex;

    if (pthread_mutexattr_init(&attr) != 0) {
        perror("pthread_mutex_attr_init() error");
    }
```

```
    exit(1);
}

if (pthread_mutexattr_setkind_np(&attr, __MUTEX_RECURSIVE) != 0) {
    perror("pthread_mutex_attr_setkind_np() error");

pthread_mutexattr_getkind_np() – Get kind from a mutex attribute object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#define _OPEN_SYS
#include <pthread.h>

int pthread_mutexattr_getkind_np(pthread_mutexattr_t *attr, int *kind);
```

General description

Gets the attribute *kind* from the mutex attribute object *attr*. With a mutex attribute object, you can manage the characteristics of mutexes in your application. It defines the set of values to be used for the mutex during its creation. By establishing a mutex attribute object, you can create many mutexes with the same set of characteristics without defining those characteristics for each and every mutex.

The values for the attribute *kind* are:

__MUTEX_NONRECURSIVE

A nonrecursive mutex can be locked only once. That is, the mutex is either in a locked or unlocked state for a thread. If a thread attempts to lock a mutex that it has already locked, an error is returned.

_MUTEX_RECURSIVE

A recursive mutex can be locked more than once by the same thread. A count of the number of times the mutex has been locked is maintained. The mutex is unlocked when pthread_mutex_unlock() is performed an equal number of times.

__MUTEX_NONRECURSIVE + __MUTEX_NODEBUG

A nonrecursive mutex can be given an additional attribute, NODEBUG. This indicates that state changes to this mutex will *not* be reported to the debug interface, even if present.

__MUTEX_RECURSIVE + __MUTEX_NODEBUG

A recursive mutex can be given an additional attribute, NODEBUG. This indicates that state changes to this mutex will *not* be reported to the debug interface, even if present.

Returned value

If successful, pthread_mutexattr_getkind_np() returns 0.

If unsuccessful, pthread_mutexattr_getkind_np() returns -1 and sets errno to one of the following values:

Error Code**Description****EINVAL**

The value specified for *attr* is not valid.

Example**CELEBP43**

```

/* CELEBP43 */

#pragma runopts(TEST(ALL))

#ifdef _OPEN_THREADS
#define _OPEN_THREADS
#define _OPEN_SYS      /* Needed to identify __MUTEX_RECURSIVE,
                        __MUTEX_NODEBUG, and __MUTEX_NONRECURSIVE */
#endif

#include <stdio.h>
#include <pthread.h>

pthread_mutexattr_t attr;

int kind;

main() {
    if (pthread_mutexattr_init(&attr) == -1) {
        perror("pthread_mutexattr_init()");
        exit(1);
    }

    if (pthread_mutexattr_setkind_np(&attr, \
        __MUTEX_RECURSIVE + __MUTEX_NODEBUG) == -1 ) {

        perror("pthread_mutexattr_setkind_np()");
        exit(1);
    }

    if (pthread_mutexattr_getkind_np(&attr, &kind) == -1) {
        perror("pthread_mutexattr_getkind_np()");
        exit(1);
    }

    switch(kind) {

        case __MUTEX_NONRECURSIVE:
            printf("\nmutex will be nonrecursive");
            break;

        case __MUTEX_NONRECURSIVE+__MUTEX_NODEBUG:
            printf("\nmutex will be nonrecursive + nodebug");
            break;

        case __MUTEX_RECURSIVE:
            printf("\nmutex will be recursive");
            break;

        case __MUTEX_RECURSIVE+__MUTEX_NODEBUG:
            printf("\nmutex will be recursive + nodebug");
    }
}

```

```
        break;

    default:
        printf("\nattribute kind value returned by \
pthread_mutexattr_getkind_np() unrecognized");
        exit(1);
    }
    exit(0);
}
```

Output:

```
a default mutex will be nonrecursive
```

pthread_mutexattr_getpshared() – Get the process-shared mutex attribute

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------------------|
| z/OS UNIX Single UNIX Specification, Version 3 | both | POSIX(ON) OS/390 V2R7 |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_mutexattr_getpshared(const pthread_mutexattr_t *attr, int *pshared);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>
int pthread_mutexattr_getpshared(const pthread_mutexattr_t *__restrict__ attr,
                                int * __restrict__ pshared);
```

General description

The pthread_mutexattr_getpshared() function gets the attribute *pshared* for the mutex attribute object *attr*. By using *attr* with the pthread_mutexattr_getpshared() function you can determine its *process-shared* value for a mutex.

The valid values for the attribute *pshared* are:

PTHREAD_PROCESS_SHARED

Permits a mutex to be operated upon by any thread that has access to the memory where the mutex is allocated, even if the mutex is allocated in memory that is shared by multiple processes.

PTHREAD_PROCESS_PRIVATE

A mutex can only be operated upon by threads created within the same process as the thread that initialized the mutex. When a new process is created by the parent process it will receive a different copy of the private mutex and this new mutex can only be used to serialize between threads in the child process. The default value of the attribute is PTHREAD_PROCESS_PRIVATE.

Returned value

If successful, `pthread_mutexattr_getpshared()` returns 0.

If unsuccessful, `pthread_mutexattr_getpshared()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

The value specified for *attr* is not valid.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, `pthread_mutexattr_getpshared()` returns an error number to indicate the error.

pthread_mutexattr_gettype() — Get type of mutex attribute object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------------------|
| z/OS UNIX Single UNIX Specification, Version 3 | both | POSIX(ON) OS/390 V2R7 |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_mutexattr_gettype(const pthread_mutexattr_t *attr, int *type);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>
int pthread_mutexattr_gettype(const pthread_mutexattr_t * __restrict_attr,
                             int * __restrict_type);
```

General description

The `pthread_mutexattr_gettype()` function gets the attribute *type* from the mutex attribute object *attr*.

A mutex attribute object allows you to manage the characteristics of mutexes in your application. It defines the set of values to be used for the mutex during its creation. By establishing a mutex attribute object, you can create many mutexes with the same set of characteristics, without needing to define the characteristics for each and every mutex.

The values for the attribute *type* are:

PTHREAD_MUTEX_NORMAL

A normal type mutex does not detect deadlock. That is, a thread attempting to relock this mutex without first unlocking it will deadlock. The mutex is either in a locked or unlocked state for a thread.

PTHREAD_MUTEX_ERRORCHECK

An errorcheck type mutex provides error checking. That is, a thread attempting to relock this mutex without first unlocking it will return with an error. The mutex is either in a locked or unlocked state for a thread. If a thread attempts to relock a mutex that it has already locked, it will return with an error. If a thread attempts to unlock a mutex that is unlocked, it will return with an error.

PTHREAD_MUTEX_RECURSIVE

A recursive type mutex permits a thread to lock many times. That is, a thread attempting to relock this mutex without first unlocking will succeed. This type of mutex must be unlocked the same number of times it is locked before the mutex will be returned to an unlocked state. If locked, an error is returned.

PTHREAD_MUTEX_DEFAULT

The default type mutex is mapped to a normal type mutex which does not detect deadlock. That is, a thread attempting to relock this mutex without first unlocking it will deadlock. The mutex is either in a locked or unlocked state for a thread. The normal mutex is the default type mutex.

__MUTEX_NONRECURSIVE

A nonrecursive mutex can be locked only once. That is, the mutex is either in a locked or unlocked state for a thread. If a thread attempts to lock a mutex that it has already locked, an error is returned.

__MUTEX_RECURSIVE

A recursive mutex can be locked more than once by the same thread. A count of the number of times the mutex has been locked is maintained. The mutex is unlocked when pthread_mutex_unlock() is performed an equal number of times.

__MUTEX_NONRECURSIVE + __MUTEX_NODEBUG

A nonrecursive mutex can be given an additional attribute, NODEBUG. This indicates that state changes to this mutex will *not* be reported to the debug interface, even if present.

__MUTEX_RECURSIVE + __MUTEX_NODEBUG

A recursive mutex can be given an additional attribute, NODEBUG. This indicates that state changes to this mutex will *not* be reported to the debug interface, even if present.

Returned value

If successful, pthread_mutexattr_gettype() returns 0.

If unsuccessful, pthread_mutexattr_gettype() returns -1 and sets errno to one of the following values:

Error Code

Description

EINVAL

The value specified for *attr* is not valid.

Special behavior for Single UNIX Specification, Version 3:

If unsuccessful, pthread_mutexattr_gettype() returns an error number to indicate the error.

pthread_mutexattr_init() – Initialize a mutex attribute object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#define _OPEN_SYS
#include <pthread.h>

int pthread_mutexattr_init(pthread_mutexattr_t *attr);
```

SUSV3:

```
#define _UNIX03_THREADS
#define _OPEN_SYS
#include <pthread.h>

int pthread_mutexattr_init(pthread_mutexattr_t *attr);
```

General description

Initializes a mutex attribute object. With a mutex attribute object, you can manage the characteristics of mutexes in your application. It defines the set of values to be used for the mutex during its creation. By establishing a mutex attribute object, you can create many mutexes with the same set of characteristics, without defining those characteristics for each and every mutex.

For a valid mutex attribute, refer to [“pthread_mutexattr_setkind_np\(\) — Set kind for a mutex attribute object” on page 1312](#).

Note: Before freeing up the storage containing the pthread_mutexattr_t object, be sure to destroy it by calling pthread_mutexattr_destroy(). If the pthread_mutexattr_t object is not destroyed before the storage is reused, the results are undefined.

Returned value

If successful, pthread_mutexattr_init() returns 0.

If unsuccessful, pthread_mutexattr_init() returns -1 and sets errno to one of the following values:

Error Code

Description

ENOMEM

There is not enough memory to initialize *attr*.

Special behavior for Single UNIX Specification, Version 3:

If unsuccessful, pthread_mutexattr_init() returns an error number to indicate the error.

Example

CELEBP44

```
/* CELEBP44 */

#define _OPEN_THREADS
#define _OPEN_SYS      /* Needed to identify __MUTEX_RECURSIVE */
#include <pthread.h>
```

```
#include <stdio.h>

main() {
    pthread_mutexattr_t attr;
    pthread_mutex_t mutex;

    if (pthread_mutexattr_init(&attr) != 0) {
        perror("pthread_mutex_attr_init() error");
        exit(1);
    }

    if (pthread_mutexattr_setkind_np(&attr, __MUTEX_RECURSIVE) != 0) {
        perror("pthread_mutex_attr_setkind_np() error");
        exit(2);
    }

    if (pthread_mutex_init(&mutex, &attr) != 0) {
        perror("pthread_mutex_init() error");
        exit(3);
    }

    if (pthread_mutexattr_destroy(&attr) != 0) {
        perror("pthread_mutex_attr_destroy() error");
        exit(4);
    }
}
```

pthread_mutexattr_setpshared() – Set the process-shared mutex attribute

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|-----------------------|
| z/OS UNIX Single UNIX Specification, Version 3 | both | POSIX(ON) OS/390 V2R7 |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_mutexattr_setpshared(pthread_mutexattr_t *attr, int pshared);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_mutexattr_setpshared(pthread_mutexattr_t *attr, int pshared);
```

General description

The pthread_mutexattr_setpshared() function sets the attribute *pshared* for the mutex attribute object *attr*.

A mutex attribute object allows you to manage the characteristics of mutexes in your application. It defines the set of values to be used for a mutex during its creation. By establishing a mutex attribute object, you can create many mutexes with the same set of characteristics, without needing to define the characteristics for each and every mutex. By using *attr* with the pthread_mutexattr_setpshared() function you can define its *process-shared* value for a mutex.

The valid values for the attribute *pshared* are:

PTHREAD_PROCESS_SHARED

Permits a mutex to be operated upon by any thread that has access to the memory where the mutex is allocated, even if the mutex is allocated in memory that is shared by multiple processes.

PTHREAD_PROCESS_PRIVATE

A mutex can only be operated upon by threads created within the same process as the thread that initialized the mutex; if threads of differing processes attempt to operate on such a mutex, only the process to initialize the mutex will succeed. When a new process is created by the parent process it will receive a different copy of the private mutex and this new mutex can only be used to serialize between threads in the child process. The default value of the attribute is PTHREAD_PROCESS_PRIVATE

Returned value

If successful, pthread_mutexattr_setpshared() returns 0.

If unsuccessful, pthread_mutexattr_setpshared() returns -1 and sets errno to one of the following values:

Error Code**Description****EINVAL**

The value specified for *attr* or *pshared* is not valid.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_mutexattr_setpshared() returns an error number to indicate the error.

pthread_once() — Invoke a function once

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#include <pthread.h>
pthread_once_t once_control = PTHREAD_ONCE_INIT;

int pthread_once(pthread_once_t *once_control, void(*init_routine)());
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>
pthread_once_t once_control = PTHREAD_ONCE_INIT;

int pthread_once(pthread_once_t *once_control, void(*init_routine)());
```

General description

Establishes a function that will be executed only once in a given process. You may have each thread call the function, but only the first call causes the function to run. This is true even if called simultaneously by multiple threads. For example, a mutex or a thread-specific data key must be created exactly once. Calling `pthread_once()` prevents the code that creates a mutex or thread-specific data from being called by multiple threads. Without this routine, the execution must be serialized so that only one thread performs the initialization. Other threads that reach the same point in the code are delayed until the first thread is finished.

`pthread_once()` is used in conjunction with a *once control* variable of the type `pthread_once_t`. This variable is a data type that you initialize to the `PTHREAD_ONCE_INIT` constant. It is then passed as a parameter on the `pthread_once()` function call.

init_routine is a normal function. It can be invoked directly outside of `pthread_once()`. In addition, it is the *once_control* variable that determines if the *init_routine* has been invoked. Calling `pthread_once()` with the same routine but with different *once_control* variables, will result in the routine being called twice, once for each *once_control* variable.

Returned value

If successful, `pthread_once()` returns 0.

If unsuccessful, `pthread_once()` returns -1.

There are no documented `errno` values. Use `perror()` or `strerror()` to determine the cause of the error.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, `pthread_once()` returns an error number to indicate the error.

Example

CELEBP46

```
/* CELEBP46 */
#ifdef _OPEN_THREADS
#define _OPEN_THREADS
```

```

#endif

#include <stdio.h>
#include <errno.h>
#include <pthread.h>

#define threads 3

int          once_counter=0;
pthread_once_t once_control = PTHREAD_ONCE_INIT;

void once_fn(void)
{
    puts("in once_fn");
    once_counter++;
}

void          *threadfunc(void *parm)
{
    int          status;
    int          threadnum;
    int          *tnum;

    tnum = parm;
    threadnum = *tnum;

    printf("Thread %d executing\n", threadnum);

    status = pthread_once(&once_control, once_fn);
    if ( status < 0)
        printf("pthread_once failed, thread %d, errno=%d\n", threadnum,
               errno);

    pthread_exit((void *)0);
}

main() {
    int          status;
    int          i;
    int          threadparm[threads];
    pthread_t     threadid[threads];
    int          thread_stat[threads];

    for (i=0; i<threads; i++) {
        threadparm[i] = i+1;
        status = pthread_create( &threadid[i],
                                NULL,
                                threadfunc,
                                (void *)&threadparm[i]);

        if ( status < 0) {
            printf("pthread_create failed, errno=%d", errno);
            exit(2);
        }
    }

    for ( i=0; i<threads; i++) {
        status = pthread_join( threadid[i], (void *)&thread_stat[i]);
        if ( status < 0)
            printf("pthread_join failed, thread %d, errno=%d\n", i+1, errno);

        if (thread_stat[i] != 0)
            printf("bad thread status, thread %d, status=%d\n", i+1,
                   thread_stat[i]);
    }

    if (once_counter != 1)
        printf("once_fn did not get control once, counter=%d",once_counter);
    exit(0);
}

```

Output:

```

Thread 1 executing
in once_fn
Thread 2 executing
Thread 3 executing

```

pthread_rwlock_destroy() — Destroy a read or write lock object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------------------|
| z/OS UNIX Single UNIX Specification, Version 3 | both | POSIX(ON) OS/390 V2R7 |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_rwlock_destroy(pthread_rwlock_t *rlock);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_rwlock_destroy(pthread_rwlock_t *rlock);
```

General description

The `pthread_rwlock_destroy()` function deletes a read or write lock object, which is identified by *rlock* and releases any resources used by this read or write lock object. Read/write locks are used to protect shared resources.

Note: *rlock* is set to an invalid value by `pthread_rwlock_destroy()` but can be reinitialized using `pthread_rwlock_init()`.

Returned value

If successful, `pthread_rwlock_destroy()` returns 0.

If unsuccessful, `pthread_rwlock_destroy()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBUSY

An attempt was made to destroy the object referenced by *rlock* while it is locked or referenced as part of a wait on a condition variable.

EINVAL

The value specified by *rlock* is not valid.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, `pthread_rwlock_destroy()` returns an error number to indicate the error.

pthread_rwlock_init() — Initialize a read or write lock object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------------------|
| z/OS UNIX Single UNIX Specification, Version 3 | both | POSIX(ON) OS/390 V2R7 |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_rwlock_init(pthread_rwlock_t *rwlock, pthread_rwlockattr_t *attr);

pthread_rwlock_t rwlock=PTHREAD_RWLOCK_INITIALIZER;
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>
int pthread_rwlock_init(pthread_rwlock_t * __restrict__ rwlock,
                       const pthread_rwlockattr_t * __restrict__ attr);
```

General description

The pthread_rwlock_init() function creates a read or write lock, referenced by *rwlock*, with attributes specified by *attr*. If *attr* is NULL, the default read or write lock attribute (PTHREAD_PROCESS_PRIVATE) is used. Once initialized, the lock can be used any number of times without being reinitialized. Upon successful initialization, the state of the read or write lock becomes initialized and unlocked.

In cases where default read or write lock attributes are appropriate, the macro PTHREAD_RWLOCK_INITIALIZER can be used to initialize read or write locks that are statically allocated. The effect is equivalent to dynamic initialization by a call to pthread_rwlock_init() with parameter *attr* specified as NULL, except that no error checking is done.

Note: Although the SUSv3 standard does not specify a static initializer for read or write locks, the implementation-defined macro PTHREAD_RWLOCK_INITIALIZER_NP may be used for that purpose. It is functionally equivalent in the SUSv3 context to the PTHREAD_RWLOCK_INITIALIZER macro.

Returned value

If successful, pthread_rwlock_init() returns 0, and the state of the read or write lock becomes initialized and unlocked.

If unsuccessful, pthread_rwlock_init() returns -1 and sets errno to one of the following values:

Error Code

Description

EAGAIN

The system lacked necessary resources (other than memory) to initialize another read or write lock.

EINVAL

The value specified by *attr* is not valid.

ENOMEM

There is not enough memory to initialize the read or write lock.

EPERM

The caller does not have the privilege to perform the operation.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_rwlock_init() returns an error number to indicate the error.

pthread_rwlock_rdlock() — Wait for a lock on a read or write lock object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------------------|
| z/OS UNIX Single UNIX Specification, Version 3 | both | POSIX(ON) OS/390 V2R7 |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_rwlock_rdlock(pthread_rwlock_t *rwlock);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_rwlock_rdlock(pthread_rwlock_t *rwlock);
```

General description

The pthread_rwlock_rdlock() function applies a read lock to the read or write lock referenced by *rwlock*. The calling thread acquires the read lock if a writer does not hold the lock and there are no writers blocked on the lock. In z/OS UNIX, the calling thread does not acquire the lock when a writer does not hold the lock and there are writers waiting for the lock unless the thread already held *rwlock* for read. It will block and wait until there are no writers holding or waiting for the read or write lock. If a writer holds the lock, the calling thread will not acquire the read lock. If the read lock is not acquired, the calling thread blocks (that is, it does not return from the pthread_rwlock_rdlock() call) until it can acquire the lock.

A thread may hold multiple concurrent read locks on *rwlock* (that is successfully call the pthread_rwlock_rdlock() function n times). If so, the thread must perform matching unlocks (that is,

it must call the pthread_rwlock_unlock() function n times). Read/write locks are used to protect shared resources.

Note: If a thread owns locks at the time it is terminated then z/OS UNIX will release those locks.

Returned value

If successful, pthread_rwlock_rdlock() returns 0.

If unsuccessful, pthread_rwlock_rdlock() returns -1 and sets errno to one of the following values:

Error Code Description

EAGAIN

The read lock could not be acquired because the maximum number of read locks for *rwlock* has been exceeded. This errno will only occur in the shared path.

EDEADLK

The current thread already owns the read or write lock for writing.

EINVAL

The value specified by *rwlock* is not valid.

ENOMEM

There is not enough memory to acquire a lock. This errno will only occur in the private path.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_rwlock_rdlock() returns an error number to indicate the error.

Related information

pthread_rwlock_tryrdlock() — Attempt to lock a read or write lock object for reading

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------------------|
| z/OS UNIX Single UNIX Specification, Version 3 | both | POSIX(ON) OS/390 V2R7 |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_rwlock_tryrdlock(pthread_rwlock_t *rwlock);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_rwlock_tryrdlock(pthread_rwlock_t *rwlock);
```

General description

The `pthread_rwlock_tryrdlock()` function applies a read lock as in the `pthread_rwlock_rdlock()` function with the exception that the function fails if any thread holds a write lock on *rwlock* or there are writers blocked on *rwlock* unless the thread already held *rwlock* for read. Read/write locks are used to protect shared resources.

If the read or write lock identified by *rwlock* is locked, `pthread_rwlock_tryrdlock()` returns immediately.

When there are only read locks on the read or write lock, `pthread_rwlock_tryrdlock()` will effectively add to the count of the number of times `pthread_rwlock_unlock()` must be called by the thread to release the mutex (that is, it has the same behavior as a `pthread_rwlock_rdlock()` function).

Returned value

If successful, `pthread_rwlock_tryrdlock()` returns 0.

If unsuccessful, `pthread_rwlock_tryrdlock()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EAGAIN

The read lock could not be acquired because the maximum number of read locks for *rwlock* has been exceeded. This `errno` will only occur in the shared path.

EBUSY

rwlock could not be acquired because it was already locked.

EINVAL

The value specified by *rwlock* is not valid.

ENOMEM

There is not enough memory to acquire a lock. This `errno` will only occur in the private path.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, `pthread_rwlock_tryrdlock()` returns an error number to indicate the error.

#include <pthread.h>

int pthread_rwlock_trywrlock(pthread_rwlock_t *rwlock);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_rwlock_trywrlock(pthread_rwlock_t *rwlock);
```

General description

The pthread_rwlock_trywrlock() function applies a write lock as in the pthread_rwlock_wrlock() function with the exception that the function fails if any thread holds either a read lock or a write lock on *rwlock*. Read/write locks are used to protect shared resources.

If the read or write lock identified by *rwlock* is locked, pthread_rwlock_trywrlock() returns immediately.

Returned value

If successful, pthread_rwlock_trywrlock() returns 0.

If unsuccessful, pthread_rwlock_trywrlock() returns -1 and sets errno to one of the following values:

Error Code
Description

EBUSY
rwlock could not be acquired because it was already locked.

EINVAL
The value specified by *rwlock* is not valid.

ENOMEM
There is not enough memory to acquire a lock. This errno will only occur in the private path.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_rwlock_trywrlock() returns an error number to indicate the error.

pthread_rwlock_unlock() — Unlock a read or write lock object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------------------|
| z/OS UNIX Single UNIX Specification, Version 3 | both | POSIX(ON) OS/390 V2R7 |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_rwlock_unlock(pthread_rwlock_t *rwlock);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>
```

```
int pthread_rwlock_unlock(pthread_rwlock_t *rwlock);
```

General description

The `pthread_rwlock_unlock()` function releases a read or write lock object. If one or more threads are waiting to lock the rwlock, `pthread_rwlock_unlock()` causes one or more of these threads to return from the `pthread_rwlock_rdlock()` or the `pthread_rwlock_wrlock()` call with the read or write lock object acquired. If there are multiple threads blocked on *rwlock* for both read locks and write locks, z/OS UNIX will give the read or write lock to the next waiting call whether it is a read or a write request even when there is a writer blocked waiting for the lock. If no threads are waiting for the rwlock, the rwlock unlocks with no current owner.

Returned value

If successful, `pthread_rwlock_unlock()` returns 0.

If unsuccessful, `pthread_rwlock_unlock()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

The value specified for *rwlock* is not valid.

ENOMEM

There is not enough memory during the unlock process. This `errno` will only occur in the private path.

EPERM

The current thread does not own the read_write lock object.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, `pthread_rwlock_unlock()` returns an error number to indicate the error.

int pthread_rwlock_wrlock(pthread_rwlock_t *rwlock);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_rwlock_wrlock(pthread_rwlock_t *rwlock);
```

General description

The `pthread_rwlock_wrlock()` function applies a write lock to the read or write lock referenced by *rwlock*. The calling thread acquires the write lock if no other thread (reader or writer) holds the read or write lock *rwlock*. Otherwise, the thread blocks (that is, does not return from the `pthread_rwlock_wrlock()` call) until it can acquire the lock. In z/OS UNIX the calling thread does not acquire the lock when a writer does not hold the lock and there are writers waiting for the lock. It will block and wait until there are no writers holding or waiting for the read or write lock. If the thread already holds read or write lock for either read or write then a deadlock `errno` will be returned.

Note: If a thread owns locks at the time it is terminated then z/OS UNIX will release those locks.

Returned value

If successful, `pthread_rwlock_wrlock()` returns 0.

If unsuccessful, `pthread_rwlock_wrlock()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EDEADLK

The current thread already owns the read or write lock for writing or reading.

EINVAL

The value specified by *rwlock* is not valid.

ENOMEM

There is not enough memory to acquire a lock. This `errno` will only occur in the private path.

Special behavior for Single UNIX Specification, Version 3:

If unsuccessful, `pthread_rwlock_wrlock()` returns an error number to indicate the error.

pthread_rwlockattr_destroy() — Destroy a read or write lock attribute object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------------------|
| z/OS UNIX Single UNIX Specification, Version 3 | both | POSIX(ON) OS/390 V2R7 |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_rwlockattr_destroy(pthread_rwlockattr_t *attr);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_rwlockattr_destroy(pthread_rwlockattr_t *attr);
```

General description

The `pthread_rwlockattr_destroy()` function destroys an initialized rwlock attribute object.

After a read or write lock attributes object has been used to initialize one or more read or write locks any function affecting the attributes object (including destruction) does not affect any previously initialized read or write locks.

The `pthread_rwlockattr_destroy()` function destroys a read or write lock attributes object. Subsequent use of the object will cause an error until the object is reinitialized by another call to `pthread_rwlockattr_init()`.

Returned value

If successful, `pthread_rwlockattr_destroy()` returns 0.

If unsuccessful, `pthread_rwlockattr_destroy()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

The value specified for *attr* is not valid.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, `pthread_rwlockattr_destroy()` returns an error number to indicate the error.

pthread_rwlockattr_getpshared() – Get the processed-shared read or write lock attribute

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------------------|
| z/OS UNIX Single UNIX Specification, Version 3 | both | POSIX(ON) OS/390 V2R7 |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_rwlockattr_getpshared(const pthread_rwlockattr_t *attr, int *pshared);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>
int pthread_rwlockattr_getpshared(const pthread_rwlockattr_t *
    __restrict__ attr,
    int * __restrict__ pshared);
```

General description

The `pthread_rwlockattr_getpshared()` function gets the attribute *pshared* for the read or write lock attribute object *attr*. By using *attr* with the `pthread_rwlockattr_getpshared()` function you can determine its *process-shared* value for a read or write lock.

The valid values for the attribute *pshared* are:

PTHREAD_PROCESS_SHARED

Permits a read or write lock to be operated upon by any thread that has access to the memory where the read or write lock is allocated, even if the read or write lock is allocated in memory that is shared by multiple processes.

PTHREAD_PROCESS_PRIVATE

A read or write lock can only be operated upon by threads created within the same process as the thread that initialized the read or write lock. When a new process is created by the parent process it will receive a different copy of the private read or write lock and this new read or write lock can only be used to serialize between threads in the child process. The default value of the attributed is `PTHREAD_PROCESS_PRIVATE`.

Returned value

If successful, `pthread_rwlockattr_getpshared()` returns 0.

If unsuccessful, `pthread_rwlockattr_getpshared()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

The value specified for *attr* is not valid.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, `pthread_rwlockattr_getpshared()` returns an error number to indicate the error.

Related information

pthread_rwlockattr_init() — Initialize a read or write lock attribute object

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------------------|
| z/OS UNIX Single UNIX Specification, Version 3 | both | POSIX(ON) OS/390 V2R7 |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_rwlockattr_init(pthread_rwlockattr_t *attr);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_rwlockattr_init(pthread_rwlockattr_t *attr);
```

General description

The `pthread_rwlockattr_init()` function initializes a read or write lock attribute object. A read or write lock attribute object allows you to manage the characteristics of read or write locks in your application. It defines the set of values to be used for the read or write lock during its creation. By establishing a read or write lock attribute object, you can create many read or write locks with the same set of characteristics, without needing to define the characteristics for each and every read or write lock.

For a valid read or write lock attribute, refer to [“pthread_rwlockattr_setpshared\(\) — Set the process-shared read or write lock attribute” on page 1330](#).

If `pthread_rwlockattr_init()` is called specifying an already initialized read or write lock attributes object the request is rejected and the current lock attributes object is unchanged.

Returned value

If successful, `pthread_rwlockattr_init()` returns 0.

If unsuccessful, `pthread_rwlockattr_init()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

ENOMEM

There is not enough memory to initialize *attr*.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, `pthread_rwlockattr_init()` returns an error number to indicate the error.

Related information

pthread_rwlockattr_setpshared() — Set the process-shared read or write lock attribute

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------------------|
| z/OS UNIX Single UNIX Specification, Version 3 | both | POSIX(ON) OS/390 V2R7 |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_rwlockattr_setpshared(pthread_rwlockattr_t *attr, int pshared);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>

int pthread_rwlockattr_setpshared(pthread_rwlockattr_t *attr, int pshared);
```

General description

The `pthread_rwlockattr_setpshared()` function sets the attribute *pshared* for the read or write lock attribute object *attr*.

A read or write lock attribute object allows you to manage the characteristics of read or write locks in your application. It defines the set of values to be used for a read or write lock during its creation. By establishing a read or write lock attribute object, you can create many read or write locks with the same set of characteristics, without needing to define those characteristics for each and every read or write lock. By using *attr* with the `pthread_rwlockattr_setpshared()` function you can define its *process-shared* value for a read or write lock.

The valid values for the attribute *pshared* are:

PTHREAD_PROCESS_SHARED

Permits a read or write lock to be operated upon by any thread that has access to the memory where the read or write lock is allocated, even if the read or write lock is allocated in memory that is shared by multiple processes.

PTHREAD_PROCESS_PRIVATE

A read or write lock can only be operated upon by threads created within the same process as the thread that initialized the read or write lock. When a new process is created by the parent process it will receive a different copy of the private read or write lock and this new read or write lock can only be used to serialize between threads in the child process. The default value of the attributed is `PTHREAD_PROCESS_PRIVATE`.

Returned value

If successful, `pthread_rwlockattr_setpshared()` returns 0.

If unsuccessful, `pthread_rwlockattr_setpshared()` returns -1 and sets `errno` to one of the following values:

Error Code Description

EINVAL

The value specified for *attr* or *pshared* is not valid.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, pthread_rwlockattr_setpshared() returns an error number to indicate the error.

                              int identity_type,
                              size_t identity_length,
                              void *identity,
                              char *password,
                              int options,
                              const char *applid);
```

General description

pthread_security_np() creates or deletes a thread-level security environment for the calling thread.

The __pthread_security_applid_np() function is equivalent to pthread_security_np() with the added feature that it also allows the application identifier (APPLID) to be supplied that will be passed on to the security product to assist with authentication. This is useful, for example, in situations where a pass ticket is provided and the pass ticket was created with a USERID/APPLID combination. When applid is NULL or a pointer to NULL, no application identifier will be passed on to the security product.

The function supports the following parameters:

Parameter Description

function_code

Specify one of the following:

__CREATE_SECURITY_ENV

Create a thread-level security environment for the calling thread. If a thread-level security environment already exists, it is deleted before a new one is created.

Note: This routine cannot be called from the Initial Processing Thread (IPT) with function code `__CREATE_SECURITY_ENV`.

__DAEMON_SECURITY_ENV

Creates a thread-level security environment for the caller's thread without the need for a password if the caller meets either of the following requirements:

- The caller has READ access to the BPX.DAEMON resource in the FACILITY class and is a superuser.
- The caller has UPDATE access to the BPX.DAEMON resource in the FACILITY class.

If a thread-level security environment already exists, it is deleted before the new environment is created. Using the `__DAEMON_SECURITY_ENV` function code and not specifying a password is similar to using the current BPX.SRV.userid surrogate support. The difference is that the installation does not have to setup individual surrogate profiles for each of the clients that desire a thread level identity in the target server process.

The server will be allowed to create any identity without authentication if it is given permission to the BPX.DAEMON facility class profile.

__DELETE_SECURITY_ENV

Delete the thread-level security environment for the calling thread, if one exists. If the security environment was created using the `__TLS_TASK_ACEE` option, then only the z/OS UNIX security data is deleted (the task-level ACEE is unchanged).

__TLS_TASK_ACEE

Initializes the z/OS UNIX security data for a task that has an existing task-level security environment (task-level ACEE). If the z/OS UNIX security data already exists for the calling task, the existing z/OS UNIX security data is deleted and a new set of z/OS UNIX security data is established.

__TLS_TASK_ACEE_USP

Takes a pre-existing user security packet (USP) from a task-level ACEE and extracts the UID and GID information. This information is then used to build a complete z/OS UNIX security environment for the calling thread. If the calling thread does not have a USP associated with the task-level ACEE, this call is treated as if the `__TLS_TASK_ACEE` function was specified.

identity_type

Specifies the format of the user identity in the argument *identity*. It can have one of the following values:

__USERID_IDENTITY

User identity in the form of a character string (1 to 8 bytes in length).

__CERTIFICATE_IDENTITY

User identity in the form of a `__certificate_t`.

A `__certificate_t` is a structure containing the following elements:

__cert_type

The type of security certificate. Setting value `__CERT_X509`, for example, indicates the certificate is an X.509 security certificate.

__userid

An output field in the `__certificate` structure that will be filled with the user ID associated with the certificate. This output will be up to 8 characters long and NULL-terminated.

__cert_length

The length in bytes of the security certificate.

__cert_ptr

A pointer to the start of the security certificate.

identity_length

Specifies the length of the *identity* parameter. If *identity_type* is `__USERID_IDENTITY`, *identity_length* is the length of the user identity character string. If *identity_type* is `__CERTIFICATE_IDENTITY`, *identity_length* is the length of the `__certificate` structure.

identity

Specifies the user identity according to the *identity_type* parameter.

password

Specifies a user password or PassTicket, or a password phrase. The password must be a NULL terminated string.

options

Specifies options used to tailor the request. *options* must be set to 0.

applid

Specifies the application identifier that will be used for authentication with the security product.

This function is intended to be used by servers which process requests from multiple clients. By creating and building a thread-level security environment for the client, a server can process many client requests without the overhead of issuing *fork/setuid/exec*. See usage notes in `pthread_security_np`, `pthread_security_applid_np` (BPX1TLS, BPX4TLS) — Create or delete thread-level security in z/OS UNIX *System Services Programming: Assembler Callable Services Reference* for additional information.

Returned value

If successful, `pthread_security_np()` returns 0.

If unsuccessful, `pthread_security_np()` returns -1 and sets `errno` to one of the following values:

Error Code**Description****EACCES**

The password or PassTicket, or the password phrase provided is not valid for the passed userid.

EINVAL

A parameter is not valid.

EMVSERR

An MVS environmental error or internal error occurred.

EMVSEXPIRE

The password or PassTicket, or the password phrase provided has expired.

EMVSSAF2ERR

The SAF call to the security product incurred an error.

EMVSSAFEXTRERR

The SAF or RACF RACROUTE EXTRACT service incurred an error. One possible reason is that the user's access was revoked.

ENOSYS

The function is not implemented.

EPERM

One or more of the following conditions were detected:

- The process does not have appropriate privileges to set a thread-level security environment. The caller is not permitted to the BPX.SERVER FACILITY class profile or BPX.SERVER is not defined and the caller is not a superuser.
- No password, PassTicket or password phrase is provided and the BPX.SRV SURROGAT class has not been activated; or no BPX.SRV SURROGAT class profile has been defined for the specified user identity.
- No password, PassTicket or password phrase is provided and the caller is not permitted to the specified user identity's BPX.SRV SURROGAT class profile.

- For function_code __DAEMON_SECURITY_ENV, the caller is not a superuser; or the BPX.DAEMON FACILITY class is defined and the caller is not permitted to the BPX.DAEMON FACILITY class profile.
- A load from an unauthorized (not Program Control protected) library was done in the address space.

ESRCH

The user ID provided as input is not defined to the security product or does not have an OMVS segment defined.

pthread_self() — Get the caller

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

pthread_t pthread_self(void);
```

General description

Returns the thread ID of the calling thread.

Returned value

There are no documented errno values. Use perror() or strerror() to determine the cause of the error.

Example**CELEBP47**

```
/* CELEBP47 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>

pthread_t thid, IPT;

void *thread(void *arg) {
    if (pthread_equal(IPT, pthread_self()))
        puts("the thread is the IPT...?");
    else
        puts("the thread is not the IPT");

    if (pthread_equal(thid, pthread_self()))
        puts("the thread is the one created by the IPT");
    else
        puts("the thread is not the one created by the IPT...?");
}

main() {
    IPT = pthread_self();
    if (pthread_create(&thid, NULL, thread, NULL) != 0) {
```

```

    perror("pthread_create() error");
    exit(1);
}

if (pthread_join(thid, NULL) != 0) {
    perror("pthread_create() error");
    exit(3);
}
}

```

Output:

```

the thread is not the IPT
the thread is the one created by the IPT

```

pthread_setcancelstate() — Set a thread cancelability state format

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|---------------------|
| Single UNIX Specification, version 3 | both | z/OS V1R7 POSIX(ON) |

Format

```

#define _OPEN_THREADS 2
#include <pthread.h>

int pthread_setcancelstate(int state, int *oldstate);

```

General description

pthread_setcancelstate() controls whether the thread acts on a cancelation request caused by a call to pthread_cancel(). The old *state* is stored into the location pointed to by *oldstate*. The cancelability states can be:

PTHREAD_CANCEL_ENABLE

The thread can be canceled, but is subject to type. The cancelability types can be found in [“pthread_setcanceltype\(\) — Set a thread cancelability type format” on page 1336](#).

PTHREAD_CANCEL_DISABLE

The thread cannot be canceled.

Returned value

If successful, pthread_setcancelstate() returns 0. Upon failure, returns the following EINVAL error code:

- *state* is an invalid value.

Related information

- "Thread Cancellation" in the [z/OS XL C/C++ Programming Guide](#)

pthread_setcanceltype() — Set a thread cancelability type format

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|---------------------|
| Single UNIX Specification, version 3 | both | z/OS V1R7 POSIX(ON) |

Format

```
#define _OPEN_THREADS 2
#include <pthread.h>

int pthread_setcanceltype(int type, int *oldtype);
```

General description

pthread_setcanceltype() controls when a cancel request is acted on. The old *type* is stored into the location pointed to by *oldtype*. The cancelability types can be:

PTHREAD_CANCEL_ASYNCHRONOUS

The thread can be canceled at any time.

PTHREAD_CANCEL_DEFERRED

The thread can be canceled, but only at cancelation points introduced by invocation of particular functions. For more information, see the [z/OS XL C/C++ Programming Guide](#).

Returned value

If successful, pthread_setcanceltype() returns 0. Upon failure, returns the following EINVAL error code:

- *type* is an invalid value.

Related information

- “[pthread_testcancel\(\)](#) — Establish a cancelation point” on page 1347

pthread_setconcurrency() — Set the level of concurrency

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|---------------------|
| Single UNIX Specification, version 3 | both | z/OS V1R7 POSIX(ON) |

Format

```
#define _OPEN_THREADS 2
#include <pthread.h>

int pthread_setconcurrency(int new_level);
```

General description

pthread_setconcurrency() sets the desired thread concurrency level to *new_level*.

Usage notes

1. z/OS UNIX does not support multiplexing POSIX threads onto TCBs. If successful, pthread_setconcurrency() saves *new_level* for subsequent calls to pthread_getconcurrency() but takes no other action. For related information on the relationship between pthreads and TCBs, see [“pthread_attr_setweight_np\(\) — Set weight of thread attribute object”](#) on page 1246 and [“pthread_attr_setsynctype_np\(\) — Set thread sync type”](#) on page 1245.

Returned value

If successful, pthread_setconcurrency() returns 0. Upon failure, returns one of the following error values:

- EINVAL – The value specified by *new_level* is negative.
- EAGAIN – The value specific by *new_level* would cause a system resource to be exceeded.

Related information

- "Thread Cancellation" in the [z/OS XL C/C++ Programming Guide](#)
- [“pthread.h — Thread interfaces”](#) on page 53
- [“pthread_getconcurrency\(\) — Get the level of concurrency”](#) on page 1280

pthread_setintr() — Set a thread cancelability state

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| POSIX.4a | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_setintr(int state);
```

General description

Controls whether the thread accepts a cancel request that was produced by a call to pthread_cancel(). The cancelability states can be:

PTHREAD_INTR_DISABLE

The thread cannot be canceled.

PTHREAD_INTR_ENABLE

The thread can be canceled, but it is subject to type. The cancelability types can be found in [“pthread_setintrtype\(\) — Set a thread cancelability type”](#) on page 1339.

Usage notes

1. If you are writing to the Single UNIX Specification, Version 3 standard, use pthread_setcancelstate() in place of pthread_setintr().

Returned value

If successful, pthread_setintr() returns the previous state.

If unsuccessful, pthread_setintr() returns -1 and sets errno to one of the following values:

Error Code

Description

EINVAL

state is an invalid value.

Example

CELEBP48

```

/* CELEBP48 */
#define _OPEN_THREADS
#include <stdio.h>
#include <string.h>
#include <pthread.h>
#include <errno.h>
#include <unistd.h>

int thstatus;
char state[60] = "enable/controlled - initial default";

void * thfunc(void *voidptr)
{
    int rc;
    char *parmptr;

    parmptr = voidptr;
    printf("parm = %s.\n", parmptr);

    strcpy(state, "disable/controlled");
    if ( pthread_setintrtype(PTHREAD_INTR_CONTROLLED) == -1 ) {
        printf("set controlled failed. %s\n", strerror(errno));
        thstatus = 103;
        pthread_exit(&thstatus);
    }

    if ( pthread_setintr(PTHREAD_INTR_ENABLE) == -1 ) {
        printf("set enable failed. %s\n", strerror(errno));
        thstatus = 104;
        pthread_exit(&thstatus);
    }

    strcpy(state, "enable/controlled");
    strcat(state, " - pthread_testintr");

    while (1) {
        pthread_testintr();
        sleep(1);
    }

    thstatus = 100;
    pthread_exit(&thstatus);
}

main(int argc, char *argv[]) {
    int rc;
    pthread_attr_t attrarea;
    pthread_t thid;
    char parm[] = "abcdefghijklmnpqrstuvwxy";
    int *statptr;

    if ( pthread_attr_init(&attrarea) == -1 ) {
        printf("pthread_attr_init failed. %s\n", strerror(errno));
        exit(1);
    }

```

```

}

if ( pthread_create(&thid, &attrarea, thfunc, (void *)&parm) == -1) {
    printf("pthread_create failed. %s\n", strerror(errno));
    exit(2);
}

sleep(5);

if ( pthread_cancel(thid) == -1 ) {
    printf("pthread_cancel failed. %s\n", strerror(errno));
    exit(3);
}

if ( pthread_join(thid, (void **)&statptr)== -1 ) {
    printf("pthread_join failed. %s\n", strerror(errno));
    exit(4);
}

if ( statptr == (int *)-1 )
    printf("thread was cancelled. state = %s.\n", state);
else
    printf("thread was not cancelled. thstatus = %d.\n", *statptr);

exit(0);
}

```

Output:

```

parm = abcdefghijklmnopqrstuvwxyz.
thread was canceled. state = enable/controlled - pthread_testintr.

```

Related information

- [“pthread.h — Thread interfaces” on page 53](#)
- [“pthread_cancel\(\) — Cancel a thread” on page 1247](#)
- [“pthread_setintrtype\(\) — Set a thread cancelability type” on page 1339](#)

pthread_setintrtype() — Set a thread cancelability type

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| POSIX.4a | both | POSIX(ON) |

Format

```

#define _OPEN_THREADS
#include <pthread.h>

int pthread_setintrtype(int type);

```

General description

Controls when a cancel request is acted on. The cancelability types can be:

PTHREAD_INTR_ASYNCHRONOUS

The thread can be canceled at any time.

PTHREAD_INTR_CONTROLLED

The thread can be canceled, but only at specific points of execution. These are:

- When waiting on a condition variable, which is `pthread_cond_wait()` or `pthread_cond_timedwait()`
- When waiting for the end of another thread, which is `pthread_join()`
- While waiting for an asynchronous signal, which is `sigwait()`
- When setting the calling thread's cancelability state, which is `pthread_setintr()`
- Testing specifically for a cancel request, which is `pthread_testintr()`
- When suspended because of POSIX functions or one of the following C standard functions: `close()`, `fcntl()`, `open()`, `pause()`, `read()`, `tcdrain()`, `tcsetattr()`, `sigsuspend()`, `sigwait()`, `sleep()`, `wait()`, or `write()`

Usage notes

1. If you are writing to the Single UNIX Specification, Version 3 standard, use `pthread_setcanceltype()` in place of `pthread_setintrtype()`.
2. The default cancelability type for newly created threads and the initial thread is `PTHREAD_INTR_CONTROLLED`. If a cancellation request is pending and the cancelability state is set to `PTHREAD_INTR_ASYNCHRONOUS`, the cancellation request is acted upon before control is returned to the invoker.

Returned value

If successful, `pthread_setintrtype()` returns the previous type.

If unsuccessful, `pthread_setintrtype()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

type is an invalid value.

Example

CELEBP50

```
/* CELEBP50 */
#define _OPEN_THREADS
#include <stdio.h>
#include <string.h>
#include <pthread.h>
#include <errno.h>
#include <unistd.h>

int thstatus;
char state[60] = "enable/controlled - initial default";

void * thfunc(void *voidptr)
{
    int rc;
    char *parmptr;

    parmptr = voidptr;
    printf("parm = %s.\n", parmptr);
    if ( pthread_setintrtype(PTHREAD_INTR_CONTROLLED) == -1 ) {
        printf("set controlled failed. %s\n", strerror(errno));
        thstatus = 103;
        pthread_exit(&thstatus);
    }
    strcpy(state, "disable/controlled");

    if ( pthread_setintr(PTHREAD_INTR_ENABLE) == -1 ) {
        printf("set enable failed. %s\n", strerror(errno));
        thstatus = 104;
        pthread_exit(&thstatus);
    }
    strcpy(state, "enable/controlled");
}
```

```

strcat(state, " - pthread_testintr");

while(1) {
    pthread_testintr();
    sleep(1);
}

thstatus = 100;
pthread_exit(&thstatus);
}

main(int argc, char *argv[]) {
    int          rc;
    pthread_attr_t attrarea;
    pthread_t     thid;
    char          parm[] = "abcdefghijklmnopqrstuvwxyz";
    int          *statptr;

    if ( pthread_attr_init(&attrarea) == -1 ) {
        printf("pthread_attr_init failed. %s\n", strerror(errno));
        exit(1);
    }

    if ( pthread_create(&thid, &attrarea, thfunc, (void *)&parm) == -1 ) {
        printf("pthread_create failed. %s\n", strerror(errno));
        exit(2);
    }

    sleep(5);

    if ( pthread_cancel(thid) == -1 ) {
        printf("pthread_cancel failed. %s\n", strerror(errno));
        exit(3);
    }

    if ( pthread_join(thid, (void **)&statptr) == -1 ) {
        printf("pthread_join failed. %s\n", strerror(errno));
        exit(4);
    }

    if ( statptr == (int *)-1 )
        printf("thread was cancelled. state = %s.\n", state);
    else
        printf("thread was not cancelled. thstatus = %d.\n", *statptr);

    exit(0);
}

```

Output:

```

parm = abcdefghijklmnopqrstuvwxyz.
thread was canceled. state = enable/controlled - pthread_testintr.

```

pthread_set_limit_np() — Set task and thread limits

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | POSIX(ON) |

Format

```
#define _OPEN_SYS
#include <pthread.h>

int pthread_set_limit_np(int action, int maxthreadtasks, int maxthreads);
```

General description

The `pthread_set_limit_np()` function allows you to control how many tasks and threads can be created for a process. On a single call, you can specify that you want to update either the maximum number of tasks, the maximum number of threads, or both. The maximum number of tasks and threads is dependent upon the size of the private area below 16M. A realistic limit is 200 to 400 tasks and threads.

The *action* can be set to one of the following symbolics, as defined in the `pthread.h` header file:

__STL_MAX_TASKS

Specify this action when only updating the maximum number of tasks.

__STL_MAX_THREADS

Specify this action when only updating the maximum number of threads.

__STL_SET_BOTH

Specify this action when updating both the maximum number of tasks and the maximum number of threads at the same time.

For more information on the allowable values for `maxthreadtasks` and `maxthreads`, see the `BPX1STL` function in [z/OS UNIX System Services Programming: Assembler Callable Services Reference](#).

Returned value

If successful, `pthread_set_limit_np()` returns 0.

If unsuccessful, `pthread_set_limit_np()` returns -1.

For more information regarding return values and reason codes, see the `BPX1STL` function in [z/OS UNIX System Services Programming: Assembler Callable Services Reference](#).

Related information

- [“pthread.h — Thread interfaces” on page 53](#)

pthread_setspecific() — Set the thread-specific value for a key

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.4a Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_setspecific(pthread_key_t key, void *value);
```

SUSV3:

```
#define _UNIX03_THREADS
#include <pthread.h>
int pthread_setspecific(pthread_key_t key, const void *value);
```

General description

Associates a thread-specific value, *value*, with a key identifier, *key*.

Many multithreaded applications require storage shared among threads but a unique value for each thread. A thread-specific data key is an identifier, created by a thread, for which each thread in the process can set a unique key *value*.

pthread_key_t is a storage area where the system places the key identifier. To create a key, a thread uses `pthread_key_create()`. This returns the key identifier into the storage area of type *pthread_key_t*. At this point, each of the threads in the application has the use of that key, and can set its own unique value by use of `pthread_setspecific()`. A thread can get its own unique value using `pthread_getspecific()`.

Returned value

If successful, `pthread_setspecific()` returns 0.

If unsuccessful, `pthread_setspecific()` returns -1 and sets `errno` to one of the following values:

Error Code**Description****EINVAL**

The key identifier *key* is not valid.

ENOMEM

Insufficient memory exists to associate the non-NULL value with the key.

Special behavior for Single UNIX Specification, Version 3: If unsuccessful, `pthread_setspecific()` returns an error number to indicate the error.

Example**CELEBP51**

```
/* CELEBP51 */
#define _OPEN_THREADS

#include <stdio.h>
#include <stdlib.h>
#include <errno.h>
#include <pthread.h>

#define threads 3
#define BUFFSZ 48
pthread_key_t key;

void *threadfunc(void *parm)
{
    int status;
    void *value;
    int threadnum;
    int tnum;
    void *getvalue;
    char Buffer[BUFFSZ];

    tnum = parm;
    threadnum = *tnum;

    printf("Thread %d executing\n", threadnum);

    if (!(value = malloc(sizeof(Buffer))))
        printf("Thread %d could not allocate storage, errno = %d\n",
              threadnum, errno);
    status = pthread_setspecific(key, (void *) value);
```

```

    if ( status < 0 ) {
        printf("pthread_setspecific failed, thread %d, errno %d",
               threadnum, errno);
        pthread_exit((void *)12);
    }
    printf("Thread %d setspecific value: %d\n", threadnum, value);

    getvalue = 0;
    status = pthread_getspecific(key, &getvalue);
    if ( status < 0 ) {
        printf("pthread_getspecific failed, thread %d, errno %d",
               threadnum, errno);
        pthread_exit((void *)13);
    }

    if (getvalue != value) {
        printf("getvalue not valid, getvalue=%d", (int)getvalue);
        pthread_exit((void *)68);
    }

    pthread_exit((void *)0);
}

void destr_fn(void *parm)
{
    printf("Destructor function invoked\n");
    free(parm);
}

main() {
    int         getvalue;
    int         status;
    int         i;
    int         threadparm[threads];
    pthread_t    threadid[threads];
    int         thread_stat[threads];

    if ((status = pthread_key_create(&key, destr_fn )) < 0) {
        printf("pthread_key_create failed, errno=%d", errno);
        exit(1);
    }

    for (i=0; i<threads; i++) {
        threadparm[i] = i+1;
        status = pthread_create( &threadid[i],
                                NULL,
                                threadfunc,
                                (void *)&threadparm[i]);

        if ( status < 0 ) {
            printf("pthread_create failed, errno=%d", errno);
            exit(2);
        }
    }

    for ( i=0; i<threads; i++) {
        status = pthread_join( threadid[i],
                               (void *)&thread_stat[i]);
        if ( status < 0 ) {
            printf("pthread_join failed, thread %d, errno=%d\n", i+1, errno);
        }

        if (thread_stat[i] != 0) {
            printf("bad thread status, thread %d, status=%d\n", i+1,
                  thread_stat[i]);
        }
    }
    exit(0);
}

pthread_sigmask() – Examine or change a thread blocked signals format

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|---------------------|
| Single UNIX Specification, version 3 | both | z/OS V1R7 POSIX(ON) |

Format

```
#define _OPEN_THREADS 2
#include <signal.h>

int pthread_sigmask(int option, const sigset_t *__restrict__ new_set,
                    sigset_t *__restrict__ old_set);
```

General description

pthread_sigmask() examines, changes, or examines and changes the signal mask of the calling thread. If there is only one thread, it does the same for the calling process.

Typically, pthread_sigmask(SIG_BLOCK, ..., ...) is used to block signals during a critical section of code. At the end of the critical section of code, pthread_sigmask(SIG_SETMASK, ..., ...) is used to restore the mask to the previous value returned by pthread_sigmask(SIG_BLOCK, ..., ...).

option indicates the way in which the existing set of blocked signals should be changed. The following are the possible values for *option*, defined in the signal.h header file:

- SIG_BLOCK – Indicates that the set of signals given by *new_set* should be blocked, in addition to the set currently being blocked.
- SIG_UNBLOCK – Indicates that the set of signals given by *new_set* should not be blocked. These signals are removed from the current set of signals being blocked.
- SIG_SETMASK – Indicates that the set of signals given by *new_set* should replace the old set of signals being blocked.

new_set points to a signal set giving the new signals that should be blocked or unblocked (depending on the value of *option*) or it points to the new signal mask if the option was SIG_SETMASK. Signal sets are described in "sigemptyset() – Initialize a Signal Mask to Exclude All Signals" in topic 3.727. If *new_set* is a NULL pointer, the set of blocked signals is not changed. pthread_sigmask() determines the current set and returns this information in **old_set*. If *new_set* is NULL, the value of *option* is not significant. The signal set manipulation functions: sigemptyset(), sigfillset(), sigaddset(), and sigdelset() must be used to establish the new signal set pointed to by *new_set*.

old_set points to a memory location where pthread_sigmask() can store a signal set. If *new_set* is NULL, *old_set* returns the current set of signals being blocked. When *new_set* is not NULL, the set of signals pointed to by *old_set* is the previous set.

If there are any pending unblocked signals, either at the process level or at the current thread's level after pthread_sigmask() has changed the signal mask, then at least one of those signals is delivered to the thread before pthread_sigmask() returns.

The signals SIGKILL, SIGSTOP, or SIGTRACE cannot be blocked. If you attempt to use pthread_sigmask() to block these signals, the attempt is ignored. pthread_sigmask() does not return an error status.

SIGFPE, SIGILL, and SIGSEGV signals that are not artificially generated by kill(), killpg(), raise(), or pthread_kill() (that is, were generated by the system as a result of a hardware or software exception) will not be blocked.

If an artificially raised SIGFPE, SIGILL, or SIGSEGV signal is pending and blocked when an exception causes another SIGFPE, SIGILL, or SIGSEGV signal, both the artificial and exception-caused signals may be delivered to the application.

If pthread_sigmask() fails, the signal mask of the thread is not changed.

Usage Notes

1. The use of the SIGHSTOP and SIGHCONT signal is not supported with this function.

Returned value

If successful, pthread_sigmask() returns 0. Otherwise, pthread_sigmask() returns one of the following error numbers:

EINVAL

option does not have one of the recognized values.

pthread_tag_np() — Set and query thread tag data

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

int pthread_tag_np(const char *newtag, char *oldtag);
```

General description

The pthread_tag_np() function is used to set and query the contents of the calling thread's tag data.

The parameters supported are:

newtag

Specifies the new tag data to be set for the callers thread. The length of the new tag data must be in the range of 0-65 bytes. If the length is zero (NULL string) the caller's thread tag data will be cleared.

oldtag

Specifies the string where pthread_tag_np() returns the old (current) tag data for the caller's thread. Tag data can be up to 66 bytes (including the trailing NULL).

Returned value

If successful, pthread_tag_np() returns 0.

If unsuccessful, pthread_tag_np() returns -1 and sets errno to one of the following values:

Error Code

Description

EFAULT

One of the following errors was detected:

- All or part of the newtag string is not addressable by the caller.
- All or part of the oldtag string is not addressable by the caller.

EINVAL

The length of the newtag string is not within allowable range (0 to 65 bytes).

EMVSERR

An MVS environmental or internal error has occurred.

pthread_testcancel() — Establish a cancelation point

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|---------------------|
| Single UNIX Specification, version 3 | both | z/OS V1R7 POSIX(ON) |

Format

```
#define _OPEN_THREADS 2
#include <pthread.h>

void pthread_testcancel(void);
```

General description

pthread_testcancel() allows the thread to solicit cancel requests at specific points within the current thread. You must have the cancelability state set to enabled (PTHREAD_CANCEL_ENABLE) for this function to have any effect.

Returned value

pthread_testcancel() returns no values.

Related information

- "Thread Cancellation" in the [z/OS XL C/C++ Programming Guide](#)
- "[pthread.h — Thread interfaces](#)" on page 53
- "[pthread_cancel\(\) — Cancel a thread](#)" on page 1247

pthread_testintr() — Establish a cancelability point

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| POSIX.4a | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

void pthread_testintr(void);
```

General description

Allows the thread to solicit cancel requests at specific points within the current thread. You must have the cancelability state set to enabled (PTHREAD_INTR_ENABLE) for this function to have any effect.

Usage notes

1. If you are writing to the Single UNIX Specification, Version 3 standard, use pthread_testcancel() in place of pthread_testintr().

Returned value

pthread_testintr() returns no values.

There are no documented errno values. Use perror() or strerror() to determine the cause of the error.

Example

CELEBP52

```
/* CELEBP52 */
#define _OPEN_THREADS
#include <stdio.h>
#include <string.h>
#include <pthread.h>
```

```

#include <errno.h>
#include <unistd.h>

int thstatus;
char state[60] = "enable/controlled - initial default";

void * thfunc(void *voidptr)
{
    int rc;
    char *pamptr;

    pamptr = voidptr;
    printf("parm = %s.\n", pamptr);
    if ( pthread_setintrtype(PTHREAD_INTR_CONTROLLED) == -1 ) {
        printf("set controlled failed. %s\n", strerror(errno));
        thstatus = 103;
        pthread_exit(&thstatus);
    }
    strcpy(state, "disable/controlled");

    if ( pthread_setintr(PTHREAD_INTR_ENABLE) == -1 ) {
        printf("set enable failed. %s\n", strerror(errno));
        thstatus = 104;
        pthread_exit(&thstatus);
    }
    strcpy(state, "enable/controlled");

    strcat(state, " - pthread_testintr");

    while(1) {
        pthread_testintr();
        sleep(1);
    }

    thstatus = 100;
    pthread_exit(&thstatus);
}

main(int argc, char *argv[]) {
    int rc;
    pthread_attr_t attrarea;
    pthread_t thid;
    char parm[] = "abcdefghijklmnopqrstuvwxyz";
    int *statptr;

    if ( pthread_attr_init(&attrarea) == -1 ) {
        printf("pthread_attr_init failed. %s\n", strerror(errno));
        exit(1);
    }

    if ( pthread_create(&thid, &attrarea, thfunc, (void *)&parm) == -1 ) {
        printf("pthread_create failed. %s\n", strerror(errno));
        exit(2);
    }

    sleep(5);

    if ( pthread_cancel(thid) == -1 ) {
        printf("pthread_cancel failed. %s\n", strerror(errno));
        exit(3);
    }

    if ( pthread_join(thid, (void **)&statptr) == -1 ) {
        printf("pthread_join failed. %s\n", strerror(errno));
        exit(4);
    }

    if ( statptr == (int *)-1 )
        printf("thread was cancelled. state = %s.\n", state);
    else
        printf("thread was not cancelled. thstatus = %d.\n", *statptr);

    exit(0);
}

```

Output:

```

parm = abcdefghijklmnopqrstuvwxyz.
thread was canceled. state = enable/controlled - pthread_testintr.

```

pthread_yield() — Release the processor to other threads

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| POSIX.4a | both | POSIX(ON) |

Format

```
#define _OPEN_THREADS
#include <pthread.h>

void pthread_yield(NULL);
```

General description

The pthread_yield() function allows a thread to give up control of a processor so that another thread can have the opportunity to run.

The parameter to the function must be NULL, because non-NULL values are reserved.

The speed at which the pthread_yield() function releases a processor can be configured by using the _EDC_PTHREAD_YIELD and _EDC_PTHREAD_YIELD_MAX environment variables. The _EDC_PTHREAD_YIELD environment variable is used to configure the pthread_yield() function to release the processor immediately, or to release the processor after a delay. The _EDC_PTHREAD_YIELD_MAX environment variable is used to change the maximum delay to a value less than the default (32 milliseconds).

For more information about the _EDC_PTHREAD_YIELD and _EDC_PTHREAD_YIELD_MAX environment variables, see “Using Environment Variables” in [z/OS XL C/C++ Programming Guide](#).

Returned value

pthread_yield() returns no values.

There are no documented errno values.

Example

CELEBP53

```
/* CELEBP53 */
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>
#include <unistd.h>

void *thread(void *arg) {

    /* A simple loop with only puts() would allow a thread to write several
    lines in a row.
    With pthread_yield(), each thread gives another thread a chance before
    it writes its next line */
```

```

    while (1) {
        puts((char*) arg);
        pthread_yield(NULL);
    }
}

main() {
    pthread_t t1, t2, t3;

    if (pthread_create(&t1, NULL, thread, "thread 1") != 0) {
        perror("pthread_create() error");
        exit(1);
    }

    if (pthread_create(&t2, NULL, thread, "thread 2") != 0) {
        perror("pthread_create() error");
        exit(2);
    }

    if (pthread_create(&t3, NULL, thread, "thread 3") != 0) {
        perror("pthread_create() error");
        exit(3);
    }

    sleep(1);

    exit(0); /* this will tear all threads down */
}

```

Output:

```

thread 1
thread 3
thread 2
thread 1
thread 3
thread 2
thread 1
thread 3
thread 2
thread 1
thread 3

```

ptsname() — Get name of the subsidiary pseudoterminal device

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```

#include <stdlib.h>

char *ptsname(int fildes);

```

General description

The ptsname() function returns the name of the subsidiary pseudoterminal device associated with a manager pseudoterminal device. The *fildev* argument is a file descriptor that refers to the manager device. ptsname() returns a pointer to a string containing the path name of the corresponding subsidiary device.

Returned value

If successful, ptsname() returns a pointer to a string which is the name of the pseudoterminal subsidiary device.

If unsuccessful, ptsname() returns a NULL pointer. This could occur if *fildev* is an invalid file descriptor or if the subsidiary device name does not exist in the file system.

No errors are defined.

putc(), putchar() – Write a character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdio.h>

int putc(int c, FILE *stream);
int putchar(int c);
```

General description

Converts *c* to unsigned char and then writes *c* to the output *stream* at the current position. The putchar() function is identical to:

```
putc(c, stdout);
```

These functions are also available as macros in the IBM z/OS C/C++ product. For performance purposes, it is recommended that the macro forms rather than the functional forms be used.

By default, if the stdio.h header file is included, the macro is invoked. Therefore, the stream argument expression should never be an expression with side effects.

The actual function can be accessed using one of the following methods:

- For C only: do *not* include `stdio.h`.
- Specify `#undef`, for example, `#undef putc`.
- Surround the function name by parentheses, for example: `(putc)('a')`.

In a multithread application, in the presence of the feature test macro, `_OPEN_THREADS`, these macros are in an `#undef` status because they are not thread-safe.

`putc()` and `putchar()` are not supported for files opened with `type=record` or `type=blocked`.

`putc()` and `putchar()` have the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

If the application is not multithreaded, then setting the `_ALL_SOURCE_NO_THREADS` feature test macro may improve performance of the application, because it allows use of the inline version of this function.

Returned value

If successful, `putc()` and `putchar()` return the character written.

If unsuccessful, `putc()` and `putchar()` return EOF.

Example

CELEBP54

```
/* CELEBP54

   This example writes the contents of a buffer to a data
   stream.
   The body of the "for" statement is null because the
   example carries out the writing operation in the test
   expression.

*/
#include <stdio.h>
#include <string.h>
#define LENGTH 80

int main(void)
{
    FILE *stream = stdout;
    int i, ch;
    char buffer[LENGTH + 1] = "Hello world\n";

    /* This could be replaced by using the fwrite routine */
    for ( i = 0;
          (i < strlen(buffer)) && ((ch = putc(buffer[i], stream)) != EOF);
          ++i);
}
```

Output:

```
Hello world
```

Related information

putenv() – Change or add an environment variable

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <stdlib.h>

int putenv(char *envvar);
```

General description

Adds a new environment variable or changes the value of an existing one. The argument *envvar* is a pointer to a NULL-terminated character string that should be of the form:

name=value

Where:

1. The first part, *name*, is a character string that represents the name of the environment variable. It is this part of the environment variable that `putenv()` will use when it searches the array of environment variable to determine whether to add or change this environment variable.
2. The second part, `=`, is a separator character (since the equal sign is used as a separator character it cannot appear in the *name*).
3. The third part, *value*, is a NULL-terminated character string that represents the value that the environment variable, *name*, will be set to.

`putenv()` is a simplified form of `setenv()` and is equivalent to

`setenv(name, value, 1)`

Note: Starting with, z/OS V1R2, the storage used to define the environment variable pointed to by *envvar* is added to the array of environment variables. Previously, the system copied the string into system allocated storage. A new environment variable, `_EDC_PUTENV_COPY`, will allow the previous behavior to continue if set to YES. If `_EDC_PUTENV_COPY` is not set or is set to any other value the new behavior will take place.

Special behavior for POSIX C: You can use the external variable `**environ` (defined as `extern char **environ`) to access the array of pointers to environment variables.

Returned value

If successful, `putenv()` returns 0.

If unsuccessful, `putenv()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

ENOMEM

Insufficient memory was available.

Special behavior for z/OS UNIX Services:

EINVAL

The environment variable pointed to by the argument *envvar* does not follow the prescribed format.
The equal sign (=) separating the environment variable name from the value was not found.

putmsg(), putpmsg() — Send a message on a STREAM

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stropts.h>

int putmsg(int fildes, const struct strbuf *ctlptr,
           const struct strbuf *dataptr, int flags);

int putpmsg(int fildes, const struct strbuf *ctlptr,
            const struct strbuf *dataptr, int band, int flags);
```

General description

The `putmsg()` function creates a message from a process buffer(s) and sends the message to a STREAMS file. The message may contain either a data part, a control part, or both. The data and control parts are distinguished by placement in separate buffers, as described below. The semantics of each part is defined by the STREAMS module that receives the message.

The `putpmsg()` function does the same thing as `putmsg()`, but the process can send messages in different priority bands. Except where noted, all requirements on `putmsg()` also pertain to `putpmsg()`.

The *fildes* argument specifies a file descriptor referencing an open STREAM. The *ctlptr* and *dataptr* arguments each point to a **strbuf** structure.

The *ctlptr* argument points to the structure describing the control part, if any, to be included in the message. The **buf** member in the **strbuf** structure points to the buffer where the control information resides, and the **len** member indicates the number of bytes to be sent. The **maxlen** member is not used by `putmsg()`. In a similar manner, the argument *dataptr* specifies the data, if any, to be included in the message. The *flags* argument indicates what type of message should be sent and is described further below.

To send the data part of a message, *dataptr* must not be a NULL pointer and the **len** member of *dataptr* must be 0 or greater. To send the control part of a message, the corresponding values must be set for *ctlptr*. No data (control) part will be sent if either *dataptr* (*ctlptr*) is a NULL pointer or the **len** member of *dataptr* (*ctlptr*) is set to -1.

For `putmsg()`, if a control part is specified and *flags* is set to `RS_HIPRI`, a high priority message is sent. If no control part is specified, and *flags* is set to `RS_HIPRI`, `putmsg()` fails and sets `errno` to `EINVAL`. If *flags* is set to 0, a normal message (priority band equal to 0) is sent. If a control part and data part are not specified and *flags* is set to 0, no message is sent and 0 is returned.

The `STREAM` head guarantees that the control part of a message generated by `putmsg()` is at least 64 bytes in length.

For `putpmsg()`, the flags are different. The *flags* argument is a bitmask with the following mutually-exclusive flags defined: `MSG_HIPRI` and `MSG_BAND`. If *flags* is set to 0, `putpmsg()` fails and sets `errno` to `EINVAL`. If a control part is specified and *flags* is set to `MSG_HIPRI` and *band* is set to 0, a high-priority message is sent. If *flags* is set to `MSG_HIPRI` and either no control part is specified or *band* is set to a nonzero value, `putpmsg()` fails and sets `errno` to `EINVAL`. If *flags* is set to `MSG_BAND`, then a message is sent in the priority band specified by *band*. If a control part and data part are not specified and *flags* is set to `MSG_BAND`, no message is sent and 0 is returned.

The `putmsg()` function blocks if the `STREAM` write queue is full due to internal flow control conditions, with the following exceptions:

- For high-priority messages, `putmsg()` does not block on this condition and continues processing the message.
- For other messages, `putmsg()` does not block but fails when the write queue is full and `O_NONBLOCK` is set.

The `putmsg()` function also blocks, unless prevented by lack of internal resources, while waiting for the availability of message blocks in the `STREAM`, regardless of priority or whether `O_NONBLOCK` has been specified. No partial message is sent.

The following symbolic constants are defined under `_XOPEN_SOURCE_EXTENDED 1` in `<stropts.h>`.

MSG_ANY

Receive any message.

MSG_BAND

Receive message from specified band.

MSG_HIPRI

Send/Receive high priority message.

MORECTL

More control information is left in message.

MOREDATA

More data is left in message.

Returned value

If successful, `putmsg()` and `putpmsg()` return 0.

If unsuccessful, `putmsg()` and `putpmsg()` return -1 and set `errno` to one of the following values.

Note: z/OS UNIX services do not supply any `STREAMS` devices or pseudodevices. It is impossible for `putmsg()` and `putpmsg()` to send a message on a `STREAM`. It will always return -1 with `errno` set to indicate the failure. See [“open\(\) — Open a file” on page 1157](#)

Error Code**Description****EAGAIN**

A non-priority message was specified, the `O_NONBLOCK` flag is set, and the `STREAM` write queue is full due to internal flow control conditions; or buffers could not be allocated for the message that was to be created.

EBADF

fildev is not a valid file descriptor open for writing.

EINTR

A signal was caught during `putmsg()`.

EINVAL

An undefined value is specified in *flags*, or *flags* is set to `RS_HIPRI` or `MSG_HIPRI` and no control part is supplied, or the STREAM or multiplexer referenced by *fildev* is linked (directly or indirectly) downstream from a multiplexer, or *flags* is set to `MSG_HIPRI` and *band* is nonzero (for `putpmsg()` only).

ENOSR

Buffers could not be allocated for the message that was to be created due to insufficient STREAMS memory resources.

ENOSTR

A STREAM is not associated with *fildev*.

ENXIO

A hang-up condition was generated downstream for the specified STREAM.

EPIPE or EIO

The *fildev* argument refers to a STREAMS-based pipe and the other end of the pipe is closed. A SIGPIPE signal is generated for the calling process.

ERANGE

The size of the data part of the message does not fall within the range specified by the maximum and minimum packet sizes of the topmost STREAM module. This value is also returned if the control part of the message is larger than the maximum configured size of the control part of a message, or if the data part of a message is larger than the maximum configured size of the data part of a message.

In addition, `putmsg()` and `putpmsg()` will fail if the STREAM head had processed an asynchronous error before the call. In this case, the value of `errno` does not reflect the result of `putmsg()` or `putpmsg()` but reflects the prior error.

puts() — Write a string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```
#include <stdio.h>

int puts(const char *string);

#define _OPEN_SYS_UNLOCKED_EXT 1
```

```
#include <stdio.h>

int puts_unlocked(const char *string);
```

General description

Writes the string pointed to by *string* to the stream pointed to by `stdout`, and appends the newline character to the output. The terminating NULL character is not written.

If `stdout` points to the text stream, and the output string is longer than the length of the stream's record, the output is *wrapped*. That is, the record is filled with the output characters, the last character of the record is set to a newline character, and the remaining output characters are written to the next record. Such wrapping is repeated until the remaining output characters fit into the record. Please note that the newline character is appended to the last portion of the output string. If the output string is shorter than the record, the remaining characters of the record are filled with blanks—if `stdout` is opened in a text mode—or with NULL characters if the `stdout` is opened in binary mode.

The `puts()` function is not supported for files opened with `type=record` or `type=blocked`.

`puts()` has the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

`puts_unlocked()` is functionally equivalent to `puts()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

If successful, `puts()` returns the number of bytes written. However, newline characters used to wrap the data are not counted.

If unsuccessful, `puts()` returns EOF.

If a system write-error occurs, the write stops at the point of failure.

After truncation, `puts()` does not count the truncated characters, but returns the actual number of bytes written.

Example

CELEBP55

```
/* cCELEBP55
   This example writes "Hello World" to stdout.
*/
#include <stdio.h>

int main(void)
{
    if ( puts("Hello World") == EOF )
        printf( "Error in puts\n" );
}
```

Output:

```
Hello World
```

pututxline(), pututxline64() — Write entry to utmpx database

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

pututxline:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <utmpx.h>

struct utmpx *pututxline(const struct utmpx *utmpx);
```

pututxline64:

```
#define _XOPEN_SOURCE_EXTENDED 1
#define _LARGE_TIME_API
#include <utmpx.h>

struct utmpx64 *pututxline64(const struct utmpx64 *utmpx64);
```

General description

The `pututxline()` function writes out the structure into the `utmpx` database, when the calling process has appropriate privileges. The `pututxline()` function uses `getutxid()` to search for a record that satisfies the request. If the `getutxid()` search succeeds, then the entry is replaced. Otherwise, a new entry is made at the end of the database. If the `utmpx` database does not already exist, then `pututxline()` creates the `utmpx` database with file permissions 0644.

If the `ut_type` field in the entry being added is `EMPTY`, it is always placed at the start of the `utmpx` database. For this reason, `pututxline()` must not be used to place `EMPTY` entries in the `utmpx` database.

The `pututxline()` function obtains an exclusive lock in the `utmpx` database on the byte range of the record which is ready to write and releases the lock before returning to its caller. The functions `getutxent()`, `getutxid()`, and `getutxline()` might continue to read and are not affected by `pututxline()`.

Because the `pututxline()` function processes thread-specific data the `pututxline()` function can be used safely from a multithreaded application. If multiple threads in the same process open the database, then each thread opens the database with a different file descriptor. The thread's database file descriptor is closed when the calling thread terminates or the `endutxent()` function is called by the calling thread.

The name of the database file defaults to `/etc/utmpx`. To process a different database file name use the `__utmpxname()` function.

`pututxline()` is not supported when all of the following conditions are true:

- The security environment for the current address space has the trusted attribute.
- Either the effective UID is different than the real UID, or the effective GID is different than the real GID.
- The effective UID is not 0.
- The `utmpx` file is not writable by normal (non-trusted) processes with the current effective UID and GID.

- `pututxline()` is called after `getutxline()`, `getutxid()`, or `getutxent()`, with no intervening calls to `endutxent()` or `__utmpxname()`.

For all entries that match a request, the `ut_type` member indicates the type of the entry. Other members of the entry will contain meaningful data based on the value of the `ut_type` member as follows:

EMPTY

No other members have meaningful data.

BOOT_TIME

`ut_tv` is meaningful.

__RUN_LVL

`ut_tv` and `ut_line` are meaningful

OLD_TIME

`ut_tv` is meaningful.

NEW_TIME

`ut_tv` is meaningful.

USER_PROCESS

`ut_id`, `ut_user` (login name of the user), `ut_line`, `ut_pid`, and `ut_tv` are meaningful.

INIT_PROCESS

`ut_id`, `ut_pid`, and `ut_tv` are meaningful.

LOGIN_PROCESS

`ut_id`, `ut_user` (implementation-specific name of the login process), `ut_pid`, and `ut_tv` are meaningful.

DEAD_PROCESS

`ut_id`, `ut_pid`, and `ut_tv` are meaningful.

The `pututxline64()` function behaves exactly like `pututxline()` except `pututxline64()` uses structure `utmpx64` instead of `struct utmpx` to support time beyond 03:14:07 UTC on January 19, 2038.

Returned value

If successful, `pututxline()` returns a pointer to a `utmpx` structure containing a copy of the entry written to the database.

If unsuccessful, `pututxline()` returns a NULL pointer.

`pututxline()` might fail if the process does not have appropriate privileges.

putw() — Put a machine word on a stream

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4 XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE
#include <stdio.h>

int putw(int w, FILE *stream);
```

General description

The `putw()` function writes the word *w* to the output *stream* (at the position at which the file offset, if defined, is pointing). The size of the word is the size of a type `int`, and varies from machine to machine. The `putw()` function neither assumes nor causes special alignment in the file. The *st_ctime* and *st_mtime* fields of the file will be marked for update between the successful execution of `putw()` and the next successful call to `fflush()` or `fclose()` on the same stream or a call to `exit()` or `abort()`.

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use character-based output functions to replace `putw()` for portability.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

If successful, `putw()` returns 0.

If unsuccessful, `putw()` returns a nonzero value, sets the error indicators for *stream*, and sets `errno` to indicate the error. Refer to [“fread\(\) — Read items” on page 613](#) for `errno` values.

Related information

putwc() – Output a wide character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 Language Environment | both | |

Format

Non-XPG4:

```
#include <stdio.h>
#include <wchar.h>

wint_t putwc(wchar_t wc, FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

wint_t putwc_unlocked(wchar_t wc, FILE *stream);
```

XPG4:

```
#define _XOPEN_SOURCE
#include <stdio.h>
#include <wchar.h>

wint_t putwc(wint_t wc, FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

wint_t putwc_unlocked(wchar_t wc, FILE *stream);
```

XPG4 and MSE:

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <stdio.h>
#include <wchar.h>

wint_t putwc(wchar_t wc, FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

wint_t putwc_unlocked(wchar_t wc, FILE *stream);
```

General description

The putwc() function is equivalent to the fputc() function, except that if it is implemented as a macro, it may evaluate stream more than once. Therefore, the argument should never be an expression with side effects. The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you use a non-wide-oriented function with putwc(), undefined results can occur.

putwc() has the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

putwc_unlocked() is functionally equivalent to putwc() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking

thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Special behavior for XPG4: If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then the compiler assumes that your program is using the XPG4 variety of the putwc() function, unless you also define the _MSE_PROTOS feature test macro. Please see [Table 2 on page 4](#) for a list of XPG4 and other feature test macros.

The prototype for the XPG4 variety of the putwc() function is:

```
wint_t putwc(wint_t wc, FILE *stream);
```

The difference between this variety and the MSE variety of the putwc() function is that the first parameter has type wint_t rather than type wchar_t.

Returned value

If successful, putwc() returns the wide character written.

If a write error occurs, the error indicator for the stream is set and WEOF is returned. If an encoding error occurs when converting from a wide character to a multibyte character, the value of the macro EILSEQ is stored in errno and WEOF is returned.

Example

CELEBP56

```
/* CELEBP56 */
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>
#include <errno.h>

int main(void)
{
    FILE    *stream;
    wchar_t *wcs = L"This test string should not cause a WEOF condition";
    int      i;
    int      rc;

    if ((stream = fopen("myfile.dat", "w")) == NULL) {
        printf("Unable to open file\n");
        exit(1);
    }

    for (i=0; wcs[i] != L'\0'; i++) {
        errno = 0;
        if ((rc = putwc(wcs[i], stream)) == WEOF) {
            printf("Unable to putwc() the wide character.\n");
            printf("wcs[%d] = 0x%X\n", i, wcs[i]);
            if (errno == EILSEQ)
                printf("An invalid wide character was encountered.\n");
            exit(1);
        }
    }

    fclose(stream);
}
```

putwchar() – Output a wide character to standard output

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

Non-XPG4:

```
#include <stdio.h>
#include <wchar.h>

wint_t putwchar(wchar_t wc);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

wint_t putwchar_unlocked(wchar_t wc);
```

XPG4:

```
#define _XOPEN_SOURCE
#include <stdio.h>
#include <wchar.h>

wint_t putwchar(wint_t wc);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

wint_t putwchar_unlocked(wchar_t wc);
```

XPG4 and MSE:

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <stdio.h>
#include <wchar.h>

wint_t putwchar(wchar_t wc);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

wint_t putwchar_unlocked(wchar_t wc);
```

General description

The `putwchar()` function is equivalent to: `putwc()(wc stdout)`.

The behavior of this wide-character function is affected by the `LC_CTYPE` category of the current locale. If you use a non-wide-oriented function with `putwchar()`, undefined results can occur.

`putwchar()` has the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

You may not use `putwc()` or `putwchar()` with files opened as `type=record` or `type=blocked`.

`putwchar_unlocked()` is functionally equivalent to `putwchar()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Special behavior for XPG4: If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the `wchar` header, then the compiler assumes that your program is using the XPG4 variety of the `putwchar()` function, unless you also define the `_MSE_PROTOS` feature test macro. Please see [Table 2 on page 4](#) for a list of XPG4 and other feature test macros.

The prototype for the XPG4 variety of the `putwchar()` function is:

```
wint_t putwchar(wint_t wc);
```

The difference between this variety and the MSE variety of the `putwchar()` function is that its parameter has type `wint_t` rather than type `wchar_t`.

Returned value

If successful, `putwchar()` returns the wide character written.

If a write error occurs, the error indicator for the stream is set and `WEOF` is returned. If an encoding error occurs when converting from a wide character to a multibyte character, the value of the macro `EILSEQ` is stored in `errno` and `WEOF` is returned.

Example

CELEBP57

```
/* CELEBP57 */
#include <stdio.h>
#include <stdlib.h>
#include <wchar.h>
#include <errno.h>

int main(void)
{
    wchar_t *wcs = L"This test string should not cause a WEOF condition";
    int i;
    int rc;

    for (i=0; wcs[i] != L'\0'; i++) {
        errno = 0;
        if ((rc = putwchar(wcs[i])) == WEOF) {
            printf("Unable to putwchar() the wide character.\n");
            printf("wcs[%d] = 0x%X\n", i, wcs[i]);
            if (errno == EILSEQ)
                printf("An invalid wide character was encountered.\n");
            exit(1);
        }
    }
}
```

pwrite() — Write data on a file or socket without file pointer change

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 | both | OS/390 V2R10 |

Format

```
#define _XOPEN_SOURCE 500
#include <unistd.h>

ssize_t pwrite(int fildes, const void *buf, size_t nbyte, off_t offset);
```

General description

The `pwrite()` function performs the same action as `write()`, except that it writes into a given position without changing the file pointer.

The first three arguments to `pwrite()` are the same as `write()` with the addition of a fourth argument *offset* for the desired position inside the file.

Returned value

If successful, `pwrite()` returns the number of bytes actually written to the file associated with *fildes*. This number will never be greater than *nbyte*.

If unsuccessful, `pwrite()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EAGAIN

Resources temporarily unavailable. Subsequent requests may complete normally.

EBADF

fildes is not a valid file or socket descriptor.

ECONNRESET

A connection was forcibly closed by a peer.

EDESTADDRREQ

The socket is not connection-oriented and no peer address is set.

EFAULT

Using the *buf* and *nbyte* parameters would result in an attempt to access storage outside the caller's address space.

EFBIG

An attempt was made to write a file that exceeds the system-established maximum file size or the process's file size limit supported by the implementation.

The file is a regular file, *nbyte* is greater than 0 and the starting position is greater than or equal to the offset maximum established in the open file description associated with *fields*.

EINTR

`pwrite()` was interrupted by a signal before it had written any output.

EINVAL

The request is invalid or not supported. The STREAM or multiplexer referenced by *fildes* is linked (directly or indirectly) downstream from a multiplexer.

The *offset* argument is invalid. The value is negative.

EIO

The process is in a background process group and is attempting to write to its controlling terminal, but TOSTOP (defined in the `termios.h` header file) is set, the process is neither ignoring nor blocking SIGTTOU signals, and the process group of the process is orphaned. An I/O error occurred.

EMSGSIZE

The message was too big to be sent as a single datagram.

ENOBUFS

Buffer space is not available to send the message.

ENOSPC

There is no available space left on the output device.

ENOTCONN

The socket is not connected.

ENXIO

A hang-up occurred on the STREAM being written to.

EPIPE

`pwrite()` is trying to write to a pipe that is not open for reading by any other process. This error also generates a SIGPIPE signal. For a connected stream socket the connection to the peer socket has been lost.

ERANGE

The transfer request size was outside the range supported by the STREAMS file associated with *fildev*.

ESPIPE

fildev is associated with a pipe or FIFO.

EWOULDBLOCK

socket is in nonblocking mode and no data buffers are available or the SO_SNDTIMEO timeout value was reached before buffers became available.

Related information

- [“unistd.h — Implementation-specific functions” on page 77](#)
- [“pread\(\) — Read from a file or socket without file pointer change” on page 1213](#)
- [“write\(\) — Write data on a file or socket” on page 2070](#)

qsort() — Sort array

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdlib.h>

void qsort(void *base, size_t num, size_t width,
           int(*compare)(const void *element1, const void *element2));
```

General description

The `qsort()` function sorts an array of *num* elements, each of *width* bytes in size, where the first element of the array is pointed to by *base*.

The *compare* pointer points to a function, which you supply, that compares two array elements and returns an integer value specifying their relationship. The `qsort()` function calls the comparison function one or more times during the sort, passing pointers to two array elements on each call. The comparison function must compare the elements and return one of the following values:

Value

Meaning

< 0

element1 less than *element2*

0

element1 equal to *element2*

> 0

element1 greater than *element2*

The sorted array elements are stored in increasing order, as returned by the comparison function. You can sort in reverse order by reversing the "greater than" and "less than" logic in the comparison function. If two elements are equal, their order in the sorted array is unspecified. The `qsort()` function overwrites the contents of the array with the sorted elements.

Special behavior for C++: C++ and C linkage conventions are incompatible, and therefore the `qsort()` function cannot receive C++ function pointers. If you attempt to pass a C++ function pointer to the `qsort()` function, the compiler will flag it as an error. To use the C++ `qsort()` function, you must ensure that the comparison function has C linkage, by declaring it as `extern "C"`.

Returned value

The `qsort()` function returns no values.

Example

CELEBQ01

```
/* CELEBQ01

   This example sorts the arguments (argv) in ascending sequence, based on
   the ASCII value of each character and string, and using the comparison
   function compare() supplied in the example.

*/
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/* Declaration of compare() as a function */
#ifdef __cplusplus
extern "C" int compare(const void *, const void *);
#else
int compare(const void *, const void *); /* macro is automatically */
#endif                               /* defined by the C++/MVS compiler */

int main (int argc, char *argv[ ])
{
    int i;
    argv++;
    argc--;
    qsort((char *)argv, argc, sizeof(char *), compare);
    for (i = 0; i < argc; ++i)
        printf("%s\n", argv[i]);
    return 0;
}

int compare (const void *arg1, const void *arg2)
```

```

{
    /* Compare all of both strings */
    return(strcmp((char **)arg1, *(char **)arg2));
}

```

Output

If the program is passed the arguments:

```
Does, this, really, sort, the, arguments, correctly?
```

then expect the following output.

```

arguments
correctly?
really
sort

quantexpd32(), quantexpd64(), quantexpd128() - Compute the quantum exponent

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.11 |

Format

```

#define __STDC_WANT_DEC_FP__
#include <math.h>

int quantexpd32(_Decimal32 x);
int quantexpd64(_Decimal64 x);
int quantexpd128(_Decimal128 x);

int quantexp(_Decimal32 x);    /* C++ only */
int quantexp(_Decimal64 x);    /* C++ only */
int quantexp(_Decimal128 x);   /* C++ only */

```

General description

The `quantexp()` functions compute the quantum exponent of a finite argument.

Notes:

1. These functions work in IEEE decimal floating-point format. See [“IEEE decimal floating-point” on page 97](#) IEEE Decimal Floating-Point for more information.
2. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
3. The "quantum" when referring to a finite decimal floating-point number is defined as the "magnitude of a value of one in the rightmost digit position of the significand". For example, pennies and dollars can be represented respectively as $1 * 10$ with a quantum of -2 and 0, or $1 * 10^{-2}$ and $1 * 10^0$. For more information on the term quantum, see *z/Architecture Principles of Operation*.

Returned value

The quantexp() functions return the quantum exponent of x.
If x is infinite or NaN, they compute INT_MIN and a domain error occurs.

Example

```
/* CELEBQ03
   This example illustrates the quantexpd128() function.
*/
#define __STDC_WANT_DEC_FP__
#include <stdio.h>
#include <math.h>

void main(void)
{
    _Decimal128 x, y;

    x = 4.56DL;
    y = quantexpd128(x);

    printf("quantexpd128( %DDf ) = %DDf\n", x, y);
}
```

quantized32(), quantized64(), quantized128() — Set the exponent of X to the exponent of Y

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 quantized32(_Decimal32 x, _Decimal32 y);
_Decimal64 quantized64(_Decimal64 x, _Decimal64 y);
_Decimal128 quantized128(_Decimal128 x, _Decimal128 y);
```

General description

The quantize functions set the exponent of argument x to the exponent of argument y, while trying to keep the value the same. If the exponent is being increased, the value is correctly rounded according to the current rounding mode. If the result does not have the same value as x, the "inexact" (FP_INEXACT) floating-point exception is raised. If the exponent is being decreased, and the significand of the result has more digits than the type would allow, the result is NaN and the "invalid" (FP_INVALID) floating-point exception is raised.

If one of both operands are NaN, the result is NaN, and the "invalid" floating-point exception may be raised. Otherwise, if only one operand is infinity, the result is NaN, and the "invalid" floating-point exception is raised. If both operands are infinity, the result is DEC_INFINITY, and the sign is the same as x.

The quantize functions do not signal underflow (FP_UNDERFLOW) or overflow (FP_OVERFLOW).

Argument

Description

x

Input value to be converted and perhaps rounded using the exponent of y.

y

Input value whose exponent is used for the output value

Usage notes

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

The quantize functions return the number which is equal in value (except for any rounding) and sign to x, and which has been set to be equal to the exponent of y.

Example

```
/* CELEBQ02

   This example illustrates the quantized128() function.
*/

#define __STDC_WANT_DEC_FP__
#include <stdio.h>
#include <math.h>

int main(void)
{
    _Decimal128 price = 64999.99DL;
    _Decimal128 rate  = 0.09875DL;
    _Decimal128 tax    = quantized128(price * rate, 0.01DL);
    _Decimal128 total  = price + tax;

    printf( "price = %22.16DDF\n"
           "  tax = %22.16DDF (price * rate = %-.16DDF)\n"
           "total = %22.16DDF\n"
           , price
           , tax ,           price * rate
           , total
           );

    return 0;
}
```

QueryMetrics() – Query WLM system information

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <sys/__wlm.h>

int QueryMetrics(struct sysi *sysi_ptr, int *anslen);
```

General description

The QueryMetrics() function provides the ability for an application to query WLM system information.

*sysi_ptr

Points to a buffer that the service is to return the WLM system information. The data returned is in the format of the structure sysi.

*anslen

Points to an integer data field that contains the length of the buffer to return the WLM system information into.

Returned value

If successful, QueryMetrics() returns 0.

If unsuccessful, QueryMetrics() returns -1 and sets errno to one of the following values. If the returned errno and __errno2() indicate the supplied buffer is too small, the *anslen* argument is updated to contain the length required to hold WLM system information.

Error Code

Description

EFAULT

An argument of this function contained an address that was not accessible to the caller.

EINVAL

An argument of this function contained an incorrect value.

EMVSSAF2ERR

An error occurred in the security product.

EMVSWLMERROR

The WLM query system information failed. Use __errno2() to obtain the WLM service reason code for the failure.

EPERM

The calling thread's address space is not permitted to the BPX.WLMSEVER Facility class. The caller's address space must be permitted to the BPX.WLMSEVER Facility class if it is defined. If BPX.WLMSEVER is not defined, the calling process is not defined as a superuser (UID=0).

QuerySchEnv() — Query WLM scheduling environment

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <sys/__wlm.h>

int QuerySchEnv(struct sethdr *sysi_ptr, int *anslen);
```

General description

The QuerySchEnv() function provides the ability for an application to query WLM scheduling environment.

*sysi_ptr

Points to a buffer that the service is to return the WLM system information. The data returned is in the format of the structure sysi.

*anslen

Points to an integer data field that contains the length of the buffer to return the WLM system information into.

Returned value

If successful, QuerySchEnv() returns 0.

If unsuccessful, QuerySchEnv() returns -1 and sets errno to one of the following values. If the returned errno and __errno2() indicate the supplied buffer is too small, the *anslen* argument is updated to contain the length required to hold WLM system information.

Error Code

Description

EFAULT

An argument of this function contained an address that was not accessible to the caller.

EINVAL

An argument of this function contained an incorrect value.

EMVSSAF2ERR

An error occurred in the security product.

EMVSWLMERROR

The WLM query scheduling environment failed. Use __errno2() to obtain the WLM service reason code for the failure.

EPERM

The calling thread's address space is not permitted to the BPX.WLMSEVER Facility class. The caller's address space must be permitted to the BPX.WLMSEVER Facility class if it is defined. If BPX.WLMSEVER is not defined, the calling process is not defined as a superuser (UID=0).

QueryWorkUnitClassification() — WLM query enclave classification service

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | OS/390 V2R9 |

Format

```
#include <sys/_wlm.h>

int QueryWorkUnitClassification(wlmetok_t *e_token,
                               struct sysec *sysec_ptr,
                               int *ans_len);
```

General description

Returns the classification attributes of an enclave, using the following parameters:

***e_token**

Points to a work unit enclave token.

***sysec_ptr**

Points to the enclave classification data (mapped by sysec) returned by the QueryWorkUnitClassification function.

***anslen**

The length of the data area provided by the caller to receive the information generated by the service. WLM will update this value with the size of the area needed for the service to work. The minimum area should hold the entire sysec structure through version 3. The existing area will be populated with as much of the information as can be returned.

Returned value

If successful, QueryWorkUnitClassification() returns 0.

If unsuccessful, `QueryWorkUnitClassification()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EFAULT

An argument of this function contained an address that was not accessible to the caller.

EINVAL

An argument of this function contained a value that is not correct.

EMVSSAF2ERR

An error occurred in the security product.

EMVSWLMERROR

A WLM service failed. Use `__errno2()` to obtain the WLM service reason code for the failure.

EPERM

The calling thread's address space is not permitted to the BPX.WLMSEVER Facility class. The caller's address space must be permitted to the BPX.WLMSEVER Facility class, if the BPX.WLMSEVER class is defined. If BPX.WLMSEVER is not defined, the calling process is not defined as a superuser (UID=0).

raise() – Raise signal

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <signal.h>

int raise(int sig);
```

General description

Sends the signal *sig* to the program that issued `raise()`. See [Table 59 on page 1637](#) for the list of signals supported.

You can use `signal()` to specify how a signal will be handled when `raise()` is invoked.

In C++ only, the use of `signal()` and `raise()` with `try()`, `catch()`, or `throw()` is undefined. The use of `signal()` and `raise()` with destructors is also undefined.

Special behavior for POSIX: To obtain access to the special POSIX behavior for `raise()`, the POSIX runtime option must be set ON, and the version of MVS must be 4.3 or higher.

The `raise()` function sends the signal, `sig`, to the process that issued the `raise()`. If the signal is not blocked, it is delivered to the sender before `raise()` returns. See [Table 57 on page 1606](#) in the description of the `sigaction()` function for the list of signals supported.

You can use `signal()` or `sigaction()` to specify how a signal will be handled when `raise()` is invoked.

Special behavior for XPG4.2: To obtain access to the special POSIX behavior for `raise()`, the POSIX runtime option must be set ON, and the version of MVS must be 4.3 or higher.

Several other functions are available to the XPG4.2 application for affecting the behavior of a signal:

- `bsd_signal()`
- `sigignore()`
- `sigset()`

Special behavior for C++: The behavior when mixing signal-handling with C++ exception handling is undefined. Also, the use of signal-handling with constructors and destructors is undefined.

Usage note

The use of the SIGTHSTOP and SIGTHCONT signal is not supported with this function.

Returned value

If successful, `raise()` returns 0.

If unsuccessful, `raise()` returns nonzero.

Special behavior for XPG4: The `raise()` function sets `errno` to one of the following values:

Error Code

Description

EINVAL

The value of the `sig` argument is an invalid signal number.

Example

CELEBR01

```
/* CELEBR01

This example establishes a signal handler called sig_hand for the
signal SIGUSR1.
The signal handler is called whenever the SIGUSR1 signal is raised and
will ignore the first nine occurrences of the signal.
On the tenth raised signal, it exits the program with an error code of 10.
Note that the signal handler must be reestablished each time it is called.

*/
#include <signal.h>
#include <stdio.h>
#include <stdlib.h>

#ifdef __cplusplus
extern "C" {
#endif
    void sig_hand(int);
#ifdef __cplusplus
}
#endif
int i;

int main(void)
```

```

{
    signal(SIGUSR1, sig_hand); /* set up handler for SIGUSR1 */
    for (i=0; i<10; ++i)
        raise(SIGUSR1);      /* signal SIGUSR1 is raised */
}                             /* sig_hand() is called */

void sig_hand(int dummy)
{
    static int count = 0;      /* initialized only once */

    count++;
    if (count == 10) /* ignore the first 9 occurrences of this signal */
    {
        printf("reached 10th signal\n");
        exit(10);
    }
    else
        signal(SIGUSR1, sig_hand); /* set up the handler again */
}

```

rand() — Generate random number

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```

#include <stdlib.h>

int rand(void);

```

General description

Generates a pseudo-random integer in the range 0 to RAND_MAX. Use the srand() function before calling rand() to set a seed for the random number generator. If you do not make a call to srand(), the default seed is 1.

Returned value

Returns the calculated value.

Example

CELEBR02

```
/* CELEBR02
   This example prints the first 10 random numbers generated.
*/
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    int x;

    for (x = 1; x <= 10; x++)
        printf("iteration %d, rand=%d\n", x, rand());
}
```

Output

```
iteration 1, rand=16838
iteration 2, rand=5758
iteration 3, rand=10113
iteration 4, rand=17515
iteration 5, rand=31051
iteration 6, rand=5627
iteration 7, rand=23010
iteration 8, rand=7419
iteration 9, rand=16212
iteration 10, rand=4086
```

rand_r() – Pseudo-random number generator

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 | both | OS/390 V2R8 |

Format

```
#define _XOPEN_SOURCE 500
#include <stdlib.h>

int rand_r(unsigned int *seed);
```

General description

The `rand_r()` function generates a sequence of pseudo-random integers in the range 0 to **RAND_MAX**. (The value of the **RAND_MAX** macro will be at least 32767.)

If `rand_r()` is called with the same initial value for the object pointed to by *seed* and that object is not modified between successive returns and calls to `rand_r()`, the same sequence shall be generated.

Returned value

`rand_r()` returns a pseudo-random integer.

There are no documented errno values.

Related information

- [“stdlib.h — Standard library functions” on page 65](#)
- [“rand\(\) — Generate random number” on page 1377](#)
- [“srand\(\) — Set seed for rand\(\) function” on page 1703](#)

random() — A better random-number generator

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

long random(void);
```

General description

The `random()` function uses a nonlinear additive feedback random-number generator employing a default state array size of 31 long integers to return successive pseudo-random numbers in the range from 0 to $2^{31}-1$. The period of this random-number generator is approximately $16 \times (2^{31}-1)$. The size of the state array determines the period of the random-number generator. Increasing the state array size increases the period.

With 256 bytes of state information, the period of the random-number generator is greater than 2^{69} .

Like `rand()`, `random()` produces by default a sequence of numbers that can be duplicated by calling `srandom()` with 1 as the seed. The state information for the random functions is maintained on a per-thread basis. For example, calls to `srandom()` in one thread will have no effect on the numbers generated by calls to `random()` in another thread.

Returned value

`random()` returns the generated pseudo-random number.

read() — Read from a file or socket

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define POSIX_SOURCE
#include <unistd.h>

ssize_t read(int fs, void *buf, size_t N);
```

X/Open

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

ssize_t read(int fs, void *buf, ssize_t N);
```

Berkeley sockets

```
#define _OE_SOCKETS
#include <unistd.h>

ssize_t read(int socket, void *buf, ssize_t N);
```

General description

From the file indicated by the file descriptor *fs*, the `read()` function reads *N* bytes of input into the memory area indicated by *buf*. A successful `read()` updates the access time for the file.

If *fs* refers to a regular file or any other type of file on which the process can seek, `read()` begins reading at the file offset associated with *fs*. If successful, `read()` changes the file offset by the number of bytes read. *N* should not be greater than `INT_MAX` (defined in the `limits.h` header file).

If *fs* refers to a file on which the process cannot seek, `read()` begins reading at the current position. There is no file offset associated with such a file.

If *fs* refers to a socket, `read()` is equivalent to `recv()` with no flags set.

Parameter

Description

fs

The file or socket descriptor.

buf

The pointer to the buffer that receives the data.

N

The length in bytes of the buffer pointed to by the *buf* parameter.

Behavior for sockets: The `read()` call reads data on a socket with descriptor `fs` and stores it in a buffer. The `read()` call applies only to connected sockets. This call returns up to *N* bytes of data. If there are fewer bytes available than requested, the call returns the number currently available. If data is not available for the socket `fs`, and the socket is in blocking mode, the `read()` call blocks the caller until data arrives. If data is not available, and the socket is in nonblocking mode, `read()` returns a -1 and sets the error code to `EWOULDBLOCK`. See “`ioctl()` — Control device” on page 872 or “`fcntl()` — Control open file descriptors” on page 483 for a description of how to set nonblocking mode.

For datagram sockets, this call returns the entire datagram that was sent, provided that the datagram fits into the specified buffer. Excess datagram data is discarded. Stream sockets act like streams of information with no boundaries separating data. For example, if applications A and B are connected with a stream socket and application A sends 1000 bytes, each call to this function can return 1 byte, or 10 bytes, or the entire 1000 bytes. Therefore, applications using stream sockets should place this call in a loop, calling this function until all data has been received.

Behavior for streams: A `read()` from a STREAMS file can read data in three different modes: byte-stream mode, message-nondiscard mode, and message-discard mode. The default is byte-stream mode. This can be changed using the `I_SRDOPT` `ioctl()` request, and can be tested with the `I_GRDOPT` `ioctl()`. In byte-stream mode, `read()` retrieves data from the STREAM until as many bytes as were requested are transferred, or until there is no more data to be retrieved. Byte-stream mode ignores message boundaries.

In STREAMS message-nondiscard mode, `read()` retrieves data until as many bytes as were requested are transferred, or until a message boundary is reached. If `read()` does not retrieve all the data in a message, the remaining data is left on the STREAM, and can be retrieved by the next `read()` call. Message-discard mode also retrieves data until as many bytes as were requested are transferred, or a message boundary is reached. However, unread data remaining in a message after the `read()` returns is discarded, and is not available for a subsequent `read()`, `readv()` or `getmsg()` call.

How `read()` handles zero-byte STREAMS messages is determined by the current read mode setting. In byte-stream mode, `read()` accepts data until it has read *N* bytes, or until there is no more data to read, or until a zero-byte message block is encountered. The `read()` function then returns the number of bytes read, and places the zero-byte message back on the STREAM to be retrieved by the next `read()`, `readv()` or `getmsg()`. In message-nondiscard mode or message-discard mode, a zero-byte message returns 0 and the message is removed from the STREAM. When a zero-byte message is read as the first message on a STREAM, the message is removed from the STREAM and 0 is returned, regardless of the read mode.

A `read()` from a STREAMS file returns the data in the message at the front of the STREAM head read queue, regardless of the priority band of the message.

By default, STREAMS are in control-normal mode, in which a `read()` from a STREAMS file can only process messages that contain a data part but do not contain a control part. The `read()` fails if a message containing a control part is encountered at the STREAM head. This default action can be changed by placing the STREAM in either control-data mode or control-discard mode with the `I_SRDOPT` `ioctl()` command. In control-data mode, `read()` converts any control part to data and passes it to the application before passing any data part originally present in the same message. In control-discard mode, `read()` discards message control parts but returns to the process any data part in the message.

In addition, `read()` and `readv()` will fail if the STREAM head had processed an asynchronous error before the call. In this case, the value of `errno` does not reflect the result of `read()` or `readv()` but reflects the prior error. If a hang-up occurs on the STREAM being read, `read()` continues to operate normally until the STREAM head read queue is empty. Thereafter, it returns 0.

Large file support for z/OS UNIX files: Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the long long data type support enabled and define the `_LARGE_FILES` feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the `_LARGE_FILES` feature test macro as well.

Returned value

If successful, `read()` returns the number of bytes actually read and placed in *buf*. This number is less than or equal to *N*. It is less than *N* only if:

- `read()` reached the end of the file before reading the requested number of bytes.
- `read()` was interrupted by a signal.
- In POSIX C programs only, the file is a pipe, FIFO special file, or a character special file that has fewer than *N* bytes immediately available for reading.
- If the Physical File System does not support simple reads from directories, `read()` will return 0 if it is used for a directory. Users should use `Opendir()` and `readdir()` instead.

In POSIX C programs only, if `read()` is interrupted by a signal, the effect is one of the following:

- If `read()` has not read any data yet, it returns -1 and sets `errno` to `EINTR`.
- If `read()` has successfully read some data, it returns the number of bytes it read before it was interrupted.

If the starting position for the read operation is at the end of the file or beyond, `read()` returns 0.

In POSIX C programs, if `read()` attempts to read from an empty pipe or a FIFO special file, it has one of the following results:

- If no process has the pipe open for writing, `read()` returns 0 to indicate the end of the file.
- If some process has the pipe open for writing and `O_NONBLOCK` is set to 1, `read()` returns -1 and sets `errno` to `EAGAIN`.
- If some process has the pipe open for writing and `O_NONBLOCK` is set to 0, `read()` blocks (that is, does not return) until some data is written, or the pipe is closed by all other processes that have the pipe open for writing.

With other files that support nonblocking read operations (for example, character special files), a similar principle applies:

- If data is available, `read()` reads the data immediately.
- If no data is available and `O_NONBLOCK` is set to 1, `read()` returns -1 and sets `errno` to `EAGAIN`.
- If no data is available and `O_NONBLOCK` is set to 0, `read()` blocks until some data becomes available.

`read()` causes the signal `SIGTTIN` to be sent when all these conditions exist:

- The process is attempting to read from its controlling terminal.
- The process is running in a background process group.
- The `SIGTTIN` signal is not blocked or ignored.
- The process group of the process is not orphaned.

If `read()` is reading a regular file and encounters a part of the file that has not been written (but before the end of the file), `read()` places 0 bytes into *buf* in place of the unwritten bytes.

If the number of bytes of input that you want to read is 0, `read()` simply returns 0 without attempting any other action.

If the connection is broken on a stream socket, but data is available, then the `read()` function reads the data and gives no error. If the connection is broken on a stream socket, but no data is available, then the `read()` function returns 0 bytes as EOF.

Note: z/OS UNIX services do not supply any STREAMS devices or pseudodevices. It is impossible for `read()` to read any data from a STREAMS-based file indicated by *fs*. It will always return -1 with `errno` set to `EBADF`. `EINVAL` will never be set because there are no multiplexing STREAMS drivers. See [“open\(\) — Open a file” on page 1157](#) for more information.

If unsuccessful, `read()` returns -1 and sets `errno` to one of the following:

Error Code Description

EAGAIN

O_NONBLOCK is set to 1, but data was not available for reading.

EBADF

fs is not a valid file or socket descriptor.

ECONNRESET

A connection was forcibly closed by a peer.

EFAULT

Using the *buf* and *N* parameters would result in an attempt to access memory outside the caller's address space.

EINTR

read() was interrupted by a signal that was caught before any data was available.

EINVAL

N contains a value that is less than 0, or the request is invalid or not supported, or the STREAM or multiplexer referenced by *fs* is linked (directly or indirectly) downstream from a multiplexer.

EIO

The process is in a background process group and is attempting to read from its controlling terminal, and either the process is ignoring or blocking the SIGTTIN signal or the process group of the process is orphaned. For sockets, an I/O error occurred.

ENOBUFS

Insufficient system resources are available to complete the call.

ENOTCONN

A receive was attempted on a connection-oriented socket that is not connected.

EOVERFLOW

The file is a regular file and an attempt was made to read or write at or beyond the offset maximum associated with the file.

ETIMEDOUT

The connection timed out during connection establishment, or due to a transmission timeout on active connection.

EWOULDBLOCK

socket is in nonblocking mode and data is not available to read, or the SO_RCVTIMEO timeout value was reached before data was available.

AT-TLS considerations: If AT-TLS is being used to provide transparent TLS/SSL support for a TCP socket and EWOULDBLOCK is returned on a blocking socket, reissue the select call or receive call to continue. For more information about AT-TLS and determining whether a TCP connection is using AT-TLS, see [Application Transparent Transport Layer Security \(AT-TLS\)](#) in *z/OS Communications Server: IP Programmer's Guide and Reference*.

Example

CELEBR03

```
/* CELEBR03

   This example opens a file and reads input.

*/
#define _POSIX_SOURCE
#include <fcntl.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
    int ret, fd;
    char buf[1024];
```

```

system("ls -l / >| ls.output");

if ((fd = open("ls.output", O_RDONLY)) < 0)
    perror("open() error");
else {
    while ((ret = read(fd, buf, sizeof(buf)-1)) > 0) {
        buf[ret] = 0x00;
        printf("block read: \n<%s>\n", buf);
    }
    close(fd);
}

unlink("ls.output");
}

```

Output

```

block read:
<total 0
drwxr-xr-x  3 USER1   SYS1      0 Apr 16 07:59 bin
drwxr-xr-x  2 USER1   SYS1      0 Apr  6 10:20 dev
drwxr-xr-x  4 USER1   SYS1      0 Apr 16 07:59 etc
drwxr-xr-x  2 USER1   SYS1      0 Apr  6 10:15 lib
drwxrwxrwx  2 USER1   SYS1      0 Apr 16 07:55 tmp
drwxr-xr-x  2 USER1   SYS1      0 Apr  6 10:15 u
drwxr-xr-x  6 USER1   SYS1      0 Apr  6 10:15 usr
>

readdir() — Read an entry from a directory

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define POSIX_SOURCE
#include <dirent.h>

struct dirent *readdir(DIR *dir);
```

General description

Returns a pointer to a `dirent` structure describing the next directory entry in the directory stream associated with *dir*.

A call to `readdir()` overwrites data produced by a previous call to `readdir()` or `__readdir2()` on the same directory stream. Calls for different directory streams do not overwrite each other's data.

Each call to `readdir()` updates the `st_atime` (access time) field for the directory.

A `dirent` structure contains the character pointer *d_name*, which points to a string that gives the name of a file in the directory. This string ends in a terminating NULL, and has a maximum of NAME_MAX characters.

Save the data from `readdir()`, if required, before calling `closedir()`, because `closedir()` frees the data.

If the contents of a directory have changed since the directory was opened (files added or removed); a call should be made to `rewinddir()` so that subsequent `readdir()` requests can read the new contents.

Special behavior for XPG4: If entries for dot or dot-dot exist, one entry will be returned for dot and one entry will be returned for dot-dot; otherwise they will not be returned.

After a call to `fork()`, either the parent or child (but not both) may continue processing the directory stream using `__readdir2()`, `readdir()`, `rewinddir()`, or `seekdir()`. If both the parent and child processes use these functions, the result is undefined.

Special behavior for XPG4.2: If the entry names a symbolic link, the value of `d_ino` member in *dirent* structure is unspecified.

Returned value

If successful, `readdir()` returns a pointer to a `dirent` structure describing the next directory entry in the directory stream. When `readdir()` reaches the end of the directory stream, it returns a NULL pointer.

If unsuccessful, `readdir()` returns a NULL pointer and sets `errno` to one of the following values:

Error Code

Description

EBADF

dir does not yield an open directory stream.

EINVAL

The buffer was too small to contain any directories.

ENOENT

The current position of the directory stream is invalid.

E_OVERFLOW

One of the values in the structure to be returned cannot be represented correctly.

Note: The environment variable `_EDC_SUSV3` can be used to control the behavior of `readdir()` with respect to detecting an `E_OVERFLOW` condition. By default, `readdir()` will not detect that values in the structure returned can be represented correctly. When `_EDC_SUSV3` is set to 1, `readdir()` will check for overflow conditions.

Example**CELEBR04**

```
/* CELEBR04

   This example reads the contents of a root directory.

*/
#define _POSIX_SOURCE
#include <dirent.h>
#include <errno.h>
#include <sys/types.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
    DIR *dir;
    struct dirent *entry;

    if ((dir = opendir("/")) == NULL)
        perror("opendir() error");
    else {
        puts("contents of root:");
        while ((entry = readdir(dir)) != NULL)
            printf("  %s\n", entry->d_name);
        closedir(dir);
    }
}
```

Output

```
contents of root:
.
..
bin
dev
etc
lib
tmp
u
usr
```

__readdir2(), __readdir2_64() — Read directory entry and get file information

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | OS/390 V2R6 |

Format

__readdir2:

```
#define _OPEN_SYS_DIR_EXT
#include <dirent.h>

struct dirent *__readdir2(DIR *dir, struct stat *info);
```

__readdir2_64:

```
#define _LARGE_TIME_API
#define _OPEN_SYS_DIR_EXT
#include <dirent.h>

struct dirent *__readdir2_64(DIR *dir, struct stat64 *info);
```

Compile requirement: Use of the `__readdir2_64` function requires the `long long` data type. For more information on how to make the `long long` data type available, see [z/OS XL C/C++ Language Reference](#).

General description

The `__readdir2()` function returns a pointer to a `dirent` structure describing the next directory entry in the directory stream associated with `dir`.

The `__readdir2_64()` function behaves exactly like `__readdir2()` except `__readdir2_64()` uses structure `stat64` instead of `struct stat` to support time beyond 03:14:07 UTC on January 19, 2038.

A `dirent` structure contains the character pointer `d_name`, which points to a string that gives the name of a file in the directory. This string ends in a terminating NULL, and has a maximum of `NAME_MAX` characters.

The `info` argument points to an area of storage that will be filled in with information about the file `d_name`. This information is returned in a `stat` structure defined in the `sys/stat.h` header file. The format of this structure is described in the section about the `lstat()` function. If `info` is NULL, no `stat` information is passed back.

If entries for dot or dot-dot exist, one entry will be returned for dot and one entry will be returned for dot-dot; otherwise they will not be returned.

A call to `__readdir2()` overwrites data produced by a previous call to `__readdir2()` or `readdir()` on the same directory stream. Calls for different directory streams do not overwrite each other's data.

Save the `dirent` data from `__readdir2()`, if required, before calling `closedir()`, because `closedir()` frees the `dirent` data.

The `__readdir2()` function may buffer several directory entries per actual read operation. `__readdir2()` updates the `st_atime` (access time) field of the directory each time the directory is actually read.

After a call to `fork()`, either the parent or child (but not both) may continue processing the directory stream using `__readdir2()`, `readdir()`, `rewinddir()` or `seekdir()`. If both the parent and child processes use these functions, the result is undefined.

If the entry names a symbolic link, the value of `d_ino` member in *dirent* structure is unspecified.

Unpredictable results can occur if `closedir()` is used to close the directory stream before `__readdir2()` is called. If the contents of a directory have changed since the directory was opened (files added or removed), a call should be made to `rewinddir()` so that subsequent `__readdir2()` requests can read the new contents.

The output from this function is similar to a combination of `readdir()` and `lstat()`. In some cases, certain information in the output `stat` structure differs from what `lstat()` would return. Also, the `d_extra` field in *dir* is always NULL for `__readdir2()`.

Returned value

If successful, `__readdir2()` returns a pointer to a *dirent* structure describing the next directory entry in the directory stream. When `__readdir2()` reaches the end of the directory stream, it returns a NULL pointer.

If unsuccessful, `__readdir2()` returns a NULL pointer and sets `errno` to one of the following values:

Error Code

Description

EBADF

dir does not yield an open directory stream.

EINVAL

The buffer was too small to contain any directories.

ELOOP

A loop exists in symbolic links. This error occurs if the number of symbolic links in a file name in the directory is greater than `POSIX_SYMLLOOP`.

ENOENT

The current position of the directory stream is invalid.

readdir_r() — Read an entry from a directory

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 | both | OS/390 V2R8 |

Format

```
#define _XOPEN_SOURCE 500
#include <dirent.h>

int readdir_r(DIR *__restrict__dir, struct dirent *__restrict__entry,
              struct dirent **__restrict__result);
```

General description

The `readdir_r()` function initializes the `dirent` structure referenced by *entry* to represent the directory entry at the current position in the directory stream referred to by *dir*, stores a pointer to this structure at the location referenced by *result*, and positions the directory stream at the next entry.

The storage pointed to by *entry* will be large enough for a `dirent` with an array of `char d_name` member containing at least **NAME_MAX**+1 elements.

On successful return, the pointer returned at **result* will have the same value as the argument *entry*. Upon reaching the end of the directory stream, this pointer will have the value `NULL`.

The `readdir_r()` function will not return directory entries containing empty names. It is unspecified whether entries are returned for dot or dot-dot.

If a file is removed from or added to the directory after the most recent call to `opendir()` or `rewinddir()`, whether a subsequent call to `readdir_r()` returns an entry for that file is unspecified.

The `readdir_r()` function may buffer several directory entries per actual read operation. The `readdir_r()` function marks for update the `st_atime` field of the directory each time the directory is actually read.

Applications wishing to check for error situations should set `errno` to 0 before calling `readdir_r()`. If `errno` is set to non-zero on return, an error occurred.

Returned value

If successful, `readdir_r()` returns 0.

If unsuccessful, `readdir_r()` sets `errno` to one of the following values:

Error Code

Description

EBADF

dir does not refer to an open directory stream.

readlink() — Read the value of a symbolic link

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1a XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX1_SOURCE 2
#include <unistd.h>

int readlink(const char *path,
             char *buf, size_t bufsiz);

#define _POSIX_C_SOURCE 200112L
#include <unistd.h>

ssize_t readlink(const char *__restrict__path,
                 char *__restrict__buf, size_t bufsiz);
```

General description

Places the contents of the symbolic link *path* in the buffer *buf*. The size of the buffer is set by *bufsiz*. The result stored in *buf* does not include a terminating NULL character.

If the buffer is too small to contain the value of the symbolic link, that value is truncated to the size of the buffer (*bufsiz*). If the value returned is the size of the buffer, use `lstat()` to determine the actual size of the symbolic link.

Returned value

If successful, when *bufsiz* is greater than 0, `readlink()` returns the number of bytes placed in the buffer. When *bufsiz* is 0 and `readlink()` completes successfully, it returns the number of bytes contained in the symbolic link and the buffer is not changed.

If the returned value is equal to *bufsiz*, you can determine the contents of the symbolic link with either `lstat()` or `readlink()`, with a 0 value for *bufsiz*.

If unsuccessful, `readlink()` returns -1 and sets `errno` to one of the following values:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

EACCES
Search permission is denied for a component of the path prefix.

EINVAL

The named file is not a symbolic link.

EIO

An I/O error occurred while reading from the file system.

ELOOP

A loop exists in symbolic links. This error is issued if more than POSIX_SYMLINK_MAX symbolic links are encountered during resolution of the *path* argument.

ENAMETOOLONG

pathname is longer than **PATH_MAX** characters, or some component of *pathname* is longer than **NAME_MAX** characters while **_POSIX_NO_TRUNC** is in effect. For symbolic links, the length of the path name string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values can be determined using `pathconf()`.

ENOENT

The named file does not exist.

ENOTDIR

A component of the path prefix is not a directory.

Example**CELEBR05**

```
/* CELEBR05 */
#define _POSIX_SOURCE 1
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE

main() {
    char fn[]="readlink.file";
    char sl[]="readlink.symlink";
    char buf[30];
    int fd;

    if ((fd = creat(fn, S_IWUSR)) < 0)
        perror("creat() error");
    else {
        close(fd);
        if (symlink(fn, sl) != 0)
            perror("symlink() error");
        else {
            if (readlink(sl, buf, sizeof(buf)) < 0)
                perror("readlink() error");
            else printf("readlink() returned '%s' for '%s'\n", buf, sl);

            unlink(sl);
        }
        unlink(fn);
    }
}
```

Output

```
readlink() returned 'readlink.file' for 'readlink.symlink'
```

readlinkat() — Read value of a symbolic link relative to a directory file descriptor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1-2008 Single UNIX Specification, Version 4 | both | |

Format

```
#define _POSIX_C_SOURCE 200809L
#include <fcntl.h>           /* Definition of AT_* constants */
#include <unistd.h>

ssize_t readlinkat(int dirfd, const char *pathname, char *buf, size_t bufsz);
```

General description

readlinkat() operates in the same way as readlink() except for the following differences.

- If the *pathname* is relative, it is interpreted relative to the directory that is referred to by the file descriptor *dirfd*, rather than relative to the current working directory of the calling process, as is done by readlink() for a relative *pathname*.
- If *pathname* is relative and *dirfd* is the special value AT_FDCWD, *pathname* is interpreted relative to the current working directory of the calling process.
- If *pathname* is absolute, *dirfd* is ignored.

Returned value

If successful, readlinkat() returns the number of bytes that are placed in *buf*. If the returned value equals *bufsize*, truncation might occur.

If unsuccessful, readlinkat() returns -1 and sets errno to one of the following values:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

- | | |
|---------------------|--|
| EACCES | Search permission is denied for a component of the path prefix. |
| EBADF | <i>pathname</i> is relative but <i>dirfd</i> is not AT_FDCWD or a valid file descriptor. |
| EINVAL | The named file is not a symbolic link, or there is a problem with the supplied buffer. |
| ELOOP | A loop exists in symbolic links. This error is issued if more than POSIX_SYMLINK_MAX symbolic links are encountered during resolution of <i>pathname</i> . |
| ENAMETOOLONG | <i>pathname</i> is longer than PATH_MAX characters, or some component of <i>pathname</i> is longer than NAME_MAX characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the path name string that is substituted for a symbolic link exceeds PATH_MAX. The PATH_MAX and NAME_MAX values can be determined by using pathconf(). |
| ENOENT | The named file does not exist, or <i>pathname</i> is relative and <i>dirfd</i> refers to a directory that is deleted. |

ENOTDIR

A component of the path prefix is not a directory, or *pathname* is relative and *dirfd* is a file descriptor that refers to a file other than a directory.

readv() — Read data on a file or socket and store in a set of buffers

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format**X/Open**

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/uio.h>

ssize_t readv(int fs, const struct iovec *iov, int iocnt);
```

Berkeley sockets

```
#define _OE_SOCKETS
#include <sys/uio.h>

int readv(int fs, struct iovec *iov, int iocnt);
```

General description

The `readv()` function reads data from a file or a socket with descriptor *fs* and stores it in a set of buffers. The data is scattered into the buffers specified by `iov[0]...iov[iocnt-1]`.

Parameter**Description*****fs***

The file or socket descriptor.

iov

A pointer to an **iovec** structure.

iocnt

The number of buffers pointed to by the *iov* parameter.

The **iovec** structure is defined in **uio.h** and contains the following fields:

Element**Description*****iov_base***

The pointer to the buffer.

iov_len

The length of the buffer.

If the descriptor refers to a socket, then it must be a connected socket.

This call returns a number of bytes of data equal to but not exceeding the sum of all the *iov_len* fields. If less than the number of bytes requested is available, the call returns the number currently available. If data is not available for the socket *fs*, and the socket is in blocking mode, *readv()* call blocks the caller until data arrives. If data is not available and *fs* is in nonblocking mode, *readv()* returns a -1 and sets the error code to EWOULDBLOCK. See [“fcntl\(\) — Control open file descriptors” on page 483](#) or [“ioctl\(\) — Control device” on page 872](#) for a description of how to set nonblocking mode.

For datagram sockets, this call returns the entire datagram that was sent, provided that the datagram fits into the specified buffer. Excess datagram data is discarded. Stream sockets act like streams of information with no boundaries separating data. For example, if applications A and B are connected with a stream socket and application A sends 1000 bytes, each call to this function can return 1 byte, or 10 bytes, or the entire 1000 bytes. Therefore, applications using stream sockets should place this call in a loop, calling this function until all data has been received.

For X/Open sockets, if the total number of bytes to read is 0, *readv()* returns 0. If *readv()* is for a file and no data is available, *readv()* returns 0. If a *readv()* is interrupted by a signal before it reads any data, it returns -1 with *errno* set to EINTR. If *readv()* is interrupted by a signal after it has read data, it returns the number of bytes read. If *fs* refers to a socket, *readv()* is the equivalent of *recv()* with no flags set.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` 1 feature test macro.

Returned value

If successful, *readv()* returns the number of bytes read into the buffer.

If the connection is broken on a stream socket and data is available, then the *readv()* function reads the data and gives no error. If the connection is broken on a stream socket and no data is available, then the *readv()* function returns 0 bytes as EOF.

If unsuccessful, *readv()* returns -1 and sets *errno* to one of the following values:

Error Code**Description****EAGAIN**

The **O_NONBLOCK** flag is set for the file descriptor and the process would be delayed by the *readv()*.

EBADF

fs is not a valid file or socket descriptor.

ECONNRESET

A connection was forcibly closed by a peer.

EFAULT

Using *iov* and *iovcnt* would result in an attempt to access storage outside the caller's address space.

EINTR

readv() was interrupted by a signal that was caught before any data was available.

EINVAL

iovcnt was not valid, or one of the fields in the *iov* array was not valid.

ENOBUFS

Insufficient system resources are available to complete the call.

ENOTCONN

A receive is attempted on a connection-oriented socket that is not connected.

ETIMEDOUT

The connection timed out during connection establishment, or due to a transmission timeout on active connection.

EWOULDBLOCK

socket is in nonblocking mode and data is not available to read, or the `SO_RCVTIMEO` timeout value was reached before data was available.

AT-TLS considerations: If AT-TLS is being used to provide transparent TLS/SSL support for a TCP socket and `EWOULDBLOCK` is returned on a blocking socket, reissue the `select` call or `receive` call to continue. For more information about AT-TLS and determining whether a TCP connection is using AT-TLS, see [Application Transparent Transport Layer Security \(AT-TLS\)](#) in *z/OS Communications Server: IP Programmer's Guide and Reference*.

realloc() — Change reserved storage block size

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdlib.h>

void *realloc(void *ptr, size_t size);
```

General description

Changes the size of a previously reserved storage block. The *ptr* argument points to the beginning of the block. The *size* argument gives the new size of the block in bytes. The contents of the block are unchanged up to the shorter of the new and old sizes.

If the *ptr* is NULL, `realloc()` reserves a block of storage of *size* bytes. It does not give all bits of each element an initial value of 0.

If *size* is 0 and *ptr* is not NULL, the storage pointed to by *ptr* is freed and NULL is returned.

If you use `realloc()` with a pointer that does not point to a *ptr* created previously by `malloc()`, `calloc()`, or `realloc()`, or if you pass *ptr* to storage already freed, you get undefined behavior—usually an exception.

If you ask for more storage, the contents of the extension are undefined and are not guaranteed to be 0.

The storage to which the returned value points is aligned for storage of any type of object. Under IBM z/OS C only, if 4K alignment is required, the `__4kmalc()` function should be used. (This function is only available to C applications in stand-alone System Programming C (SPC) Facility applications.) The library functions specific to the System Programming C (SPC) environment are described in [z/OS XL C/C++ Programming Guide](#).

To investigate the cause of `realloc()` running out of heap storage, see [z/OS Language Environment Programming Reference](#)

Note: The environment variable `_CEE_REALLOC_CONTROL` controls reallocation that can lead to improved application performance. For more information about the `_CEE_REALLOC_CONTROL` environment variable, see [z/OS XL C/C++ Programming Guide](#).

Special behavior for C++: The C++ keywords `new` and `delete` are not interoperable with `aligned_alloc()`, `calloc()`, `free()`, `malloc()`, `posix_memalign()`, or `realloc()`.

Note: To use the `aligned_alloc()` function, compile the source code with [C11 standard based compilation](#).

Returned value

If successful, `realloc()` returns a pointer to the reallocated storage block. The storage location of the block might be moved. Thus, the returned value is not necessarily the same as the *ptr* argument to `realloc()`.

The returned value is NULL if *size* is 0. If there is not enough storage to expand the block to the given size, the original block is unchanged and a NULL pointer is returned. If `realloc()` returns NULL because there is not enough storage, it will also set `errno` to one of the following values:

Error Code

Description

ENOMEM

Insufficient memory is available

Example

CELEBR06

```
/* CELEBR06

This example allocates storage for the prompted size of array
and then uses &realloc. to reallocate the block to hold the
new size of the array.
The contents of the array are printed after each allocation.

*/
#include <stdio.h>
#include <stdlib.h>

int main(void)
```

```

{
    long * array;      /* start of the array */
    long * ptr;        /* pointer to array */
    int i;             /* index variable */
    int num1, num2;    /* number of entries of the array */

    void print_array( long *ptr_array, int size);

    printf( "Enter the size of the array\n" );
    scanf( "%i", &num1 );

    /* allocate num1 entries using malloc() */
    if ( (array = (long *)malloc( num1 * sizeof( long ))) != NULL ) {
        for ( ptr = array, i = 0; i < num1 ; ++i ) /* assign values */
            *ptr++ = i;
        print_array( array, num1 );
        printf("\n");
    }
    else { /* malloc error */
        printf( "Out of storage\n" );
        abort();
    }

    /* Change the size of the array ... */
    printf( "Enter the size of the new array\n" );
    scanf( "%i", &num2);

    if ( (array = (long *)realloc( array, num2* sizeof( long ))) != NULL )
    {
        for ( ptr = array + num1, i = num1; i <= num2; ++i )
            *ptr++ = i + 2000; /* assign values to new elements */
        print_array( array, num2 );
    }
    else { /* realloc error */
        printf( "Out of storage\n" );
        abort();
    }
}

void print_array( long * ptr_array, int size )
{
    int i;
    long * index = ptr_array;

    printf("The array of size %d is:\n", size);
    for ( i = 0; i < size; ++i ) /* print the array out */
        printf( " array[ %i ] = %li\n", i, ptr_array[i] );
}

```

Output: If the initial value entered is 2 and the second value entered is 4, then expect the following output:

```

Enter the size of the array
The array of size 2 is:
array[ 0 ] = 0
array[ 1 ] = 1

Enter the size of the new array
The array of size 4 is:
array[ 0 ] = 0
array[ 1 ] = 1
array[ 2 ] = 2002
array[ 3 ] = 2003

```

realpath() — Resolve path name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

char *realpath(const char *__restrict__file_name, char *__restrict__resolved_name);
```

General description

The realpath() function derives, from the path name pointed to by *file_name*, an absolute path name that names the same file, whose resolution does not involve ":", "..", or symbolic links. The generated path name is stored, up to a maximum of **PATH_MAX** bytes, in the buffer pointed to by *resolved_name*.

Returned value

If successful, realpath() returns a pointer to the resolved name.

If unsuccessful, the contents of the buffer pointed to by *resolved_name* are undefined, realpath() returns a NULL pointer and sets errno to one of the following values:

Error Code

| Description |
|---|
| EACCES Read or search permission was denied for a component of <i>file_name</i> . |
| EINVAL Either the <i>file_name</i> or <i>resolved_name</i> argument is a NULL pointer. |
| EIO An error occurred while reading from the file system. |
| ELOOP Too many symbolic links were encountered in resolving <i>path</i> |
| ENAMETOOLONG Path name is longer than PATH_MAX characters, or some component of path name is longer than NAME_MAX characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the path name string substituted for a symbolic link exceeds PATH_MAX . The PATH_MAX and NAME_MAX values are determined using pathconf(). |
| ENOENT A component of <i>file_name</i> does not name an existing file or <i>file_name</i> points to an empty string. |
| ENOTDIR A component of the path prefix is not a directory. |
| ERANGE File system will return ERANGE if the result to be stored in 'resolved_name' is larger than PATH_MAX . |

re_comp() — Compile regular expression

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <re_comp.h>

char *re_comp(const char *string);
```

General description

Restriction: This function is not supported in AMODE 64.

The `re_comp()` function converts a regular expression string into an internal form suitable for pattern matching by `re_exec()`.

The parameter *string* is a pointer to a character string defining a source regular expression to be compiled.

If `re_comp()` is called with a NULL argument, the current regular expression remains unchanged.

Strings passed to `re_comp()` must be terminated by a NULL byte, and may include newline characters.

Notes:

1. The `re_comp()` and `re_exec()` functions are supported on the thread-level. They must be issued from the *same* thread to work properly.
2. The `re_comp()` and `re_exec()` functions are provided for historical reasons. These functions were part of the Legacy Feature in Single UNIX Specification, Version 2. They have been withdrawn and are not supported as part of Single UNIX Specification, Version 3. New applications should use the newer functions `fnmatch()`, `glob()`, `regcomp()` and `regexexec()`, which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001.
3. The z/OS UNIX implementation of the `re_comp()` function supports only the POSIX locale. Any other locales will yield unpredictable results.

The `re_comp()` function supports simple regular expressions, which are defined below.

Simple regular expressions: A Simple Regular Expression (SRE) specifies a set of character strings. The simplest form of regular expression is a string of characters with no special meaning. A small set of special characters, known as metacharacters, do have special meaning when encountered in patterns.

The following one-character regular expressions (RE) match a single character:

1. An ordinary character *c* (*not* a special character) is a one character regular expression that matches itself.
2. A backslash (\) followed by any special character (that is, |*c* where *c* is any special character) is a one character regular expression that matches the special character itself. The special characters are:

- a. ., *, [, and \ (period, asterisk, left square bracket, and backslash, respectively) which are always special, except when they appear within square brackets ([]).
- b. ^ (caret or circumflex), which is special at the beginning of the entire regular expression, or when it immediately follows the left of a pair of square brackets ([]).
- c. \$ (dollar symbol), which is special at the end of the regular expression.
- d. The character used to bound (delimit) an entire regular expression, which is special for that regular expression.

Note: A backslash (\) followed by an ordinary character is a one character regular expression that matches the ordinary character itself.

- 3. A period (.) is a one-character RE that matches any character, except newline.
- 4. A non-empty string within square brackets (*[string]*) is a one-character RE that matches any one character in that *string*. Thus, *[abc]*, if compared to other strings, would match any which contained a, b, or c.

If the caret symbol (^) is the first character of the string within square brackets (that is, *^[string]*), the one-character RE matches any characters except newline and the remaining characters within the square brackets. Thus, *^[abc]*, if compared to other strings, would *fail* to match any which contains even one a, b, or c.

Ranges may be specified as *c-c*. The hyphen symbol, within square brackets, means "through". It may be used to indicate a range of consecutive ASCII characters. For example, *[0-9]* is equivalent to *[0123456789]*.

The - (hyphen) can be used by itself, but only if it is the first (after an initial ^, if any), or last character in the expression.

The right square bracket (]) can be used as part of the string but only if it is the first character within it (after an initial ^, if any). For example, the expression *[]a-d]* matches either a right square bracket or one of the characters a through d.

The following rules may be used to construct REs from one character REs:

- 1. A one-character RE is a RE that matches whatever the one-character RE matches.
- 2. A one-character RE followed by an asterisk symbol (*) is a RE that matches 0 or more occurrences of the one-character RE. For example, *(a*e)* will match any of the following: e, ae, aaaaae. The longest leftmost match is chosen.
- 3. A one-character RE followed by *\{m\}*, *\{m,\}*, or *\{m,u\}* is a RE that matches a range of occurrences of the one-character RE. Nonnegative integer values enclosed in *\{\}* indicate the number of times to apply the preceding one-character RE. *m* is the minimum number and *u* is the maximum number. *u* must be less than 256. If you specify only *m*, it indicates the exact number of times to apply the regular expression.

\{m,\} is equivalent to *\{m,u\}*. They both match *m* or more occurrences of the expression. The * (asterisk) operation is equivalent to *\{0,\}*.

The maximum number of occurrences is matched.

- 4. REs can be concatenated. The concatenation of REs is a RE that matches the concatenation of the strings matched by each component of the RE.
- 5. A RE enclosed between the character sequences *\(and \)* is a RE that matches whatever the unadorned RE matches. The *\(and \)* sequences are ignored.
- 6. The expression *\n* (where $1 \leq n \leq 9$) matches the same string of characters as was matched by an expression enclosed between *\(and \)* earlier in the same regular expression. The sub-expression it specified is that beginning with the *n*th occurrence of *\(* (counting from the left). For example, in the expression, *\(a\)r\((e)\)1*, the *1* is equivalent to *a*, giving *area*.

An entire RE may be constrained to match only an initial segment or final segment of a line (or both).

- 1. A caret (^) at the beginning of an entire RE constrains that RE to match an initial segment of a line.

2. A dollar symbol (\$) at the end of an entire RE constrains that RE to match a final segment of a line. For example, the construct *^entire RE\$* constrains the entire RE to match the entire line.

Returned value

If the string pointed to by the *string* argument is successfully converted, `re_comp()` returns a NULL pointer. If unsuccessful, `re_comp()` returns a pointer to an error message string (NULL-terminated).

The following `re_comp()` error messages are defined:

```
EDC7008E No previous regular expression
EDC7009E Regular expression too long
EDC7010E \(\) imbalance
EDC7011E \{\} imbalance
EDC7012E [] imbalance
EDC7013E Too many \(\) pairs.
EDC7014E Incorrect range values in \{\}
EDC7015E Back reference number in \digit incorrect
EDC7016E Incorrect endpoint in range expression
```

Note: The error message string is not to be freed by the application. It will be freed when the thread terminates.

recv() — Receive data on a socket

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

ssize_t recv(int socket, void *buffer, size_t length, int flags);
```

Berkeley sockets

```
#define _OE_SOCKETS
#include <sys/socket.h>

int recv(int socket, char *buffer, int length, int flags);
```

General description

The `recv()` function receives data on a socket with descriptor *socket* and stores it in a buffer. The `recv()` call applies only to connected sockets.

Parameter

Description

socket

The socket descriptor.

buf

The pointer to the buffer that receives the data.

len

The length in bytes of the buffer pointed to by the *buf* parameter. If the `MSG_CONNTERM` flag is set, the length of the buffer must be zero.

flags

The *flags* parameter is set by specifying one or more of the following flags. If more than one flag is specified, the logical OR operator (`|`) must be used to separate them. The `MSG_CONNTERM` flag is mutually exclusive with other flags.

MSG_CONNTERM

Requests that the function completes only when a TCP connection is terminated. It is valid for TCP sockets only. Other normal receive requests are also completed. The application must be able to deal with the fact that a normal receive and this special connection termination receive might be driven in parallel.

MSG_OOB

Reads any out-of-band data on the socket. Out-of-band data is sent when the `MSG_OOB` flag is on for a `send()`, `sendto()`, or `sendmsg()`.

The `fcntl()` command should be used with `F_SETOWN` to specify the recipient, either a pid or a gid, of a SIGURG signal that will be sent when out-of-band data is sent. If no recipient is set, no signal will be sent. For more information, see the `fcntl()` command. The recipient of the data determines whether to receive out-of-band data inline or not inline by the setting of the `SO_OOBINLINE` option of `setsockopt()`. If `SO_OOBINLINE` is set off and the `MSG_OOB` flag is set on, the out-of-band data byte will be read out-of-line. It is invalid for the `MSG_OOB` flag to be set on when `SO_OOBINLINE` is set on. If there is out-of-band data available, and the `MSG_OOB` flag is not set (`SO_OOBINLINE` can be on or off), then the data up to, but not including, the out-of-band data will be read. When the read cursor has reached the out-of-band data byte, then only the out-of-band data will be read on the next read. The `SIOCATMARK` option of `ioctl()` can be used to determine if the read cursor is currently at the out-of-band data byte. For more information, refer to the `setsockopt()` and `ioctl()` commands.

MSG_PEEK

Peeks at the data present on the socket; the data is returned but not consumed, so that a subsequent receive operation sees the same data.

MSG_WAITALL

Requests that the function block until the full amount of data requested can be returned. The function may return a smaller amount of data if a signal is caught, the connection is terminated, an error is pending, or `SO_RCVTIMEO` is set and the timer is expired for the socket.

This call returns the length of the incoming message or data. If a datagram packet is too long to fit in the supplied buffer, datagram sockets discard excess bytes. If data is not available for the socket *socket*, and *socket* is in blocking mode, the `recv()` call blocks the caller until data arrives. If data is not available and *socket* is in nonblocking mode, `recv()` returns a -1 and sets the error code to `EWOULDBLOCK`. See “[fcntl\(\) — Control open file descriptors](#)” on page 483 or “[ioctl\(\) — Control device](#)” on page 872 for a description of how to set nonblocking mode.

For datagram sockets, this call returns the entire datagram that was sent, provided that the datagram fits into the specified buffer. Stream sockets act like streams of information with no boundaries separating data. For example, if applications A and B are connected with a stream socket and application A sends

1000 bytes, each call to this function can return 1 byte, or 10 bytes, or the entire 1000 bytes. Therefore, applications using stream sockets should place this call in a loop, calling this function until all data has been received.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` feature test macro.

Returned value

If successful, `recv()` returns the length of the message or datagram in bytes. The value 0 indicates the connection is closed.

If unsuccessful, `recv()` returns -1 and sets `errno` to one of the following values:

Error Code Description

EBADF

socket is not a valid socket descriptor.

ECONNRESET

A connection was forcibly closed by a peer.

EFAULT

Using the *buf* and *len* parameters would result in an attempt to access storage outside the caller's address space.

EINTR

The `recv()` call was interrupted by a signal that was caught before any data was available.

EINVAL

The request is invalid or not supported. The `MSG_OOB` flag is set and no out-of-band data is available.

EIO

There has been a network or transport failure.

ENOBUFS

Insufficient system resources are available to complete the call.

ENOTCONN

A receive is attempted on a connection-oriented socket that is not connected.

ENOTSOCK

The descriptor is for a file, not for a socket.

EOPNOTSUPP

The specified flags are not supported for this socket type or protocol.

ETIMEDOUT

The connection timed out during connection establishment, or due to a transmission timeout on active connection.

EWOULDBLOCK

socket is in nonblocking mode and data is not available to read, or the `SO_RCVTIMEO` timeout value was reached before data was available.

AT-TLS considerations: If AT-TLS is being used to provide transparent TLS/SSL support for a TCP socket and `EWOULDBLOCK` is returned on a blocking socket, reissue the `select` call or receive call to continue. For more information about AT-TLS and determining whether a TCP connection is using AT-TLS, see [Application Transparent Transport Layer Security \(AT-TLS\)](#) in *z/OS Communications Server: IP Programmer's Guide and Reference*.

recvfrom() — Receive messages on a socket

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int recvfrom(int socket, void *__restrict__ buffer,
             size_t length, int flags,
             struct sockaddr *__restrict__ address,
             socklen_t *__restrict__ address_length);
```

Berkeley sockets

```
#define _OE_SOCKETS
#include <sys/socket.h>

int recvfrom(int socket, char *buffer,
             int length, int flags,
             struct sockaddr *address,
             int *address_length);
```

General description

The `recvfrom()` function receives data on a socket named by descriptor *socket* and stores it in a buffer. The `recvfrom()` function applies to any datagram socket, whether connected or unconnected.

Parameter Description

socket

The socket descriptor.

buffer

The pointer to the buffer that receives the data.

length

The length in bytes of the buffer pointed to by the *buffer* parameter. If the MSG_CONNTERM flag is set, the length of the buffer must be zero.

flags

A parameter that can be set to 0, MSG_CONNTERM, MSG_PEEK, MSG_OOB, or MSG_WAITALL. The MSG_CONNTERM flag is mutually exclusive with other flags.

MSG_CONNTERM

Requests that the function completes only when a TCP connection is terminated. It is valid for TCP sockets only. Other normal receive requests are also completed. The application must be able to deal with the fact that a normal receive and this special connection termination receive might be driven in parallel.

AT-TLS considerations: If AT-TLS is being used to provide transparent TLS/SSL support for a TCP socket and a receive request with MSG_CONNTERM is outstanding, AT-TLS will immediately honor any TLS/SSL close notify alerts sent by the peer and initiate TLS/SSL session shutdown. For more information about AT-TLS and determining whether a TCP connection is using AT-TLS, see [Application Transparent Transport Layer Security \(AT-TLS\)](#) in *z/OS Communications Server: IP Programmer's Guide and Reference*.

MSG_OOB

Reads any out-of-band data on the socket. Out-of-band data is sent when the MSG_OOB flag is on for a send(), sendto(), or sendmsg().

The fcntl() command should be used with F_SETOWN to specify the recipient, either a pid or a gid, of a SIGURG signal that will be sent when out-of-band data is sent. If no recipient is set, no signal will be sent. For more information, see the fcntl() command. The recipient of the data determines whether to receive out-of-band data inline or not inline by the setting of the SO_OOBINLINE option of setsockopt(). If SO_OOBINLINE is set off and the MSG_OOB flag is set on, the out-of-band data byte will be read out-of-line. It is invalid for the MSG_OOB flag to be set on when SO_OOBINLINE is set on. If there is out-of-band data available, and the MSG_OOB flag is not set (SO_OOBINLINE can be on or off), then the data up to, but not including, the out-of-band data will be read. When the read cursor has reached the out-of-band data byte, then only the out-of-band data will be read on the next read. The SIOCATMARK option of ioctl() can be used to determine if the read cursor is currently at the out-of-band data byte. For more information, refer to the setsockopt() and ioctl() commands.

MSG_PEEK

Peeks at the data present on the socket; the data is returned but not consumed, so that a subsequent receive operation sees the same data.

MSG_WAITALL

Requests that the function block until the full amount of data requested can be returned. The function may return a smaller amount of data if a signal is caught, the connection is terminated, an error is pending or SO_RCVTIMEO is set and the timer is expired for the socket. For AF_UNIX, the function may also return earlier if out-of-band (OOB) data is inline and there is OOB data to be read. In this case, the data up to the OOB data is returned on the first recvfrom(). The OOB data is returned on the subsequent read request.

address

A pointer to a socket address structure from which data is received. If *address* is nonzero, the source address is returned.

address_length

Must initially point to an integer that contains the size in bytes of the storage pointed to by *address*. On return, that integer contains the size required to represent the address of the connecting socket.

If this value is larger than the size supplied on input, then the information contained in `sockaddr` is truncated to the length supplied on input. If `address` is NULL, `address_length` is ignored.

If `address` is nonzero the source address of the message is filled. `address_length` must first be initialized to the size of the buffer associated with `address` and is then modified on return to indicate the actual size of the address stored there.

If either `address` or `address_length` is a NULL pointer, then `address` and `address_length` are unchanged.

If `address` is nonzero, the source address of the message is filled. `address_length` must first be initialized to the size of the buffer associated with `address`, and is then modified on return to indicate the actual size of the address stored there.

This call returns the length of the incoming message or data. If a datagram packet is too long to fit in the supplied buffer, datagram sockets discard excess bytes. If data is not available for the socket `socket`, and `socket` is in blocking mode, the `recvfrom()` call blocks the caller until data arrives. If data is not available and `socket` is in nonblocking mode, `recvfrom()` returns a -1 and sets the error code to EWOULDBLOCK. See [“fcntl\(\) — Control open file descriptors” on page 483](#) or [“ioctl\(\) — Control device” on page 872](#) for a description of how to set nonblocking mode.

For datagram sockets, this call returns the entire datagram that was sent, provided that the datagram fits into the specified buffer. Stream sockets act like streams of information with no boundaries separating data. For example, if applications A and B are connected with a stream socket and application A sends 1000 bytes, each call to this function can return 1 byte, or 10 bytes, or the entire 1000 bytes. Therefore, applications using stream sockets should place this call in a loop, calling this function until all data has been received.

Socket address structure for IPv6: For an AF_INET6 socket, the address is returned in a `sockaddr_in6` address structure. The `sockaddr_in6` structure is defined in the header file **netinet/in.h**.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` 1 feature test macro.

Note: The `recvfrom()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support ” on page 2123](#) for details.

Returned value

If successful, `recvfrom()` returns the length of the message or datagram in bytes. The value 0 indicates the connection is closed.

If unsuccessful, `recvfrom()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

`socket` is not a valid socket descriptor.

ECONNRESET

The connection was forcibly closed by a peer.

EFAULT

Using the `buffer` and `length` parameters would result in an attempt to access storage outside the caller's address space.

EINTR

A signal interrupted `recvfrom()` before any data was available.

EINVAL

The request is invalid or not supported. The MSG_OOB flag is set and no out-of-band data is available.

EIO

There has been a network or transport failure.

ENOBUFS

Insufficient system resources are available to complete the call.

ENOTCONN

A receive is attempted on a connection-oriented socket that is not connected.

ENOTSOCK

The descriptor is for a file, not for a socket.

EOPNOTSUPP

The specified flags are not supported for this socket type.

ETIMEDOUT

The connection timed out during connection establishment, or due to a transmission timeout on active connection.

EWOULDBLOCK

socket is in nonblocking mode and data is not available to read, or the `SO_RCVTIMEO` timeout value was been reached before data was available.

AT-TLS considerations: If AT-TLS is being used to provide transparent TLS/SSL support for a TCP socket and `EWOULDBLOCK` is returned on a blocking socket, reissue the `select` call or receive call to continue. For more information about AT-TLS and determining whether a TCP connection is using AT-TLS, see [Application Transparent Transport Layer Security \(AT-TLS\)](#) in *z/OS Communications Server: IP Programmer's Guide and Reference*.

recvmsg() — Receive messages on a socket and store in array of message headers

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

ssize_t recvmsg(int socket, struct msghdr *msg, int flags);
```

Berkeley sockets

```
#define _OE_SOCKETS
#include <sys/socket.h>

int recvmsg(int socket, struct msghdr *msg, int flags);
```

General description

The `recvmsg()` function receives messages on a socket with descriptor *socket* and stores them in an array of message headers.

Parameter

Description

socket

The socket descriptor.

msg

An array of message headers into which messages are received.

flags

The *flags* parameter is set by specifying one or more of the following flags. If more than one flag is specified, the logical OR operator (`|`) must be used to separate them. The `MSG_CONNTERM` flag is mutually exclusive with other flags.

MSG_CONNTERM

Requests that the function completes only when a TCP connection is terminated. It is valid for TCP sockets only. Other normal receive requests are also completed. The application must be able to deal with the fact that a normal receive and this special connection termination receive might be driven in parallel.

AT-TLS considerations: If AT-TLS is being used to provide transparent TLS/SSL support for a TCP socket and `EWOULDBLOCK` is returned on a blocking socket, reissue the `select` call or `receive` call to continue. For more information about AT-TLS and determining whether a TCP connection is using AT-TLS, see [Application Transparent Transport Layer Security \(AT-TLS\) in z/OS Communications Server: IP Programmer's Guide and Reference](#).

MSG_OOB

Reads any out-of-band data on the socket. Out-of-band data is sent when the `MSG_OOB` flag is on for a `send()`, `sendto()` or `sendmsg()`.

The `fcntl` command should be used with `F_SETOWN` to specify the recipient, either a pid or a gid, of a `SIGURG` signal that will be sent when out-of-band data is sent. If no recipient is set, no signal will be sent. For more information, see the `fcntl()` command. The recipient of the data determines whether to receive out-of-band data inline or not inline by the setting of the `SO_OOBINLINE` option of `setsockopt()`. If `SO_OOBINLINE` is set off and the `MSG_OOB` flag is set on, the out-of-band data byte will be read out-of-line. It is invalid for the `MSG_OOB` flag to be set on when `SO_OOBINLINE` is set on. If there is out-of-band data available, and the `MSG_OOB` flag is not set (`SO_OOBINLINE` can be on or off), then the data up to, but not including, the out-of-band data will be read. When the read cursor has reached the out-of-band data byte, then only the out-of-band data will be read on the next read, and the output `MSG_OOB msg_flag` in the message header will be set on. The `SIOCATMARK` option of `ioctl()` can be used to determine if the read cursor is currently at the out-of-band data byte. For more information, refer to the `setsockopt()` and `ioctl()` commands.

MSG_PEEK

Peeks at the data present on the socket; the data is returned but not consumed, so that a subsequent receive operation will see the same data.

MSG_WAITALL

Requests that the function block until the full amount of data requested can be returned. The function may return a smaller amount of data if a signal is caught, the connection is terminated, an error is pending or SO_RCVTIMEO is set and the timer is expired for the socket.

A message header is defined by a `msg_hdr` structure. A definition of this structure can be found in the `sys/socket.h` include file and contains the following elements:

Element**Description*****msg_iov***

An array of *iovec* buffers into which the message is placed.

msg_iovlen

The number of elements in the *msg_iov* array. If the MSG_CONNTERM flag is set, the number of elements must be zero.

msg_name

An optional pointer to a buffer where the sender's address is stored.

msg_namelen

The size of the address buffer.

caddr_t msg_accrights

Access rights sent/received (ignored if specified by the user).

int msg_accrightslen

Length of access rights data (ignored if specified by the user).

msg_control

Ancillary data, see below.

msg_controllen

Ancillary data buffer length.

msg_flags

Flags on received message.

Ancillary data consists of a sequence of pairs, each consisting of a `cmsg_hdr` structure followed by a data array. The data array contains the ancillary data message, and the `cmsg_hdr` structure contains descriptive information that allows an application to correctly parse the data.

The `sys/socket.h` header file defines the `cmsg_hdr` structure that includes at least the following members:

Element**Description*****cmsg_len***

Data byte count, including header.

cmsg_level

Originating protocol.

cmsg_type

Protocol-specific type.

The following ancillary data are available at the IPv4 level:

Ancillary data**Description****IP_PKTINFO**

(RAW and UDP) Returns the source IP address for an outgoing packet and the outgoing interface. The data is passed in an `in_pktinfo` structure as defined in `netinet/in.h`.

The following ancillary data are available at the IPv6 level:

Ancillary data Description

IPV6_HOPLIMIT

(RAW, TCP, and UDP) Returns the maximum hop limit for an incoming packet. The data is passed in a structure as defined in `netinet/in.h`.

IPV6_PATHMTU

(RAW and UDP) Returns the path MTU value for the source of a connected socket. The data is passed in a structure as defined in `netinet/in.h`.

IPV6_PKTINFO

(RAW and UDP) Returns the source IP address for an outgoing packet and the outgoing interface. The data is passed in an `in6_pktinfo` structure as defined in `netinet/in.h`.

The following ancillary data are available at the socket level:

Ancillary data Description

SCM_RIGHTS

Returns the data array that contains the access rights to be sent or received. This ancillary data is valid only for the `AF_UNIX` domain. The structure is defined in `sys/socket.h`.

The `sys/socket.h` header file defines the following macros to gain access to the data arrays in the ancillary data associated with a message header:

CMMSG_DATA(*cmsg*)

If the argument is a pointer to a `cmsg_hdr` structure, this macro returns an unsigned character pointer to the data array associated with the `cmsg_hdr` structure.

CMMSG_NXTHDR(*mhdr, cmsg*)

If the first argument is a pointer to a `msg_hdr` structure and the second argument is a pointer to a `cmsg_hdr` structure in the ancillary data, pointed to by the `msg_control` field of that `msg_hdr` structure, this macro returns a pointer to the next `cmsg_hdr` structure, or a NULL pointer if this structure is the last `cmsg_hdr` in the ancillary data.

CMMSG_FIRSTHDR(*mhdr*)

If the argument is a pointer to a `msg_hdr` structure, this macro returns a pointer to the first `cmsg_hdr` structure in the ancillary data associated with this `msg_hdr` structure, or a NULL pointer if there is no ancillary data associated with the `msg_hdr` structure.

The `recvmsg()` function applies to sockets, regardless of whether they are in the connected state.

This call returns the length of the data received. If data is not available for the socket *socket*, and *socket* is in blocking mode, the `recvmsg()` call blocks the caller until data arrives. If data is not available and *socket* is in nonblocking mode, `recvmsg()` returns a -1 and sets the error code to `EWOULDBLOCK`. See [“fcntl\(\) — Control open file descriptors” on page 483](#) or [“ioctl\(\) — Control device” on page 872](#) for a description of how to set nonblocking mode.

For datagram sockets, this call returns the entire datagram that was sent, provided that the datagram fits into the specified buffer. Stream sockets act like streams of information with no boundaries separating data. For example, if applications A and B are connected with a stream socket and application A sends 1000 bytes, each call to this function can return 1 byte, or 10 bytes, or the entire 1000 bytes. Therefore, applications using stream sockets should place this call in a loop, calling this function until all data has been received.

On successful completion, the `msg_flags` member for the message header is the bitwise inclusive-OR of all of the following flags that indicate conditions detected for the received message:

MSG_OOB

Out-of-band data was received.

MSG_TRUNC

Normal data was truncated.

MSG_CTRUNC

Control data was truncated.

Socket address structure for IPv6: For an AF_INET6 socket, the address is returned in a sockaddr_in6 address structure. The sockaddr_in6 structure is defined in the header file `netinet/in.h`.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` 1 feature test macro.

Note: The `recvmsg()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support”](#) on page 2123 for details.

Returned value

If successful, `recvmsg()` returns the length of the message in bytes. The value 0 indicates the connection is closed.

If unsuccessful, `recvmsg()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

socket is not a valid socket descriptor.

ECONNRESET

The connection was forcibly closed by a peer.

EFAULT

Using *msg* would result in an attempt to access storage outside the caller's address space.

EINTR

The function was interrupted by a signal before any data was available.

EINVAL

The request is invalid or not supported. The sum of the **iov_len** values overflows a **ssize_t**.

EIO

There has been a network or transport failure.

ENOBUFS

Insufficient system resources are available to complete the call.

ENOTCONN

A receive is attempted on a connection-oriented socket that is not connected.

ENOTSOCK

The descriptor is for a file, not for a socket.

EOPNOTSUPP

The specified flags are not supported for this socket type.

ETIMEDOUT

The connection timed out during connection establishment, or due to a transmission timeout on active connection.

EWOULDBLOCK

socket is in nonblocking mode and data is not available to read, or the `SO_RCVTIMEO` timeout value was reached before data was available.

AT-TLS considerations: If AT-TLS is being used to provide transparent TLS/SSL support for a TCP socket and `EWOULDBLOCK` is returned on a blocking socket, reissue the select call or receive call to continue. For more information about AT-TLS and determining whether a TCP connection is using AT-TLS, see [Application Transparent Transport Layer Security \(AT-TLS\)](#) in *z/OS Communications Server: IP Programmer's Guide and Reference*.

re_exec() — Match regular expression

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <re_comp.h>

int re_exec(const char *string);
```

General description

Restriction: This function is not supported in AMODE 64.

The `re_exec()` function attempts to match the string pointed to by the *string* argument with the last regular expression passed to `re_comp()`.

The parameter *string* is a pointer to a character string to be compared.

Strings passed to `re_exec()` must be terminated by a NULL byte, and may include newline characters.

Notes:

1. The `re_comp()` and `re_exec()` functions are provided for historical reasons. These functions were part of the Legacy Feature in Single UNIX Specification, Version 2. They have been withdrawn and are not supported as part of Single UNIX Specification, Version 3. New applications should use the newer functions `fnmatch()`, `glob()`, `regcomp()` and `regexexec()`, which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001.
2. The z/OS UNIX implementation of the `re_exec()` function supports only the POSIX locale. Any other locales will yield unpredictable results.
3. The `re_comp()` and `re_exec()` functions are supported on the thread-level. They must be issued from the *same* thread to work properly.

The `re_exec()` function supports simple regular expressions, which are defined in [“re_comp\(\) — Compile regular expression”](#) on page 1399.

Returned value

If successful, `re_exec()` returns 1 if the input *string* matches the last compiled regular expression.

If unsuccessful, `re_exec()` returns 0 if the input *string* fails to match the last compiled regular expression, and -1 if the compiled regular expression is invalid (indicating an internal error).

regcmp() — Compile regular expression

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | C only | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <libgen.h>

char *regcmp(const char *pattern[...], (char *)0);
char *regex(const char *cmppat, const char *subject[,subexp,...]);
extern char *__loc1;
```

General description

Restriction: This function is not supported in AMODE 64.

The `regcmp()` function concatenates regular expression (RE) patterns specified by a list of one or more *pattern* arguments. The end of this list must be delimited by a NULL pointer. The `regcmp()` function then converts the concatenated RE pattern into an internal form suitable for use by the pattern matching `regex()` function. If conversion is successful, `regcmp()` returns a pointer to the converted pattern. Otherwise, it returns a NULL pointer. The `regcmp()` function uses `malloc()` to obtain storage for the converted pattern. It is the application's responsibility to free unneeded space so allocated.

The `regex()` function executes a converted pattern *cmppat* against a *subject* string. If *cmppat* matches all or part of the *subject* string, the `regex()` function returns a pointer to the next unmatched character in the *subject* string and sets the external variable `__loc1` to point the first matched character in the *subject* string. If no match is found between *cmppat* and the *subject* string, the `regex()` function returns a NULL pointer.

The `regcmp()` and `regex()` functions are supported in any locale. However, results are unpredictable if they are not run in the same locale.

Following are valid RE symbols and their meaning to the `regcmp()` and `regex()` functions:

Expression Meaning

NUL

Terminate RE pattern and text string

c

Any non-special character, c, is a one-character RE which matches itself.

\s

A backslash (\) followed by a special character, s, is a one-character RE which matches the special character itself.

The following characters are special:

period, ., asterisk, *, plus, +, dollar, \$, left square bracket, [, left brace, {, right brace, }, left parenthesis, (, right parenthesis,), and backslash, \, are always special except when they appear within square brackets ([]).

caret (^) is special at the beginning of an entire RE (which is another name for a pattern).

Note: An non-special character preceded by \ is a one-character RE which matches the non-special character.

yz

Concatenation of REs y and z matches concatenation of strings matched by y and z.

.

The period (.) special character RE matches any single character except the <newline> character.

^

The caret (^) at the beginning of an entire RE is an RE which matches the beginning of a string. Thus, it **anchors** or limits matches by the entire RE to the beginning of strings.

\$

The dollar (\$) at the end of an entire RE is an RE which only the end of a string (delimited by the <NUL> character). Thus, it **anchors** or limits matches by the entire RE to the end of strings.

Note: \n (the C language designation for a <newline> character) must be used in an entire RE to match any embedded or trailing <newline> character in a text string.

(...)

Parentheses are used to delimit a sub-expression which matches whatever the REs comprising the sub-expression would have matched without the delimiting parentheses.

(...)\$n

\$n, where n is a digit between 0 and 9, inclusive, may be used to tag a sub-expression. The tag tells the regex() function to return the substring matched by the sub-expression at address specified by (n+1)th argument after *subject*.

*

A one-character RE or sub-expression followed by an asterisk (*) is a RE that matches zero or more occurrences of the one-character RE or sub-expression. If there is any choice, the longest leftmost string that permits a match is chosen.

+

A one-character RE or sub-expression followed by a plus (+) is a RE that matches one or more occurrences of the one-character RE or sub-expression. Whenever a choice exists, the RE matches as many occurrences as possible.

{m,n}

A one-character RE or sub-expression followed by integer values, m and n, enclosed in braces is a RE which matches repeated occurrences of whatever the preceding one-character RE or sub-expression matched. The value of m, which must be in the range 0 to 255, inclusive, is the minimum number of occurrences required for a match. The value of n which, if specified, must also must be in the range 0 to 255, inclusive, is the maximum. The value of n, if specified, must be greater than or equal to the value m. The following brace expressions are valid:

{m}

Matches exactly m occurrences of the preceding one-character RE or sub-expression.

{m,}

Matches m or more occurrences of the preceding one-character RE or sub-expression. There is no limit on the number of occurrences which will be matched. The plus (+) and asterisk (*) operations are equivalent to {1,} and {0,}, respectively.

{m,n}

Matches between m and n occurrences, inclusive.

Whenever a choice exists, the RE matches as many occurrence as possible.

[...]

A non-empty list of characters enclosed by square brackets is a one-character RE that matches any one character in the list.

[^...]

A non-empty list of characters preceded by a caret (^) enclosed by square brackets is a one-character RE that matches any character except <newline> and the characters in the list. The ^ has special meaning only if it is the first character after the left bracket ([).

[c1-c2]

The hyphen (-) between two characters c1 and c2 within square brackets designates the list of characters whose collating values fall between the collating values of c1 and c2 in the current locale. The collating value of c2 must be greater than or equal to c1. Also, c2 may not be used as the ending point of one range and the starting point of another range. In other words, c1-c2-c3 is invalid.

The - loses special meaning if it occurs first or last in the bracket expression or if it is used for c1 or c2.

The right bracket,], does not terminate a bracket expression when it is the first character within it (after an initial ^, if any). For example, the expression [][0-9] matches a right bracket or a digit in the range 0-9, inclusive.

Notes:

1. Multiple duplication symbols applied to the same RE will be interpreted in the following order of precedence:
 - a. *
 - b. +
 - c. {}
2. RE Order of precedence is as follows, from high to low:
 - a. escaped character \character
 - b. bracket expression [...]
 - c. sub-expression (...)
 - d. duplication * + {}
 - e. concatenation yz
 - f. anchors ^ \$

Note:

The regcmp() and regex() functions are provided for historical reasons. These functions were part of the Legacy Feature in Single UNIX Specification, Version 2. They have been withdrawn and are not supported as part of Single UNIX Specification, Version 3. New applications should use the newer functions fnmatch(), glob(), regcomp() and regexec(), which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001.

If it is necessary to continue using these functions in an application written for Single UNIX Specification, Version 3, define the feature test macro _UNIX03_WITHDRAWN before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

If the pattern formed by concatenating the list of *pattern* arguments is successfully converted, regcmp() returns a pointer to the converted pattern. Otherwise, it returns a NULL pointer. If regcmp() is unable to allocate storage for the converted pattern, it sets errno to ENOMEM.

If regex() successfully matches the converted pattern *cmppat* to all or part of the *subject* string, it returns a pointer to the next unmatched character in *subject*. Otherwise, it returns a NULL pointer.

regcomp() — Compile regular expression

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 z/OS UNIX | both | |

Format

```
#include <regex.h>

int regcomp(regex_t *_restrict_ preg, const char *_restrict_ pattern, int cflags);
```

General description

Compiles the regular expression specified by *pattern* into an executable string of op-codes.

preg is a pointer to a compiled regular expression.

pattern is a pointer to a character string defining a source regular expression (described below).

cflags is a bit flag defining configurable attributes of compilation process:

- REG_EXTENDED**
Support extended regular expressions.
- REG_ICASE**
Ignore case in match.
- REG_NEWLINE**
Eliminate any special significance to the newline character.

REG_NOSUB

Report only success or fail in `regexexec()`, that is, verify the syntax of a regular expression. If this flag is set, the `regcomp()` function sets `re_nsub` to the number of parenthesized sub-expressions found in *pattern*. Otherwise, a sub-expression results in an error.

The `regcomp()` function uses the definition of characters according to the current `LC_SYNTAX` category. The characters, `[`, `]`, `{`, `}`, `|`, `^`, and `$`, have varying code points in different encoded character sets.

Regular expressions

The functions `regcomp()`, `regerror()`, `regexexec()`, and `regfree()` use regular expressions in a similar way to the UNIX `awk`, `ed`, `grep`, and `egrep` commands.

The simplest form of regular expression is a string of characters with no special meaning. The following characters do have special meaning; they are used to form extended regular expressions:

Symbol**Description**

•

The period symbol matches any one character except the terminal newline character.

[character–character]

The hyphen symbol, within square brackets, means “through”. It fills in the intervening characters according to the current collating sequence. For example, `[a–z]` can be equivalent to `[abc...xyz]` or, with a different collating sequence, it can be equivalent to `[aAbBcC...xXyYzZ]`.

[string]

A string within square brackets specifies any of the characters in *string*. Thus `[abc]`, if compared to other strings, would match any that contained a, b, or c.

No assumptions are made at compile time about the actual characters contained in the range.

{m}{m,}{m,u}

Integer values enclosed in `{}` indicate the number of times to apply the preceding regular expression. *m* is the minimum number, and *u* is the maximum number. *u* must not be greater than `RE_DUP_MAX` (see “[limits.h — Standard values for limits on resources](#)” on page 34).

If you specify only *m*, it indicates the exact number of times to apply the regular expression. `{m,}` is equivalent to `{m,u}`. They both match *m* or more occurrences of the expression.

★

The asterisk symbol indicates 0 or more of any characters. For example, `[a*e]` is equivalent to any of the following: `99ae9`, `aaaaae`, `a999e99`.

\$

The dollar symbol matches the end of the string. (Use `\n` to match a newline character.)

character+

The plus symbol specifies one or more occurrences of a character. Thus, `smith+ern` is equivalent to, for example, `smithhheern`.

[^string]

The caret symbol, when inside square brackets, negates the characters within the square brackets. Thus `[^abc]`, if compared to other strings, would *fail* to match any that contains even one a, b, or c.

(expression)\$n

Stores the value matched by the enclosed regular expression in the $(n+1)^{\text{th}}$ *ret* parameter. Ten enclosed regular expressions are allowed. Assignments are made unconditionally.

(expression)

Groups a sub-expression allowing an operator, such as `*`, `+`, or `[|.]`, to work on the sub-expression enclosed in parentheses. For example, `(a*(cb+)*)$0`.

Note:

- 1. Do *not* use multibyte characters.
- 2. You can use the] (right square bracket) alone within a pair of square brackets, but only if it immediately follows either the opening left square bracket or if it immediately follows [^ . For example: []-] matches the] and – characters.
- 3. All the preceding symbols are *special*. You precede them with \ to use the symbol itself. For example, a\.e is equivalent to a.e.
- 4. You can use the – (hyphen) by itself, but only if it is the first or last character in the expression. For example, the expression [--0] matches either the] or else the characters – through 0. Otherwise, use \-.

Returned value

If successful, regcomp() returns 0.

If unsuccessful, regcomp() returns nonzero, and the content of preg is undefined.

Example

CELEBR07

```
/* CELEBR07
   This example compiles an extended regular expression.
*/
#include <regex.h>
#include <locale.h>
#include <stdio.h>
#include <stdlib.h>

main() {
    regex_t    preg;
    char       *string = "a simple string";
    char       *pattern = ".*(simple).*";
    int        rc;

    if ((rc = regcomp(&preg, pattern, REG_EXTENDED)) != 0) {
        printf("regcomp() failed, returning nonzero (%d)", rc);
        exit(1);
    }
}
```

regerror() – Return error message

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#include <regex.h>

size_t regerror(int errcode, const regex_t *_restrict preg,
                char *_restrict errbuf, size_t errbuf_size);
```

General description

Finds the description for *errcode*. (For a description of regular expressions, see [“Regular expressions”](#) on page 1417.)

Returned value

regerror() returns the integer value that is the size of the buffer needed to hold the generated description string for the error condition corresponding to *errcode*.

regerror() returns the following messages.

errcode

Description String

REG_BADBR

Invalid `\{ \}` range exp

REG_BADPAT

Invalid regular expression

REG_BADRPT

`?*+` not preceded by valid RE

REG_EBOL

`^` anchor and not BOL

REG_EBRACE

`\{ \}` or `{ }` imbalance

REG_EBRACK

`[]` imbalance

REG_ECHAR

Invalid multibyte character

REG_ECOLLATE

Invalid collating element

REG_ECTYPE

Invalid character class

REG_EEOL

`$` anchor and not EOL

REG_EESCAPE

Last character is `\`

REG_EPAREN

`\(\)` or `()` imbalance

REG_ERANGE

Invalid range exp endpoint

REG_ESPACE

Out of memory

REG_ESUBREG

Invalid number in `\digit`

REG_NOMATCH

RE pattern not found

The LC_SYNTAX characters in the messages will be converted to the code points from the current LC_SYNTAX category.

Example

CELEBR08

```
/* CELEBR08

   This example compiles an invalid regular expression, and
   print error message &regerror..

*/
#include <regex.h>
#include <locale.h>
#include <stdio.h>
#include <stdlib.h>

main() {
    regex_t    preg;
    char       *pattern = "a[missing.bracket";
    int        rc;
    char       buffer[100];

    if ((rc = regcomp(&preg, pattern, REG_EXTENDED)) != 0) {
        regerror(rc, &preg, buffer, 100);
        printf("regcomp() failed with '%s'\n", buffer);
        exit(1);
    }
}
```

regex() — Execute compiled regular expression

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | C only | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <libgen.h>

char *regex(const char *cmppat, const char *subject[,subexp,...]);
extern char *__loc1;
```

General description

Restriction: This function is not supported in AMODE 64.

The regex() function executes a converted pattern *cmppat* produced by the regcomp() function against a *subject* string. If *cmppat* matches all or part of the *subject* string, the regex() function returns a pointer to the next unmatched character in the *subject* string and sets the external variable `__loc1` to point the first

matched character in the *subject* string. If no match is found between *cmppat* and the *subject* string, the `regex()` function returns a NULL pointer.

The `regex()` and `regcomp()` functions are supported in any locale. However, results are unpredictable if they are not run in the same locale.

Refer to [“`regcomp\(\)` — Compile regular expression](#)” on page 1413 for a description of regular expression syntax and semantics supported by the `regex()` and `regcomp()` functions.

Note:

The `regcomp()` and `regex()` functions are provided for historical reasons. These functions were part of the Legacy Feature in Single UNIX Specification, Version 2. They have been withdrawn and are not supported as part of Single UNIX Specification, Version 3. New applications should use the newer functions `fnmatch()`, `glob()`, `regcomp()` and `regexec()`, which provide full internationalized regular expression functionality compatible with IEEE Std 1003.1-2001.

If it is necessary to continue using these functions in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

If `regex()` successfully matches the converted pattern *cmppat* to all or part of the *subject* string, it returns a pointer to the next unmatched character in *subject*.

If unsuccessful, `regex()` returns a NULL pointer.

regexec() — Execute compiled regular expression

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4 XPG4.2 | both | |

Format

```
#include <regex.h>

int regexec(const regex_t *preg, const char *string,
            size_t nmatch, regmatch_t *pmatch, int eflags);
```

XPG4

```
#define _XOPEN_SOURCE
#include <regex.h>
```

```
int regexec(const regex_t *__ preg,
            const char *__ string,
            size_t nmatch, regmatch_t *__ pmatch, int eflags);
```

General description

Compares the NULL-terminated string specified by *string* against the compiled regular expression, *preg*. (For a description of regular expressions, see [“Regular expressions”](#) on page 1417.)

preg is a pointer to a compiled regular expression to compare against STRING.

string is a pointer to a string to be matched.

nmatch is the number of sub-expressions to match.

pmatch is an array of offsets into STRING which matched the corresponding sub-expressions in *preg*.

eflags is a bit flag defining customizable behavior of regexec().

REG_NOTBOL

Indicates that the first character of STRING is not the beginning of the line.

REG_NOTEOL

Indicates that the first character of STRING is not the end of the line.

If *nmatch* parameter is 0 or REG_NOSUB was set on the call to regcomp(), regexec() ignores the *pmatch* argument. Otherwise, the *pmatch* argument points to an array of at least *nmatch* elements. The regexec() function fills in the elements of the array with offsets of the substrings of STRING that correspond to the parenthesized sub-expressions of the original *pmatch* specified to regcomp(). The 0th element of the array corresponds to the entire pattern. If there are more than *nmatch* sub-expressions, only the first *nmatch*-1 are recorded.

When matching a basic or extended regular expression, any given parenthesized sub-expression of *pmatch* might participate in the match of several different substrings of STRING. The following rules determine which substrings are reported in *pmatch*.

1. If a sub-expression participated in a match several times, the offset of the last matching substring is reported in *pmatch*.
2. If a sub-expression did not match in the source STRING, the offset shown in *pmatch* is set to -1.
3. If a sub-expression contains sub-expressions, the data in *pmatch* refers to the last such sub-expression.
4. If a sub-expression matches a zero-length string, the offsets in *pmatch* refer to the byte immediately following the matching string.

If EREG_NOSUB was set when regcomp() was called, the contents of *pmatch* are unspecified.

If REG_NEWLINE was set when regcomp() was called, newline characters are allowed in STRING.

Notes:

1. The string passed to the regexec() function is assumed to be in the initial shift state, unless REG_NOTBOL is specified. If REG_NOTBOL is specified, the shift state used is the shift state after the last call to the regexec() function.
2. The information returned by the regexec() function in the regmatch_t structure has the shift-state at the start and end of the string added. This will assist an application to perform replacements or processing of the partial string. To perform replacements, the application must add the required shift-out and shift-in characters where necessary. No library functions are available to assist the application.
3. If MB_CUR_MAX is specified as 4, but the charmap file does not specify the DBCS characters, and a collating-element (for example, [:a:]) is specified in the pattern, the DBCS characters will not match against the collating-element even if they have an equivalent weight to the collating-element.

Returned value

If a match is found, `regex()` returns 0.

If unsuccessful, `regex()` returns nonzero indicating either no match or an error.

Example

CELEBR09

```
/* CELEBR09

   This example compiles an extended regular expression, and
   match against a string.

   */
#include <regex.h>
#include <locale.h>
#include <stdio.h>
#include <stdlib.h>

main() {
    regex_t    preg;
    char       *string = "a simple string";
    char       *pattern = ".*(simple).*";
    int        rc;
    size_t     nmatch = 2;
    regmatch_t pmatch[2];

    if ((rc = regcomp(&preg, pattern, REG_EXTENDED)) != 0) {
        printf("regcomp() failed, returning nonzero (%d)\n", rc);
        exit(1);
    }

    if ((rc = regexexec(&preg, string, nmatch, pmatch, 0)) != 0) {
        printf("failed to ERE match '%s' with '%s', returning %d.\n",
            string, pattern, rc);
    }

    regfree(&preg);
}
```

regfree() — Free memory for regular expression

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#include <regex.h>

void regfree(regex_t *preg);
```

General description

Frees any memory that was allocated by regcomp() to implement *preg*. The expression defined by *preg* is no longer a compiled regular or extended expression. (For a description of regular expressions, see [“Regular expressions” on page 1417.](#))

Example

CELEBR10

```
/* CELEBR10

   This example compiles an extended regular expression and a
   free regular expression.

*/
#include <regex.h>
#include <locale.h>
#include <stdio.h>
#include <stdlib.h>

main() {
    regex_t    preg;
    char       *pattern = ".*(simple).*";
    int        rc;

    if ((rc = regcomp(&preg, pattern, REG_EXTENDED)) != 0) {
        printf("regcomp() failed, returning nonzero (%d)\n", rc);
        exit(1);
    }

    regfree(&preg);
}
```

release() – Delete a load module

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | C only | |

Format

```
#include <stdlib.h>

int release(void(*fetch_ptr)());
```

General description

Removes from memory the load modules retrieved by `fetch()` or fetch control blocks created by `fetchep()`. The *fetch_ptr* parameter is obtained from a call to `fetch()` or `fetchep()`. Once released, the `fetch()` and any associated `fetchep()` pointers are no longer valid.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

Note: The external entry point name for `release()` is `__rlse()`, *NOT* `__release()`.

All fetched modules and fetch control blocks created by `fetchep()` are released automatically on program termination.

Using `release()` on a module obtained by using `fetch()` will also cause the `release()` of any child fetch control blocks created by `fetchep()` for this module. However, using `release()` on a child fetch control block will have no effect on the parent modules or sibling fetch control blocks obtained by using `fetch()`. Trying to use a fetch control block after it has been released will result in undefined behavior. (A Fetch Control Block (FCB) is an internal executable control block. The fetch pointer points to it.

When non-reentrant modules have been fetched multiple times, you should release them in the reverse order; otherwise, the load modules may not be deleted immediately.

Returned value

If successful, `release()` returns 0.

If unsuccessful, `release()` returns nonzero.

Example

```
/* The following C example uses the fetch() function to load a module, and
   later uses release() to delete the module from memory.
   */
#include <stdlib.h>

void (*fetch_ptr)();

int main(void) {
    fetch_ptr = fetch("sample");
    :
    release(fetch_ptr); /* all modules are released */
}
```

Related information

- [“stdlib.h — Standard library functions” on page 65](#)

remainder(), remainderf(), remainderl() – Computes the remainder $x \text{ REM } y$

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <math.h>

double remainder(double x, double y);
```

C99

```
#define _ISOC99_SOURCE
#include <math.h>

float remainderf(float x, float y);
long double remainderl(long double x, long double y);
```

C++ TR1 C99

```
#define _TR1_C99
#include <math.h>

float remainder(float x, float y);
long double remainder(long double x, long double y);
```

General description

The remainder() function returns the floating-point remainder when y is nonzero and following the relation

$$r = x - ny$$

The value n is the integral value nearest the exact value x/y and when $|n - x/y| = 1/2$ then the value of n is even.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|------------|-----|------|
| remainder | X | X |
| remainderf | X | X |
| remainderl | X | X |

Restriction: The remainderf() function does not support the _FP_MODE_VARIABLE feature test macro.

Returned value

If successful, remainder() returns the remainder of the division of x by y as described.

If y is zero, `remainder()` returns `HUGE_VAL` and sets `errno` to `EDOM`.

If $r = 0$, then its sign will be that of x .

Special behavior for IEEE: If successful, `remainder()` returns the remainder of the division of x by y .

If y is zero, `remainder()` returns `NaNQ` and sets `errno` to `EDOM`.

Example

```
/*
 * This program illustrates the use of remainder() function
 */
#define _ISOC99_SOURCE
#include <math.h>
#include <stdio.h>

void main() {
    double number1=3.0, number2=3.5;

    printf("Illustrates the remainder() function");

    #ifdef _BFP
        printf(" (IEEE version)\n\n");
    #else
        printf(" (HFP version)\n\n");
    #endif

    printf("remainder(%.2f,%.2f)=%.2f\n",number1,number2,
           remainder(number1,number2));
    number1=1; number2=2;
    printf("remainder(%.2f,%.2f)=%.2f\n",number1,number2,
           remainder(number1,number2));
    number1=1; number2=0;
    printf("remainder(%.2f,%.2f)=%.2f\n",number1,number2,
           remainder(number1,number2));
}
```

Output

Illustrates the remainder() function (IEEE version)

```
remainder(3.00,3.50)=-0.50
remainder(1.00,2.00)=1.00
remainder(1.00,0.00)=NaNQ(1)
```

```

General description

The remainder() function returns the decimal floating-point remainder when y is nonzero and following the relation

$$r = x - ny$$

The value n is the integral value nearest the exact value x/y and when

$$|n - x/y| = 1/2$$

then the value of n is even.

These functions work in IEEE decimal floating-point format. See [“IEEE decimal floating-point” on page 97](#) for more information.

Note: To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

If successful, remainder() returns the remainder of the division of x by y .

If y is zero, remainder() returns NaNQ and sets errno to EDOM.

Example

CELEBR23

```

/* CELEBR23

   This example illustrates the remainderd32() function.

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

void main() {
    _Decimal32 n1=3.0DF, n2=3.5DF;

    printf("Illustrates the remainderd32() function\n");

    printf("remainderd32(%.2Hf,%.2Hf)=%.2Hf\n",n1,n2,remainderd32(n1,n2));
    n1=1.0DF; n2=2.0DF;
    printf("remainderd32(%.2Hf,%.2Hf)=%.2Hf\n",n1,n2,remainderd32(n1,n2));
    n1=1.0DF; n2=0.0DF;
    printf("remainderd32(%.2Hf,%.2Hf)=%.2Hf\n",n1,n2,remainderd32(n1,n2));
}

```

remove() — Delete file

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdio.h>

int remove(const char *filename);
```

General description

Deletes the file specified by *filename*, unless the file is open. The `remove()` function removes memory files and DASD data sets. (non-DASD data sets, such as tapes, are not supported.) It also removes individual members of PDSs and PDSEs, and even removes memory files that simulate PDSs.

The interpretation of the file name passed to `remove()` depends on whether `POSIX(ON)` is specified. For full details about *filename* considerations, see the topics about opening files in [z/OS XL C/C++ Programming Guide](#).

Memory files must exist and they must be closed. However, if you have z/OS UNIX C application running `POSIX(ON)`, memory files don't need to be closed when removing a memory file. The z/OS UNIX services rules of interoperability apply. See the topics about opening files in [z/OS XL C/C++ Programming Guide](#), for specifying file names for MVS data sets and z/OS UNIX files.

Special behavior for XPG4: If *filename* does not name a directory, `remove(filename)` is equivalent to `unlink(filename)`. If *filename* names a directory, `remove(filename)` is equivalent to `rmdir(filename)`.

Returned value

If successful, `remove()` returns 0.

If unsuccessful, `remove()` returns nonzero to indicate an error.

Example

CELEBR12

```
/* CELEBR12

   When you invoke this example with a file name, the program attempts to
   remove that file.
   It issues a message if an error occurs.

*/
#include <stdio.h>

int main(int argc, char ** argv)
{
    if ( argc != 2 )
        printf( "Usage: %s fn\n", argv[0] );
    else
        if ( remove( argv[1] ) != 0 )
```

```
    printf( "Could not remove file\n" );
}
```

removexattr(), lremovexattr(), fremovexattr() — Remove an extended attribute

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <sys/xattr.h>

int removexattr(const char *path, const char *name);
int lremovexattr(const char *path, const char *name);
int fremovexattr(int fd, const char *name);
```

General description

Extended attributes are extensions to the normal attributes that are associated with all inodes in the system. They are used as name : value pairs that are associated with files and directories to provide more functions to a file system.

removexattr() removes the extended attribute that is identified by *name* and associated with the given *path* in the file system.

lremovexattr() is identical to removexattr() except that in the case of a symbolic link, the extended attribute is removed from the link itself by lremovexattr(), not the file that it refers to.

fremovexattr() is identical to removexattr() except that the extended attribute is removed from the open file that is referred to by *fd* by fremovexattr() in place of *path*.

Returned value

If successful, 0 is returned.
If unsuccessful, -1 is returned and errno is set to one of the following values:

Error Code
Description

ENAMETOOLONG
pathname is longer than PATH_MAX characters.

ENOATTR
The specified attribute is not set.
Attribute name is NULL or blank.

ENODATA
The specified attribute is not set.

Attribute name is NULL or blank.

ENOTSUP

Extended attributes are not supported by the file system.

Attempting to remove a read-only attribute.

Attempting to remove a general attribute of symbolic link.

ERANGE

Attribute name is longer than 256 characters.

EINVAL

Attempting to remove a general attribute with `fremovexattr()`.

Related information

remque() — Remove an element from a double linked list

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <search.h>

void remque(void *element);
```

General description

The `remque()` function removes the element pointed to by *element* from a doubly-linked list. The function operates on pointers to structures which have a pointer to their successor in the list as their first element, and a pointer to their predecessor as the second. The application is free to define the remaining contents of the structure, and manages all storage itself.

Returned value

`remque()` returns no values.

Related information

- [“search.h — Searching tables” on page 58](#)
- [“insque\(\) — Insert an element into a doubly-linked list” on page 871](#)

remquo(), remquof(), remquol() – Computes the remainder.

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R5 |

Format

```
#define _ISOC99_SOURCE
#include <math.h>

double remquo(double x, double y, int *quo);
float remquof(float x, float y, int *quo);
long double remquol(long double x, long double y, int *quo);
```

C++ TR1 C99

```
#define _TR1_C99
#include <math.h>

float remquo(float x, float y, int *quo);
long double remquo(long double x, long double y, int *quo);
```

General description

The remquo functions compute the same remainder as the remainder functions. In the object pointed to by *quo* they store a value whose sign is the sign of x/y and whose magnitude is congruent modulo 2 to the power n to the magnitude of the integral quotient of x/y , where n is an implementation defined integer greater than or equal to 3.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------|-----|------|
| remquo | X | X |
| remquof | X | X |
| remquol | X | X |

Restriction: The remquof() function does not support the _FP_MODE_VARIABLE feature test macro.

Returned value

The remquo functions return $x \text{ REM } y$.

Example

```
/*
 * This program illustrates the use of remquol() function
 *
 */
#define _ISOC99_SOURCE
#include <math.h>
#include <stdio.h>

void main() {
```

```

long double number1=3.0L, number2=3.5L;
int quo=0;

printf("Illustrates the remquol() function");

#ifdef _BFP
    printf(" (IEEE version)\n\n");
#else
    printf(" (HFP version)\n\n");
#endif

printf("remquol(%.2Lf,%.2Lf,&quo)=%.2Lf", number1, number2, remquol(number1, number2, &(quo)));
printf("    quo=%i\n", quo);
number1=1.0L; number2=2.0L;
printf("remquol(%.2Lf,%.2Lf,&quo)=%.2Lf", number1, number2, remquol(number1, number2, &(quo)));
printf("    quo=%i\n", quo);
number1=1.0L; number2=0.0L;
printf("remquol(%.2Lf,%.2Lf,&quo)=%.2Lf", number1, number2, remquol(number1, number2, &(quo)));
printf("    quo=%i\n", quo);
}

```

Output

Illustrates the remquol() function (IEEE version)

```

remquol(3.00,3.50,&quo)=-0.50    quo=1
remquol(1.00,2.00,&quo)=1.00    quo=0
remquol(1.00,0.00,&quo)=NaNQ(1) quo=0

```

Related information

__remquod32(), __remquod64(), __remquod128() — Computes the remainder.

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | z/OS V1.11 |

Format

```

#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 __remquod32(_Decimal32 x, _Decimal32 y, int *quo);
_Decimal64 __remquod64(_Decimal64 x, _Decimal64 y, int *quo);
_Decimal128 __remquod128(_Decimal128 x, _Decimal128 y, int *quo);

```

General description

The `__remquo()` functions compute the same remainder as the remainder functions. In the object pointed to by *quo* they store a value whose sign is the sign of *x* or *y* and whose magnitude is congruent modulo 2 to the power *n* to the magnitude of the integral quotient of *x* or *y*, where *n* is an implementation defined integer greater than or equal to 3.

Notes:

1. These functions work in IEEE decimal floating-point format. See [“IEEE decimal floating-point” on page 97](#) for more information.
2. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

The `__remquo()` functions return $x \text{ REM } y$.

Example

```
/* CELEBR24

   This example illustrates the __remquod64() function.

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>
void main() {
    _Decimal64 x, y, z;
    int n;

    x = 3.0DD;
    y = 3.5DD;
    z = __remquod64(x, y, &n);

    printf("__remquod64( %Df, %Df, %d ) = %Df\n", x, y, n, z);
}
```

rename() — Rename file

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdio.h>

int rename(const char *oldname, const char *newname);
```

General description

Changes the name of the file, from the name pointed to by *oldname* to the name pointed to by *newname*. The *oldname* pointer must point to the name of an existing file. The *newname* pointer must not specify the name of an existing file. You cannot rename an open file. In case of an error, the name of the file is not changed.

The `rename()` function renames memory files and DASD data sets. (Non-DASD data sets, such as tapes, are not supported.) It also renames individual members of PDSs (and PDSEs); it even renames files that simulate PDSs.

Special behavior for POSIX C: Memory files must be closed unless you are working under z/OS UNIX services.

The interpretation of the file name passed to `rename()` depends on whether the program is running POSIX(ON) or POSIX(OFF).

You cannot rename a z/OS UNIX file to an MVS data set name or rename an MVS data set to a z/OS UNIX file name.

Both *oldname* and *newname* must be of the same type, that is, both directories or both files.

If *newname* already exists, it is removed before *oldname* is renamed to *newname*. Thus, if *newname* specifies the name of an existing directory, it must be an empty directory.

If the *oldname* argument points to a symbolic link, the symbolic link is renamed. If the *newname* argument points to a symbolic link, the link is removed and *oldname* is renamed to *newname*. `rename()` does not affect any file or directory named by the contents of the symbolic link.

For `rename()` to succeed, the process needs write permission on the directory containing *oldname* and the directory containing *newname*. If *oldname* and *newname* are directories, `rename()` also needs write permission on the directories themselves.

If *oldname* and *newname* both refer to the same file, `rename()` returns successfully and performs no other action.

When `rename()` is successful, it updates the change and modification times for the parent directories of *oldname* and *newname*.

Returned value

If successful, `rename()` returns 0.

If unsuccessful, `rename()` returns nonzero and sets `errno` to one of the following values:

Error Code Description

EACCES

An error occurred for one of these reasons:

- The process did not have search permission on some component of the old or new path name.
- The process did not have write permission on the parent directory of the file or directory to be renamed.
- *oldname* or *newname* were directories.
- The process did not have write permission on *oldname* or *newname*.

EBUSY

oldname and *newname* specify directories, but one of them cannot be renamed because it is in use as a root or a mount point.

EINVAL

This error occurs for one of these reasons:

- *oldname* is part of the path name prefix of *newname*.
- *oldname* or *newname* refers to either `.` (dot) or `..` (dot-dot).

EIO

A physical I/O error has occurred.

EISDIR

newname is a directory, but *oldname* is not a directory.

ELOOP

A loop exists in symbolic links. This error is issued if the number of symbolic links encountered during resolution of *oldname* or *newname* is greater than `POSIX_SYMLINK_MAX`.

ENAMETOOLONG

pathname is longer than `PATH_MAX` characters, or some component of *pathname* is longer than `NAME_MAX` characters while `_POSIX_NO_TRUNC` is in effect. For symbolic links, the length of

the path name string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values can be determined using `pathconf()`.

ENOENT

No file or directory named *oldname* was found, or either *oldname* or *newname* was not specified.

ENOSPC

The directory intended to contain *newname* cannot be extended.

ENOTDIR

A component of the path name prefix for *oldname* or *newname* is not a directory, or *oldname* is a directory and *newname* is a file that is not a directory.

ENOTEMPTY

newname specifies a directory, but the directory is not empty.

EPERM or EACCES

The `S_ISVTX` flag is set on the directory containing the file referred to by *oldname* and the caller is not the file owner, nor is the caller the directory owner, nor does the caller have appropriate privileges; or *newname* refers to an existing file, the `S_ISVTX` flag is set on the directory containing this file and the caller is not the file owner, nor is the caller the directory owner, nor does the caller have appropriate privileges.

EROFS

Renaming would require writing on a read-only file system.

EXDEV

oldname and *newname* identify files or directories on different file systems. z/OS UNIX services do not support links between different files systems.

Example

CELEBR13

```
/* CELEBR13

   This example takes two file names as input and uses rename() to change
   the file name from the first name to the second name.

*/
#include <stdio.h>

int main(int argc, char ** argv )
{
    if ( argc != 3 )
        printf( "Usage: %s old_fn new_fn\n", argv[0] );
    else if ( rename( argv[1], argv[2] ) != 0 )
        printf( "Could not rename file\n" );
}
```

Related information

renameat() — Change the name or location of a file

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1-2008 Single UNIX Specification, Version 4 | both | |

Format

```
#define _POSIX_C_SOURCE 200809L
#include <fcntl.h>
#include <stdio.h>
int renameat(int olddirfd, const char *oldpath, int newdirfd, const char *newpath);
```

General description

`renameat()` changes the name of the file from the name that is pointed to by *oldpath* to the name that is pointed to by *newpath*.

If *oldpath* is relative, it is interpreted relative to the directory that is referred to by the file descriptor *olddirfd* (rather than relative to the current working directory of the calling process, as is done by `rename()` for a relative path name).

If *oldpath* is relative and *olddirfd* is the special value `AT_FDCWD`, *oldpath* is interpreted relative to the current working directory of the calling process (like `rename()`).

If *oldpath* is absolute, *olddirfd* is ignored.

The interpretation of *newpath* is as for *oldpath*, except that a relative path name is interpreted relative to the directory that is referred to by the file descriptor *newdirfd*.

Returned value

If successful, `renameat()` returns 0.

If unsuccessful, `renameat()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

- The process does not have search permission on some component of *oldpath* or *newpath*.
- The process does not have write permission on *oldpath* or *newpath* or on the parent directory of the file or directory to be renamed.

EAGAIN

One of the files or directories is temporarily unavailable.

EBUSY

oldpath and *newpath* specify directories, but one of them cannot be renamed because it is in use as a root or a mount point.

EINVAL

- *oldpath* is part of the path name prefix of *newpath*.
- *oldpath* or *newpath* refers to either `.` (dot) or `..` (dot-dot).

EISDIR

newpath is a directory, but *oldpath* is not a directory.

ELOOP

A loop exists in symbolic links. This error is issued if the number of symbolic links that are encountered during the resolution of *newpath* or *oldpath* is greater than `POSIX_SYMLINK_MAX`.

ENAMETOOLONG

The path name is longer than `PATH_MAX` characters, or some component of the path name is longer than `NAME_MAX` characters while `_POSIX_NO_TRUNC` is in effect. For symbolic links, the length of the path name string that is substituted for a symbolic link exceeds `PATH_MAX`. The `PATH_MAX` and `NAME_MAX` values can be determined by using `pathconf()`.

ENOENT

No file or directory that is named *oldpath* is found, or either *oldpath* or *newpath* is not specified.

ENOSPC

The directory that is intended to contain *newpath* cannot be extended.

ENOTDIR

A component of the path name prefix for *oldpath* or *newpath* is not a directory, or *oldpath* is a directory and *newpath* is a file but not a directory.

ENOTEMPTY

newpath specifies a directory that is not empty.

EROFS

Renaming requires writing on a read-only file system.

EXDEV

oldpath and *newpath* identify files or directories on different file systems. z/OS UNIX does not support links between different files systems.

EBADF

- *oldpath* is relative but *olddirfd* is not a valid file descriptor.
- *newpath* is relative but *newdirfd* is not a valid file descriptor.

ENOTDIR

- *oldpath* is relative and *olddirfd* is a file descriptor that refers to a file other than a directory.
- *newpath* is relative and *newdirfd* is a file descriptor that refers to a file other than a directory;

Related information

renameat2() — Change the name or location of a file

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <fcntl.h>
#include <stdio.h>

int renameat2(int olddirfd, const char *oldpath, int newdirfd, const char *newpath, unsigned
int flags);
```

General description

renameat2() has an extra *flags* argument comparing to renameat(). A renameat2() call without the *flags* argument is equivalent to renameat().

The *flags* argument is a bit mask that consists of zero or the following flag:

RENAME_NOREPLACE

Do not overwrite *newpath*. Return an error if *newpath* exists.

Returned value

If successful, `renameat2()` returns 0.

If unsuccessful, `renameat2()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

- The process does not have search permission on some component of *oldpath* or *newpath*.
- The process does not have the write permission on *oldpath* or *newpath* or on the parent directory of the file or directory to be renamed.

EAGAIN

One of the files or directories is temporarily unavailable.

EBUSY

oldpath and *newpath* specify directories, but one of them cannot be renamed because it is in use as a root or a mount point.

EINVAL

- *oldpath* is part of the path name prefix of *newpath*.
- *oldpath* or *newpath* refers to either `.` (dot) or `..` (dot-dot).
- An invalid flag was specified in *flags*.

EISDIR

newpath is a directory, but *oldpath* is not a directory.

ELOOP

A loop exists in symbolic links. This error is issued if the number of symbolic links that are encountered during the resolution of *oldpath* or *newpath* is greater than `POSIX_SYMLINK_MAX`.

ENAMETOOLONG

The path name is longer than `PATH_MAX` characters, or some component of the path name is longer than `NAME_MAX` characters while `_POSIX_NO_TRUNC` is in effect. For symbolic links, the length of the path name string that is substituted for a symbolic link exceeds `PATH_MAX`. The `PATH_MAX` and `NAME_MAX` values can be determined by using `pathconf()`.

ENOENT

No file or directory that is named *oldpath* is found, or either *oldpath* or *newpath* is not specified.

ENOSPC

The directory that is intended to contain *newpath* cannot be extended.

ENOTDIR

A component of the path name prefix for *oldpath* or *newpath* is not a directory, or *oldpath* is a directory and *newpath* is a file but not a directory.

ENOTEMPTY

newpath specifies a directory that is not empty.

EROFS

Renaming requires writing on a read-only file system.

EXDEV

oldpath and *newpath* identify files or directories on different file systems. z/OS UNIX do not support links between different files systems.

res_init() — Domain name resolver initialization

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| BSD 4.3 | both | OS/390 V2R8 |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
#include <netinet/in.h>
#include <arpa/nameser.h>
#include <resolv.h>

int res_init(void);
struct __res_state _res;
```

General description

The `res_init()` function is the Resolver function that initializes the `__res_state` structure for use by other Resolver functions. Initialization normally occurs on the first call to any of the IP address resolution routines commonly called the XL C/C++ Runtime Library Resolver.

The `res_init()` routine does its initialization by passing the `__res_state` structure to the CS for z/OS Resolver. The Resolver reads the "TCPIP.DATA" configuration file and updates the `__res_state` structure. The data in the `__res_state` structure is filled in based on the contents of the "TCPIP.DATA" configuration file and can then be referenced in the `_res` variable. Global configuration and state information that is used by the Resolver routines is kept in the structure `_res`. Most of the values have reasonable defaults and can be left unchanged.

Value

Description

`_res.retrans`

Retransmission time interval is taken from the `ResolverTimeOut` statement found in the "TCPIP.DATA" configuration file.

`_res.retry`

The number of times to retransmit a request. It is taken from the `ResolverUDPRetries` statement found in the "TCPIP.DATA" configuration file.

`_res.options`

Options stored in `_res.options` are defined in `<resolv.h>` and are listed below. Options are stored as a simple bit mask containing the bitwise OR of the options enabled.

Option

Description

RES_INIT

True after the initial name server address and default domain name are initialized, because `res_init()` has been called. This option should only be tested but not set, except by the `res_init()` function.

RES_DEBUG

Print debugging messages.

RES_AAONLY

Accept authoritative answers only. With this option, `res_send()` should continue until it finds an authoritative answer or finds an error. Currently this is not implemented.

RES_USEVC

Use TCP connections for queries instead of UDP datagrams.

RES_STAYOPEN

Used with `RES_USEVC` to keep the TCP connection open between queries. This is useful only in programs that regularly do many queries. UDP should be the normal mode used.

RES_IGNTC

Ignore truncation errors, that is, don't retry with TCP. Currently unused.

RES_RECURSE

Set the recursion-desired bit in queries. This is the default. (`res_send()` does not do iterative queries and expects the name server to handle recursion.)

RES_DEFNAMES

If set, `res_search()` will append the default domain name to single-component names (those that do not contain a dot). This option is enabled by default.

RES_DNSRCH

If this option is set, `res_search()` will search for host names in the current domain and in parent domains. This is used by the standard host lookup routine `gethostbyname()`. This option is enabled by default.

RES_NOALIASES

This option turns off the user level aliasing feature controlled by the "HOSTALIASES" environment variable. Network daemons should set this option.

_res.nscount

The number of name servers specified in the "TCPIP.DATA" configuration file.

_res.*nsaddr_list[0]

The addresses of name servers specified by the `NSINTERADDR` or `NameServer` statements found in the "TCPIP.DATA" configuration file.

_res.dnsrch[0]

The beginning of the list of domains to be searched, as specified in the `SEARCH` statement found in the "TCPIP.DATA" configuration file. The structure will have either a `Default DOMAIN` or `SEARCH`.

_res.defdname[0]

The `Default Domain` name, as specified in the `Domain` or `DomainOrigin` statement found in the "TCPIP.DATA" configuration file. The structure will have either a `Default DOMAIN` or `SEARCH`.

_res.pfcode

Currently this is not implemented.

_res.ndots

The threshold for the number of dots in the domain name, as specified by the `OPTIONS` statement value `ndots:n` found in the "TCPIP.DATA" configuration file. The default is 1.

_res.nsort

The number of elements in `sort_list[]` as listed in the `SORTLIST` statement found in the "TCPIP.DATA" configuration file.

_res.sort_list[0]

The network address and subnet mask in the `SORTLIST` statement found in the "TCPIP.DATA" configuration file.

Returned value

If successful, `res_init()` returns 0.

If unsuccessful, `res_init()` returns -1 and sets `h_errno` to one of the following values:

Error Code

Description

NO_RECOVERY

An error occurred that will continue to fail if tried again. Storage could not be obtained for this thread to contain the `_res` structure.

TRY_AGAIN

An error occurred while initializing the `__res_state` structure name selected, which can be retried.

If successful, `_res` returns the address of `__res_state` structure.

If unsuccessful, `_res` returns NULL and sets `errno` to one of the following values:

Error Code

Description

ENOMEM

The storage needed to define the `_res` structure could not be obtained.

res_mkquery() — Make resolver query for domain name servers

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| BSD 4.3 | both | OS/390 V2R8 |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
```

```
#include <netinet/in.h>
#include <arpa/nameser.h>
#include <resolv.h>

int res_mkquery(int op, const char *dname, int class, int type, const u_char *data,
               int datalen, const u_char *newrr_in, u_char *buf, int buflen);
```

General description

This routine is one of several functions used for making, sending and interpreting query and reply messages with Internet domain name servers (DNS).

The `res_mkquery()` function constructs a standard query message and places it in *buf*. It returns the size of the query, or -1 if the query is larger than *buflen*. The query type *op* is usually QUERY, but can be any of the query types defined in `<arpa/nameser.h>`. The domain name for the query given by *dname*. The argument *newrr_in* is currently unused but is intended for making update messages.

Note: The `res_mkquery()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support” on page 2123](#) for details.

Returned value

If successful, `res_mkquery()` returns the size of the query.

If unsuccessful, `res_mkquery()` returns -1. The errors defined in `<arpa/nameser.h>` can be found in the *buf.rcode*, if an answer was supplied in the *buf* buffer.

res_query() — Resolver query for domain name servers

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| BSD 4.3 | both | OS/390 V2R8 |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
```

```
#include <netinet/in.h>
#include <arpa/nameser.h>
#include <resolv.h>

int res_query(const char *dname, int class, int type, u_char *answer, int anslen);
```

General description

This routine is one of several functions used for making, sending and interpreting query and reply messages with Internet domain name servers (DNS).

The `res_query()` function provides an interface to the server query mechanism. It constructs a query, sends it to the local server, awaits a response, and makes preliminary checks on the reply. The query requests information of the specified type and class for the specified fully-qualified domain name *dname*. The reply message is left in the *answer* buffer with length *anslen* supplied by the caller.

Note: The `res_query()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support”](#) on page 2123 for details.

Returned value

If successful, `res_query()` returns the reply message in the *answer* buffer with length *anslen*.

If unsuccessful, `res_query()` returns -1 and sets `herrno` to one of the following values:

Error Code

Description

HOST_NOT_FOUND

The host name provided is not known at any of the domain name servers queried for this request.

NO_DATA

An answer was received but no data was supplied in the *answer* buffer.

NO_RECOVERY

An error occurred that will continue to fail if tried again.

TRY_AGAIN

A error occurred querying the name selected, which can be retried.

res_querydomain() – Build domain name and resolver query

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| BSD 4.3 | both | OS/390 V2R8 |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
#include <netinet/in.h>
#include <arpa/nameser.h>
#include <resolv.h>

int res_querydomain(const char *name, const char *domain, int class, int type,
                   u_char *answer, int anslen);
```

General description

This routine is one of several functions used for making, sending and interpreting query and reply messages with Internet domain name servers (DNS).

The `res_querydomain()` function builds a fully qualified domain name and returns a `res_query()` to the caller.

Note: The `res_querydomain()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support”](#) on page 2123 for details.

Returned value

If successful, `res_querydomain()` returns a `res_query()` to the caller.

If unsuccessful, `res_querydomain()` returns -1 and sets `herrno` to one of the following values:

Error Code

Description

HOST_NOT_FOUND

The host name provided is not known at any of the domain name servers queried for this request.

NO_DATA

An answer was received but no data was supplied in the *answer* buffer.

NO_RECOVERY

An error occurred that will continue to fail if tried again.

TRY_AGAIN

A error occurred querying the name selected, which can be retried.

res_search() — Resolver query for domain name servers

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| BSD 4.3 | both | OS/390 V2R8 |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
#include <netinet/in.h>
#include <arpa/nameser.h>
#include <resolv.h>

int res_search(const char *dname, int class, int type, u_char *answer, int anslen);
```

General description

This routine is one of several functions used for making, sending and interpreting query and reply messages with Internet domain name servers (DNS).

The `res_search()` routine makes a query and awaits a response like `res_query()` but, in addition, it implements the default and search rules controlled by the `RES_DEFNAMES` and `RES_DNSRCH` options. It returns the first successful reply.

Note: The `res_search()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support”](#) on page 2123 for details.

Returned value

If successful, `res_search()` returns the first successful reply.

If unsuccessful, `res_search()` returns -1 and sets `herrno` to one of the following values:

Error Code

Description

HOST_NOT_FOUND

The host name provided is not known at any of the domain name servers queried for this request.

NO_DATA

An answer was received but no data was supplied in the *answer* buffer.

NO_RECOVERY

An error occurred that will continue to fail if tried again.

TRY_AGAIN

A error occurred querying the name selected, which can be retried.

res_send() — Send resolver query for domain name servers

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| BSD 4.3 | both | OS/390 V2R8 |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
#include <netinet/in.h>
#include <arpa/nameser.h>
#include <resolv.h>

int res_send(const u_char *msg, int msglen, u_char *answer, int anslen);
```

General description

This routine is one of several functions used for sending query and reply messages with Internet domain name servers (DNS).

The `res_send()` routine sends a pre-formatted query and returns an answer. It will call `res_init()` if `RES_INIT` is not set, send the query to the local name server, and handle timeouts and retries. The length of the reply message is returned, or -1 if there were errors.

Note: The `res_send()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support ” on page 2123](#) for details.

Returned value

If successful, `res_send()` returns the length of the reply message.

If unsuccessful, `res_send()` returns -1. The errors defined in `<arpa/nameser.h>` can be found in the `buf.rcode`, if an answer was supplied in the `answer` buffer.

__reset_exception_handler() — Unregister an exception handler routine

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | |

Format

```
#include <__le_api.h>

int __reset_exception_handler(void);
```

General description

A nonstandard function that unregisters the 'Exception Handler' function, that was previously registered via the `__set_exception_handler()` function, for the current stack frame.

Returned value

If successful, `__reset_exception_handler()` returns 0. Otherwise, -1 is returned and `errno` is set to indicate the error. The following is a possible value for `errno`:

- `EINVAL` — No Exception Handler is registered in the current stack frame.

Related information

- [“__set_exception_handler\(\) — Register an exception handler routine” on page 1528](#)

rewind() – Set file position to beginning of file

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```
#include <stdio.h>

void rewind(FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

void rewind_unlocked(FILE *stream);
```

General description

Repositions the file position indicator of the stream pointed to by *stream*. A call to `rewind()` is the same as the statement below, except that `rewind()` also clears the error indicator for the *stream*.

```
(void) fseek(stream, 0L, SEEK_SET);
```

`rewind_unlocked()` is functionally equivalent to `rewind()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

`rewind()` returns no values.

If an error occurs, `errno` is set. After the error, the file position does not change. The next operation may be either a read or a write operation.

Special behavior for XPG4.2: The `rewind()` function returns -1 and sets `errno` to `ESPIPE` if the underlying file type for the stream is a PIPE or a socket.

Example

CELEBR14

```
/* CELEBR14

   This example first opens a file myfile for input
   and output.
   It writes integers to the file, uses &rewind. to reposition
   the file pointer to the beginning of the file, and then reads
   the data back in.

*/
#include <stdio.h>

int main(void)
{
```

```
FILE *stream;
int data1, data2, data3, data4;
data1 = 1; data2 = -37;

/* Place data in the file */
stream = fopen("myfile.dat", "w+");
fprintf(stream, "%d %d\n", data1, data2);

/* Now read the data file */
rewind(stream);
fscanf(stream, "%d", &data3);
fscanf(stream, "%d", &data4);
printf("The values read back in are: %d and %d\n",
      data3, data4);
}
```

Output

The values read back in are: 1 and -37

Related information

- [“stdio.h – Standard input and output” on page 63](#)
- [“fgetpos\(\) – Get file position” on page 534](#)
- [“fseek\(\) – Change file position” on page 638](#)

rewinddir() – Reposition a directory stream to the beginning

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define POSIX_SOURCE
#include <dirent.h>

void rewinddir(DIR *dir);
```

General description

Repositions an open directory stream to the beginning. *dir* points to a DIR object associated with an open directory.

The next call to readdir() reads the first entry in the directory. If the contents of the directory have changed since the directory was opened, a call to rewinddir() updates the directory stream so that a subsequent readdir() can read the new contents.

Returned value

rewinddir() returns no values.

Example

CELEBR15

```

/* CELEBR15

   This example produces the contents of a directory by opening it,
   rewinding it, and closing it.

   */
#define _POSIX_SOURCE
#include <dirent.h>
#include <errno.h>
#include <sys/types.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
    DIR *dir;
    struct dirent *entry;

    if ((dir = opendir("/")) == NULL)
        perror("opendir() error");
    else {
        puts("contents of root:");
        while ((entry = readdir(dir)) != NULL)
            printf("%s ", entry->d_name);
        rewinddir(dir);
        puts("");
        while ((entry = readdir(dir)) != NULL)
            printf("%s ", entry->d_name);
        closedir(dir);
        puts("");
    }
}

```

Output

```

contents of root:
. .. bin dev etc lib tmp u usr
. .. bin dev etc lib tmp u usr

```

rexec() — Execute commands one at a time on a remote host

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | POSIX(ON) |

Format

```
#include <rexec.h>

int rexec(char **Host, int Port, char *User, char *Password,
          char *Command, int *ErrFileDescParam)
```

General description

The rexec (remote execution) subroutine allows the calling process to execute commands on a remote host. If the rexec connection succeeds, a socket in the Internet domain of type SOCK_STREAM is returned to the calling process and is given to the remote command as standard input and standard output.

Host contains the name of a remote host that is listed in the /etc/hosts file or /etc/resolv.config file. If the name of the host is not found in either file, the rexec fails.

Port specifies the well-known Defense Advanced Research Projects Agency (DARPA) Internet port to use for the connection. A pointer to the structure that contains the necessary port can be obtained by issuing the following library call: getservbyname("exec","tcp").

User and Password points to a user ID and password valid at the host. Password phrases are not supported.

Command points to the name of the command to be executed at the remote host.

ErrFileDescParam specifies one of the following values:

- Not 0 (zero) = an auxiliary channel to a control process is set up, and a descriptor for it is placed in the ErrFileDescParam parameter. The control process provides diagnostic output from the remote command on this channel and also accepts bytes as signal numbers to be forwarded to the process group of the command. This diagnostic information does not include remote authorization failure, since this connection is set up after authorization has been verified.
- 0 (zero) = the standard error of the remote command is the same as standard output, and no provision is made for sending arbitrary signals to the remote process. In this case, however, it may be possible to send out-of-band data to the remote command.

This function is supported only in a POSIX program.

Note: The rexec() function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support ” on page 2123](#) for details.

Returned value

If rexec() is successful, the system returns a socket to the remote command.

If rexec() is unsuccessful, the system returns a -1 indicating that the specified host name does not exist.

Related information

- [“rexec.h — rexec\(\) and rexec_af\(\) functions” on page 57](#)
- [“getservbyname\(\) — Get a server entry by name” on page 772](#)
- [“rexec_af\(\) — Execute commands one at a time on a remote host” on page 1452](#)

rexec_af() — Execute commands one at a time on a remote host

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| RCF2292 | both | z/OS V1R4 |

Format

```
#define _OPEN_SYS_SOCKET_IPV6
#include <rexec.h>

int rexec_af(char **ahost, unsigned short rport,
             const char *name, const char *pass, const char *cmd,
             int *fd2p, int af);
```

General description

The `rexec_af()` function behaves the same as the `rexec()` function. Instead of creating an `AF_INET` socket, `rexec_af` can also create an `AF_INET6` socket. The *af* argument specifies the address family. It is set to either `AF_INET` or `AF_INET6`.

Note: The `rexec_af()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support”](#) on page 2123 for details.

Returned value

When successful, `rexec_af()` returns a socket to the remote command. If unsuccessful, `rexec_af()` returns -1 and may set `errno` to one of the following:

EAFNOSUPPORT

The specified address family is not supported.

Related information

- [“rexec.h — rexec\(\) and rexec_af\(\) functions”](#) on page 57

rindex() — Search for character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <strings.h>

char *rindex(const char *string, int c);
```

General description

The `rindex()` function locates the last occurrence of *c* (converted to an unsigned char) in the string pointed to by *string*.

The string argument to the function must contain a NULL character (`\0`) marking the end of the string.

The `rindex()` function is identical to [“strrchr\(\) — Find last occurrence of character in string”](#) on page 1753.

Note: The `rindex()` function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The `strrchr()` function is preferred for portability.

Returned value

If successful, `rintex()` returns a pointer to the first occurrence of `c` (converted to an unsigned character) in the string pointed to by *string*.

If `c` was not found, `rintex()` returns a NULL pointer.

There are no `errno` values defined.

rint(), rintf(), rintl() — Round to nearest integral value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <math.h>

double rint(double x);
```

C99

```
#define _ISOC99_SOURCE
#include <math.h>

float rintf(float x);
long double rintl(long double x);
```

C++ TR1 C99

```
#define _TR1_C99
#include <math.h>

float rint(float x);
long double rint(long double x);
```

General description

The `rint()` functions return the integral value (represented in a floating-point mode) nearest `x` using the round to nearest mode and may raise the "inexact" floating-point exception if the result differs in value from the argument.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------|-----|------|
| rint | X | X |
| rintf | X | X |
| rintl | X | X |

Returned value

rint() is always successful in IEEE.

Special behavior for hex: The rint() functions always round toward zero in hexadecimal math.

Related information

rintd32(), rintd64(), rintd128() — Round to nearest integral value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 rintd32(_Decimal32 x);
_Decimal64 rintd64(_Decimal64 x);
_Decimal128 rintd128(_Decimal128 x);

_Decimal32 rint(_Decimal32 x);      /* C++ only */
_Decimal64 rint(_Decimal64 x);     /* C++ only */
_Decimal128 rint(_Decimal128 x);   /* C++ only */
```

General description

These functions return the integral value (represented in a decimal floating-point mode) nearest *x* according to the rounding mode and might raise the "inexact" decimal floating-point exception if the result differs in value from the argument.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

These functions are always successful.

Example

```

/* CELEBR21

   This example illustrates the rintd32() function.
*/

#pragma strings(readonly)

#define __STDC_WANT_DEC_FP__
#include <fenv.h>
#include <math.h>
#include <stdio.h>

static void try_rm(int);

/* pass back printable rounding mode */

static
char *rm_str(int rm)
{
    char *s = "undetermined";

    switch (rm)
    {
        case FE_DEC_TONEAREST :
            s = "FE_DEC_TONEAREST" ; break;
        case FE_DEC_TOWARDZERO :
            s = "FE_DEC_TOWARDZERO" ; break;
        case FE_DEC_UPWARD :
            s = "FE_DEC_UPWARD" ; break;
        case FE_DEC_DOWNWARD :
            s = "FE_DEC_DOWNWARD" ; break;
        case FE_DEC_TONEARESTFROMZERO :
            s = "FE_DEC_TONEARESTFROMZERO" ; break;
        case _FE_DEC_TONEARESTTOWARDZERO :
            s = "_FE_DEC_TONEARESTTOWARDZERO" ; break;
        case _FE_DEC_AWAYFROMZERO :
            s = "_FE_DEC_AWAYFROMZERO" ; break;
        case _FE_DEC_PREPAREFORSHORTER :
            s = "_FE_DEC_PREPAREFORSHORTER" ; break;
    }

    return s;
}

/* Try out one passed-in number with rounding mode */

static void try_rm(int rm)
{
    _Decimal32 r32;
    _Decimal32 d32 = 500.99DF;

    (void)fe_dec_setround(rm);

    r32 = rintd32(d32);

    printf("rintd32(%.2HF) = %HG - rounding mode = %s\n",
        d32, r32, rm_str(rm)
    );

    return;
}

int main()
{
    try_rm( FE_DEC_TONEAREST );
    try_rm( FE_DEC_TOWARDZERO );
    try_rm( FE_DEC_UPWARD );
    try_rm( FE_DEC_DOWNWARD );
    try_rm( FE_DEC_TONEARESTFROMZERO );
    try_rm( _FE_DEC_TONEARESTTOWARDZERO );
    try_rm( _FE_DEC_AWAYFROMZERO );
    try_rm( _FE_DEC_PREPAREFORSHORTER );

    return 0;
}

```

rmdir() — Remove a directory

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define POSIX_SOURCE
#include <unistd.h>

int rmdir(const char *pathname);
```

General description

Removes a directory, *pathname*, provided that the directory is empty. *pathname* must not end in . (dot) or .. (dot-dot).

If *pathname* refers to a symbolic link, `rmdir()` does not affect any file or directory named by the contents of the symbolic link. `rmdir()` does not remove a directory that still contains files or subdirectories.

Special behavior for XPG4.2: If *pathname* refers to a symbolic link, `rmdir()` fails and sets `errno` to `ENOTDIR`.

If no process currently has the directory open, `rmdir()` deletes the directory itself. The space occupied by the directory is freed for new use. If one or more processes have the directory open when it is removed, the directory itself is not removed until the last process closes the directory. New files cannot be created under a directory after the last link is removed, even if the directory is still open.

`rmdir()` removes the directory even if it is the working directory of a process.

If `rmdir()` is successful, the change and modification times for the parent directory are updated.

Returned value

If successful, `rmdir()` returns 0.

If unsuccessful, `rmdir()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

The process did not have search permission for some component of *pathname*, or it did not have write permission for the directory containing the directory to be removed.

EBUSY

pathname cannot be removed, because it is currently being used by the system or a process.

EINVAL

The last component of *pathname* contains a . (dot) or a .. (dot-dot).

EIO

A physical I/O error has occurred.

ELOOP

A loop exists in symbolic links. More than POSIX_SYMLINK_MAX (an integer defined in the limits.h header file) symbolic links are detected in the resolution of *pathname*.

ENAMETOOLONG

pathname is longer than **PATH_MAX** characters or some component of *pathname* is longer than **NAME_MAX** characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the path name string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values can be determined using pathconf().

ENOENT

pathname does not exist, or it is an empty string.

ENOTDIR

Some component of the *pathname* prefix is not a directory.

ENOTEMPTY

The directory still contains files or subdirectories.

EPERM or EACCES

The S_ISVTX flag is set on the parent directory of the directory to be removed and the caller is not the owner of the directory to be removed, nor is the caller the owner of the parent directory, nor does the caller have the appropriate privileges.

EROFS

The directory to be removed is on a read-only file system.

Example**CELEBR16**

```
/* CELEBR16

   This example removes a directory.

*/
#define _OPEN_SYS
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/stat.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
    char new_dir[]="new_dir";
    char new_file[]="new_dir/new_file";
    int fd;

    if (mkdir(new_dir, S_IRWXU|S_IRGRP|S_IXGRP) != 0)
        perror("mkdir() error");
    else if ((fd = creat(new_file, S_IWUSR)) < 0)
        perror("creat() error");
    else {
        close(fd);
        unlink(new_file);
    }

    if (rmdir(new_dir) != 0)
        perror("rmdir() error");
    else
        puts("removed!");
}
```

round(), roundf(), roundl() — Round to the nearest integer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _ISOC99_SOURCE
#include <math.h>

double round(double x);
float roundf(float x);
long double roundl(long double x);
```

C++ TR1 C99

```
#define _TR1_C99
#include <math.h>

float round(float x);
long double round(long double x);
```

General description

The `round()` family of functions round x to the nearest integer, in floating-point format and rounding halfway cases away from zero, regardless of the current rounding mode.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|---------------------|-----|------|
| <code>round</code> | X | X |
| <code>roundf</code> | X | X |
| <code>roundl</code> | X | X |

Returned value

The `round()` family of functions returns the rounded integer value.

roundd32(), roundd64(), roundd128() – Round to the nearest integer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 roundd32(_Decimal32 x);
_Decimal64 roundd64(_Decimal64 x);
_Decimal128 roundd128(_Decimal128 x);

_Decimal32 round(_Decimal32 x);      /* C++ only */
_Decimal64 round(_Decimal64 x);      /* C++ only */
_Decimal128 round(_Decimal128 x);    /* C++ only */
```

General description

These functions round x to the nearest integer, in decimal floating-point format and rounding halfway cases away from zero, regardless of the current rounding mode.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

These functions return the rounded integer value.

Example

```
/* CELEBR22

   This example illustrates the round64() function.
*/

#pragma strings(readonly)

#define __STDC_WANT_DEC_FP__
#include <fenv.h>
#include <math.h>

rpmatch() — Test for a yes or no response match

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <stdlib.h>

int rpmatch(const char *response);
```

External entry point: @@RPMATCH, __rpmatch

General description

Tests whether a string pointed to by *response* matches either the affirmative or the negative response set by LC_MESSAGES category in the current locale.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

Returned value

If the string pointed to by *response* matches the affirmative expression in the current locale, rpmatch() returns:

1

If the response string matches the affirmative expression.

0

If the response string matches the negative expression.

-1

If the response string does not match either the affirmative or the negative expression.

Example

CELEBR17

```
/* CELEBR17

   This example asks for a reply, and checks the response.

*/
#include "locale.h"
#include "stdio.h"
#include "stdlib.h"

main() {
    char *response;
    char buffer??(100??);
    int rc;

    printf("Enter reply");
    response = fgets(buffer, 100, stdin);
    rc = rpmatch(response);
    if (rc > 0)
        printf("Response was affirmative\n");
    else if (rc == 0)
        printf("Response was negative\n");
    else
        printf("Response was neither negative or affirmative\n");
}
```

samequantumd32(), samequantumd64(), samequantumd128() — Determine if exponents X and Y are the same

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Bool samequantumd32(_Decimal32 x, _Decimal32 y);
_Bool samequantumd64(_Decimal64 x, _Decimal64 y);
_Bool samequantumd128(_Decimal128 x, _Decimal128 y);
```

General description

The samequantum functions determine if the representation exponents of x and y are the same. If both x and y are NaN or infinity, they have the same representation exponents. If exactly one operand is infinity or exactly one operand is NaN, they do not have the same representation exponents. The samequantum functions raise no floating point exceptions.

| Argument | Description |
|----------|--------------------|
| x | First input value |
| y | Second input value |

Note:

- To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
- These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

The samequantum functions return true when x and y have the same representation exponents, and false otherwise.

Example

```
/* CELEBS72
   This example illustrates the samequantumd64() function
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
```

```
_Decimal64 a1 = strtod64("1.23" , NULL);
_Decimal64 a2 = strtod64("0.01" , NULL);
_Decimal64 b1 = strtod64("1.234" , NULL);
_Decimal64 b2 = strtod64("0.01" , NULL);
_Decimal64 c1 = strtod64("1.000" , NULL);
_Decimal64 c2 = strtod64("1.00" , NULL);
_Decimal64 d1 = strtod64("0.000" , NULL);
_Decimal64 d2 = strtod64("0.00" , NULL);

printf( "x=%-8.2DF y=%-8.2DF samequantum=%d\n"
        "x=%-8.3DF y=%-8.2DF samequantum=%d\n"
        "x=%-8.3DF y=%-8.2DF samequantum=%d\n"
        "x=%-8.3DF y=%-8.2DF samequantum=%d\n"
        , a1, a2, (int)samequantumd64(a1, a2)
        , b1, b2, (int)samequantumd64(b1, b2)
        , c1, c2, (int)samequantumd64(c1, c2)
        , d1, d2, (int)samequantumd64(d1, d2)
        );

return 0;
}

sbrk() — Change space allocation

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 2 | both | |

Format

Non-Single UNIX Specification, Version 2:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

void *sbrk(int incr);
```

Single UNIX Specification, Version 2:

```
#define _XOPEN_SOURCE 500
#include <unistd.h>

void *sbrk(intptr_t incr);
```

General description

Restriction: This function is not supported in AMODE 64.

The sbrk() function is used to change the space allocated for the calling process. The change is made by adding incr bytes to the process's break value and allocating the appropriate amount of space. The amount of allocated space increases when incr is positive and decreases when incr is negative. If incr is zero the current value of the program break is returned by sbrk(). The newly-allocated space is set to

0. However, if the application first decrements and then increments the break value, the contents of the reallocated space are not zeroed.

The storage space from which the `brk()` and `sbrk()` functions allocate storage is separate from the storage space that is used by the other memory allocation functions (`malloc()`, `calloc()`, etc.). Because this storage space must be a contiguous segment of storage, it is allocated from the initial heap segment only and thus is limited to the initial heap size specified for the calling program or the largest contiguous segment of storage available in the initial heap at the time of the first `brk()` or `sbrk()` call. Since this is a separate segment of storage, the `brk()` and `sbrk()` functions can be used by an application that is using the other memory allocation functions. However, it is possible that the user's region may not be large enough to support extensive usage of both types of memory allocation.

Prior usage of the `sbrk()` function has been limited to specialized cases where no other memory allocation function performed the same function. Because the `sbrk()` function may be unable to sufficiently increase the space allocation of the process when the calling application is using other memory functions, the use of other memory allocation functions, such as `mmap()`, is now preferred because it can be used portably with all other memory allocation functions and with any function that uses other allocation functions. Applications that require the use of `brk()` and/or `sbrk()` should refrain from using the other memory allocation functions and should be run with an initial heap size that will satisfy the maximum storage requirements of the program.

The `sbrk()` function is not supported from a multithreaded environment, it will return in error if it is invoked in this environment.

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use `malloc()` instead of `brk()` or `sbrk()`.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

If successful, `sbrk()` returns the previous break value.

If unsuccessful, `sbrk()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

ENOMEM

The requested change would allocate more space than allowed for the calling process.

scalb() — Load exponent

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <math.h>

double scalb(double x, double n);
```

General description

The scalb() function computes $x \cdot radix^n$.

If *n* is not an integer, it is silently truncated.

Note: This function works in both IEEE Binary Floating-Point and hexadecimal floating-point formats. The *radix* is 16 for hexadecimal floating-point and 2 for IEEE Binary Floating-Point. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

Returned value

If it succeeds, scalb() returns the function of its arguments as described above.

scalb() will fail under the following conditions:

- If the result would underflow, scalb() will return 0 and set errno to ERANGE.
- If the result would overflow, scalb() will return ±HUGE_VAL according to the sign of *x* and set errno to ERANGE.

Special behavior for IEEE: If successful, scalb() returns the value of the *x* parameter times 2 to the power of the *y* parameter.

If the result would overflow, scalb() returns ±HUGE_VAL according to the sign of *x* and sets errno to ERANGE. No other errors can occur.

| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _ISOC99_SOURCE
#include <math.h>

double scalbn(double x, int n);
float scalbnf(float x, int n);
long double scalbnl(long double x, int n);

double scalbln(double x, long int n);
```

```
float scalblnf(float x, long int n);
long double scalblnl(long double x, long int n);
```

C++ TR1 C99

```
#define _TR1_C99
#include <math.h>

float scalbln(float x, long n);
long double scalbln(long double x, long n);
float scalbln(float x, long int n);
long double scalbln(long double x, long int n);
```

General description

The `scalbn()` and `scalbln()` families of functions compute $(x * (\text{FLT_RADIX})^n)$ efficiently, not normally, by computing FLT_RADIX raised to n explicitly.

The radix for z/OS C applications, `FLT_RADIX`, is defined to be 16 under HEX implementation and 2 under IEEE implementation.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|-----------------------|-----|------|
| <code>scalbn</code> | X | X |
| <code>scalbnf</code> | X | X |
| <code>scalbnl</code> | X | X |
| <code>scalbln</code> | X | X |
| <code>scalblnf</code> | X | X |
| <code>scalblnl</code> | X | X |

Restriction: The `scalbnf()` and `scalblnf()` functions do not support the `_FP_MODE_VARIABLE` feature test macro.

Returned value

The `scalbn()` and `scalbln()` families of functions return $(x * (\text{FLT_RADIX})^n)$.

```

General description

The scalbn() and scalbln() families of functions compute (x * 10 raised to n) efficiently, not normally, by computing 10 raised to n explicitly.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

The scalbn() and scalbln() families of functions return (x * 10 raised to n).

Example

```
/* CELEBS68

   This example illustrates the scalbnd128() function.

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal128 x, y;

    x = 7.2DL;
    y = scalbnd128(x, 6000);
```

```
    printf("scalbnd128(%DDf, 6000) = %DDe\n", x, y);
}
```

scanf() — Read and format data

The information for this function is included in [“fscanf\(\), scanf\(\), sscanf\(\) — Read and format data” on page 626](#).

sched_yield() — Release the processor to other threads

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|---------------------|
| Single UNIX Specification, version 3 | both | z/OS V1R7 POSIX(ON) |

Format

```
#define _UNIX03_SOURCE
#include <sched.h>

int sched_yield(void);
```

General description

The `sched_yield()` function allows a thread to give up control of a processor so that another thread can have the opportunity to run. It takes no arguments.

The speed at which the `sched_yield()` function releases a processor can be configured by using the `_EDC_PTHREAD_YIELD` and `_EDC_PTHREAD_YIELD_MAX` environment variables. The `_EDC_PTHREAD_YIELD` environment variable is used to configure the `sched_yield()` function to release the processor immediately, or to release the processor after a delay. The `_EDC_PTHREAD_YIELD_MAX` environment variable is used to change the maximum delay to a value less than the default (32 milliseconds).

For more information about the `_EDC_PTHREAD_YIELD` and `_EDC_PTHREAD_YIELD_MAX` environment variables, see [“Using Environment Variables” in *z/OS XL C/C++ Programming Guide*](#).

Returned value

`sched_yield()` always returns 0.

There are no documented errno values. Use perror() or strerror() to determine the cause of the error.

seed48() — Pseudo-random number initializer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <stdlib.h>

unsigned short int *seed48(unsigned short int seed16v[3]);
```

General description

The drand48(), erand48(), jrand48(), lrand48(), mrand48() and nrand48() functions generate uniformly distributed pseudo-random numbers using a linear congruential algorithm and 48-bit integer arithmetic.

The lcong48(), seed48(), and srand48() functions are initialization functions, one of which should be invoked before either the drand48(), lrand48() or mrand48() function is called.

The drand48(), lrand48() and mrand48() functions generate a sequence of 48-bit integer values, X(i), according to the linear congruential formula:

$$X(n+1) = (aX(n) + c) \bmod (2^{**}48) \qquad n \geq 0$$

The initial values of X, a, and c are:

```
X(0)= 1
a   = 5deece66d (base 16)
c   = b         (base 16)
```

C/370 provides storage to save the most recent 48-bit integer value of the sequence, X(i). This storage is shared by the drand48(), lrand48() and mrand48() functions. The seed48() function is used to reinitialize the most recent 48-bit value in this storage. The seed48() function replaces the low-order (rightmost) 16 bits of this storage with seed16v[0], the middle-order 16 bits with seed16v[1], and the high-order 16 bits with seed16v[2].

The values a and c, may be changed by calling the lcong48() function. The seed48() function restores the initial values of a and c.

Special behavior for z/OS UNIX Services: You can make the seed48() function and other functions in the drand48 family thread-specific by setting the environment variable _RAND48 to the value THREAD before calling any function in the drand48 family.

If you do not request thread-specific behavior for the drand48 family, C/370 serializes access to the storage for X(n), a and c by functions in the drand48 family when they are called by a multithreaded application.

If thread-specific behavior is requested, calls to the `drand48()`, `lrand48()` and `rand48()` functions from thread `t` generate a sequence of 48-bit integer values, $X(t,i)$, according to the linear congruential formula:

$$X(t,n+1) = (a(t)X(t,n) + c(t)) \bmod(2^{**}48) \quad n \geq 0$$

C/370 provides thread-specific storage to save the most recent 48-bit integer value of the sequence, $X(t,i)$. When the `seed48()` function is called from thread `t`, it reinitializes the most recent 48-bit value in this storage. The `seed48()` function replaces the low-order (rightmost) 16 bits of this storage with `seed16v[0]`, the middle-order 16 bits with `seed16v[1]`, and the high-order 16 bits with `seed16v[2]`.

The values of $a(t)$ and $c(t)$ may be changed by calling the `lcong48()` function from thread `t`. When the `seed48()` function is called from this thread, it restores the initial values of $a(t)$ and $c(t)$ for the thread which are:

```
a(t) = 5deece66d (base 16)
c(t) = b         (base 16)
```

Returned value

When `seed48()` is called, it saves the most recent 48-bit integer value in the sequence, $X(i)$, in an array of unsigned short ints provided by C/370 before reinitializing storage for the most recent value in the sequence, $X(i)$. `seed48()` returns a pointer to the array containing the saved value.

Special behavior for z/OS UNIX Services: If thread-specific behavior is requested for the `drand48` family and `seed48()` is called on thread `t`, it saves the most recent 48-bit integer value in the sequence, $X(t,i)$, for the thread in a thread-specific array of unsigned short ints before reinitializing storage for the most recent value in the sequence, $X(t,i)$. `seed48()` returns a pointer to this thread-specific array containing the saved value.

seekdir() – Set position of directory stream

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <dirent.h>
```

```
void seekdir(DIR *dirp, long int loc);
```

General description

The seekdir() function sets the position of the next readdir() operation on the directory stream specified by dirp to the position specified by loc. The value of loc should have been returned from an earlier call to telldir(). The new position reverts to the one associated with the directory stream when telldir() was performed. If the value of loc was not obtained from an earlier call to telldir() or if a call to rewinddir() occurred between the call to telldir() and the call to seekdir(), the result of subsequent calls to readdir() are unspecified.

Note: If files were added or removed from the directory after telldir() was called and before seekdir() is done, the results are also unspecified.

Returned value

seekdir() returns no values.

If the loc argument is negative, the directory stream is unchanged.

select(), pselect() — Monitor activity on files or sockets and message queues

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#define _OPEN_MSGQ_EXT
#include <sys/types.h>
#include <sys/time.h>
#include <sys/msg.h>

int select(int nmsgsfds, fd_set *__restrict__ readlist,
```

```
fd_set *__restrict__ writelist, fd_set *__restrict__ exceptlist,
struct timeval *__restrict__ timeout);
```

SUSV3:

```
#define _POSIX_C_SOURCE 200112L
#include <sys/select.h>

int pselect(int nmsgsfds, fd_set *__restrict__ readlist,
            fd_set *__restrict__ writelist, fd_set *__restrict__ exceptlist,
            const struct timespec *__restrict__ timeout,
            const sigset *__restrict__ sigmask);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#define _OPEN_MSGQ_EXT
#include <sys/types.h>
#include <sys/time.h>
#include <sys/msg.h>

int select(int nmsgsfds, fd_set *readlist,
           fd_set *writelist, fd_set *exceptlist,
           struct timeval *timeout);
```

`_OPEN_MSGQ_EXT` must be defined if message queues are to be monitored (X/Open sockets only).

General description

The `pselect()` and `select()` functions monitor activity on a set of sockets and/or a set of message queue identifiers until a timeout occurs, to see if any of the sockets and message queues have read, write, or exception processing conditions pending. This call also works with regular file descriptors, pipes, and terminals.

The `select()` function is equivalent to the `pselect()` function, except as follows:

- For the `select()` function, the timeout period is given in seconds and microseconds in an argument of type struct *timeval*, whereas for the `pselect()` function the timeout period is given in seconds and nanoseconds in an argument of type struct *timespec*.
- The `select()` function has no *sigmask* argument; it will behave as `pselect()` does when *sigmask* is a null pointer.
- Upon successful completion, the `select()` function can modify the object pointed to by the timeout argument.
- The `pselect()` function always behaves as if `_OPEN_MSGQ_EXT` and `_OPEN_SYS_HIGH_DESCRIPTOR` feature test macros are NOT defined.

Parameter

Description

nmsgsfds

The number of message queues and the number of file or socket descriptors to check.

This parameter is divided into two parts. The first half (the high-order 16 bits) gives the number of elements of an array that contains message queue identifiers. This number must not exceed the value 32767.

The second half (the low-order 16 bits) gives the number of bits within a bit set that correspond to the file or socket descriptors to check. This value should equal the greatest descriptor number to check + 1.

If either half of the *nmsgsfds* parameter is equal to a value of 0, the corresponding bit sets or arrays are assumed not to be present.

If `_OPEN_MSGQ_EXT` is not defined, only file or socket descriptors may be monitored. In this case *nmsgsfds* must be less than or equal to `FD_SETSIZE` (defined to be 2048 in `sys/time.h`), and greater than or equal to zero. Also, `FD_SETSIZE` may not be defined by your program.

The bit set used to specify file or socket descriptors is fixed in size with 1 bit for every possible file or socket. Use the *nmsgsfds* parameter to force `pselect()` or `select()` to check only a subset of the allocated bit set.

If your application allocates sockets 3, 4, 5, 6, and 7 and you want to check all of your allocations, the second half of *nmsgsfds* should be set to 8, the highest descriptor you specified + 1. If your application checks sockets 3 and 4, the second half of *nmsgsfds* should be set to 5.

To select on descriptor numbers between 2048 and 65534, either the `_OPEN_MSGQ_EXT` or `_OPEN_SYS_HIGH_DESCRIPTOR` feature test macro must be defined, and a bit set larger than the default size must be used. Note that when you are also selecting on message queues, as is possible when `_OPEN_MSGQ_EXT` is defined, the largest descriptor number is restricted to 2047. To select on descriptor numbers between 65535 and 524287, feature test macro `_OPEN_SYS_HIGH_DESCRIPTOR` must be defined and feature test macro `_OPEN_MSGQ_EXT` must not be defined. In addition, the process' `MAXFILEPROC` limit must be greater than 65536. With this feature, any number of sockets can be selected on (without message queues). `FD_SETSIZE` may also be redefined in this case, though it is recommended that the application explicitly allocate the larger bit set using `malloc()`.

readlist, writelist, exceptlist

Pointers to `fd_set` types, arrays of message queue identifiers, or `sellist` structures to check for reading, writing, and exceptional conditions, respectively. The type of parameter to pass depends on whether you want to monitor file/socket descriptors, message queue identifiers, or both. To monitor file/socket descriptors only, set the high-order halfword of *nmsgsfds* to 0, the low-order halfword to (highest descriptor number + 1), and use `fd_set` pointers. To monitor message queues only, set the low-order halfword of *nmsgsfds* to 0, the high-order halfword to the number of elements in each array you want `select()` to consider, and pass pointers to arrays of message queue identifiers. To monitor both, set *nmsgsfds* as described above, and pass pointers to `sellist` structures.

The `sellist` structure allows you to specify both file/socket descriptors and message queues. Your program must define the `sellist` structure in the following form:

```
struct sellist {
    fd_set fdset;          /* file/socket descriptor bit set */
    int    msgids[max_size]; /* array of message queue identifiers */
};
```

If you use a `sellist` structure, the highest descriptor you can monitor is 2047.

The description of the type *fd_set* is given below. Each integer of the `msgids` array specifies a message queue identifier whose status is to be checked. Elements with a value of -1 are acceptable and will be ignored. The value contained in the first half of *nmsgsfds* determines exactly how many elements of the array are to be checked.

timeout

The pointer to the time to wait for the `pselect()` or `select()` call to complete.

sigmask

The signal mask of the caller by the set of signals pointed to by *sigmask* before examining the descriptors, and will restore the signal mask of the calling thread before returning.

If *timeout* is not a NULL pointer, it specifies a maximum interval to wait for the selection to complete. The maximum timeout value is 31 days. If *timeout* is a NULL pointer, the `pselect()` and `select()` call blocks until a socket or message becomes ready. To poll the sockets and return immediately, *timeout* should be a non-NULL pointer to a zero-valued **timeval** structure or `timespec` structure.

If *sigmask* is not a null pointer, then the `pselect()` function will replace the signal mask of the caller by the set of signals pointed to by *sigmask* before examining the descriptors, and will restore the signal mask of the calling thread before returning.

To allow you to test more than one socket at a time, the sockets to test are placed into a bit set of type *fd_set*. A bit set is a string of bits such that if *x* is an element of the set, the bit representing *x* is set to 1. If *x* is not an element of the set, the bit representing *x* is set to 0. For example, if socket 33 is an element of a bit set, then bit 33 is set to 1. If socket 33 is not an element of a bit set, then bit 33 is set to 0.

Because the bit sets contain a bit for every socket that a process can allocate, the size of the bit sets is constant. If your program needs to allocate a large number of sockets, you may need to increase the size of the bit sets. Increasing the size of the bit sets should be done when you compile the program. To increase the size of the bit sets, define `FD_SETSIZE` before including **sys/time.h**. `FD_SETSIZE` is the largest value of any socket that your program expects to use `pselect()` or `select()` on. It is defined to be 2048 in **sys/time.h**.

Note: `FD_SETSIZE` may only be defined by the application program if the extended version of `select()` is used (by defining `_OPEN_MSGQ_EXT`). Do NOT define `FD_SETSIZE` in your program if a `select` structure will be used.

Note: The z/OS UNIX POSIX.1 implementation allows you to control the maximum number of open descriptors allowed per process. This maximum possible value is 524288. If your application program requires a large number of either socket or file descriptors, you should protect your code from possible runtime errors by:

- Adding a check before your `pselect()`, `select()` or `selectex()` calls to see if the bit set size contained in `nmsgsfds` is larger than `FD_SETSIZE`.
- Dynamically allocate bit strings large enough to hold the largest descriptor value in your application program, rather than rely on the static bit strings created at compile time. When allocating your own bit strings, use `malloc()` to define an area large enough to represent each bit, rounded up to the next 4-byte multiple. For example, if your largest descriptor value is 31, you need 4 bytes; if your largest descriptor is 32, you need 8 bytes.
- If you dynamically allocate your own bit strings, the `FD_ZERO()` macro will *not* work. The application must zero that storage, by using the `memset` function—that is, `memset(ptr,0,mallocsize)`. The other macros can be used with the dynamically allocated bit strings, as long as the descriptor you are manipulating is within the bit string. If the descriptor number is larger than the bit string, unpredictable results can occur.

The application program must make sure that the parameters *readlist*, *writelist*, and *exceptlist* point to bit strings that are as large as the bit string size in parameter `nmsgsfds` z/OS UNIX services will try to access bits 0 through $n - 1$ (where n = the value of the second halfword of `nmsgsfds`), for each of the bit strings. If the bit strings are too short, you will receive unpredictable results when you run your application program.

The following macros are provided to manipulate bit sets.

Macro

Description

FD_ZERO(&fdset)

Sets all bits in the bit set *fdset* to zero. After this operation, the bit set does not contain sockets as elements. This macro should be called to initialize the bit set before calling `FD_SET()` to set a socket as a member.

Note: If you used `malloc()` to dynamically allocate a new area, the `FD_ZERO()` macro can cause unpredictable results and should *not* be used. You should zero the area using the `memset()` function.

FD_SET(sock, &fdset)

Sets the bit for the socket *sock* to a 1, making *sock* a member of the bit set *fdset*.

FD_CLR(sock, &fdset)

Clears the bit for the socket *sock* in bit set *fdset*. This operation sets the appropriate bit to a zero.

FD_ISSET(sock, &fdset)

Returns nonzero if *sock* is a member of the bit set *fdset*. Returns 0 if *sock* is not a member of *fdset*. (This operation returns the bit representing *sock*.)

The following macros are provided to manipulate the `nmsgsfds` parameter and the return value from `pselect()` and `select()`:

Macro

Description

_SET_FDS_MSGS(*nmsgsfds*, *nmsgs*, *nfds*)

Sets the high-order halfword of *nmsgsfds* to *nmsgs*, and sets the low-order halfword of *nmsgsfds* to *nfds*.

_NFDS(*n*)

If the return value *n* from `pselect()` or `select()` is nonnegative, returns the number of descriptors that meet the read, write, and exception criteria. A descriptor may be counted multiple times if it meets more than one given criterion.

_NMSGs(*n*)

If the return value *n* from `pselect()` or `select()` is nonnegative, returns the number of message queues that meet the read, write, and exception criteria. A message queue may be counted multiple times if it meets more than one given criterion.

A socket is ready for reading when incoming data is buffered for it or when a connection request is pending. To test whether any sockets are ready for reading, use either `FD_ZERO()` or `memset()`, if the function was dynamically allocated, to initialize the fdset bit set in *readlist* and invoke `FD_SET()` for each socket to test.

A socket is ready for writing if there is buffer space for outgoing data. A socket is ready for reading if there is data on the socket to be received. For a nonblocking stream socket in the process of connecting the `connect()` will return with a -1. The program needs to check the `errno`. If the `errno` is `EINPROGRESS`, the socket is selected for write when the `connect()` completes. In the situation where the `errno` is not `EINPROGRESS`, the socket will still be selected for write which indicates that there is a pending error on the socket. A call to `write()`, `send()`, or `sendto()` does not block provided that the amount of data is less than the amount of buffer space. If a socket is selected for write, the amount of available buffer space is guaranteed to be at least as large as the size returned from using `SO_SNDBUF` with `getsockopt()`. To test whether any sockets are ready for writing, initialize the fdset bit set in *writelst* with either `FD_ZERO()` or `memset()`, if dynamically allocated, and use `FD_SET()` for each socket to test.

A message queue is ready for reading when any time it has a message on it. It is considered ready for writing when any time it is not full. A message queue is full when it has either reached its number of messages limit or its number of bytes limit. An exception condition exists when a message queue is deleted while a `select()` caller is waiting on the queue.

The programmer can pass `NULL` for any of the *readlist*, *writelst*, and *exceptlist* parameters. However, when they are not `NULL`, they must all point to the same type of structures. For example, suppose the *readlist* points to a *sellist*. If the *writelst* is not `NULL`, it must point to a *sellist* also. Now, let us say the *writelst* is not `NULL`. If the programmer wants to check a set of file descriptors for read status only, the appropriate bits in the bit set in the *sellist* structure pointed to by the *writelst* must be set to 0. If the programmer wants to check a set of message queues for write status only, the appropriate elements in the array in the *sellist* structure pointed to by the *readlist* must be set to -1. Regular files are always ready for reading and writing.

Because the sets of sockets passed to `pselect()` and `select()` are bit sets, the `pselect()` and `select()` call must test each bit in each bit set before polling the socket for its status. The `pselect()` and `select()` call tests only sockets in the range 0 to *n*-1 (where *n* = the value of the second halfword of *nmsgsfds*).

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` 1 feature test macro.

Returned value

The value -1 indicates the error code should be checked for an error. The value zero indicates an expired time limit.

When the return value is greater than 0, then it is similar to *nmsgsfds* in that the high-order 16 bits give the number of message queues, and the low-order 16 bits give the number of descriptors. These values indicate the sum total that meet each of the read, write, and exception criteria. Note that a descriptor or a message queue may be counted multiple times if it meets more than one given criterion. Should the return value for message queues exceed the value 32767, only 32767 will be reported. This is to ensure

that the return value does not appear to be negative. Should the return value for file/socket descriptors be greater than 65535, only 65535 will be reported.

If the return value is greater than 0, the files/sockets that are ready in each bit set are set to 1. Files/ Sockets in each bit set that are not ready are set to zero. Use the macro `FD_ISSET()` with each file/socket to test its status. For those message queues that do not meet the conditions their identifiers in the `msgsid` arrays will be replaced with a value of -1.

Error Code

Description

EBADF

One of the bit sets specified an invalid socket or a message queue identifier is invalid. `FD_ZERO()` was probably not called to clear the bit set before the sockets were set.

EFAULT

One of the parameters contained an invalid address.

EINTR

The `pselect()` or `select()` function was interrupted before any of the selected events occurred and before the timeout interval expired.

EINVAL

One of the fields in the **timeval** structure or **timespec** structure is invalid, or there was an invalid *nmsgsfds* value.

EIO

One of the descriptors in the select mask has become inoperative and it is being repeatedly included in a select even though other operations against this descriptor have been failing with EIO. A socket descriptor, for example, can become inoperative if TCP/IP is shut down. When a descriptor fails a failure from select could not tell you which descriptor had failed so generally select will succeed and these descriptors will be reported to you as being ready for whatever events were specified on the select. Subsequently when the descriptor is used on a receive or other operation you will receive the EIO failure then and can react to the problem with the individual descriptor. In general you would `close()` the descriptor and remove it from the next select mask. If the individual descriptor's failing return code is ignored though and an inoperative descriptor is repeatedly selected on and used, even though each time it is used that call fails with EIO, eventually the select call itself will fail with EIO.

Note: The `pselect()` function can also return `errno`'s set by the `sigprocmask()` function.

Example

In the following example, `select()` is used to poll sockets for reading (socket `sr`), writing (socket `sw`), and exception (socket `se`) conditions, and to check message queue ids `mr`, `mw`, and `me`.

```
#define _XOPEN_SOURCE_EXTENDED 1
#define _OPEN_MSGQ_EXT

#include <sys/types.h>
#include <sys/time.h>
#include <sys/msg.h>

struct sellist {
    fd_set fdset;
    int msgids[2];
};

/*
 * sock_msg_stats(sr, sw, se, mr, mw, me) - Print the status of
 *     sockets sr, sw, and se, and of message queue ids mr, mw,
 *     and me.
 */
int sock_msg_stats(sr, sw, se, mr, mw, me)
int sr, sw, se, mr, mw, me;
{
    struct sellist *reading, *writing, *excepting;
    struct sellist read, write, except;
    struct timeval timeout;
    int rc, max_sock, sock_size, nmsgsfds;
    int msgids[1];          /* we only check 1 message queue */
}
```

select

```
/* What's the maximum socket number? */
max_sock = MAX( sr, sw );
max_sock = MAX( max_sock, se );

/* initialize the static bit sets */
FD_ZERO( &read.fdset );   reading = &read;
FD_ZERO( &write.fdset );  writing = &write;
FD_ZERO( &except.fdset ); excepting = &except;

/* add sr, sw, and se to the appropriate bit set */
FD_SET( sr, &reading->fdset );
FD_SET( sw, &writing->fdset );
FD_SET( se, &excepting->fdset );

/* initialize the message id arrays */
reading->msgids[0] = mr;
writing->msgids[0] = mw;
excepting->msgids[0] = me;

/* set the nmsgsfds parameter */
_SET_FDS_MSGS( nmsgsfds, 1, max_sock+1 );

/* make select poll by sending a 0 timeval */
memset( &timeout, 0, sizeof(timeout) );
/* poll */
rc = select( nmsgsfds, reading, writing, excepting, &timeout);

if ( rc < 0 ) {
    /* an error occurred during the SELECT() */
    perror( "select" );
}
else if ( rc == 0 ) {
    /* no sockets or messages were ready in our little poll */
    printf( "nobody is home.\n" );
}
else {
    if ( _NFDS(rc) > 0 ) {
        /* at least one of the sockets is ready */
        printf("sr is %s\n",
            FD_ISSET(sr,&reading->fdset) ? "READY" : "NOT READY");
        printf("sw is %s\n",
            FD_ISSET(sw,&writing->fdset) ? "READY" : "NOT READY");
        printf("se is %s\n",
            FD_ISSET(se,&excepting->fdset) ? "READY": "NOT READY");
    }
    else {
        if ( _NMSGs(rc) > 0 ) {
            /* at least one message queue is ready */
            printf("mr is %s\n",
                reading->msgids[0] == -1 ? "NOT READY" : "READY");
            printf("mw is %s\n",
                writing->msgids[0] == -1 ? "NOT READY" : "READY");
            printf("me is %s\n",
                excepting->msgids[0] == -1 ? "NOT READY" : "READY");
        }
    }
}
```

CELEBP72

```
/* CELEBP72
```

This example demonstrates the use of pselect()

Expected output:

Parent: Issuing pselect

This is the child

Child: Sending signal to the parent at:

This is the signal handler

Signal received: 14 (14 is SIGALRM)

The pselect call was made at:

The SIGALRM was caught at:

TEST PASSED!

selectex() — Monitor activity on files or sockets and message queues

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#define _ALL_SOURCE
#define _OPEN_MSGQ_EXT
#include <sys/types.h>
#include <sys/time.h>
#include <sys/msg.h>

int selectex(int nmsgsfds, fd_set *readlist,
             fd_set *writelist,
             fd_set *exceptlist,
             struct timeval *timeout, int *ecbptr);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#define _ALL_SOURCE
#define _OPEN_MSGQ_EXT
#include <sys/types.h>
#include <sys/time.h>
#include <sys/msg.h>

int selectex(int nmsgsfds, fd_set *readlist,
             fd_set *writelist,
             fd_set *exceptlist,
             struct timeval *timeout, int *ecbptr);
```

_OPEN_MSGQ_EXT must be defined if message queues are to be monitored (X/Open sockets only).

General description

The selectex() function provides an extension to the select() call by allowing you to use an ECB that defines an event not described by readlist, writelist, or exceptlist.

The `selectex()` call monitors activity on a set of files/sockets and message queues until a timeout occurs, or until the ECB is posted, to see if any of the files/sockets and message queues have read, write, or exception processing conditions pending.

When the storage key of the first (or only) ECB matches the caller's PSW key, the kernel performs the wait in the caller's PSW key; otherwise, the kernel performs the wait in the TCB key (TCBPFK). However, if the caller is running in key 0, then the kernel performs the wait in key 0, regardless of the storage key.

See `select()` for more information.

Parameter Description

nmsgsfds

The number of message queues and the number of file or socket descriptors to check. (Refer to `select()` for a full description of this and other parameters below.)

Note: This function is limited to descriptor numbers less than or equal to 65535.

readlist

A pointer to an `fd_set` type, array of message queue identifiers, or *sellist* structure specifying descriptors and message queues to check for reading.

writelist

A pointer to an `fd_set` type, array of message queue identifiers, or *sellist* structure specifying descriptors and message queues to check for writing.

exceptlist

A pointer to an `fd_set` type, array of message queue identifiers, or *sellist* structure specifying descriptors and message queues to be checked for exceptional pending conditions.

timeout

The pointer to the time to wait for the `selectex()` call to complete.

ecbptr

This variable can contain one of the following values:

1. A pointer to a user event control block. To specify this usage of *ecbptr*, the high-order bit must be set to '0' B.
2. A pointer to a list of ECBs. To specify this usage of *ecbptr*, the high-order bit must be set to '1' B.
The list can contain the pointers for up to 1013 ECBs. The high-order bit of the last pointer in the list must be set to '1' B.
3. A NULL pointer. This indicates no ECBs are specified.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

Returned value

The value -1 indicates the error code should be checked for an error. The value 0 indicates an expired time limit or that the ECB is posted.

When the return value is greater than 0, then it is similar to *nmsgsfds* in that the high-order 16 bits give the number of message queues, and the low-order 16 bits give the number of descriptors. These values indicate the sum total that meet each of the read, write, and exception criteria. Note that a descriptor or a message queue may be counted multiple times if it meets more than one requested criterion. Should the return value for message queues exceed the value 32767, only 32767 will be reported. This is to ensure that the return value does not appear to be negative. Should the return value for file/socket descriptors be greater than 65535, only 65535 will be reported.

If the return value is greater than 0, the files/sockets that are ready in each bit set are set to 1. Files/Sockets in each bit set that are not ready are set to zero. Use the macro `FD_ISSET()` with each socket to test its status. For those message queues that do not meet the conditions their identifiers in the *msgsid* array will be replaced with a value of -1.

Error Code Description

EBADF

One of the descriptor sets specified an incorrect descriptor or a message queue identifier is invalid.

EFAULT

One of the parameters contained an invalid address.

EINTR

`selectex()` was interrupted before any of the selected events occurred and before the timeout interval expired.

EINVAL

One of the fields in the *timeval* structure is incorrect.

EIO

One of the descriptors in the select mask has become inoperative and it is being repeatedly included in a select even though other operations against this descriptor have been failing with EIO. A socket descriptor, for example, can become inoperative if TCP/IP is shut down. A failure from select can not tell you which descriptor has failed so generally select will succeed and these descriptors will be reported to you as being ready for whatever event they were being selected for. Subsequently when the descriptor is used on a receive or other operation you will receive the EIO failure and can react to the problem with the individual descriptor. In general you would close() the descriptor and remove it from the next select mask. If the individual descriptor's failing return code is ignored though and an inoperative descriptor is repeatedly selected on and used, even though each time it is used that call fails with EIO, eventually the select call itself will fail with EIO.

semctl(), semctl64() — Semaphore control operations

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

semctl:

```
#define _XOPEN_SOURCE
#include <sys/sem.h>

int semctl(int semid, int semnum, int cmd, ...);
```

semctl64:

```
#define _LARGE_TIME_API
#define _XOPEN_SOURCE
#include <sys/sem.h>

int semctl64(int semid, int semnum, int cmd, ...);
```

Compile requirement: Use of the `semctl64()` function requires the `long long` data type. For more information on how to make the `long long` data type available, see [z/OS XL C/C++ Language Reference](#).

General description

The `semctl()` or `semctl64()` function performs control operations in semaphore set *semid* as specified by the argument *cmd*.

Depending on the value of argument *cmd*, argument *semnum* may be ignored or identify one specific semaphore number.

The fourth argument is optional and depends upon the operation requested. If required, it is of type *union semun*, which the application program must explicitly declare:

```
union semun {
    int          val;
    struct semid_ds *buf;
    unsigned short *array;
} arg;
```

Each semaphore in the semaphore set is represented by the following anonymous data structure:

| | | |
|--------------------|---------|---|
| unsigned short int | semval | Semaphore value |
| pid_t | sempid | Process ID of last operation |
| unsigned sort int | semcnt | Number of processes waiting for semval to become greater than current value |
| unsigned short int | semzcnt | Number of processes waiting for semval to become zero |

When `semctl()` or `semctl64()` is used to identify one specific semaphore number for commands `GETVAL`, `SETVAL`, `GETPID`, `GETNCNT`, and `GETZCNT`, then references are made to this anonymous data structure for the semaphore *semnum*.

The following semaphore control operations as specified by argument *cmd* may be specified. The level of permission required for each operation is shown with each command. These symbolic constants are defined by the `<sys/sem.h>` header:

GETVAL

Returns the value of `semval`, if the current process has read permission.

SETVAL

Sets the value of `semval` to `arg.val`, where `arg` is the value of the fourth argument to `semctl()` or `semctl64()`. When this command is successfully executed, the `semadj` value corresponding to the specified semaphore in all processes is cleared. This command requires alter permission. For an `__IPC_BINSEM` semaphore set the only values that may be set are zero and one.

GETPID

Returns the most recent process to update the semaphore (*sempid*), if the current process has read permission.

GETNCNT

Returns the number of threads waiting on the semaphore to become greater than the current value, if the current process has read permission.

GETZCNT

Returns the number of threads waiting on the semaphore to become zero, if the current process has read permission. For an `__IPC_BINSEM` semaphore set this operation will always return a zero; threads are not allowed to wait for the semaphore to become zero in this type of semaphore set.

GETALL

Stores *semvals* for each semaphore in the semaphore set and place into the array pointed to by *arg.array*, where *arg.* is the fourth argument to `semctl()` or `semctl64()`. `GETALL` requires read permission. It is the caller's responsibility to ensure that the storage allocated is large enough to hold the number of semaphore elements. The number of semaphore values stored is *sem_nsems*, which may be obtained using the **IPC_STAT** command.

SETALL

Sets *semval* values for each semaphore in the semaphore set according to the array pointed to by *arg.array*, where *arg* is the fourth argument to `semctl()` or `semctl64()`. `SETALL` requires alter permission. Each *semval* value must be zero or positive. When this command is successfully executed, the *semadj* values corresponding to each specified semaphore in all processes are cleared. It is the caller's responsibility to ensure that the storage allocated is large enough to hold the number of semaphore elements. The number of semaphore values set is *sem_nsems*, which may be obtained using the **IPC_STAT** command. If `__IPC_BINSEM` was specified on the `semget`, this option should not be used while there is the possibility of other threads performing semaphore operations on this semaphore, as there may be no serialization while updating the semaphore values; therefore a `SETALL` will not be allowed after a `semop` has been done to the `__IPC_BINSEM` semaphore set. Also, for the `__IPC_BINSEM` semaphore set, the only values that may be set are zero and one.

IPC_STAT

This command obtains status information for the semaphore identifier specified by *semid*. This requires read permission. This information is stored in the address specified by the fourth argument defined by data structure *semid_ds* or *semid_ds64*.

IPC_SET

Set the value of the *sem_perm.uid*, *sem_perm.gid*, and *sem_perm.mode* in *semid_ds* or *semid_ds64* data structure for the semaphore identifier specified by *semid*. These values are set to the values found in *semid_ds* or *semid_ds64* structure pointed to by the fourth argument.

Any value for *sem_perm.uid* and *semperm.gid* may be set.

Only mode bits defined under `semget()` function argument *semflg* may be set in *sem_perm.mode*.

This command can only be executed by a process that has an effective user ID equal to either that of a process with appropriate privileges or to the value of *sem_perm.cuid* or *sem_perm.uid* in the *semid_ds* or *semid_ds64* structure associated with *semid*.

IPC_RMID

Remove the semaphore identifier specified by argument *semid* from the system and free the storage for the set of semaphores in the *semid_ds* or *semid_ds64* structure.

This command can only be executed by a process that has an effective user ID equal to either that of a process with appropriate privileges or to the value of *sem_perm.cuid* or *sem_perm.uid* in the *semid_ds* or *semid_ds64* structure associated with *semid*. For an `__IPC_BINSEM` semaphore set, it is recommended that all use of `semop` should be completed before removing the semaphore ID.

The `semctl64()` function behaves exactly like `semctl()` except `semctl64()` uses union `semun64` instead of union `semun` if required to support time beyond 03:14:07 UTC on January 19, 2038. `semun64` needs application program's explicit declaration:

```
union semun64 {
    int val;
    struct semid_ds64 *buf;
    unsigned short *array;
} arg;
```

Union `semun64` uses struct `semid_ds64` pointer as its second member instead of struct `semid_ds` pointer.

Returned value

If successful, the value returned by `semctl()` or `semctl64()` depends on the value of the argument *cmd* as follows:

GETVAL

value of `semval` is returned

GETPID

value of `sempid` is returned

GETNCNT

value of `semncnt` is returned

GETZCNT

value of `semzcnt` is returned

All others

value of zero is returned

If unsuccessful, `semctl()` or `semctl64()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

Operation permission (read or write) is denied to the calling process.

EINVAL

The value of argument *semid* is not a valid semaphore identifier, or the value of *semnum* is less than zero or greater than or equal to the number of semaphores in the set, or the argument *cmd* is not a valid command, or the bits specified for `sem_perm.mode` are undefined. Note that the valid range of *semnum* is 0 to (number of semaphores in the set minus 1).

EPERM

The argument *cmd* has a value of **IPC_RMID** or **IPC_SET** and the effective user ID of the caller is not that of a process with appropriate privileges and is not the value of `sem_perm.cuid` or `sem_perm.uid` in the `semid_ds` or `semid_ds64` data structure associated with *semid*.

ERANGE

The argument *cmd* has a value of **SETVAL** or **SETALL** and the `semval` value to be set exceeds the system limit as defined in `<sys/sem.h>`.

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <sys/sem.h>

int semget(key_t key, int nsems, int semflg);
```

General description

The `semget()` function returns the semaphore identifier associated with *key*.

A semaphore identifier is created with a `semid_ds` data structure, see `<sys/sem.h>`, associated with *nsems* semaphores when any of the following is true:

- Argument *key* has a value of **IPC_PRIVATE**
- Argument *key* is not associated with a semaphore ID and (`semflg & IPC_CREAT`) is non zero.

Valid values for the field *semflg* include any combination of the following defined in `<sys/ipc.h>` and `<sys/modes.h>`:

IPC_CREAT

Creates a semaphore if the *key* specified does not already have an associated ID. **IPC_CREATE** is ignored when **IPC_PRIVATE** is specified.

IPC_EXCL

Causes the `semget()` function to fail if the *key* specified has an associated ID. **IPC_EXCL** is ignored when **IPC_CREAT** is not specified or **IPC_PRIVATE** is specified.

__IPC_BINSEM

Binary semaphore - semaphore must behave in a binary manner: number of semaphore operations must be 1 and the `semop` must be 1 with a `semval` of 0 or the `semop` must be -1 with a `semval` of 0 or 1. `SEM_UNDO` is now allowed on a `semop()` with this option. The use of this flag will cause improved performance if the PLO instruction is available on the hardware.

See [z/OS XL C/C++ Programming Guide](#) for further information on semaphore performance.

__IPC_SHORTHOLD

This flag states that it is known that the application will only hold the resource being serialized for extremely short time intervals. When this flag is combined with the `__IPC_BINSEM` flag, the default first-in-first-out (FIFO) ordering of semaphore obtain requesters will be bypassed, to allow short duration requesters to successfully obtain the semaphore (and hopefully release it) within the interval it normally takes to dispatch the next pending waiter for that semaphore.

S_IRUSR

Permits read access when the effective user ID of the caller matches either `sem_perm.cuid` or `sem_perm.uid`.

S_IWUSR

Permits write access when the effective user ID of the caller matches either `sem_perm.cuid` or `sem_perm.uid`.

S_IRGRP

Permits read access when the effective group ID of the caller matches either `sem_perm.cgid` or `sem_perm.gid`.

S_IWGRP

Permits write access when the effective group ID of the caller matches either `sem_perm.cgid` or `sem_perm.gid`.

S_IROTH

Permits others read access

S_IWOTH

Permits others write access

When a semaphore set associated with argument *key* already exists, setting **IPC_EXCL** and **IPC_CREAT** in argument *semflg* will force `semget()` to fail.

When a `semid_ds` data structure is created the following anonymous data structure is created for each semaphore in the set:

| | | |
|--------------------|----------------------|--|
| unsigned short int | <code>semval</code> | Semaphore value |
| pid_t | <code>sempid</code> | Process ID of last operation |
| unsigned sort int | <code>semcnt</code> | Number of processes waiting for <code>semval</code> to become greater than current value |
| unsigned short int | <code>semzcnt</code> | Number of processes waiting for <code>semval</code> to become zero |

The following fields are initialized when a `semid_ds` data structure is created:

- The fields `sem_perm.cuid` and `sem_perm.uid` are set equal to the effective user ID of the calling process.
- The fields `sem_perm.cgid` and `sem_perm.gid` are set equal to effective group ID of the calling process.
- The low-order 9 bits of `sem_perm.mode` are set to the value in the low-order 9 bits of *semflg*.
- The field `sem_nsems` is set to the value of *nsems*.
- The field `sem_otime` is set to 0.
- The field `sem_ctime` is set to the current time.
- The anonymous data structure containing `semval` for each semaphore is not initialized. `semctl()` commands **SETVAL** and **SETALL** should be used to initialize each semaphore's `semval` value.

Usage notes

1. Semaphores created with `__IPC_BINSEM` will show this bit and may show the `IPC_PLOINUSE` bit in the `S_MODE` byte returned with *w_getipc*.

Returned value

If successful, `semget()` returns a nonnegative semaphore identifier.

If unsuccessful, `semget()` returns -1 and sets `errno` to one of the following values:

Error Code**Description****EACCES**

A semaphore identifier exists for the argument *key*, but access permission as specified by the low-order 9 bits of *semflg* could not be granted.

EEXIST

A semaphore identifier exists for the argument *key* and both **IPC_CREAT** and **IPC_EXCL** are specified in *semflg*.

EINVAL

The value of *nsems* is either less than zero or greater than the system limit. A semaphore identifier associated with *key* does not exist and the *nsems* is zero. A semaphore identifier associated with *key* already exists and the *nsems* value specified on `semget()` when the semaphore identifier was created is less than the *nsems* value on the current `semget()`. The *semflg* argument specified flags not currently supported.

ENOENT

A semaphore identifier does not exist for the argument *key* and **IPC_CREAT** is not specified.

ENOSPC

A system limit of number of semaphore identifiers has been reached.

When *semflg* equals 0, the following applies:

- If a semaphore identifier has already been created with *key* earlier, and the calling process of this `semget()` has read and/or write permissions to it, then `semget()` returns the associated semaphore identifier.
- If a semaphore identifier has already been created with *key* earlier, and the calling process of this `semget()` does not have read and/or write permissions to it, then `semget()` returns -1 and sets `errno` to `EACCES`.
- If a semaphore identifier has not been created with *key* earlier, then `semget()` returns -1 and sets `errno` to `ENOENT`.

semop() — Semaphore operations

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <sys/sem.h>

int semop(int semid, struct sembuf *sops, size_t nsops);
```

General description

The `semop()` function performs semaphore operations atomically on a set of semaphores associated with argument *semid*. The argument *sops* is a pointer to an array of `sembuf` data structures. The argument *nsops* is the number of `sembuf` structures in the array.

The structure `sembuf` is defined as follows:

```
short  sem_num  Semaphore number in the range 0 to (nsems - 1)
short  sem_op   Semaphore operation
short  sem_flg  Operation flags
```

Each semaphore in the semaphore set, identified by `sem_num`, is represented by the following anonymous data structure. This data structure for all semaphores is updated atomically when `semop()` returns successfully:

```
unsigned short int    semval    Semaphore value
pid_t                sempid    Process ID of last operation
unsigned short int    semcnt    Number of processes waiting for semval to become
                                greater than current value
unsigned short int    semzcnt    Number of processes waiting for semval to become zero
```

Each semaphore operation specified by `sem_op` is performed on the corresponding semaphore specified by `semid` and `sem_num`.

The variable `sem_op` specifies one of three semaphore operations:

1. If `sem_op` is a negative integer and the calling process has alter permission, one of the following will occur:
 - If `semval`, see `<sys/sem.h>`, is greater than or equal to the absolute value of `sem_op`, the absolute value of `sem_op` is subtracted from `semval`.
 - If `semval` is less than the absolute value of `sem_op` and `(sem_flg & IPC_NOWAIT)` is nonzero, `semop()` will return immediately.
 - If `semval` is less than the absolute value of `sem_op` and `(sem_flg & IPC_NOWAIT)` is zero, `semop()` will increment the `semcnt` associated with the specified semaphore and suspend execution of the calling process until one of the following conditions occurs:
 - The value of `semval` becomes greater than or equal to the absolute value of `sem_op`. When this occurs, the value of `semcnt` associated with the specified semaphore is decremented, the absolute value of `sem_op` is subtracted from `semval`.
 - The `semid` for which the calling process is awaiting action is removed from the system. When this occurs, `errno` is set equal to `EIDRM` and `-1` is returned.
 - The calling process receives a signal that is to be caught. When this occurs, the value of `semcnt` associated with the specified semaphore is decremented, and the calling process resumes execution in the manner prescribed in `sigaction()`.
2. If `sem_op` is a positive integer and the calling process has alter permission, the value of `sem_op` is added to `semval`.
3. If `sem_op` is zero and the calling process has read permission, one of the following will occur:
 - If `semval` is zero, `semop()` will return immediately.
 - If `semval` is nonzero and `(sem_flg & IPC_NOWAIT)` is nonzero, `semop()` will return immediately.
 - If `semval` is nonzero and `(sem_flg & IPC_NOWAIT)` is 0, `semop()` will increment the `semzcnt` associated with the specified semaphore and suspend execution of the calling thread until one of the following occurs:
 - The value of `semval` becomes 0, at which time the value of `semzcnt` associated with the specified semaphore is decremented.
 - The `semid` for which the calling process is awaiting action is removed from the system. When this occurs, `errno` is set equal to `EIDRM` and `-1` is returned.
 - The calling process receives a signal that is to be caught. When this occurs, the value of `semzcnt` associated with the specified semaphore is decremented, and the calling process resumes execution in the manner prescribed in `sigaction()`.

- Upon successful completion, the value of `sempid` for each semaphore specified in the array pointed to by `sops` is set equal to the process ID of the calling process.

`sem_flg` contains the **IPC_NOWAIT** and **SEM_UNDO** flags described as follows:

IPC_NOWAIT

Will cause `semop()` to return `EAGAIN` rather than place the thread into wait state.

SEM_UNDO

Will result in `semadj` adjustment values being maintained for each semaphore on a per process basis. If `sem_op` value is not equal to zero and **SEM_UNDO** is specified, then `sem_op` value is subtracted from the current process's `semadj` value for that semaphore. When the current process is terminated, see `exit()`, the `semadj` value(s) will be added to the `semval` for each semaphore. The `semctl()` command **SETALL** may be used to clear all `semadj` values in all processes. If `__IPC_BINSEM` was specified on `semget` for this semaphore, the `SEM_UNDO` flag will cause an error to be returned.

A semaphore set created with the `__IPC_BINSEM` flag must behave in the following manner: number of semaphore operations must be 1 and the `semop` must be +1 with a `semval` of 0 or the `semop` must be -1 with a `semval` of 0 or 1. `SEM_UNDO` is not allowed on a `semop()` with this option. The use of this flag will cause improved performance if the PLO instruction is available on the hardware.

Returned value

If successful, `semop()` returns 0. Also the `semid` parameter value for each semaphore that is operated upon is set to the process ID of the calling process.

If unsuccessful, `semop()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

E2BIG

The value `nsops` is greater than the system limit.

EACCES

Operation permission is denied to the calling process. Read access is required when `sem_op` is zero. Write access is required when `sem_op` is not zero.

EAGAIN

The operation would result in suspension of the calling process but **IPC_NOWAIT** in `sem_flg` was specified.

EFBIG

`sem_num` is less than zero or greater or equal to the number of semaphores in the set specified on in `semget()` argument `nsems`.

EIDRM

`semid` was removed from the system while the invoker was waiting.

EINTR

`semop()` was interrupted by a signal.

EINVAL

The value of argument `semid` is not a valid semaphore identifier. For an `__IPC_BINSEM` semaphore set, the `sem_op` is other than +1 for a `sem_val` of 0 or -1 for a `sem_val` of 0 or 1. Also, for an `__IPC_BINSEM` semaphore set, the number of semaphore operations is greater than one.

ENOSPC

The limit on the number of individual processes requesting a **SEM_UNDO** would be exceeded.

ERANGE

An operation would cause `semval` or `semadj` to overflow the system limit as defined in `<sys/sem.h>`.

__semop_timed() — Semaphore operations with timeout

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | OS/390 V2R10 |

Format

```
#define _OPEN_SYS_TIMED_EXT 1
#include <time.h>
#include <sys/sem.h>

int __semop_timed(int semid, struct sembuf *sops, size_t nsops,
                  struct timespec *set)
```

General description

Performs semaphore operations atomically on a set of semaphores associated with argument *semid*. The argument *sops* is a pointer to an array of *sembuf* data structures. The argument *nsops* is the number of *sembuf* structures in the array. The argument *set* the structure *timespec* with the timeout values.

The structure *sembuf* is defined as follows:

```
short sem_num  Semaphore number in the range 0 to (nsems - 1)
short sem_op   Semaphore operation
short sem_flg  Operation flags
```

Each semaphore in the semaphore set, identified by *sem_num*, is represented by the following anonymous data structure. This data structure for all semaphores is updated automatically when *semop()* returns successfully:

| | | |
|--------------------|----------------|--|
| unsigned short int | <i>semval</i> | Semaphore value |
| pid_t | <i>sempid</i> | Process ID of last operation |
| unsigned sort int | <i>semcnt</i> | Number of processes waiting for <i>semval</i> to become greater than current value |
| unsigned short int | <i>semzcnt</i> | Number of processes waiting for <i>semval</i> to become zero |

Each semaphore operation specified by *sem_op* is performed on the corresponding semaphore specified by *semid* and *sem_num*.

The variable *sem_op* specifies one of three semaphore operations:

1. If `sem_op` is a negative integer and the calling process has alter permission, one of the following will occur:
 - If `semval`, see `<sys/sem.h>`, is greater than or equal to the absolute value of `sem_op`, the absolute value of `sem_op` is subtracted from `semval`.
 - If `semval` is less than the absolute value of `sem_op` and `(sem_flg & IPC_NOWAIT)` is nonzero, `semop()` will return immediately.
 - If `semval` is less than the absolute value of `sem_op` and `(sem_flg & IPC_NOWAIT)` is zero, `semop()` will increment the `semncnt` associated with the specified semaphore and suspend execution of the calling process until one of the following conditions occurs:
 - The value of `semval` becomes greater than or equal to the absolute value of `sem_op`. When this occurs, the value of `semncnt` associated with the specified semaphore is decremented, the absolute value of `sem_op` is subtracted from `semval`.
 - The `semid` for which the calling process is awaiting action is removed from the system. When this occurs, `errno` is set equal to `EIDRM` and `-1` is returned.
 - The calling process receives a signal that is to be caught. When this occurs, the value of `semncnt` associated with the specified semaphore is decremented, and the calling process resumes execution in the manner prescribed in `sigaction()`.
2. If `sem_op` is a positive integer and the calling process has alter permission, the value of `sem_op` is added to `semval`.
3. If `sem_op` is zero and the calling process has read permission, one of the following will occur:
 - If `semval` is zero, `semop()` will return immediately.
 - If `semval` is nonzero and `(sem_flg & IPC_NOWAIT)` is nonzero, `semop()` will return immediately.
 - If `semval` is nonzero and `(sem_flg & IPC_NOWAIT)` is 0, `semop()` will increment the `semzcnt` associated with the specified semaphore and suspend execution of the calling thread until one of the following occurs:
 - The value of `semval` becomes 0, at which time the value of `semzcnt` associated with the specified semaphore is decremented.
 - The `semid` for which the calling process is awaiting action is removed from the system. When this occurs, `errno` is set equal to `EIDRM` and `-1` is returned.
 - The calling process receives a signal that is to be caught. When this occurs, the value of `semzcnt` associated with the specified semaphore is decremented, and the calling process resumes execution in the manner prescribed in `sigaction()`.
 - Upon successful completion, the value of `sempid` for each semaphore specified in the array pointed to by `sops` is set equal to the process ID of the calling process.

The variable, `set`, gives the timeout specification.

- If the `__semop_timed()` function finds that none of the semaphores specified by `semid` are received, it waits for the time interval specified in the **timespec** structure referenced by `set`. If the **timespec** structure pointed to by `set` is zero-valued and if none of the semaphores specified by `semid` are received, then `__semop_timed()` returns immediately with `EAGAIN`. A **timespec** with the `tv_sec` field set with `INT_MAX`, as defined in `<limits.h>`, will cause the `__semop_timed()` service to wait until a semaphore is received. If `set` is the `NULL` pointer, it will be treated the same as when **timespec** structure was supplied with the `tv_sec` field set with `INT_MAX`.

Returned value

If successful, `__semop_timed()` returns 0. Also the `semid` parameter value for each semaphore that is operated upon is set to the process ID of the calling process.

If unsuccessful, `__semop_timed()` returns `-1` and sets `errno` to one of the following values:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

E2BIG

The value *nsops* is greater than the system limit.

EACCES

Operation permission is denied to the calling process. Read access is required when *sem_op* is zero. Write access is required when *sem_op* is not zero.

EAGAIN

The operation would result in suspension of the calling process but **IPC_NOWAIT** in *sem_flg* was specified. This would result if the timeout specified expires before a semop is posted.

EFBIG

sem_num is less than zero or greater or equal to the number of semaphores in the set specified on in *semget()* argument *nsems*.

EIDRM

semid was removed from the system while the invoker was waiting.

EINTR

__semop_timed() was interrupted by a signal.

EINVAL

The value of argument *semid* is not a valid semaphore identifier.

ENOSPC

The limit on the number of individual processes requesting a **SEM_UNDO** would be exceeded.

ERANGE

An operation would cause *semval* or *semadj* to overflow the system limit as defined in `<sys/sem.h>`.

send() – Send data on a socket

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format**X/Open:**

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

ssize_t send(int socket, const void *buffer, size_t length, int flags);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/socket.h>

int send(int socket, char *buffer, int length, int flags);
```

General description

The `send()` function sends data on the socket with descriptor *socket*. The `send()` call applies to all connected sockets.

Parameter Description

socket

The socket descriptor.

msg

The pointer to the buffer containing the message to transmit.

length

The length of the message pointed to by the *msg* parameter.

flags

The *flags* parameter is set by If more than one flag is specified, the logical OR operator (`|`) must be used to separate them.

MSG_OOB

Sends out-of-band data on sockets that support this notion. Only `SOCK_STREAM` sockets support out-of-band data. The out-of-band data is a single byte.

Before out-of-band data can be sent between two programs, there must be some coordination of effort. If the data is intended to not be read inline, the recipient of the out-of-band data must specify the recipient of the `SIGURG` signal that is generated when the out-of-band data is sent. If no recipient is set, no signal is sent. The recipient is set up by using `F_SETOWN` operand of the `fcntl` command, specifying either a pid or gid. For more information on this operand, refer to the `fcntl` command.

The recipient of the data determines whether to receive out-of-band data inline or not inline by the setting of the `SO_OOBINLINE` option of `setsockopt()`. For more information on receiving out-of-band data, refer to the `setsockopt()`, `recv()`, `recvfrom()` and `recvmsg()` commands.

MSG_DONTRROUTE

The `SO_DONTRROUTE` option is turned on for the duration of the operation. This is usually used only by diagnostic or routing programs.

If there is not enough available buffer space to hold the socket data to be transmitted, and the socket is in blocking mode, `send()` blocks the caller until additional buffer space becomes available. If the socket is in nonblocking mode, `send()` returns -1 and sets the error code to `EWOULDBLOCK`. See [“fcntl\(\) — Control open file descriptors” on page 483](#) or [“ioctl\(\) — Control device” on page 872](#) for a description of how to set nonblocking mode.

For datagram sockets, this call sends the entire datagram, provided that the datagram fits into the TCP/IP buffers. Stream sockets act like streams of information with no boundaries separating data. For example, if an application wishes to send 1000 bytes, each call to this function can send 1 byte, or 10 bytes, or the entire 1000 bytes. Therefore, applications using stream sockets should place this call in a loop, calling this function until all data has been sent.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` 1 feature test macro.

Returned value

If successful, `send()` returns 0 or greater indicating the number of bytes sent. However, this does not assure that data delivery was complete. A connection can be dropped by a peer socket and a `SIGPIPE` signal generated at a later time if data delivery is not complete.

If unsuccessful, `send()` returns -1 indicating locally detected errors and sets `errno` to one of the following values. No indication of failure to deliver is implicit in a `send()` routine.

Error Code Description

EBADF

socket is not a valid socket descriptor.

ECONNRESET

A connection was forcibly closed by a peer.

EDESTADDRREQ

The socket is not connection-oriented and no peer address is set.

EFAULT

Using the *msg* and *length* parameters would result in an attempt to access storage outside the caller's address space.

EINTR

A signal interrupted `send()` before any data was transmitted.

EIO

There has been a network or transport failure.

EMSGSIZE

The message was too big to be sent as a single datagram.

ENOBUFS

Buffer space is not available to send the message.

ENOTCONN

The socket is not connected.

ENOTSOCK

The descriptor is for a file, not for a socket.

EOPNOTSUPP

The *socket* argument is associated with a socket that does not support one or more of the values set in *flags*.

EPIPE

For a connected stream socket the connection to the peer socket has been lost. A SIGPIPE signal is sent to the calling process.

EWOULDBLOCK

socket is in nonblocking mode and no data buffers are available or the SO_SNDTIMEO timeout value was reached before buffers became available.

send_file() — Send file data over a socket

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _OPEN_SYS_SOCKET_EXT2
#include <sys/socket.h>

int send_file(int *socket_ptr, struct sf_parms *sf_struct, int options);
```

General description

The `send_file()` function sends data from the file associated with the open file handle over the connection associated with the socket.

The function takes the following arguments:

socket_ptr

A pointer to a socket file descriptor.

sf_struct

A pointer to a structure that contains variables needed by `sendfile` - header information, file information, trailer information and results of operation. See below for details.

options

Specifies one of the following options:

SF_CLOSE

Close the connection after the data has been successfully sent or queued for transmission.

SF_REUSE

Prepare the socket for reuse after the data has been successfully sent or queued for transmission and the existing connection closed.

0

Do not close the socket (use zero for no options).

Send_File Structure - sf_parms

Argument `sf_struct` points to a struct `sf_parms` that contains the file descriptor, a header data buffer, and a trailer data buffer.

The struct `sf_parms` is defined in `<sys/sockets.h>` and contains the following elements:

header_data

Pointer to a buffer that contains header data which is to be sent before the file data. It may be a NULL pointer if `header_length` is zero.

header_length

Specifies the number of bytes in the `header_data`. It must be set to zero to indicate that header data is not to be sent.

file_descriptor

File descriptor for a file that has been opened for read. This is the descriptor for the file that contains the data to be transmitted.

file_size

The size, in bytes, of the file associated with *file_descriptor*. This field is filled in by the system.

file_offset

Specifies the byte offset into the file from which to start sending data.

file_bytes

Specifies the number of bytes from the file to be transmitted. Setting *file_bytes* to -1 will transmit the entire file from the *offset*. In this case the system will replace the -1 with (actual file size - *file_offset*). Setting *file_bytes* to 0 will result in no file data being transmitted and *file_descriptor* is ignored. If *file_descriptor* is not a regular file it may be necessary to supply a specific value for *file_bytes* unless a normal End Of File (EOF) indication is expected from *file_descriptor* during this operation or you simply want the operation to run forever transferring bytes as they arrive.

trailer_data

Pointer to a buffer that contains trailer data which is to be sent after the file data.

trailer_length

Specifies the number of bytes in the *trailer_data*.

bytes_sent

Number of bytes that were sent in this call to `send_file()`. If it takes multiple calls to `send_file()` to send all the data (due to signal-handling) then this field contains the value for the last call to `send_file()`, it is not a running total. This field is set by the system.

The `send_file()` function attempts to write *header_length* bytes from the buffer pointed to by *header_data*, followed by *file_bytes* from the file associated with *file_descriptor*, followed by *trailer_length* bytes from the buffer pointed to by *trailer_data*, over the connection associated with the socket pointed to by *socket_ptr*.

As data is sent, the system will update elements in *sf_struct* so that if the `send_file()` function is interrupted by a signal, the application simply needs to reissue `send_file()`.

If the application sets *file_offset* > the actual file size, or *file_bytes* > (the actual file size - *file_offset*), the return value will be -1 and `errno` set to *EINVAL*.

If `O_NONBLOCK` is set on the socket file descriptor, the function may return -1 with `errno` set to *EWOULDBLOCK* or *EAGAIN*, or it may complete before all the data is sent. If `O_NONBLOCK` is not set, `send_file()` blocks until the requested data can be sent.

`SF_CLOSE` and `SF_REUSE` will only be effective after all the data has been sent successfully.

If *options* = `SF_REUSE`, and socket reuse is not supported, the system will close the socket and set the socket pointed to by *socket_ptr* to -1. See “Application usage” on page 1497 for details.

Application usage

The function `send_file()` is designed to work with `accept_and_recv()` to provide an efficient file transfer capability for a connection oriented server with short connection times and high connection rates.

On the first call to `accept_and_recv()`, it is recommended that the application set the socket pointed to by *accept_socket* to -1. This will cause the system to assign the accepting socket. On the call to `send_file()`, if the application requests socket reuse (*options* = `SF_REUSE`) and the system does not support it, the system will close the socket pointed to by *socket_ptr* and will set the socket pointed to by *socket_ptr* to -1. The application then passes this value onto the next call to `accept_and_recv()` (by setting *accept_socket* = **socket_ptr*).

To take full advantage of the performance improvements offered by the `accept_and_recv()` and `send_file()` functions, a process/thread model different from the one where a parent accepts in a loop and spins off child process threads is needed. The parent/process thread is eliminated. Multiple worker processes/threads are created, and each worker process/thread then executes the `accept_and_recv()`.

and `send_file()` functions in a loop. The performance benefits of `accept_and_recv()` and `send_file()` include fewer buffer copies, recycled sockets, and optimal scheduling.

Note: The function `send_file()` can be useful by itself for long living socket connections. It does not have to be paired with `accept_and_recv()`. To leave the socket open after `send_file()`, specify a 0 for the *options* parameter.

Returned value

If successful, `send_file()` returns 0.

`send_file()` returns 1 if the request was interrupted by a signal, or because a nonblocking descriptor would have blocked, while sending data. Since the *sf_parms* structure is updated by the system to account for the data that has been sent you can continue the operation from where it was interrupted by recalling `send_file()` without changing the *sf_parms* structure.

If unsuccessful, `send_file()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

The calling process does not have the appropriate privileges.

EAGAIN

`socket_ptr` is in nonblocking mode and no data buffers are available or the `SO_SNDTIMEO` timeout value was reached before buffers became available.

EBADF

One of the following occurred:

1. *socket_ptr* is not a valid descriptor or was not open for writing.
2. *file_descriptor* is not a valid descriptor or was not open for reading.

ECONNABORTED

A connection has been aborted.

ECONNRESET

A connection has been forcibly closed by a peer.

EFAULT

The data buffer pointed to by *socket_ptr*, *file_size*, *header_data*, or *trailer_data* was not valid.

EINTR

`send_file()` was interrupted by a signal that was caught before any data was sent.

EINVAL

The value specified by *options* is not valid.

EIO

An I/O error occurred.

EMSGSIZE

The message is too large to be sent all at once, as the socket requires.

ENETDOWN

The local interface to reach the destination is unknown.

ENETUNREACH

No route to the destination is present.

ENOBUFS

No buffer space is available.

ENOMEM

There was insufficient memory available to complete the operation.

ENOSR

There were insufficient STREAMS resources available for the operation to complete.

ENOSYS

This function is not supported in the current environment.

ENOTCONN

The socket is not connected.

ENOTSOCK

The file descriptor pointed to by the *socket_ptr* argument does not refer to a socket.

EPIPE

The socket is shutdown for writing, or the socket is in connection mode and is no longer connected.

EWOULDBLOCK

socket_ptr is in nonblocking mode and no data buffers are available or the SO_SNDTIMEO timeout value was reached before buffers became available.

sendmsg() — Send messages on a socket

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format**X/Open:**

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

ssize_t sendmsg(int socket, struct msghdr *msg, int flags);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/socket.h>

int sendmsg(int socket, struct msghdr *msg, int flags);
```

General description

The `sendmsg()` function sends messages on a socket with a socket descriptor passed in an array of message headers.

Parameter**Description****socket**

The socket descriptor.

msg

An array of message headers from which messages are sent.

flags

Specifying one or more of the following flags. If more than one flag is specified, the logical OR operator (|) must be used to separate them.

MSG_OOB

Sends out-of-band data on the socket. Only SOCK_STREAM sockets support out-of-band data. The out-of-band data is a single byte.

Before out-of-band data can be sent between two programs, there must be some coordination of effort. If the data is intended to not be read inline, the recipient of the out-of-band data must specify the recipient of the SIGURG signal that is generated when the out-of-band data is sent. If no recipient is set, no signal is sent. The recipient is set by setting the *action* parameter of the fcntl() function to F_SETOWN and specifying either a PID or GID. For more information on setting a recipient for out-of-band data, see [“fcntl\(\) — Control open file descriptors” on page 483](#).

The recipient of the data determines whether to receive out-of-band data inline or not inline by the setting of the SO_OOBINLINE socket option using the setsockopt() function. For more information on receiving out-of-band data, see [“setsockopt\(\) — Set options associated with a socket” on page 1573](#), [“recv\(\) — Receive data on a socket” on page 1401](#), [“recvfrom\(\) — Receive messages on a socket” on page 1404](#), and [“recvmsg\(\) — Receive messages on a socket and store in array of message headers” on page 1407](#).

MSG_DONTROUTE

The SO_DONTROUTE socket option is turned on for the duration of the operation. This flag is typically used by diagnostic or routing programs.

A message header is defined by the msghdr structure, which can be found in the sys/socket.h header file and contains the following elements:

Element**Description****msg_iov**

An array of *iovec* buffers containing the message.

msg_iovlen

The number of elements in the *msg_iov* array.

msg_name

An optional pointer to the buffer containing the recipient's address.

msg_namelen

The size of the address buffer.

caddr_t msg_accrightrights

Access rights sent or received (ignored if specified by the user). This field is ignored by z/OS UNIX services.

int msg_accrightrightslen

Length of access rights data (ignored if specified by the user). This field is ignored by z/OS UNIX services.

msg_control

Ancillary data.

msg_controllen

Ancillary data buffer length.

msg_flags

Flags on received message.

Ancillary data consists of a sequence of pairs, each consisting of a cmsghdr structure followed by a data array. The data array contains the ancillary data message and the cmsghdr structure contains descriptive information that allows an application to correctly parse the data.

The sys/socket.h header file defines the cmsghdr structure that includes at least the following elements:

| Element | Description |
|---------|-------------|
|---------|-------------|

cmsg_len

| |
|------------------------------------|
| Data byte count, including header. |
|------------------------------------|

cmsg_level

| |
|-----------------------|
| Originating protocol. |
|-----------------------|

cmsg_type

| |
|-------------------------|
| Protocol-specific type. |
|-------------------------|

The following ancillary data are available at the IPv4 level:

| Ancillary data | Description |
|----------------|-------------|
|----------------|-------------|

IP_PKTINFO

| |
|---|
| (RAW and UDP) Specifies the interface packets are sent over and the IP address used as the packet source IP. The data is passed in an <code>in_pktinfo</code> structure as defined in <code>netinet/in.h</code> . |
|---|

The following ancillary data are available at the IPv6 level:

| Ancillary data | Description |
|----------------|-------------|
|----------------|-------------|

IPV6_HOPLIMIT

| |
|---|
| (RAW, TCP, and UDP) Specifies the maximum hop limit for an outgoing packet. The data is passed in a structure as defined in <code>netinet/in.h</code> . |
|---|

IPV6_PATHMTU

| |
|---|
| (RAW and UDP) Specifies the path MTU value for the destination of a connected socket. The data is passed in a structure as defined in <code>netinet/in.h</code> . |
|---|

IPV6_PKTINFO

| |
|--|
| (RAW and UDP) Specifies the interface packets are sent over and the IP address used as the packet source IP. The data is passed in an <code>in6_pktinfo</code> structure as defined in <code>netinet/in.h</code> . |
|--|

The following ancillary data are available at the socket level:

| Ancillary data | Description |
|----------------|-------------|
|----------------|-------------|

SCM_RIGHTS

| |
|---|
| Specifies the data array that contains the access rights to be sent or received. This ancillary data is valid only for the <code>AF_UNIX</code> domain. The data is passed in a structure as defined in <code>sys/socket.h</code> . |
|---|

The `sys/socket.h` header file defines the following macros to gain access to the data arrays in the ancillary data associated with a message header:

CMMSG_DATA(*cmsg*)

If the argument is a pointer to a `cmsg_hdr` structure, this macro returns an unsigned character pointer to the data array associated with the `cmsg_hdr` structure.

CMMSG_NXTHDR(*mhdr, cmsg*)

If the first argument is a pointer to a `msg_hdr` structure and the second argument is a pointer to a `cmsg_hdr` structure in the ancillary data (pointed to by the `msg_control` field of that `msg_hdr` structure), this macro returns a pointer to the next `cmsg_hdr` structure or a NULL pointer if this structure is the last `cmsg_hdr` structure in the ancillary data.

CMMSG_FIRSTHDR(*mhdr*)

If the argument is a pointer to a `msg_hdr` structure, this macro returns a pointer to the first `cmsg_hdr` structure in the ancillary data associated with this `msg_hdr` structure, or a NULL pointer if there is no ancillary data associated with the `msg_hdr` structure.

The `sendmsg()` call applies to sockets regardless of whether they are in the connected state.

This call returns the length of the data sent. If there is not enough available buffer space to hold the socket data to be transmitted, and the socket is in blocking mode, `sendmsg()` blocks the caller until additional buffer space becomes available. If the socket is in nonblocking mode, `sendmsg()` returns -1 and

sets the error code to EWOULDBLOCK. See [“fcntl\(\) — Control open file descriptors”](#) on page 483 or [“ioctl\(\) — Control device”](#) on page 872 for a description of how to set nonblocking mode.

For datagram sockets, this call sends the entire datagram, provided that the datagram fits into the TCP/IP buffers. Stream sockets act like streams of information with no boundaries separating data. For example, if an application wishes to send 1000 bytes, each call to this function can send 1 byte, or 10 bytes, or the entire 1000 bytes. Therefore, applications using stream sockets should place this call in a loop, calling this function until all data has been sent.

Socket address structure for IPv6: For an AF_INET6 socket, if msg_name is specified then the address should be in a sockaddr_in6 address structure. The sockaddr_in6 structure is defined in the header file netinet/in.h.

Special behavior for C++: To use this function with C++, you must use the _XOPEN_SOURCE_EXTENDED 1 feature test macro.

Note: The sendmsg() function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support”](#) on page 2123 for details.

Returned value

If successful, sendmsg() returns the length of the message in bytes.

A value of 0 or greater indicates the number of bytes sent, however, this does not assure that data delivery was complete. A connection can be dropped by a peer socket and a SIGPIPE signal generated at a later time if data delivery is not complete.

If unsuccessful, sendmsg() returns -1 and sets errno to one of the following values:

Error Code Description

EADDRNOTAVAIL

The *ip6_addr* is not available for use on the *ip6_ifindex* interface.

EAFNOSUPPORT

The address family is not supported (it is not AF_UNIX, AF_INET, or AF_INET6).

EBADF

socket is not a valid socket descriptor.

ECONNREFUSED

The attempt to connect was rejected.

ECONNRESET

A connection was forcibly closed by a peer.

EFAULT

Using *msg* would result in an attempt to access storage outside the caller's address space.

EHOSTUNREACH

No route to the destination exists over the interface specified by *ifi6_index*.

EINTR

A signal interrupted sendmsg() before any data was transmitted.

EINVAL

msg_namelen is not the size of a valid address for the specified address family.

EIO

There has been a network or transport failure.

EMSGSIZE

The message was too big to be sent as a single datagram. The default is *large-envelope-size*. (Envelopes are used to hold datagrams and fragments during TCP/IP processing. Large envelopes hold UDP datagrams greater than 2KB while they are processed for output, and when they are waiting for an application program to receive them on input.)

ENETDOWN

The interface specified by *ip6_ifindex* is not enabled for IPv6 use.

ENOBUFS

Buffer space is not available to send the message.

ENOTCONN

The socket is not connected.

ENOTSOCK

The descriptor is for a file, not for a socket.

ENXIO

The interface specified by *ip6_ifindex* does not exist.

EOPNOTSUPP

The *socket* argument is associated with a socket that does not support one or more of the values set in *flags*.

EPIPE

For a connected stream socket the connection to the peer socket has been lost. A SIGPIPE signal is sent to the calling process.

EWouldBlock

socket is in nonblocking mode and no data buffers are available or the SO_SNDTIMEO timeout value was reached before buffers became available.

The following are for AF_UNIX only:

Error Code**Description****EACCES**

Search permission is denied for a component of the path prefix, or write access to the named socket is denied.

EIO

An I/O error occurred while reading from or writing to the file system.

ELOOP

Too many symbolic links were encountered in translating the pathname in the socket address.

ENAMETOOLONG

A component of a pathname exceeded **NAME_MAX** characters, or an entire pathname exceeded **PATH_MAX** characters.

ENOENT

A component of the pathname does not name an existing file or the pathname is an empty string.

ENOTDIR

A component of the path prefix of the pathname in the socket address is not a directory.

sendto() — Send data on a socket

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

ssize_t sendto(int socket, const void *buffer, size_t length, int flags,
               const struct sockaddr *address, size_t address_len);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/socket.h>

int sendto(int socket, char *buffer, int length, int flags,
           struct sockaddr *address, int address_len);
```

General description

The `sendto()` function sends data on the socket with descriptor *socket*. The `sendto()` call applies to either connected or unconnected sockets.

Parameter

Description

socket

The socket descriptor.

buffer

The pointer to the buffer containing the message to transmit.

length

The length of the message in the buffer pointed to by the *msg* parameter.

flags

Setting these flags is not supported in the AF_UNIX domain. The following flags are available:

MSG_OOB

Sends out-of-band data on the socket. Only SOCK_STREAM sockets support out-of-band data. The out-of-band data is a single byte.

Before out-of-band data can be sent between two programs, there must be some coordination of effort. If the data is intended to not be read inline, the recipient of the out-of-band data must

specify the recipient of the SIGURG signal that is generated when the out-of-band data is sent. If no recipient is set, no signal is sent. The recipient is set up by using `F_SETOWN` operand of the `fcntl()` command, specifying either a pid or gid. For more information on this operand, refer to the `fcntl()` command.

The recipient of the data determines whether to receive out-of-band data inline or not inline by the setting of the `SO_OOBINLINE` option of `setsockopt()`. For more information on receiving out-of-band data, refer to the `setsockopt()`, `recv()`, `recvfrom()` and `recvmsg()` commands.

MSG_DONTROUTE

The `SO_DONTROUTE` option is turned on for the duration of the operation. This is usually used only by diagnostic or routing programs.

address

The address of the target.

addr_len

The size of the address pointed to by *address*.

If there is not enough available buffer space to hold the socket data to be transmitted, and the socket is in blocking mode, `sendto()` blocks the caller until additional buffer space becomes available. If the socket is in nonblocking mode, `sendto()` returns -1 and sets the error code to `EWOULDBLOCK`. See [“fcntl\(\) — Control open file descriptors” on page 483](#) or [“ioctl\(\) — Control device” on page 872](#) for a description of how to set nonblocking mode.

For datagram sockets, this call sends the entire datagram, provided that the datagram fits into the TCP/IP buffers. Stream sockets act like streams of information with no boundaries separating data. For example, if an application wishes to send 1000 bytes, each call to this function can send 1 byte, or 10 bytes, or the entire 1000 bytes. Therefore, applications using stream sockets should place this call in a loop, calling this function until all data has been sent.

Socket address structure for IPv6: The `sockaddr_in6` structure is added to the **netinit/in.h** header. It is used to pass IPv6 specific addresses between applications and the system.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` 1 feature test macro.

Note: The `sendto()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support ” on page 2123](#) for details.

Returned value

If successful, `sendto()` returns the number of characters sent.

A value of 0 or greater indicates the number of bytes sent, however, this does not assure that data delivery was complete. A connection can be dropped by a peer socket and a SIGPIPE signal generated at a later time if data delivery is not complete.

No indication of failure to deliver is implied in the return value of this call when used with datagram sockets.

If unsuccessful, `sendto()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EAFNOSUPPORT

The address family is not supported (it is not `AF_UNIX` or `AF_INET`).

EBADF

socket is not a valid socket descriptor.

ECONNREFUSED

The attempt to connect was rejected.

ECONNRESET

A connection was forcibly closed by a peer.

EFAULT

Using the *msg* and *length* parameters would result in an attempt to access storage outside the caller's address space.

EINTR

A signal interrupted `sendto()` before any data was transmitted.

EINVAL

addr_len is not the size of a valid address for the specified address family.

EIO

There has been a network or transport failure.

EMSGSIZE

The message was too big to be sent as a single datagram. The default is *large-envelope-size*. (Envelopes are used to hold datagrams and fragments during TCP/IP processing. Large envelopes hold UDP datagrams greater than 2KB while they are processed for output, and when they are waiting for an application program to receive them on input.)

ENOBUFS

Buffer space is not available to send the message.

ENOTCONN

The socket is not connected.

ENOTSOCK

The descriptor is for a file, not for a socket.

EOPNOTSUPP

The *socket* argument is associated with a socket that does not support one or more of the values set in *flags*.

EPIPE

For a connected stream socket the connection to the peer socket has been lost. A SIGPIPE signal is sent to the calling process.

EPROTOTYPE

The protocol is the wrong type for this socket. A SIGPIPE signal is sent to the calling process.

EWouldBlock

socket is in nonblocking mode and no data buffers are available or the SO_SNDTIMEO timeout value was reached before buffers became available.

The following are for AF_UNIX only:

Error Code**Description****EACCES**

Search permission is denied for a component of the path prefix, or write access to the named socket is denied.

EIO

An I/O error occurred while reading from or writing to the file system.

ELOOP

Too many symbolic links were encountered in translating the path name in the socket address.

ENAMETOOLONG

A component of a path name exceeded **NAME_MAX** characters, or an entire path name exceeded **PATH_MAX** characters.

ENOENT

A component of the path name does not name an existing file or the path name is an empty string.

ENOTDIR

A component of the path prefix of the path name in the socket address is not a directory.

__server_classify() — Set classify area field

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <sys/server.h>

int __server_classify(server_classify_t handle,
                     server_classify_field_t field,
                     const char *value);
```

General description

The `__server_classify()` function sets fields in a classify data area. The 'classify data area' is created and initialized by invoking the `__server_classify_create()` function. This 'classify data area' is subsequently used with the `__server_pwu()` function to interface with WorkLoad Manager (WLM).

The *handle* argument is a 'classify data area' created on a previous invocation of the `__server_classify_create()` function.

The *field* argument must be one of the following values:

_SERVER_CLASSIFY_ACCTINFO

Set the accounting information. When specified, value contains a NULL-terminated character string of up to 143 characters containing the account information for the work unit to be created.

_SERVER_CLASSIFY_COLLECTION

Set the customer defined name for a group of associated packages. When specified, value contains a NULL-terminated character string of up to 18 characters containing the collection name associated with the work unit to be created.

_SERVER_CLASSIFY_CONNECTION

Set the name associated with the environment creating the work unit. When specified, value contains a NULL-terminated character string of up to 8 characters containing the connection name associated with the environment creating the work unit.

_SERVER_CLASSIFY_CONNTKN

Set the connection token that was returned on a call to `__ConnectWorkMgr()` or `__ConnectServerMgr()`. When specified, value contains a integer value representing the connection token returned on a call to `__ConnectWorkMgr()` or `__ConnectServerMgr()`.

_SERVER_CLASSIFY_CORRELATION

Set the name associated with the user/program creating the work unit. When specified, value contains a NULL-terminated character string of up to 12 characters that contains the name associated with the user/program creating the work unit.

_SERVER_CLASSIFY_LUNAME

Set the local LU name associated with the requester. When specified, value contains a NULL-terminated character string of up to 8 characters containing the local LU name associated with the requester.

_SERVER_CLASSIFY_NETID

Set the network ID associated with the requester. When specified, value contains a NULL-terminated character string of up to 8 characters containing the network ID associated with the requester.

_SERVER_CLASSIFY_PACKAGE

Set the package name for a set of associated SQL statements. When specified, value contains a NULL-terminated character string of up to 8 characters containing the package name associated with the work unit to be created.

_SERVER_CLASSIFY_PERFORM

Set the performance group number (PGN) associated with the work unit. When specified, value contains a NULL-terminated character string of up to 8 characters containing the PGN associated with the work unit to be created.

_SERVER_CLASSIFY_PLAN

Set the access plan name for a set of associated SQL statements. When specified, value contains a NULL-terminated character string of up to 8 characters containing the access plan name associated with the work unit to be created.

_SERVER_CLASSIFY_PRCNAME

Set the DB2® stored SQL procedure name associated with the work unit. When specified, value contains a NULL-terminated character string of up to 18 characters containing the DB2 stored SQL procedure name associated with the work unit to be created.

_SERVER_CLASSIFY_PRIORITY

Set the priority associated with the work unit to be created. When specified, value contains a integer value representing the priority of the work unit to be created.

_SERVER_CLASSIFY_RPTCLSNM@

Set the pointer to an 8 character buffer to receive the output report class name for the work unit to be created. When specified, value contains the pointer to an 8 character buffer to receive the output report class name for the work unit to be created.

_SERVER_CLASSIFY_SCHEDENV

Set the scheduling environment information. When specified, value contains a NULL-terminated character string of up to 16 characters containing the scheduling environment name associated with the work unit.

_SERVER_CLASSIFY_SERVCLS@

Set the pointer to an integer field to receive the output service class for the work unit to be created. When specified, value contains the pointer to a integer field to receive the output service class for the work unit to be created.

_SERVER_CLASSIFY_SERVCLSNM@

Set the pointer to an 8 character buffer to receive the output service class name for the work unit to be created. When specified, value contains the pointer to an 8 character buffer to receive the output service class name for the work unit to be created.

_SERVER_CLASSIFY_SOURCELU

Set the source LU name associated with the requester. When specified, value contains a NULL-terminated character string of up to 17 characters containing the source LU name associated with the requester.

_SERVER_CLASSIFY_SUBCOLN

Set the subsystem collection name. When specified, the value contains a NULL-terminated character string of up to 8 characters, containing the subsystem collection name associated with the work unit.

_SERVER_CLASSIFY_SUBSYSTEM_PARM

Set the transaction subsystem parameter. When specified, *value* contains a NULL-terminated character string of up to 255 characters containing the subsystem parameter being used for the __server_pwu() call.

_SERVER_CLASSIFY_TRANSACTION_CLASS

Set the transaction class. When specified, *value* contains a NULL-terminated character string of up to 8 characters containing the name of the transaction class for the __server_pwu() call.

_SERVER_CLASSIFY_TRANSACTION_NAME

Set the transaction name. When specified, *value* contains a NULL-terminated character string of up to 8 characters containing the name of the transaction for the __server_pwu() call.

_SERVER_CLASSIFY_USERID

Set the user ID. When specified, *value* contains a NULL-terminated character string of up to 8 characters containing the name of the user for the __server_pwu() call.

The *value* argument is the value that the specified 'classify data area' field is to be set to. (For valid values, refer to [z/OS MVS Programming: Workload Management Services](#).)

The classify area is specific to the calling thread. The __server_classify() function call must be done on the same thread of execution as the __server_classify_create(). Use of the classify area by another thread can lead to unpredictable results.

Returned value

If successful, __server_classify() returns 0.

If unsuccessful, __server_classify() returns -1 and sets errno to one of the following values:

Error Code**Description****E2BIG**

The character string specified for a classify field is too large.

EINVAL

The classify field symbolic is not valid.

__server_classify_create() – Create a classify area

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <sys/server.h>

server_classify_t __server_classify_create(void);
```

General description

The `__server_classify_create()` function creates a classify data area to be used on a subsequent `__server_pwu()` or `CreateWorkUnit()` call. The resulting classify data area can be filled in by calls to the `__server_classify()` function. The information in the classify area is used to establish the Transaction class, Transaction Name, user ID, and subsystem parameters for the `__server_pwu()` call or to establish the classification rules for the `CreateWorkUnit()` call.

The resulting classify area is specific to the calling thread. Use of the classify area by another thread can lead to unpredictable results.

Returned value

If successful, `__server_classify_create()` returns a *classify_t* which is a handle to the classify area.

If unsuccessful, `__server_classify_create()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

ENOMEM

Not enough storage is available.

Related information

The classify data area created by this function can be used without serialization only by the creating thread. In addition, storage for this structure is automatically freed at thread termination.

__server_classify_destroy() – Delete a classify area

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <sys/server.h>

void __server_classify_destroy(server_classify_t area);
```

General description

The `__server_classify_destroy()` function deletes a classify data area previously created by a `__server_classify()` call. The *area* parameter specifies the classify area to be deleted. Storage for the classify area is freed. This function must be executed by the same thread that created the classify area.

Returned value

`__server_classify_destroy()` returns no values.

Related information

- [“sys/server.h — WorkLoad Manager services” on page 70](#)
- [“__server_classify\(\) — Set classify area field” on page 1507](#)

[__server_classify_reset\(\) — Reset a classify area to an initial state](#)

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <sys/server.h>

void __server_classify_reset(server_classify_t area);
```

General description

The `__server_classify_reset()` function resets a classify data area to its initial state. This is equivalent to destroying the classify area and creating another, and is intended to be a higher performance path for applications which must repeatedly change parameters in a classify area. The *area* parameter specifies the handle of the classify area to be reset, and was previously obtained by a `__server_classify()` call. This function must be executed by the same thread that created the classify area.

Returned value

`__server_classify_reset()` returns no values.

__server_init() — Initialize server

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <sys/server.h>

int __server_init(int *managertype, const char *subsysname,
                  const char *applen, int paralleu);
```

General description

The `__server_init()` function provides the ability for a server address space to connect to WorkLoad Manager (WLM) for the purpose of queueing and servicing work requests.

The parameters supported are:

***managertype**

Points to one or more of the following values that indicate the type of WLM manager the caller is requesting to become. The following are the supported values:

SRV_WORKMGR

Indicates that WLM work management services be made available to the calling address space. This value can be combined with the `SRV_QUEUEMGR` and `SRV_SERVERMGR` values.

SRV_QUEUEMGR

Indicates that WLM queue management services be made available to the calling address space. This value can be combined with the `SRV_WORKMGR` and `SRV_SERVERMGR` values.

SRV_SERVERMGR

Indicates that WLM server management services be made available to the calling address space. This value can be combined with the `SRV_WORKMGR` and `SRV_QUEUEMGR` values.

SRV_SERVERMGRDYNAMIC

Indicates that the WLM work management is to track the number of threads this address space will need. It prepares the address space to support the `__service_thread_query()` function. For `SRV_SERVERMGRDYNAMIC` the *paralleu* parameter has the same effect as it does for `SRV_SERVERMGR`, in that, it indicates the maximum number of parallel work units that the server can create. The server would initially create some number of threads less than this maximum. The dynamic capability then allows the server to tap into WLM to tell the server when to increase or decrease the number of threads in the address space.

***subsysname**

Points to a NULL-terminated character string containing the generic subsystem type (CICS, IMS, WEB, etc.). When `SRV_WORKMGR` is specified for the *managertype* parameter this is the primary category under which WLM classification rules are grouped. The character string can be up to 4 bytes in length.

***subsysname**

Points to a NULL-terminated character string containing the subsystem name used for classifying work requests when SRV_WORKMGR is specified for the *managertype* parameter. When SRV_SERVERMGR is specified for the *managertype* parameter the subsystem name should match the subsystem name specified on the corresponding call to `__server_init()` for a work manager (SRV_WORKMGR *managertype*). The character string can be up to 8 bytes in length. When SRV_QUEUEMGR is specified for the *managertype* parameter the combination of the *subsysname* and *subsysname* parameter values must be unique to a single MVS system.

***applenv**

Points to a NULL-terminated character string that contains the name of the application environment under which work requests are served. The character string can be up to 32 bytes in length. This parameter is only valid when SRV_SERVERMGR is specified for the *managertype* parameter. It should be NULL for all other *managertype* values.

paralleleu

Specifies the maximum number of tasks within the address space which will be created to process concurrent work requests. This parameter is valid when both or either SRV_SERVERMGR and SRV_SERVERMGRDYNAMIC are specified for the *managertype* parameter. It is ignored for all other *managertype* values.

A successful call to `__server_init()` results in the calling address space being connected to WLM for the WLM management services requested. Additionally, for a successful server manager WLM connection call (SRV_SERVERMGR *managertype*), the calling process is made a child of, and is placed in the session and process group of the corresponding work manager. The corresponding work manager is the process that called `server_init()` for the *managertype* combination SRV_WORKMGR+SRV_QUEUEMGR with the same *subsysname* and *subsysname* values specified as the server manager process. This parent/child relationship allows the server manager and the work manager to use signals to communicate with each other.

Returned value

If successful, `__server_init()` returns 0.

If unsuccessful, `__server_init()` returns -1 and sets `errno` to one of the following values:

Error Code**Description****EINVAL**

The *managertype* parameter contains a value that is not correct.

EMVSSAF2ERR

An error occurred in the security product.

EMVSWLMERROR

A WLM service failed. Use `__errno2()` to obtain the WLM service reason code for the failure.

EPERM

The calling thread's address space is not permitted to the BPX.WLMSEVER Facility class. The caller's address space must be permitted to the BPX.WLMSEVER Facility class, if the BPX.WLMSEVER is defined. If BPX.WLMSEVER is not defined, the calling process is not defined as a superuser (UID=0).

__server_pwu() – Process server work unit

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <sys/server.h>

int __server_pwu(int fcncode, const char *transclass,
                const char *applenv, server_classify_t classify,
                int *appldatalen, void **appldata,
                struct __srv_fd_list **fdlstruc);
```

General description

The `__server_pwu()` function provides a general purpose interface for managing and processing work using WorkLoad Manager (WLM) services. The capabilities this service provides include the ability to put work requests onto the WLM work queues, obtain work from the WLM work queues, transfer work to other WLM work servers, end units of work, delete WLM enclaves and refresh WLM work servers.

The parameters supported are:

fcncode

Contains one or more of the following values that indicate the function that is requested:

SRV_PUT_NEWWRK

Indicates that a new work request be put onto the work queue for an application environment server identified by the *applenv* parameter as part of a newly created WLM enclave. This value cannot be combined with any other *fcncode* value.

SRV_PUT_SUBWRK

Indicates that a new work request be put onto the work queue for an application environment server identified by the *applenv* parameter as part of the WLM enclave associated with the calling thread. This value can be combined with the `SRV_END_WRK` *fcncode* value.

SRV_TRANSFER_WRK

Indicates that the last work request obtained by the calling thread be transferred to the work queue of the target application environment server. As part of the transfer, the calling thread is disassociated from its WLM enclave. This value cannot be combined with any other *fcncode* value.

SRV_GET_WRK

Indicates that a new work request be obtained from the WLM work queue for the calling application environment server. The `SRV_GET_WRK` *fcncode* also results in the calling thread being associated with the WLM enclave of the work request. If the calling thread is already associated with a WLM enclave due to a prior call to `__server_pwu()` for `SRV_GET_WRK`, it is disassociated from the prior WLM enclave, as well as associated with the obtained work request. When the calling thread goes thru task termination or when its process is terminated the work request is ended and the associated WLM enclave is deleted if it is owned by the terminating task or process. The `SRV_GET_WRK` caller owns the enclave, if the work was queued using the `SRV_PUT_NEWWRK` or `SRV_TRANSFER_WRK` functions. If the caller is a thread created using `pthread_create` (*pthread*), the thread task owns the enclave. If the caller is not a *pthread*, the process owns the enclave. This value can be combined with the `SRV_END_WRK` and `SRV_DEL_ENC` *fcncode* values.

SRV_REFRESH_WRK

Indicates that the servers associated with the application environments managed by the calling work and queue manager are to be refreshed. This will cause all servers to complete existing work

requests and then terminate. New servers will then be started to process new work. This value cannot be combined with any other *fcncode* value.

SRV_END_WRK

Indicates that the calling thread is to be disassociated from its WLM enclave. This value can be combined with the SRV_DEL_ENC, SRV_PUT_SUBWRK and SRV_GET_WRK *fcncode* values.

SRV_DEL_ENC

Indicates that the WLM enclave associated with the calling thread is to be deleted. This value can be combined with the SRV_GET_WRK and SRV_END_WRK *fcncode* values.

SRV_DISCONNECT

Indicates that the calling server's connection to WLM is to be severed. Once a server is disconnected from WLM, it can no longer use this service to process more requests for the application environment it had been connected to (using a call to the `server_init()` function). If a SRV_DISCONNECT is performed by a work and queue manager, all related server managers implicitly lose their connection to WLM. This also results in the related server managers losing their ability to process more requests using this service.

SRV_DISCONNECT_COND

Indicates that the calling server's connection to WLM is to be severed only if the caller has no more WLM enclaves that it is still managing. A work and queue manager is still managing an enclave if it has yet to be serviced by a server manager. Once a server is disconnected from WLM, it can no longer use this service to process more requests for the application environment it had been connected to (using a call to the `server_init()` function). If a SRV_DISCONNECT_COND is performed by a work and queue manager, all related server managers implicitly lose their connection to WLM. This also results in the related server managers losing their ability to process more requests using this service.

***transclass**

Points to a NULL-terminated character string that represents the name of the transaction class to be associated with the work request. This parameter is only valid when the SRV_PUT_NEWWRK *fcncode* parameter value is specified. It should be NULL for the other *fcncode* parameter values. The character string can be up to 8 bytes in length.

***applenv**

Points to a NULL-terminated character string that contains the name of the application environment under which work requests are served. This parameter is valid for the set of SRV_PUT *fcncode* values, the SRV_TRANSFER_WRK *fcncode* value and the SRV_REFRESH_WRK *fcncode* value. It should be NULL for the other *fcncode* parameter values. The character string can be up to 32 bytes in length.

***classify**

Points to a character string that contains the classification information for the work request macro.

***apldatalen**

When one of the SRV_PUT or SRV_TRANSFER *fcncode* parameter values is specified this is a supplied parameter that points to an integer containing the length of the application data specified by the ****apldata** parameter. When the SRV_GET_WRK *fcncode* value is specified, this is an output parameter where the `__server_pwu()` function is to return the length of the application data associated with the obtained work request. **apldatalen* is only valid when one of the SRV_PUT, SRV_GET_WRK or SRV_TRANSFER *fcncode* parameter values is specified, it is ignored otherwise. The maximum length supported for the application data is 10 megabytes.

****apldata**

When one of the SRV_PUT or SRV_TRANSFER *fcncode* parameter values is specified this is a supplied parameter that points to the application data string. This application data allows the caller to uniquely identify the specific work the caller is requesting. When the SRV_GET_WRK *fcncode* value is specified, this is an output parameter where the `__server_pwu()` function is to return a pointer to the application data associated with the obtained work request. The returned data area will be an identical copy of the data area that was supplied on the corresponding `__server_pwu()` call to put the work request on a WLM work queue. ****apldata** is only valid when one of the SRV_PUT, SRV_GET_WRK or SRV_TRANSER *fcncode* parameter values is specified, it is ignored otherwise.

****fdlstruc**

When one of the SRV_PUT or SRV_TRANSFER *fcncode* parameter values is specified the ****fdlstruc** parameter is an input parameter that contains a pointer to a __srv_fd_list structure. The __srv_fd_list structure contains the following members:

| | | |
|-----|-------------|---------------------------|
| int | fdcount | count of file descriptors |
| int | flags | flag SRV_FDCLOSE |
| int | fd(SRV_FDS) | file descriptor list |

The supplied __srv_fd_list structure contains the count of file descriptors to be propagated, followed by the list of file descriptors that are to be propagated to the process that calls server_pwu() to obtain the work request created by the call to this service. If the SRV_FDCLOSE flag is turned on in the flags field of the __srv_fd_list structure, all file descriptors in the list are closed in the calling process. If a NULL pointer is specified, no file descriptors are propagated. When the ****fdlstruc** parameter is used to propagate file descriptors, the caller must ensure that all of the file descriptors in the list are valid open file descriptors in the caller's process, and are not being closed during the processing of this service. If this is not the case, then this function cannot guarantee the proper propagation of the specified file descriptors. When the SRV_GET_WRK *fcncode* parameter value is specified the ****fdlstruc** parameter is an output parameter where the __server_pwu() function returns a pointer to the __srv_fd_list structure associated with the obtained work request. The returned __srv_fd_list structure will contain the count of file descriptors in the returned structure, followed by the list of remapped file descriptor values in the calling process of the file descriptors that were supplied in the __srv_fd_list structure on the corresponding __server_pwu() call to put the work request on a WLM work queue. The flags field in the returned __srv_fd_list structure will be NULL. The ****fdlstruc** parameter is only valid when one of the SRV_PUT, SRV_TRANSFER or SRV_GET_WRK *fcncode* parameter values are specified. It is ignored otherwise. The maximum number of file descriptors supported in the file descriptor list structure is 64.

A successful call to __server_pwu() for the SRV_PUT_NEWWRK *fcncode* not only creates a work request that is placed onto a WLM work queue, but it also creates a new WLM enclave for that work to run in when the work request is obtained. By comparison, the SRV_PUT_SUBWRK and SRV_TRANSFER_WRK *fcncode*s, queue work requests that are part of the existing WLM enclave of the calling thread.

A successful call to __server_pwu() for the SRV_GET_WRK *fcncode* not only results in the caller obtaining a work request from a WLM work queue associated with the caller's application environment, but also results in the calling thread being associated with the WLM enclave associated with the obtained work request.

Usage of the server_pwu function requires the calling address space to have successfully issued a call to the __server_init() function.

For the SRV_PUT_NEWWRK function to run successfully, the caller must have successfully issued a call to the __server_init() service for one of the following *managertype* parameter combinations:

- SRV_WORKMGR + SRV_QUEUEMGR
- SRV_WORKMGR + SRV_QUEUEMGR + SRV_SERVERMGR

For the SRV_PUT_SUBWRK and SRV_TRANSFER_WRK functions to run successfully, the caller must have successfully issued a call to the __server_init() service for one of the following *managertype* parameter combinations:

- SRV_WORKMGR + SRV_QUEUEMGR SRV_SERVERMGR
- SRV_SERVERMGR

For the SRV_GET_WRK, SRV_END_WRK and SRV_DEL_ENC functions to run successfully, the caller must have successfully issued a call to the __server_init() service for one of the following *managertype* parameter combinations:

- SRV_WORKMGR + SRV_QUEUEMGR SRV_SERVERMGR
- SRV_SERVERMGR

For the SRV_REFRESH_WRK function to run successfully, the caller must have successfully issued a call to the __server_init() service for any of the following *managertype* parameter combinations:

- SRV_WORK_MGR + SRV_QUEUE_MGR
- SRV_WORK_MGR + SRV_QUEUE_MGR + SRV_SERVER_MGR

Returned value

If successful, __server_pwu() returns 0.

If unsuccessful, __server_pwu() returns -1 and sets errno to one of the following values:

Error Code

Description

EAGAIN

The requested service could not be performed at the current time. Use __errno2() to obtain the reason code for the failure.

EFAULT

An argument of this service contained an address that was not accessible to the caller.

EINVAL

The *managertype* parameter contains a value that is not correct.

EMVSERR

A MVS environmental or internal error has occurred. Use __errno2() to obtain the exact reason for the failure.

EMVSWLMERROR

A WLM service failed. Use __errno2() to obtain the WLM service reason code for the failure.

__server_threads_query() — Query the number of threads

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | OS/390 V2R10 |

Format

```
#include <sys/server.h>

int __server_threads_query(int *threads);
```

General description

Provides information about the number of threads a server should be using for this server environment. After a successful query, *threads* will contain the number of threads that the WorkLoad Manager (WLM) recommends for this address space.

Usage notes

This service is a privileged service that requires the caller to be authorized in one of the following ways:

- Have read access to the BPX.WLMSEVER FACILTY class profile
- Have a UID=0 when the BPX.WLMSEVER FACILTY class profile is not defined

Returned value

If successful, __server_threads_query() returns 0.

If unsuccessful, __server_threads_query() returns -1 and sets errno to one of the following values:

Error Code
Description

EINTR
The wait was interrupted by an unblocked, caught signal. No further waiting will occur for this call. __server_threads_query() can be reissued to begin waiting again.

EPERM
The caller is not permitted to perform the specified operation.

Related information

- [“sys/server.h — WorkLoad Manager services” on page 70](#)

setbuf() — Control buffering

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdio.h>

void setbuf(FILE *__restrict__stream, char *__restrict__buffer);
```

General description

Controls buffering for the specified *stream*. The *stream* pointer must refer to an open file, and setbuf() must be the first operation on the stream.

If the *buffer* argument is NULL, the *stream* is unbuffered. If not, the buffering mode will be full buffer and the *buffer* must point to a character array of length at least BUFSIZ, which is the buffer size defined in the `stdio.h` header file. I/O functions use the *buffer*, which you specify here, for input/output buffering instead of the default system-allocated buffer for the given *stream*. If the buffer does not meet the requirements of the IBM z/OS C/C++ product, the buffer is not used.

The setvbuf() function is more flexible than setbuf(), because you can specify the type of buffering and size of buffer.

Note: If you use `setvbuf()` or `setbuf()` to define your own buffer for a stream, you must ensure that the buffer is available the whole time that the stream associated with the buffer is in use.

For example, if the buffer is an automatic array (block scope) and is associated with the stream `s`, leaving the block causes the storage to be deallocated. I/O operations of stream `s` are prevented from using deallocated storage. Any operation on `s` would fail because the operation would attempt to access the nonexistent storage.

To ensure that the buffer is available throughout the life of a program, make the buffer a variable allocated at file scope. This can be achieved by using an identifier of type *array* declared at file scope, or by allocating storage (with `malloc()` or `calloc()`) and assigning the storage address to a pointer declared at file scope.

VSAM file types do not support unbuffered I/O, causing requests for unbuffered I/O to fail.

Returned value

`setbuf()` returns no values.

For details about `errno` values, and about buffers you may have set, see discussions about buffering in *z/OS XL C/C++ Programming Guide*.

Example

CELEBS01

```
/* CELEBS01

This example opens the file myfile.dat for writing.
It then calls the &setbuf. function to establish a buffer of
length BUFSIZ.
When string is written to the stream, the buffer buf is used
and contains the string before it is flushed to the file.

*/
#include <stdio.h>

int main(void)
{
    char buf[BUFSIZ];
    char string[] = "hello world";
    FILE *stream;

    stream = fopen("myfile.dat", "wb,recfm=f");

    setbuf(stream,buf);          /* set up buffer */

    fwrite(string, sizeof(string), 1, stream);

    printf("%s\n",buf);          /* string is found in buf now */

    fclose(stream);              /* buffer is flushed out to myfile.dat */
}
```

setcontext() — Restore user context

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <ucontext.h>

int setcontext(const ucontext_t *ucp);
```

General description

The `setcontext()` function restores the user context pointed to by `ucp`. A successful call to `setcontext()` does not return; program execution resumes at the point specified by the `ucp` argument passed to `setcontext()`. The `ucp` argument should be created either by a prior call to `getcontext()`, or by being passed as an argument to a signal handler. If the `ucp` argument was created with `getcontext()`, program execution continues as if the corresponding call of `getcontext()` had just returned. If the `ucp` argument was modified with `makecontext()`, program execution continues with the function passed to `makecontext()`. When that function returns, the process continues as if after a call to `setcontext()` with the context pointed to by the `uc_link` member of the `ucontext_t` structure if it is not equal to 0. If the `uc_link` member of the `ucontext_t` structure pointed to by the `ucp` argument is equal to 0, then this context is the main context, and the process will exit when this context returns. The effects of passing a `ucp` argument obtained from any other source are undefined.

`setcontext()` is similar in some respects to `siglongjmp()` (and `longjmp()` and `_longjmp()`). The `getcontext()`–`setcontext()` pair, the `sigsetjmp()`–`siglongjmp()` pair, the `setjmp()`–`longjmp()` pair, and the `_setjmp()`–`_longjmp()` pair cannot be intermixed. A context saved by `getcontext()` should be restored only by `setcontext()`.

Notes:

1. Some compatibility exists with `siglongjmp()`, so it is possible to use `siglongjmp()` from a signal handler to restore a context created with `getcontext()`, but it is not recommended.
2. If the `ucontext` that is input to `setcontext()` has not been modified by `makecontext()`, you must ensure that the function that calls `getcontext()` does not return before you call the corresponding `setcontext()` function. Calling `setcontext()` after the function calling `getcontext()` returns causes unpredictable program behavior.
3. If `setcontext()` is used to jump back into an XPLINK routine, any `alloca()` requests issued by the XPLINK routine after the earlier `getcontext()` was called and before `setcontext()` is called are backed out. All storage obtained by these `alloca()` requests is freed before the XPLINK routine is resumed.
4. If `setcontext()` is used to jump back into a non-XPLINK routine, `alloca()` requests made after `getcontext()` and before `setcontext()` are not backed out.
5. If `ucp` is pointing to a user context of a different execution stack from the current, the user context should be either a freshly modified one (by `makecontext()`) or the most recently saved one (by `getcontext()` or `swapcontext()`) when running on its stack.
6. If `ucp` is pointing to a user context of a different execution stack from the current, the current stack is never collapsed and any resource associated with it is never freed after `setcontext()` being called.

This function is supported only in a POSIX program.

The **<ucontext.h>** header file defines the **ucontext_t** type as a structure that includes the following members:

| | | |
|------------|-------------|--|
| mcontext_t | uc_mcontext | A machine-specific representation of the saved context. |
| ucontext_t | *uc_link | Pointer to the context that will be resumed when this context returns. |
| sigset_t | uc_sigmask | The set of signals that are blocked when this context is active. |
| stack_t | uc_stack | The stack used by this context. |

Special behavior for C++: If `getcontext()` and `setcontext()` are used to transfer control, the behavior is undefined whether the destruction of automatic C++ objects is done. The use of `getcontext()` and `setcontext()` in conjunction with `try()`, `catch()`, and `throw()` is also undefined.

Do not issue `getcontext()` in a C++ constructor or destructor, since the saved context would not be usable in a subsequent `setcontext()` or `swapcontext()` after the constructor or destructor returns.

Special behavior for XPLINK-compiled C/C++: Restrictions concerning `setjmp.h` and `ucontext.h`:

1. All XPLINK programs compiled with the V2R10 or later C compilers that are to run with Language Environment V2R10 or later libraries and use the **jmp_buf**, **sigjmp_buf** or **ucontext_t** types must not be compiled with C headers from Language Environment V2R9 or earlier.
2. Non-XPLINK functions compiled with any level of Language Environment headers must not define **jmp_buf**, **sigjmp_buf** or **ucontext_t** data items and pass them to XPLINK functions that call `getcontext()`, `longjmp()`, `_longjmp()`, `setjmp()`, `_setjmp()`, `setcontext()`, `sigsetjmp()`, or `swapcontext()` with these passed-in data items.
3. When `__XPLINK__` is defined, the Language Environment V2R10 and later headers define a larger **jmp_buf**, **sigjmp_buf** or **ucontext_t** area that is required by `setjmp()`, `getcontext()`, and related functions when they are called from a XPLINK routine. If `__XPLINK__` is not defined, the Language Environment V2R10 and later headers define a shorter **jmp_buf**, **sigjmp_buf** or **ucontext_t** area. The Language Environment headers before V2R10 also define the shorter version of these data areas. If a XPLINK function calls `setjmp()`, `getcontext()` or similar functions with a short **jmp_buf**, **sigjmp_buf** or **ucontext_t** area, a storage overlay or program check may occur when the C library tries to store past the end of the passed-in (too short) data area.

Returned value

If successful, `setcontext()` does not return.

If unsuccessful, `setcontext()` returns -1.

There are no `errno` values defined.

Example

This example saves the context in `main` with the `getcontext()` statement. It then returns to that statement from the function `func` using the `setcontext()` statement. Since `getcontext()` always returns 0 if successful, the program uses the variable `x` to determine if `getcontext()` returns as a result of `setcontext()` or not.

```
/* This example shows the usage of getcontext() and setcontext(). */

#define _XOPEN_SOURCE_EXTENDED 1
#include <stdio.h>
#include <ucontext.h>

void func(void);

int x = 0;
ucontext_t context, *cp = &context;

int main(void) {
    getcontext(cp);
    if (!x) {
        printf("getcontext has been called\n");
        func();
    }
}
```

```

    }
    else {
        printf("setcontext has been called\n");
    }
}

void func(void) {
    x++;
    setcontext(cp);
}

```

Output

```

getcontext has been called
setcontext has been called

```

setegid() — Set the effective group ID

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1a Single UNIX Specification, Version 3 | both | |

Format

```

#define _POSIX1_SOURCE 2
#include <unistd.h>

int setegid(gid_t gid);

```

General description

Sets the effective group ID (GID) of a process to *gid*, if *gid* is equal to the real GID or the saved set GID of the calling process, or if the process has appropriate privileges. The real GID, the saved set GID, and any supplementary GIDs are not changed.

Returned value

If successful, setegid() returns 0.

If unsuccessful, setegid() returns -1 and sets errno to one of the following values:

Error Code Description

EINVAL

The value specified for *gid* is incorrect and is not supported by the implementation.

EPERM

The process does not have appropriate privileges, and *gid* does not match the real GID or the saved set GID.

Example

CELEBS02

```
/* CELEBS02

   This example changes your effective GID.

*/
#define _POSIX1_SOURCE 2
#include <unistd.h>
#include <stdio.h>

main() {
    printf("your effective group id is %d\n", (int) getegid());
    if (setegid(500) != 0)
        perror("setegid() error");
    else
        printf("your effective group id was changed to %d\n",
              (int) getegid());
}
```

Output

```
your effective group id is 512
your effective group id was changed to 500
```

setenv() — Add, delete, and change environment variables

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1a Single UNIX Specification, Version 3 Language Environment | both | |

Format

POSIX - C only:

```
#define _POSIX1_SOURCE 2
#include <env.h>
```

```
int setenv(const char *var_name, const char *new_value, int change_flag)
```

Single UNIX Specification, Version 3:

```
#define _UNIX03_SOURCE
#include <stdlib.h>

int setenv(const char *var_name, const char *new_value, int change_flag)
```

Non-POSIX:

```
#include <stdlib.h>

int setenv(const char *var_name, const char *new_value, int change_flag)
```

General description

Adds, changes, and deletes environment variables.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

var_name is a pointer to a character string that contains the name of the environment variable to be added, changed, or deleted. If `setenv()` is called with *var_name* containing an equal sign ('='), `setenv()` will fail, and `errno` will be set to indicate that an invalid argument was passed to the function.

new_value is a pointer to a character string that contains the value of the environment variable named in *var_name*. If *new_value* is a NULL pointer, it indicates that all occurrences of the environment variable named in *var_name* be deleted.

change_flag is a flag that can take any integer value:

Nonzero

Change the existing entry. If *var_name* has already been defined and exists in the environment variable table, its value *will* be updated with *new_value*. If *var_name* was previously undefined, it will be appended to the table.

0

Do not change the existing entry.

If *var_name* has already been defined and exists in the environment variable table, its value will *not* be updated with *new_value*. However, if *var_name* was previously undefined, it will be appended to the table.

Notes:

1. The value of the *change_flag* is irrelevant if *new_value*=NULL.
2. You should not define environment variables that begin with '_BPXK_' since they might conflict with variable names defined by z/OS UNIX services. `setenv()` uses the BPX1ENV callable service to pass environment variables that begin with '_BPXK_' to the kernel.

Also, do not use '_EDC_' and '_CEE_'. They are used by the runtime library and the Language Environment.

Environment variables set with the `setenv()` function will only exist for the life of the program, and are not saved before program termination. Other ways to set environment variables are found in “Using Environment Variables” in [z/OS XL C/C++ Programming Guide](#).

Special behavior for POSIX C: Under POSIX, `setenv()` is available if one of the following is true:

- Code is [ISO C/C++ compliant](#), uses `#include <env.h>`, and has the POSIX feature tests turned on.
- Code is compiled with [long external names](#) and prelinked with the OMVS option.

Returned value

If successful, `setenv()` returns 0.

If unsuccessful, `setenv()` returns -1 and sets `errno` to indicate the type of failure that occurred.

Error Code

Description

EINVAL

The `name` argument is a null pointer, points to an empty string, or points to a string containing an '=' character.

Note: Starting with z/OS V1.9, environment variable `_EDC_SUSV3` can be used to control the behavior of `setenv()` with respect to setting `EINVAL` when `var_name` is a null pointer, points to an empty string or points to a string containing an '=' character. By default, `setenv()` will not set `EINVAL` for these conditions. When `_EDC_SUSV3` is set to 1, `setenv()` will set `errno` to `EINVAL` if one of these conditions is true.

ENOMEM

Insufficient memory was available to add a variable or its value to the environment.

Example

CELEBS03

```
/* CELEBS03

This example (program 1) sets the environment variable
_EDC_ANSI_OPEN_DEFAULT.
A child program (program 2) is then initiated via a system
call.
The example illustrates that environment variables are
propagated forward to a child program, but not backward to
the parent.

*/
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    char *x;

    /* set environment variable _EDC_ANSI_OPEN_DEFAULT to "Y" */
    setenv("_EDC_ANSI_OPEN_DEFAULT", "Y", 1);

    /* set x to the current value of the _EDC_ANSI_OPEN_DEFAULT */
    x = getenv("_EDC_ANSI_OPEN_DEFAULT");

    printf("program1 _EDC_ANSI_OPEN_DEFAULT = %s\n",
        (x != NULL) ? x : "undefined");

    /* call the child program */
    system("program2");

    /* set x to the current value of the _EDC_ANSI_OPEN_DEFAULT */
    x = getenv("_EDC_ANSI_OPEN_DEFAULT");

    printf("program1 _EDC_ANSI_OPEN_DEFAULT = %s\n",
        (x != NULL) ? x : "undefined");
}
```

CELEBS04

```
/* CELEBS04

Program 2:
A child program of CELEBS03, which is initiated via a system call.

*/
#include <stdio.h>
#include <stdlib.h>
```

```
int main(void)
{
    char *x;

    /* set x to the current value of the _EDC_ANSI_OPEN_DEFAULT*/
    x = getenv("_EDC_ANSI_OPEN_DEFAULT");

    printf("program2 _EDC_ANSI_OPEN_DEFAULT = %s\n",
        (x != NULL) ? x : "undefined");

    /* clear the Environment Variables Table */
    setenv("_EDC_ANSI_OPEN_DEFAULT", NULL, 1);

    /* set x to the current value of the _EDC_ANSI_OPEN_DEFAULT*/
    x = getenv("_EDC_ANSI_OPEN_DEFAULT");

    printf("program2 _EDC_ANSI_OPEN_DEFAULT = %s\n",
        (x != NULL) ? x : "undefined");
}
```

Output

```
program1 _EDC_ANSI_OPEN_DEFAULT = Y
program2 _EDC_ANSI_OPEN_DEFAULT = Y
program2 _EDC_ANSI_OPEN_DEFAULT = undefined
program1 _EDC_ANSI_OPEN_DEFAULT = Y
```

seteuid() — Set the effective user ID

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1a Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX1_SOURCE 2
#include <unistd.h>

int seteuid(uid_t uid);
```

General description

Sets the effective user ID (UID) to *uid* if *uid* is equal to the real UID or the saved set user ID of the calling process, or if the process has appropriate privileges. The real UID and the saved set UID are not changed.

The seteuid() function is not supported from an address space running multiple processes, since it would cause all processes in the address space to have their security environment changed unexpectedly.

seteuid() can be used by daemon processes to change the identity of a process in order for the process to be used to run work on behalf of a user. In z/OS UNIX, changing the identity of a process is done by changing the real and effective UIDs and the auxiliary groups. In order to change the identity of the process on MVS completely, it is necessary to also change the MVS security environment. The identity change will only occur if the EUID value is specified, changing just the real UID will have no effect on the MVS environment.

The seteuid() function invokes MVS SAF services to change the MVS identity of the address space. The MVS identity that is used is determined as follows:

- If an MVS user ID is already known by the kernel from a previous call to a kernel function (for example, getpwnam()) and the UID for this user ID matches the UID specified on the seteuid() call, then this user ID is used.
- For nonzero target UIDs, if there is no saved user ID or the UID for the saved user ID does not match the UID requested on the seteuid() call, the seteuid() function queries the security database (for example, using getpwnam) to retrieve a user ID. The retrieved user ID is then used.
- If the target UID=0 and a user ID is not known, the seteuid() function always sets the MVS user ID to BPXROOT or the value specified on the SUPERUSER parm in sysparms. BPXROOT is set up during system initialization as a superuser with a UID=0. The BPXROOT user ID is not defined to the BPX.DAEMON FACILITY class profile. This special processing is necessary to prevent a superuser from gaining daemon authority.
- A nondaemon superuser that attempts to set a user ID to a daemon superuser UID fails with an EPERM.

When the MVS identity is changed, the auxiliary list of groups is also set to the list of groups for the new user ID.

If the seteuid() function is issued from multiple tasks within one address space, use synchronization to ensure that the seteuid() functions are not performed concurrently. The execution of seteuid() function concurrently within one address space can yield unpredictable results.

Returned value

If successful, seteuid() returns 0.

If unsuccessful, seteuid() returns -1 and sets errno to one of the following values:

Error Code

Description

EINVAL

The value specified for *uid* is incorrect and is not supported by the implementation.

EPERM

The process does not have appropriate privileges, and *uid* does not match the real UID or the saved set UID.

Example

CELEBS05

```
/* CELEBS05
   This example changes the effective UID.
*/
#define _POSIX1_SOURCE 2
#include <unistd.h>
#include <stdio.h>

main() {
    printf("your effective user id is %d\n", (int) geteuid());
    if (seteuid(25) != 0)
        perror("seteuid() error");
    else
        printf("your effective user id was changed to %d\n",
```

__set_exception_handler

```
(int) geteuid());  
}
```

Output

```
your effective user id is 0  
your effective user id was changed to 25
```

__set_exception_handler() — Register an exception handler routine

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| | both | |

Format

```
#include <__le_api.h>  
  
int __set_exception_handler( void(*exception_handler) (struct __cib *, void *),  
                           void * user_data);
```

General description

Restriction: This function is only valid for AMODE 64.

A nonstandard function that registers an 'Exception Handler' function for the current stack frame. Exception Handlers are used to process 'exceptions' at the thread level (unlike signal catchers which process signals at the process level).

Parameter

Description

exception_handle

Address of a function descriptor that is associated with an 'Exception Handler' function.

user_data

A user definable token that will be passed to the 'Exception Handler' function.

Exception Handlers are invoked for the following conditions:

| Table 52. Invoked Exception Handlers | | | |
|--------------------------------------|---------------|----------------|------------------|
| Exception | Feedback Code | Message Number | Resulting Signal |
| Operation | CEE341 | CEE3201S | SIGILL |
| Privileged-operation | CEE342 | CEE3202S | SIGILL |
| Execute | CEE343 | CEE3203S | SIGILL |
| Protection | CEE344 | CEE3204S | SIGSEGV |

| Retryable abend | CEE35I | CEE3250C | SIGABND |

When one of the exceptions listed above occurs, on a specific thread with a registered Exception Handler, Language Environment will invoke the handler function with the following syntax:

```
void exception_handler(struct __cib * cib, void * user_data);
```

Parameter Description

cib

Address of the Language Environment Condition Information Block (CIB).

user_data

A user definable token that was specified when the Exception Handler was registered.

An Exception Handler function should never return to Language Environment. It should terminate the thread with `pthread_exit()`, terminate the process with `exit()`, or resume execution at a predefined point with `setjmp()` and `longjmp()`. If the Exception Handler returns to Language Environment, the thread will be abnormally terminated.

- In a Posix environment only the thread is abnormally terminated, and the thread exit status is set to -1. Equivalent to:

```
pthread_exit( (void *) -1);
```

- In a non-Posix environment the entire Language Environment (process as well as thread) is abnormally terminated. Equivalent to:

```
exit(-1);
```

Returned value

If successful, `__set_exception_handler()` returns 0. Otherwise, -1 is returned and `errno` is set to indicate the error. The following is a possible value for `errno`:

- `EINVAL` — The Exception Handler is invalid.

Application usage

1. Multiple Exception Handlers may not be registered for a single stack frame. Only the last one registered is honored.
2. Exception Handlers may be nested, but they must be on different stack frames.

3. Once an Exception Handler is registered, it remains active across calls to nested functions, and will be automatically unregistered once the flow returns from the stack frame in which the call to `__set_exception_handler()` was invoked.
4. If an Exception Handler is registered, it remains active across subsequence function calls (nested function calls), unless one of the nested functions registers another exception handler. In which case the first exception handler is suspended.
5. Exception Handlers are automatically unregistered when a `longjmp()` returns to a stack frame earlier on the stack than the frame on which the Exception Handler was registered. All Exception Handlers that are associated with stack frames that are traversed as a result of a `longjmp()` are automatically unregistered.
6. When an Exception Handler is given control, it is disabled. Any other Exception Handler (that may have been previously registered) is not set active. In other words, when the Exception Handler is given control there is no Exception Handler active. It is suspended.
 - Any exception that occurs while the Exception Handler is executing, will be processed in the same way that Language Environment processes exceptions when no Exception Handlers are present.
 - If the Exception Handler needs to be able to handle exceptions that occur during the execution of the Exception Handler, the handler must invoke `__set_exception_handler()` to register another (or re-register the same) Exception Handler.
7. One and only one, Exception Handler will be invoked for a condition (the Handler that is active for the stack frame on which the condition (or exception) occurred).
8. If an Exception Handler exists and the condition is one of those listed above, all of the standard Language Environment condition processing is bypassed (including, when `POSIX(ON)`, the mapping of the exception into a signal). Instead, the one active Exception Handler is given control, and it has one opportunity to 'handle' the exception. If it does not handle the exception then abnormal termination will occur.
9. Functions used to affect the processing of signals, have no impact on the processing of Exception Handlers. That is, blocking or ignoring `SIGABND`, `SIGFPE`, `SIGILL`, or `SIGSEGV` will not prevent Exception Handlers from getting control.
10. In order for Exception Handlers to work, the Language Environment 'TRAP' runtime option must be set on (i.e., `TRAP(ON)` or `TRAP(ON, NOSPIE)`).

setgid() – Set the group ID

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX1_SOURCE 2
#include <unistd.h>

int setgid(gid_t gid);
```

General description

Sets one or more of the group IDs (GIDs) for the current process to *gid*.

If *gid* is the same as the process's real GID or the saved set-group-ID, setgid() always succeeds and sets the effective GID to *gid*.

If *gid* is not the same as the process's real GID, setgid() succeeds only if the process has appropriate privileges. If the process has such privileges, setgid() sets the real GID, the effective GID, and saved set GID to *gid*.

setgid() does not change any supplementary GIDs of the calling process.

Returned value

If successful, setgid() returns 0.

If unsuccessful, setgid() returns -1 and sets errno to one of the following values:

Error Code

Description

EINVAL

The value of *gid* is incorrect.

EPERM

The process does not have appropriate privileges to set the GID.

Example

CELEBS06

```
/* CELEBS06

   This example sets your GID.

*/
#define _POSIX_SOURCE 1
#include <unistd.h>
#include <stdio.h>

main() {
    printf("your group id is %d\n", (int) getgid());
    if (setgid(500) != 0)
        perror("setgid() error");
    else
        printf("your group id was changed to %d\n",
```

```

        (int) getgid());
    }

```

Output

```

your group id is 512
your group id was changed to 500

```

setgrent() — Reset group database to first entry

The information for this function is included in [“endgrent\(\) — Group database entry functions” on page 419](#).

setgroups() — Set the supplementary group ID list for the process

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```

#define _OPEN_SYS
#include <sys/types.h>
#include <grp.h>

int setgroups(const int size, const gid_t list[]);

```

General description

setgroups() sets the supplementary group IDs for the process to the list provided in the *list* array. The argument *size* gives the number of `gid_t` elements in *list* array. The maximum number of supplementary groups for a strictly conforming program is **NGROUPS_MAX**, as defined in `<limits.h>` Or, refer to `sysconf()` (see [“sysconf\(\) — Determine system configuration options” on page 1794](#)) for information on dynamically determining the number of supplementary groups allowed.

The caller of this function must be a superuser.

Returned value

If successful, setgroups() returns 0.

If unsuccessful, setgroups() returns -1 and sets `errno` to one of the following values:

Error Code

Description

EFAULT

The *list* and *size* specify an array that is partially or completely outside of addressable storage for the process.

EINVAL

The *size* parameter is greater than the maximum allowed.

EMVSERR

An MVS environmental or internal error occurred.

EMVSSAF2ERR

The Security Authorization Facility (SAF) had an error.

EPERM

The caller is not authorized, only authorized users are allowed to alter the supplementary group IDs list.

sethostent() — Open the host information data set

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format**X/Open:**

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

void sethostent(int stayopen);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

void sethostent(int stayopen);
```

General description

The `sethostent()` function opens and rewinds the local host tables. If the *stayopen* flag is nonzero, the local host tables remain open after each call.

You can use the `X_SITE` environment variable to specify different local host tables and override those supplied by the z/OS global resolver during initialization.

Note: For more information on these local host tables or the environment variables, see [z/OS Communications Server: IP Configuration Guide](#).

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` 1 feature test macro.

Returned value

`sethostent()` returns no values.

Related information

- [“netdb.h — Network database operations” on page 45](#)
- [“endhostent\(\) — Close the host information data set” on page 420](#)
- [“endnetent\(\) — Close network information data sets” on page 421](#)

- [“gethostbyname\(\) — Get a host entry by name” on page 720](#)
- [“gethostent\(\) — Get the next host entry” on page 722](#)

sethostname() — Set the name of the host processor

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

Berkeley sockets:

```
#define _XPLATFORM_SOURCE
#include <unistd.h>

int sethostname(const char *name, size_t len);
```

General description

`sethostname()` sets the host name to the value that is given in the character array *name*. The *len* argument specifies the number of bytes in *name*. The *name* argument does not require a NULL terminator. `sethostname()` is supported for callers in an IBM z/OS Container Platform environment only.

Parameter

Description

name

The character array that contains the host name to be set.

len

The length of the host name.

Returned value

If successful, `sethostname()` returns 0.

If unsuccessful, `sethostname()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

ENOTSUP

`sethostname()` is not supported from a process in the default UTS namespace.

EINVAL

name is not valid. *len* is less than or equal to zero or larger than the maximum allowed size, or no associated UTS namespace is found.

EACCES

Permission denied. For callers not in an IBM z/OS Container Platform environment, the caller is not running as a superuser (UID=0) and does not have access to the BPX.SUPERUSER FACILITY resource or the caller is not APF authorized. For callers in an IBM z/OS Container Platform environment, the caller does not have access to the CONTAINER UNIXPRIV resource or the environment is not program-controlled.

EAGAIN

The resource is temporarily unavailable or the caller is not authorized to access the TCP/IP stack.

EMVSERR

An MVS environmental or internal error occurs. Contact IBM support.

Usage notes

1. The caller of `sethostname()` must be in an IBM z/OS Container Platform environment and satisfy either one of the following requirements:
 - Runs as a superuser (UID=0).
 - Has access to the BPX.SUPERUSER FACILITY resource.
 - Has access to the SAF resource CONTAINERS in the UNIXPRIV class and is in a program-controlled environment.
2. The values for the host name must conform to the following rules:
 - Maximum of 63 characters.
 - Must contain one or more tokens that are separated by a period ('.').
 - Each token must be at least one character and fewer than 64 characters.
 - Each token must start with a letter or number.
 - The remaining characters in each token must be a letter, number, hyphen ('-') or underscore ('_').

setibmopt() – Set IBM TCP/IP image

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _OPEN_SYS_SOCK_EXT
#include <sys/socket.h>

int setibmopt(int cmd, struct ibm_tcpimage *bfrp);
```

General description

The `setibmopt()` function call is used to set TCP/IP options. Currently, the only supported command is `IBMTCP_IMAGE` which allows the `setibmopt()` to choose the active TCP/IP image stack the application will connect to.

To reset `ibm_tcpimage` to nothing chosen, set the *name* to all blanks.

The chosen transport is inherited over `fork()` and preserved over `exec()`. If this is not desired, the child process should call `setibmopt()` with a blank name to reset the TCP/IP image for the child.

Parameter Description

cmd

The value in *cmd* must be set to the command to be performed. Currently, only IBMTCP_IMAGE is supported and must be paired with the *bfrp* parameter as described.

bfrp

The pointer to a `ibm_tcpimage` structure.

To set the TCP/IP image for a socket, the application should set values in the `ibm_tcpimage` structure as follows:

Element Description

status

0 means is not known and need not be checked. Currently, this is the only value with meaning.

version

0 means the version is to be set on return if known.

name

The name must be left justified, uppercase, padded with blanks, and be the name of an active TCP stack.

Returned value

If successful, `setibmopt()` returns 0.

If unsuccessful, `setibmopt()` returns -1 and sets `errno` to one of the following values:

Error Code Description

EFAULT

Using the *bfrp* supplied would result in access of a storage location that is inaccessible.

EIBMBADTCPNAME

A name of a PFS was specified that either is not configured or is not a Sockets PFS.

EOPNOTSUPP

The *cmd* is a function that is not supported.

ENXIO

The name that was specified did not match an AF_INET socket stack, but Common Inet is not configured on this system. Because this system does not have multiple AF_INET socket transports configured, there is already a natural affinity to one single stack, and this failure may not be a problem for the application.

setibmssockopt() — Set IBM specific options associated with a socket

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _OPEN_SYS_SOCKET_EXT
#include <sys/socket.h>

int setibmssocket(int s, int level, int optname, char *optval, size_t optlen);
```

General description

These options are only valid on IBM systems and can be specified to allow improved processing of requests on sockets.

Parameter Description

s

The socket descriptor.

level

The level for which the option is set.

optname

The name of a specified socket option. The socket option currently available is:

- SO_EioIfNewTP

optval

The pointer to option data.

optlen

The length of the option data.

Usage notes

The SO_EioIfNewTP option allows a socket application that has bound INADDRANY to be notified if a new common inet transport provider was activated after the socket was created. In order to activate this option, the option data should have a value of 1. To deactivate this option, supply a value of 0 for the option data. This option can be useful to a server that is listening - waiting for requests to come in from a number of sources. When a new transport provider is activated while this option is in effect, the application program will receive an EIO on the next accept, select or read request. Once this happens, the application should close the current socket and create a new one - thus enabling the socket to communicate with the new transport provider.

Returned value

If successful, setibmssocket() returns 0.

If unsuccessful, setibmssocket() returns -1 and sets errno to one of the following values:

Error Code Description

EBADF

The s parameter is not a valid socket descriptor.

EFAULT

Using *optval* and *optlen* parameters would result in an attempt to access storage outside the caller's address space.

ENOPROTOPT

The *optname* parameter is unrecognized. The *level* parameter is not SOL_SOCKET. The domain of the socket descriptor is not AF_INET. The socket descriptor is not a datagram type socket.

setipv4sourcefilter() — Set source filter

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| RFC3678 | both | z/OS V1.9 |

Format

```
#define _OPEN_SYS_SOCK_EXT3
#include <netinet/in.h>

int setipv4sourcefilter(int s, struct in_addr interface, struct in_addr group,
                      uint32_t fmode, uint32_t numsrc, struct in_addr *slist);
```

General description

This function allows applications to set and replace the current multicast filtering state for a tuple consisting of socket, interface, and multicast group values.

A multicast filter is described by a filter mode, which is MCAST_INCLUDE or MCAST_EXCLUDE, and a list of source addresses which are filtered.

This function is IPv4-specific, must be used only on AF_INET sockets with an open socket of type SOCK_DGRAM or SOCK_RAW.

If the function is unable to obtain the required storage, control will not return to the caller. Instead the application will terminate due to an out of memory condition (if the reserve stack is available and the caller is not XPLINK), or it will terminate with an abend indicating that storage could not be obtained.

Argument

Description

s

Identifies the socket.

interface

Holds the local IP address of the interface.

group

Holds the IP multicast address of the group.

fmode

Identifies the filter mode. The value of this field must be either MCAST_INCLUDE or MCAST_EXCLUDE, which are likewise defined in <netinet/in.h>.

numsrc

Holds the number of source addresses in the slist array.

slist

Points to an array of IP addresses of sources to include or exclude depending on the filter mode.

Returned value

If successful, the function returns 0. Otherwise, it returns -1 and sets errno to one of the following values.

errno

Description

EADDRNOTAVAIL

The specified interface address is incorrect for this host, or the specified interface address is not multicast capable.

EBADF

s is not a valid socket descriptor.

EINVAL

Interface or group is not a valid IPv4 address, or the socket s has already requested multicast setsockopt options.

ENOBUFS

The number of the source addresses exceeds the allowed limit.

EPROTOTYPE

The socket s is not of type SOCK_DGRAM or SOCK_RAW.

setitimer() — Set value of an interval timer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | POSIX(ON) |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/time.h>

int setitimer(int which, struct itimerval *value, struct itimerval *ovalue);
```

General description

setitimer() sets the value of an interval timer. An interval timer is a timer which sends a signal after each repetition (interval) of time.

The *which* argument indicates what kind of time is being controlled. Values for *which* are:

ITIMER_REAL

This timer is marking real (clock) time. A SIGALRM signal is generated after each interval of time.

Note: alarm() also sets the real interval timer.

ITIMER_VIRTUAL

This timer is marking process virtual time. Process virtual time is the amount of time spent while executing in the process, and can be thought of as a CPU timer. A SIGVTALRM signal is generated after each interval of time.

ITIMER_PROF

This timer is marking process virtual time plus time spent while the system is running on behalf of the process. A SIGPROF signal is generated after each interval of time.

Note: In a multithreaded environment, each of the above timers is specific to a thread of execution for both the generation of the time interval and the measurement of time. For example, an `ITIMER_VIRTUAL` timer will mark execution time for just the thread, not the entire process.

The *value* argument points to an `itimerval` structure containing the timer value to be set. The structure contains:

it_interval

timer interval

When `it_interval` is nonzero, it is used as the value which `it_value` is initialized to after each timer expiration. If `it_interval` is zero, the timer is disabled **after the next expiration**, subject to the value in `it_value`.

it_value

current timer value to be set

When `it_value` is nonzero, it is used as the initial value to establish the timer with, that is, the time to the next timer expiration. If `it_value` is zero, the timer is **immediately** disabled.

The *ovalue* argument points to an `itimerval` structure in which the current value of the timer is returned. If *ovalue* is a NULL pointer, the current timer value is not returned. The structure contains:

it_interval

current timer interval

it_value

current timer value

For both `itimerval` structures, each of the fields (`it_interval` and `it_value`) is a `timeval` structure, and contains:

tv_sec

seconds since January 1, 1970 Coordinated Universal Time (UTC)

tv_usec

microseconds

Returned value

If successful, `setitimer()` returns 0, and if *ovalue* was non-NULL, *ovalue* points to the `itimerval` structure containing the old timer values.

If unsuccessful, `setitimer()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

which is not a valid timer type, or the *value* argument has an incorrect (noncanonical) form. The `tv_seconds` field must be a nonnegative integer, and the `tv_usec` field must be a nonnegative integer in the range of 0-1,000,000.

Usage of the `ITIMER_PROF` timer generates a `SIGPROF` signal which may interrupt an in-progress function. Thus, programs using this timer may need to be able to restart an interrupted function.

setjmp() — Preserve stack environment

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <setjmp.h>

int setjmp(jmp_buf env);
```

General description

Saves a stack environment that can subsequently be restored by `longjmp()`. The `setjmp()` and `longjmp()` functions provide a way to perform a nonlocal goto. They are often used in signal handlers.

A call to `setjmp()` causes it to save the current stack environment in *env*. A subsequent call to `longjmp()` restores the saved environment and returns control to a point corresponding to the `setjmp()` call. The values of all variables, except register variables and nonvolatile automatic variables, accessible to the function receiving control, contain the values they had when `longjmp()` was called. The values of register variables are unpredictable. Nonvolatile *auto* variables that are changed between calls to `setjmp()` and `longjmp()` are also unpredictable.

An invocation of `setjmp()` must appear in one of the following contexts only:

- The entire controlling expression of a selection or iteration statement.
- One operand of a relational or equality operator with the other operand an integral constant expression, with the resulting expression being the entire controlling expression of a selection or iteration statement.
- The operand of a unary “!” operator with the resulting expression being the entire controlling expression of a selection or iteration.
- The entire expression of an expression statement (possibly cast to void).

Note: Ensure that the function that calls `setjmp()` does not return before you call the corresponding `longjmp()` function. Calling `longjmp()` after the function calling `setjmp()` returns causes unpredictable program behavior.

Special behavior for POSIX C: To save and restore a stack environment that includes a signal mask, use `sigsetjmp()` and `siglongjmp()`, instead of `setjmp()`.

The `sigsetjmp()`—`siglongjmp()` pair, the `setjmp()`—`longjmp()` pair, the `_setjmp()`—`_longjmp()` pair, and the `getcontext()`—`setcontext()` pair *cannot* be intermixed. A stack environment saved by `setjmp()` can only be restored by `longjmp()`.

Special behavior for C++: If `setjmp()` and `longjmp()` are used to transfer control, the behavior is undefined whether the destruction of automatic C++ objects is done. The use of `setjmp()` and `longjmp()` in conjunction with `try()`, `catch()`, and `throw()` is also undefined.

Special behavior for XPG4.2: In a program that was compiled with the feature test macro `_XOPEN_SOURCE_EXTENDED` defined, another pair of functions, `_setjmp()`—`_longjmp()`, are available. On this implementation, these calls are functionally identical to `setjmp()`—`longjmp()`. Therefore it is possible, but not recommended, to intermix the `setjmp()`—`longjmp()` pair with the `_setjmp()`—`_longjmp()` pair.

Special behavior for XPLINK-compiled C++: Restrictions concerning `setjmp.h` and `ucontext.h`:

1. All XPLINK programs compiled with the V2R10 or later C compilers that are to run with Language Environment V2R10 or later libraries and use the **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** types must not be compiled with C headers from Language Environment V2R9 or earlier.
2. Non-XPLINK functions compiled with any level of Language Environment headers must not define **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** data items and pass them to XPLINK functions that call `getcontext()`, `longjmp()`, `_longjmp()`, `setjmp()`, `_setjmp()`, `setcontext()`, `sigsetjmp()`, or `swapcontext()` with these passed-in data items.
3. When `__XPLINK__` is defined, the Language Environment V2R10 and later headers define a larger **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** area that is required by `setjmp()`, `getcontext()`, and related functions when they are called from an XPLINK routine. If `__XPLINK__` is not defined, the Language Environment V2R10 and later headers define a shorter **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** area. The Language Environment headers before V2R10 also define the shorter version of these data areas. If an XPLINK function calls `setjmp()`, `getcontext()` or similar functions with a short **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** area, a storage overlay or program check may occur when the C library tries to store past the end of the passed-in (too short) data area.

Returned value

`setjmp()` returns 0 after saving the stack environment.

If `setjmp()` returns as a result of a `longjmp()` call, it returns the *value* argument of `longjmp()`, or the value 1 if the *value* argument of `longjmp()` is equal to 0.

Example

This example stores the stack environment at the statement:

```
if(setjmp(mark) != 0) ...
```

When the system first performs the `if` statement, it saves the environment in *mark* and sets the condition to FALSE because `setjmp()` returns 0 when it saves the environment. The program prints the message: `setjmp has been called`.

The subsequent call to function *p* tests for a local error condition, which can cause it to perform the `longjmp()` function. Then control returns to the original `setjmp()` function using the environment saved in *mark*. This time the condition is TRUE because -1 is the returned value from the `longjmp()` function. The program then performs the statements in the block and prints: `longjmp has been called`. Finally, the program calls the `recover` function and exits.

```
/* This example shows the effect of having set the stack environment. */
#include <stdio.h>
#include <setjmp.h>

jmp_buf mark;

void p(void);
void recover(void);

int main(void)
{
    if (setjmp(mark) != 0) {
        printf("longjmp has been called\n");
        recover();
        exit(1);
    }
    printf("setjmp has been called\n");
    :
    p();
}
```

```

:
}

void p(void)
{
    int error = 0;
:
    error = 9;
:
    if (error != 0)
        longjmp(mark, -1);
:
}

void recover(void)
{
:
:
}

```

_setjmp() — Set jump point for a nonlocal goto

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```

#define _XOPEN_SOURCE_EXTENDED 1
#include <setjmp.h>

int _setjmp(jmp_buf env);

```

General description

The `_setjmp()` function saves a stack environment that can subsequently be restored by `_longjmp()`. The `_setjmp()` and `_longjmp()` functions provide a way to perform a nonlocal goto. They are often used in signal handlers.

A call to `_setjmp()` causes it to save the current stack environment in *env*. A subsequent call to `_longjmp()` restores the saved environment and returns control to a point corresponding to the `_setjmp()` call. The values of all variables, except register variables, and except nonvolatile automatic variables, accessible to the function receiving control contain the values they had when `_longjmp()` was called. The values of register variables are unpredictable. Nonvolatile *auto* variables that are changed between calls to `_setjmp()` and `_longjmp()` are also unpredictable.

An invocation of `_setjmp()` must appear in one of the following contexts only:

1. The entire controlling expression of a selection or iteration statement.
2. One operand of a relational or equality operator with the other operand an integral constant expression, with the resulting expression being the entire controlling expression of a selection or iteration statement.
3. The operand of a unary "!" operator with the resulting expression being the entire controlling expression of a selection or iteration.
4. The entire expression of an expression statement (possibly cast to void).

The X/Open standard states that `_setjmp()` and `_longjmp()` are functionally identical to `longjmp()` and `setjmp()`, respectively, with the addition restriction that `_setjmp()` and `_longjmp()` do not manipulate the signal mask. However, on this implementation `longjmp()` and `setjmp()` do not manipulate the signal mask. So on this implementation `_setjmp()` and `_longjmp()` are literally identical to `longjmp()` and `setjmp()`, respectively.

To save and restore a stack environment, including the current signal mask, use `sigsetjmp()` and `siglongjmp()` instead of `_setjmp()` and `_longjmp()`, or `setjmp()` and `longjmp()`.

The `_setjmp()`—`_longjmp()` pair, the `setjmp()`—`longjmp()` pair, the `sigsetjmp()`—`siglongjmp()` pair, and the `getcontext()`—`setcontext()` pair cannot be intermixed. A stack environment saved by `_setjmp()` can be restored only by `_longjmp()`.

Notes:

1. However, on this implementation, since the `_setjmp()`—`_longjmp()` pair are functionally identical to the `setjmp()`—`longjmp()` pair it is possible to intermix them, but it is not recommended.
2. Ensure that the function that calls `_setjmp()` does not return before you call the corresponding `_longjmp()` function. Calling `_longjmp()` after the function calling `_setjmp()` returns causes unpredictable program behavior.

Special behavior for C++: If `_setjmp()` and `_longjmp()` are used to transfer control, the behavior is undefined whether the destruction of automatic C++ objects is done. The use of `_setjmp()` and `_longjmp()` in conjunction with `try()`, `catch()`, and `throw()` is also undefined.

Special behavior for XPLINK-compiled C++: Restrictions concerning `setjmp.h` and `ucontext.h`:

1. All XPLINK programs compiled with the V2R10 or later C compilers that are to run with Language Environment V2R10 or later libraries and use the **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** types must not be compiled with C headers from Language Environment V2R9 or earlier.
2. Non-XPLINK functions compiled with any level of Language Environment headers must not define **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** data items and pass them to XPLINK functions that call `getcontext()`, `longjmp()`, `_longjmp()`, `setjmp()`, `_setjmp()`, `setcontext()`, `sigsetjmp()`, or `swapcontext()` with these passed-in data items.
3. When `__XPLINK__` is defined, the Language Environment V2R10 and later headers define a larger **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** area that is required by `setjmp()`, `getcontext()`, and related functions when they are called from an XPLINK routine. If `__XPLINK__` is not defined, the Language Environment V2R10 and later headers define a shorter **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** area. The Language Environment headers before V2R10 also define the shorter version of these data areas. If an XPLINK function calls `setjmp()`, `getcontext()` or similar functions with a short **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** area, a storage overlay or program check may occur when the C library tries to store past the end of the passed-in (too short) data area.

Returned value

`_setjmp()` returns 0 after saving the stack environment.

If `_setjmp()` returns as a result of a `_longjmp()` call, it returns the *value* argument of `_longjmp()`, or 1 if the *value* argument of `_longjmp()` was 0.

setkey() — Set encoding key

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <stdlib.h>

void setkey(const char *key);
```

General description

The `setkey()` function transforms the *key* argument array into data encryption keys which are used by the `encrypt()` function to encode blocks of data.

The *key* argument of `setkey()` is an array of length 64 bytes containing only the bytes with numerical value of 0 and 1. If this 64 byte array is divided into groups of 8, the low-order byte of each group is ignored. The `setkey()` function transforms the remaining 56 bytes, each with values 0 or 1, into 16 48-bit keys according to the Data Encryption Standard (DES) key algorithm.

Special behavior for z/OS UNIX Services: When `setkey()` is called from a thread, the array of 16 bit-bit keys produced by `setkey()` is unique to the thread. Thus, for each thread from which the `encrypt()` function is called by a threaded application, the `setkey()` function must first be called from each thread.

Returned value

`setkey()` returns no values.

Special behavior for z/OS UNIX Services: The `setkey()` function will set `errno` to one of the following values:

Error Code

Description

EINVAL

64 byte input array contains bytes with values other than 0x00 or 0x01.

ENOMEM

Unable to allocate storage for DES keys on thread from which setkey() invoked.

Note: Because setkey() returns no values, applications wishing to check for errors should set errno to 0, call setkey(), then test errno and, if it is nonzero, assume an error has occurred.

setlocale() — Set locale

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 SAA Language Environment z/OS UNIX C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <locale.h>

char *setlocale(int category, const char *locale);
```

General description

Sets, changes, or queries *locale* categories or groups of categories. It does this action according to the values of the *locale* and *category* arguments.

A *locale* is the complete definition of the part of a user's program that depends on language and cultural conventions. You can accept the default value of *locale*, or you can set it to one of the supplied locales listed in the appendix , “Supplied Locales”, in *z/OS XL C/C++ Programming Guide*. Some examples of the supplied locales are: “C”, “POSIX”, “SAA”, “S370”, “Fr_BE.IBM-1047”, “En_GB.IBM-285”, “En_US.IBM-1047”, “Fr_BE.IBM-1148@euro”, and “Fr_BE.IBM-1148”.

Note that non-POSIX programs may exploit the POSIX style of locale support. This use of environment variables also applies to non-POSIX programs that use POSIX locale support.

Effect of setlocale() on Language Environment: The current locale set with the setlocale() function affects only some C library functions. (See [Table 53 on page 1548](#)). It does not affect the CEE locale set and query functions available under Language Environment and described in the [z/OS Language Environment Programming Reference](#).

The category argument

The *category* argument may be set to one of these values:

Table 53. Values for Category Arguments of *setlocale()*

| Category | Purpose |
|-------------|--|
| LC_ALL | Specifies all categories that are associated with the program's locale. |
| LC_COLLATE | <p>Defines the collation sequence, that is, the relative order of collation elements (characters and multicharacter collation elements) in the program's locale. The collation sequence definition is used by regular expression, pattern matching, and sorting functions.</p> <p>These string functions are affected by the defined collation sequence: <code>strcoll()</code>, <code>strxfrm()</code>, <code>wscoll()</code>, and <code>wcsxfrm()</code>.</p> <p>LC_CTYPE, LC_COLLATE, and LC_SYNTAX should refer to the same locale. Changing just one of them may invalidate another.</p> |
| LC_CTYPE | <p>Defines character classification and case conversion for characters in the program's locale. Affects the behavior of character-handling functions that are defined in the <code>ctype.h</code> header file: <code>csid()</code>, <code>isalnum()</code>, <code>isalpha()</code>, <code>isblank()</code>, <code>iswblank()</code>, <code>iscntrl()</code>, <code>isdigit()</code>, <code>isgraph()</code>, <code>islower()</code>, <code>isprint()</code>, <code>ispunct()</code>, <code>isspace()</code>, <code>isupper()</code>, <code>iswalnum()</code>, <code>iswalpha()</code>, <code>iswcntrl()</code>, <code>iswctype()</code>, <code>iswdigit()</code>, <code>iswgraph()</code>, <code>iswlower()</code>, <code>iswprint()</code>, <code>iswpunct()</code>, <code>iswspace()</code>, <code>iswupper()</code>, <code>iswxdigit()</code>, <code>isxdigit()</code>, <code>tolower()</code>, <code>toupper()</code>, <code>towlower()</code>, <code>towupper()</code>, <code>wcsid()</code>, and <code>wctype()</code>.</p> <p>Affects behavior of the <code>printf()</code> and <code>scanf()</code> families of functions: <code>fprintf()</code>, <code>printf()</code>, <code>sprintf()</code>, <code>fscanf()</code>, <code>scanf()</code>, and <code>sscanf()</code>.</p> <p>Affects the behavior of wide-character input/output functions: <code>fgetwc()</code>, <code>fgetws()</code>, <code>getwc()</code>, <code>getwchar()</code>, <code>fputwc()</code>, <code>fputws()</code>, <code>putwc()</code>, <code>putwchar()</code>, and <code>ungetwc()</code>.</p> <p>Affects the behavior of multibyte and wide-character functions: <code>mblen()</code>, <code>mbtowc()</code>, <code>mbstowcs()</code>, <code>wctomb()</code>, <code>wcstombs()</code>, <code>mbrlen()</code>, <code>mbrtowc()</code>, <code>mbsrtowcs()</code>, <code>wcrtomb()</code>, <code>wcsrtombs()</code>, <code>wcswidth()</code>, <code>wcwidth()</code>, <code>wcstod()</code>, <code>wcstol()</code>, and <code>wcstoul()</code>.</p> <p>LC_CTYPE, LC_COLLATE, and LC_SYNTAX should refer to the same locale. Changing just one of them may invalidate another.</p> |
| LC_MESSAGES | <p>Under IBM z/OS C/C++ support, it affects the messages that are returned by the <code>nl_langinfo()</code> function and it also affects <code>rpmatch()</code>.</p> <p>The LC_MESSAGES <i>category</i> will <i>not</i> affect the messages for the following functions: <code>perror()</code>, <code>strerror()</code>, and <code>regerror()</code>.</p> <p>In the locale of a C program running with POSIX(ON), it defines affirmative and negative response patterns.</p> |
| LC_MONETARY | <p>Affects monetary information that is returned by <code>localeconv()</code> and the <code>strfmon()</code> function. It defines the rules and symbols that are used to format monetary numeric information in the program's locale. The formatting rules and symbols are strings. <code>localeconv()</code> returns pointers to these strings with names found in the <code>locale.h</code> header file.</p> |

Table 53. Values for Category Arguments of `setlocale()` (continued)

| Category | Purpose |
|------------|---|
| LC_NUMERIC | <p>Affects the decimal-point character for the formatted input/output and string conversion functions, and the nonmonetary formatting information returned by the <code>localeconv()</code> function, specifically:</p> <ul style="list-style-type: none"> • The <code>printf()</code> family of functions • The <code>scanf()</code> family of functions • <code>strtod()</code> • <code>atof()</code> <p>The formatting rules and symbols are strings. <code>localeconv()</code> returns pointers to the strings with names found in the <code>locale.h</code> header file.</p> |
| LC_TIME | <p>Defines time and date format information in the program's locale that is used by the <code>strftime()</code>, <code>strptime()</code>, and <code>wcsftime()</code> functions.</p> |
| LC_SYNTAX | <p>Affects the behavior of functions that use encoded values to format characters:</p> <ul style="list-style-type: none"> • <code>printf()</code> family of functions • <code>scanf()</code> family of functions • <code>regcomp()</code> • <code>strfmon()</code> <p>LC_SYNTAX also affects values that may be retrieved by using the <code>getsyntax()</code> function.</p> <p>LC_CTYPE, LC_COLLATE, and LC_SYNTAX should refer to the same locale. Changing just one of them may invalidate another.</p> |
| LC_TOD | <p>Affects the behavior of the functions that are related to time zone and Daylight Saving Time information in the program's locale, when time zone and Daylight Saving Time information is not defined by the TZ environment variable. This information is used by <code>ctime()</code>, <code>localtime()</code>, <code>mktime()</code>, and <code>strftime()</code>.</p> |

For a POSIX program, the functions `ctime()`, `localtime()`, `mktime()`, `setlocale()`, and `strftime()` call the `tzset()` function to override LC_TOD category information when TZ is defined and valid.

The locale argument

Identifies the locale. For a list of locales provided by IBM, see the topic about supplied locales in [z/OS XL C/C++ Programming Guide](#).

If the value of an environment variable is used, it must be a valid locale name. If so, `setlocale()` sets the specified category to the named locale, and returns a string giving the name of the locale. Otherwise, `setlocale()` does not change the program's locale and returns a NULL pointer. Valid *category* names include names of locales that are provided by IBM. Also, names of locales, which are created by using the z/OS XL C/C++ locale definition mechanism, are valid.

The null-string ("") locale value: If "" is specified, the locale-related environment variables are checked. If the locale name is not defined by the environment variables, the default is "S370" when running POSIX(OFF) and "C" when running POSIX(ON).

For both C and C++ languages, and whether you are using POSIX or not, if a program by using POSIX-style locale support specifies "" for the value of *locale*, then `setlocale()` interrogates locale-related environment variables in the program's environment to find a locale name or names to use. The locale name is chosen according to the first of the following conditions that applies:

1. If the environment variable LC_ALL is defined and is not NULL, the value of LC_ALL is used. That value is applied to all categories.
2. If individual environmental variables are defined, then their values are used for the categories.
3. If the environment variable LANG is defined and is not NULL, the value of LANG is used.
4. If no non-NULL environment variable is present to supply a value, "C" is used.

If a program by using POSIX-style locale support specifies LC_ALL for the value of *category* and "" for the value of *locale*, setlocale() searches environment variables in the way that is described to obtain a locale name for each category. If all the locale names obtained identify valid locales, setlocale() sets each category to the appropriate locale and returns a string naming the locale that is associated with each category. Otherwise, setlocale() does not change the program's locale and returns a NULL pointer.

Default locale: The relationship between the POSIX C and SAA C locales is as follows.

Using C or C++ languages with the runtime option POSIX(OFF):

1. The SAA C locale definition is the default. "C", "SAA", and "S370" are synonyms for the SAA C locale definition, which is prebuilt into the library.

The source file EDC\$SAAC LOCALE is provided for reference, but cannot be used to alter the definition of this prebuilt locale.

2. Issuing setlocale(*category*, "") has the following effect:

- Locale-related environment variables are checked to find the name of locales to use to set the *category* specified. Querying the locale with setlocale(*category*, NULL) returns the name of the locales that are specified by the appropriate environment variables.
 - If no non-NULL environment variable is present, it is the equivalent of having issued setlocale(*category*, "S370"). That is, the locale that is chosen is the SAA C locale definition, and querying the locale with setlocale(*category*, NULL), returns "S370" as the locale name.
3. If no setlocale() function is issued or setlocale(LC_ALL, "C") is used, then the locale that is chosen is the prebuilt SAA C locale, and querying the locale with setlocale(*category*, NULL), returns "C" as the locale name.
 4. For setlocale(LC_ALL, "SAA"), the locale that is chosen is the prebuilt SAA C locale, and querying the locale with setlocale(*category*, NULL), returns "SAA" as the locale name.
 5. For setlocale(LC_ALL, "S370"), the locale that is chosen is the prebuilt SAA C locale, and querying the locale with setlocale(*category*, NULL), returns "S370" as the locale name.
 6. For setlocale(LC_ALL, "POSIX"), the locale that is chosen is the prebuilt POSIX C locale, and querying the locale with setlocale(*category*, NULL), returns "POSIX" as the locale name.

Using z/OS XL C with the runtime option POSIX(ON):

1. The POSIX C locale definition is the default. "C" and "POSIX" are synonyms for the POSIX C locale definition, which is prebuilt into the library.

The source file EDC\$POSX LOCALE is provided for reference, but cannot be used to alter the definition of this prebuilt locale.

2. Issuing setlocale(*category*, "") has the following effect:

- Locale-related environment variables are checked to find the name of locales that can set the *category* specified. Querying the locale with setlocale(*category*, NULL) returns the name of the locale that is specified by the appropriate environment variables.
 - If no non-NULL environment variable is present, the result is equivalent to having issued setlocale(*category*, "C"). That is, the locale that is chosen is the POSIX C locale definition, and querying the locale with setlocale(*category*, NULL), returns "C" as the locale name.
3. If no setlocale() function is issued or if setlocale(LC_ALL, "C") is used, the locale that is chosen is the prebuilt POSIX C locale. Querying the locale with setlocale(*category*, NULL) returns "C" as the locale name.

4. For `setlocale(LC_ALL, "POSIX")` the locale chosen is the prebuilt POSIX C locale. Querying the locale with `setlocale(category, NULL)` returns "POSIX" as the locale name.
5. For `setlocale(LC_ALL, "SAA")` the locale chosen is the prebuilt SAA C locale. Querying the locale with `setlocale(category, NULL)` returns "SAA" as the locale name.
6. For `setlocale(LC_ALL, "S370")` the locale chosen is the prebuilt SAA C locale. Querying the locale with `setlocale(category, NULL)` returns "S370" as the locale name.

The `setlocale()` function supports locales that are built by using the `localedef` utility, as well as locales built by using the assembly language source and produced by the `EDCLOC` macro. Find more information about old format locales in "Internationalization: Locales and Character Sets", in [z/OS XL C/C++ Programming Guide](#).

Special behavior for z/OS UNIX Services

The `LOCPATH` environment variable specifies a colon-separated list of z/OS UNIX directories. If `LOCPATH` is defined, `setlocale()` searches z/OS UNIX directories in the order that is specified by `LOCPATH` for locale object files it requires. Locale object files in the HFS are produced by the `localedef` utility running under z/OS UNIX. If `LOCPATH` is not defined and `setlocale()` is called by a POSIX program, `setlocale()` looks in the default locale directory, `/usr/lib/nls/locale`, for locale object files it requires. If `setlocale()` does not find a locale object that it requires, it converts the locale name to a PDS member name and searches locale PDS load libraries that are associated with the program calling `setlocale()`.

Locale names may be file names, relative path names, or absolute path names. `LOCPATH` is used if file name rather than path name is specified. Also, `//` preceding a file name tells `setlocale()` to skip HFS search and to convert the name to a load module name of the form `EDC$xxxx`, and to search MVS load libraries for a member to load with this name. Also, `//` preceding a file name tells `setlocale()` to skip the search to convert the name to a load module PDS name. XPLINK locale object PDS names begin with `EDC`. Non-XPLINK locale object load module names begin with `CEH`. See [z/OS XL C/C++ Programming Guide](#), section titled *Locale Naming Conventions* for further information regarding locale object names.

All locales that are supplied by IBM come in two versions: non-XPLINK and XPLINK. The HFS-resident XPLINK locale objects are distinguished from their non-XPLINK versions by a ".xplink" suffix on the HFS path name. PDS-resident XPLINK locale objects are distinguished from their non-XPLINK versions by a "CEH" prefix. The non-XPLINK PDS-resident locale objects have a prefix of "EDC".

It is the convention to specify locales by using the locale descriptive names. The runtime loads the non-XPLINK or XPLINK locale as appropriate.

It is also possible to specify a locale's relative or full path name on the `setlocale` call. However, the runtime does nothing to ensure that the locale is the appropriate version. `Setlocale` uses the locale object exactly as specified whether it is a relative or fully qualified path name. For example, `setlocale()` will fail if it is given an XPLINK locale full path name but the application is a non-XPLINK application. Similarly, `setlocale()` will fail if it is given a non-XPLINK locale full path name but the application is an XPLINK application. These problems are avoided if the locale names are the descriptive locale names.

Invocation sequence for `setlocale()`

In all three variations of the `setlocale()` function call, a pointer to a string that represents the locale value is returned. Also, in all variations, if the value for either *category* or *locale* is invalid, `setlocale()` returns a NULL pointer and the operating environment is not changed.

Each variation causes a different function to be performed:

1. `setlocale(category, locale);`

When an explicit locale is named, the *category* named in the call is set according to the named locale.

2. `setlocale(category, "");`

When the locale argument of the `setlocale()` function is given as a NULL string (""), the `setlocale()` function sets the locale environment according to the environment variables. If these are not set, the

default locale "S370" is used. This locale may be customized when the z/OS XL C/C++ product is installed.

The environment variables are not currently supported under all z/OS XL C/C++ environments. The preceding processing allows the `setlocale()` function to use the environment variables if they are available, and to use the "S370" locale otherwise.

3. `setlocale(category, (char *) 0);`

When a NULL pointer is given as a locale, a pointer to a string that represents the current locale for the specified *category* is returned. The string has the property that if it were specified as the locale of a subsequent `setlocale()` call of the same *category*, the current locale would be restored. For example, the following sequence is effectively a no-op:

```
setlocale(category, setlocale(category, (char *) 0));
```

When called with a NULL string (for example `setlocale(LC_ALL, "")`), `setlocale()` determines the locale to be set, by using the environment variables, and checking them in this order:

- 1. LC_ALL. If set, it specifies the name for all categories; it can override the values in the other environmental variables.
- 2. LC_COLLATE, LC_CTYPE, LC_MESSAGES, LC_MONETARY, LC_NUMERIC, LC_TIME, LC_SYNTAX, and LC_TOD. If set, these variables specify the locale name for the given *category*.
- 3. LANG.

The `setlocale()` function uses the `getenv()` function to retrieve the environment variables if the system supports the `getenv()` function. Under CICS it is not supported.

Querying the locale

When *locale* is set to a NULL pointer, `setlocale()` returns a string indicating the program's locale without changing it. This provides a means to query the program's current locale. To query the locale, give a NULL pointer as the second parameter. For example, to query all the categories of your locale, use a statement like the following:

```
char *string = setlocale(LC_ALL, NULL);
```

Returned value

If successful, `setlocale()` returns a pointer to the string associated with the specified *category* for the new *locale*. The string can be used on a subsequent call to restore that part of the program's locale.

Note: Because the string that a successful call to `setlocale()` points to may be overwritten by subsequent calls to the `setlocale()` function, you should copy the string if you plan to use it later.

If unsuccessful, `setlocale()` returns a NULL pointer and the program's locale is not changed.

If successful, `setlocale()` returns a string whose contents depend on the values of the *category* and *locale* arguments as shown in the following table.

| Table 54. Return String as Determined by Category and Locale Values | | |
|---|---------------------|--|
| Category Value | Locale Value | Return String |
| Specific category | NULL pointer | current-locale-name for category |
| | new-locale-name | new-locale-name for category |
| | "" (Null string) | If the environmental variables are set, new-locale-name: environment-variable-value or C. If the environmental variables are not set, and if non-POSIX Program, then S370 or SAA. |

Table 54. Return String as Determined by Category and Locale Values (continued)

| Category Value | Locale Value | Return String |
|----------------|---------------------|--|
| LC_ALL | NULL pointer | One of these: <ul style="list-style-type: none"> • locale-name • locale-name-list: locale-name1, locale-name2, ..., if different names for one or more categories. |
| | new-locale-name | new-locale-name (same for all categories) |
| | "" (Null string) | One of these: <ul style="list-style-type: none"> • new-locale-name: environment-variable-value or C • locale-name-list: environment-variable-value-list if different names for one or more categories. <p>If environmental variables are not set, and if non-POSIX program, then S370 (same for all categories).</p> |

If the string returned contains a locale name list, the names have the following order:

1. LC_COLLATE locale-name
2. LC_CTYPE locale-name
3. LC_MONETARY locale-name
4. LC_NUMERIC locale-name
5. LC_TIME locale-name
6. LC_TOD locale-name
7. LC_MESSAGES locale-name
8. LC_SYNTAX locale-name

If unsuccessful, `setlocale()` returns a NULL pointer and does not change the program's locale. Failure can result if:

- An incorrect *category* value is used.
- An incorrect *locale* value is used.
- The value of the environment variable used by `setlocale()` when the value of *locale* is "" is an undefined or incorrect locale name.

Note: If `setlocale()` is called and an application has called `pthread_create()` to create another thread, setting or changing the locale with `setlocale()` returns a NULL pointer and does not change the current locale.

Example

CELEBS07

```
/* CELEBS07

   This example sets the locale of the program to be
   Fr_FR.IBM-1047 and prints the string that is associated with
   the locale.

   */
#include <stdio.h>
#include <locale.h>

char *string;
```

setlocale

```
int main(void)
{
    string = setlocale(LC_ALL, "Fr_FR.IBM-1047");
    if (string != NULL)
        printf(" %s \n",string);
}
```

CELEBS08

```
/* CELEBS08

This example uses &setenv. to set the value of the
environment variable LC_TIME to FRAN, calls &setloc. to set
all categories to default values, uses &setloc. to query all
categories, and uses &printf. to print results.

*/
#include <stdio.h>
#include <stdlib.h>
#include <env.h>
#include <locale.h>

int main(void)
{
    char *string;
    setenv("LC_TIME", "FRAN", 1);
    setlocale(LC_ALL, "");
    string = setlocale(LC_ALL, NULL);
    printf("string = %s \n", string);
}
```

Output

If the example is run with POSIX(OFF), the result of printf() is:

```
string = "S370,S370,S370,S370,FRAN,S370,S370,S370"
```

If the example is run with POSIX(ON), the result of printf() is:

```
string = "C,C,C,C,FRAN,C,C,C"
```

Example

The following example shows euro currency support:

```
/* EUROSAMP
This example sets the locale of the program to be
Fr_BE.IBM-1148 and Fr_BE.IBM-1148@euro and prints
the string associated with each locale.
*/
#include <stdio.h>
#include <locale.h>

int main(void)
{
    char *string;

    string = setlocale(LC_ALL,"Fr_BE.IBM-1148");
    if (string != NULL)
        printf("String = %s \n",string);

    string = setlocale(LC_ALL,"Fr_BE.IBM-1148@euro");
    if (string != NULL)
        printf("String = %s \n",string);
}
```

Output

```
String = Fr_BE.IBM-1148
String = Fr_BE.IBM-1148@euro
```

```

General description

The `setlogmask()` function sets the log priority mask for the current process to *maskpri* and returns the previous mask. If the *maskpri* argument is 0 (zero), the current log mask is not modified. Calls by the current process to the `syslog()` function with a priority not set in *maskpri* are rejected. The mask for an individual priority *pri* is calculated by the macro `LOG_MASK(pri)`; The mask for all priorities up to and including *toppri* is given by the macro `LOG_UPTO(toppri)`. The default log mask allows all priorities to be logged.

Returned value

If successful, `setlogmask()` returns the value of the previous mask setting.

No errors are defined.

setnetent() — Open the network information data set

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

void setnetent(int stayopen);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

void setnetent(int stayopen);
```

General description

The `setnetent()` function opens and rewinds the `tcpip.HOSTS.ADDRINFO` data set, which contains information about known networks. If the `stayopen` flag is nonzero, the `tcpip.HOSTS.ADDRINFO` remains open after each call to `setnetent()`.

You can use the **X_ADDR** environment variable to specify a data set other than `tcpip.HOSTS.ADDRINFO`.

Note: For more information on these data sets and environment variables, `tcpip.HOSTS.ADDRINFO`, see *z/OS Communications Server: IP Configuration Guide*.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

Returned value

`setnetent()` returns no values.

Related information

- [“netdb.h — Network database operations” on page 45](#)
- [“endhostent\(\) — Close the host information data set” on page 420](#)

set_new_handler() – Register a function for new_handler()

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| ISO/ANSI C++ | C++ only | |

Format

```
#include <new>

new_handler set_new_handler(new_handler ph) throw();
```

General description

The `set_new_handler()` function is part of the z/OS XL C++ error handling mechanism. If you have registered a new-handler function with `set_new_handler()`, that new-handler function will be called by the new operator if it is unable to allocate storage. If you have not registered a new-handler function, the default behavior is for the new operator to return NULL.

The argument supplied to `set_new_handler()` is of type `new_handler` as defined in the header `<new>` (that is, a pointer to a function with a void return type and no arguments).

For C++ applications that are compiled NOXPLINK, the variable containing the address of the new handler function is statically bound with the executable. This means that each executable has its own new handler function which is shared only by the other functions that are linked as part of that executable. This is true even if multiple threads are using that same executable. This means that you cannot issue a `set_new_handler()` from within a non-XPLINK DLL if the new handler function is to be invoked outside of that DLL.

For C++ applications that are compiled XPLINK, the new handler function is truly global, so the DLL restriction is lifted. In a multithreaded environment consisting of XPLINK executables, the new handler function created by a call to `set_new_handler()` still applies to all threads in the (POSIX) process.

The required behavior of a new handler is to perform one of the following operations:

- Make more storage available for allocation and then return.
- Call either `abort()` or `exit(int)`.
- Throw an object of type `bad_alloc`.

Returned value

Returns a value of type `new_handler`. The function pointed to is the function that was previously called by the `set_new_handler()` function, or NULL if a new handler function was not established.

Refer to [z/OS XL C/C++ Language Reference](#) for more information about z/OS XL C++ error handling, including the new operator and the `set_new_handler()` functions.

- [“new — Storage allocation and free” on page 88](#)

setns() – Allow for a thread to join a descendant namespace

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | C++ only | |

Format

```
#define _XPLATFORM_SOURCE
#include <sched.h>

int setns(int fd, int nstype);
```

General description

setns() moves the current process to an existing mount, network, IPC, or UTS namespace or specify the existing namespace to which subsequent children belong.

When fd refers to a PID file directory, one or more flags must be specified.

When fd refers to a /proc/[pid]/ns link, only a single flag matching the namespace type that is referred to by the file descriptor or a 0 flag might be specified.

The following nstypes are supported by the setns service:

| Table 55. Supported constants for the nstypes argument | |
|--|---|
| nstypes | Description |
| CLONE_NEWIPC | Reassociate the process into the IPC namespace that is associated with the input file descriptor. If specified, fd must refer to either an IPC link in the /proc/[pid]/ns directory or a PID file descriptor. |
| CLONE_NEWNS | Reassociate the process into the mount namespace that is associated with the input file descriptor. If specified, fd must refer to either a mount link in the /proc/[pid]/ns directory or a PID file descriptor. |
| CLONE_NEWPID | Reassociate the process into the IPC namespace that is associated with the input file descriptor. If specified, fd must refer to either a PID link in the /proc/[pid]/ns directory or a PID file descriptor. |

Table 55. Supported constants for the *nstypes* argument (continued)

| nstypes | Description |
|----------------|---|
| CLONE_NEWUTS | <p>Reassociate the process into the UTS namespace that is associated with the input file descriptor.</p> <p>If specified, <i>fd</i> must refer to either a UTS link in the <code>/proc/[pid]/ns</code> directory or a PID file descriptor.</p> <p>Restriction:</p> <p>The CLONE_NEWUTS flag cannot be specified in a multiprocess address space. This results in an <code>errno EINVAL</code>.</p> |

Returned value

If successful, `setns()` returns 0.

If unsuccessful, `setns()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

The input parameter *fd* is invalid.

EINVAL

An invalid bit was specified in *nstype*. `setns()` supports the following *nstype*: `CLONE_NEWNS`, `CLONE_NEWPID`, `CLONE_NEWIPC`, `CLONE_NEWNET`, and `CLONE_NEWUTS`. Any other type results in the operation failing with an `EINVAL` error.

ENOMEM

The process requires more space than is available.

EPERM

The calling process does not have the required privileges for this operation.

ESRCH

The calling process does not have appropriate privileges.

Related information

setpeer() — Preset the socket peer address

Standards

| Standards / Extensions | C or C++ | Dependencies |
|-------------------------------|-----------------|---------------------|
| z/OS UNIX | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>
```

```
int setpeer(int socket, struct sockaddr *address, int length, char *name);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/socket.h>

int setpeer(int socket, struct sockaddr *address, int length, char *name);
```

General description

The `setpeer()` function presets the peer address associated with a socket.

Note: Neither `AF_INET`, `AF_UNIX`, nor `AF_INET6` support this function.

Parameter Description

socket

The socket descriptor.

address

The address of the socket peer.

length

The length of the socket address.

name

The name of a field indicating the conditions of the peer request.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` 1 feature test macro.

Returned value

`setpeer()` always returns -1.

Error Code Description

EINVAL

The request is invalid or not supported.

- [“sys/socket.h — Sockets definitions” on page 70](#)

setpgid() — Set process group ID for job control

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>
```

```
int setpgid(pid_t pid, pid_t pgid);
```

General description

Sets the process group ID (PGID) of a process within the session of the calling process, so you can reassign a process to a different process group, or start a new process group with the specified process as its group leader.

`pid_t pid` is the process ID (PID) of the process whose PGID you want to change. This must either be the caller of `setpgid()` or one of its children, and it must be in the caller's session. It cannot be the PID of a session leader. If `pid` is zero, the system uses the PID of the process calling `setpgid()`.

`pid_t pgid` is the new PGID you want to assign to the process identified by `pid`. If `pgid` indicates an existing process group, it must be in the caller's session. If `pgid` is zero, the system uses the PID of the process indicated by `pid` as the ID for the new process group. The new group is created in the caller's session.

Returned value

If successful, `setpgid()` returns 0.

If unsuccessful, `setpgid()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

The value of `pid` matches the PID of a child of the calling process, but the child has successfully run one of the EXEC functions.

EINVAL

`pgid` is less than zero or has some other unsupported value.

EPERM

The caller cannot change the PGID of the specified process. Some possible reasons are:

- The specified process is a session leader.
- `pid` matches the PID of a child of the calling process, but the child is not in the same session as the caller.
- `pgid` does not match the PID of the process specified by `pid`, and it does not match the PGID of any other process in the caller's session.

ESRCH

`pid` does not match the PID of the calling process or any of its children.

Example

CELEBS09

```
/* CELEBS09

   This example sets the PGID.

*/
#define _POSIX_SOURCE
#include <unistd.h>
#include <sys/types.h>
#include <stdio.h>

main() {
    pid_t pid;
    int p1[2], p2[2];
    char c='?';

    if (pipe(p1) != 0)
        perror("pipe() #1 error");
    else if (pipe(p2) != 0)
```

```
    perror("pipe() #2 error");
else
    if ((pid = fork()) == 0) {
        printf("child's process group id is %d\n", (int) getpgrp());
        write(p2[1], &c, 1);
        puts("child is waiting for parent to complete task");
        read(p1[0], &c, 1);
        printf("child's process group id is now %d\n", (int) getpgrp());
        exit(0);
    }
    else {
        printf("parent's process group id is %d\n", (int) getpgrp());
        read(p2[0], &c, 1);
        printf("parent is performing setpgid() on pid %d\n", (int) pid);
        if (setpgid(pid, 0) != 0)
            perror("setpgid() error");
        write(p1[1], &c, 1);
        printf("parent's process group id is now %d\n", (int) getpgrp());
        sleep(5);
    }
}
```

Output

```
parent's process group id is 5767174
child's process group id is 5767174
parent is performing setpgid() on pid 131084
parent's process group id is now 5767174
child is waiting for parent to complete task
child's process group id is now 131084
```

setpgrp() — Set process group ID

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

pid_t setpgrp(void);
```

General description

If the calling process is not already a session leader, setpgrp() sets the process group ID of the calling process to the process ID of the calling process. If a new process group is created, it is created within the session of the calling process.

Returned value

If successful, `setpgrp()` returns the new process group ID.

If unsuccessful, `setpgrp()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EPERM

The calling process is a session leader.

Related information

setpriority() — Set process scheduling priority

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/resource.h>

int setpriority(int which, id_t who, int priority);
```

General description

`setpriority()` sets the scheduling priority of a process, process group or user.

Processes are specified by the values of the *which* and *who* arguments. The *which* argument may be any one of the following set of symbols defined in the `sys/resource.h` include file:

PRIO_PROCESS

indicates that the *who* argument is to be interpreted as a process ID

PRIO_PGRP

indicates that the *who* argument is to be interpreted as a process group ID

PRIO_USER

indicates that the *who* argument is to be interpreted as a user ID

The *who* argument specifies the ID (process, process group, or user). A 0 (zero) value for the *who* argument specifies the current process, process group or user ID.

The *priority* argument specifies the scheduling priority. It is specified as a signed integer in the range, -20 to 19. Negative priorities cause more favorable scheduling. The default priority is 0. If the value specified to `setrlimit()` is less than the system's lowest supported priority value, the system's lowest supported value is used; if it is greater than the system's highest supported value, the system's highest

supported value is used. The setting of a process's scheduling priority value has the equivalent effect on a process's nice value, since they both represent the process's relative CPU priority. For example, setting one's scheduling priority value to its maximum value (19) has the equivalent effect of increasing one's nice value to its maximum value ((2*NZERO)-1), and will be reflected on the nice(), getpriority() and setpriority() functions.

If more than one process is specified, setpriority() sets the priorities of all of the specified processes to the specified value.

Only a process with appropriate privilege can lower its priority.

Returned value

If successful, setpriority() returns 0.

If unsuccessful, setpriority() returns -1 and sets errno to one of the following values:

Error Code
Description

EACCES
The priority is being changed to a lower value and the current process does not have the appropriate privilege.

EINVAL
The symbol specified in the *which* argument was not recognized, or the value of the *who* argument is not a valid process ID, process group ID or user ID.

ENOSYS
The system does not support this function.

EPERM
A process was located, but neither the real nor effective user ID of the executing process match the effective user ID of the process whose priority is to be changed.

ESRCH
No process could be located using the *which* and *who* argument values specified.

Related information

- [“sys/resource.h — XSI resource operations” on page 70](#)

setprotoent() — Open the protocol information data set

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

void setprotoent(int stayopen);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

void setprotoent(int stayopen);
```

General description

The `setprotoent()` function opens and rewinds the */etc/protocol* or the *tcpip.ETC.PROTO* data set. If the *stayopen* flag is nonzero, the */etc/protocol* or the *tcpip.ETC.PROTO* data set remains open after each call.

Special behavior for C++

To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

Returned value

`setprotoent()` returns no values.

Related information

- “[netdb.h — Network database operations](#)” on page 45
- “[endprotoent\(\) — Work with a protocol entry](#)” on page 422
- “[getprotobyname\(\) — Get a protocol entry by name](#)” on page 757
- “[getprotobynumber\(\) — Get a protocol entry by number](#)” on page 759
- “[getprotoent\(\) — Get the next protocol entry](#)” on page 760

setpwent() — Reset user database search

The information for this function is included in “[endpwent\(\) — User database functions](#)” on page 423.

setregid() — Set real and effective group IDs

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int setregid(gid_t rgid, gid_t egid);
```

General description

The `setregid()` function sets the real and/or effective GIDs for the calling process to the values specified by the input real and effective GID values. If a specified value is equal to -1, the corresponding real or effective GID of the calling process is left unchanged.

A process with appropriate privileges can set the real and effective GID to any valid GID value. An unprivileged process can only set the effective GID if the EGID argument is equal to either the real,

effective, or saved GID of the process. An unprivileged process can only set the real GID if the RGID argument is equal to either the real, effective, or saved GID of the process.

If the `setregid()` function is issued from multiple tasks within one address space, use synchronization to ensure that the `setregid()` functions are not performed concurrently. The execution of `setregid()` function concurrently within one address space can yield unpredictable results.

The `setregid()` function does not change any supplementary GIDs of the calling process.

Returned value

If successful, `setregid()` returns 0.

If unsuccessful, neither of the group IDs will be changed, `setregid()` returns -1 and sets `errno` to one of the following values:

Error Code
Description

EINVAL
The value of the *rgid* or *egid* argument is invalid or out-of-range.

EMVSSAF2ERR
The SAF call IRRSSU00 incurred an error.

EPERM
The processes does not have appropriate privileges and a change other than changing the real group ID to the saved set-group-ID, or changing the effective group ID to the real group ID or the saved group ID, was requested.

Related information

- [“unistd.h — Implementation-specific functions” on page 77](#)
- [“exec functions” on page 442](#)
- [“getuid\(\) — Get the real user ID” on page 792](#)
- [“setreuid\(\) — Set real and effective user IDs” on page 1566](#)
- [“setuid\(\) — Set the effective user ID” on page 1585](#)

setreuid() — Set real and effective user IDs

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int setreuid(uid_t ruid, uid_t euid);
```

General description

The `setreuid()` function sets the real and/or effective UIDs for the calling process to the values specified by the input real and effective UID values. If a specified value is equal to -1, the corresponding real or effective UID of the calling process is left unchanged.

A process with appropriate privileges can set the real and effective UID to any valid UID value. An unprivileged process can only set the effective UID if the EUID argument is equal to either the real, effective, or saved UID of the process. An unprivileged process can only set the real UID if the RUID argument is equal to either the real, effective, or saved UID of the process.

The `setreuid()` function is not supported from an address space running multiple processes, since it would cause all processes in the address space to have their security environment changed unexpectedly.

`setreuid()` can be used by daemon processes to change the identity of a process in order for the process to be used to run work on behalf of a user. In z/OS UNIX, changing the identity of a process is done by changing the real and effective UIDs and the auxiliary groups. In order to change the identity of the process on MVS completely, it is necessary to also change the MVS security environment. The identity change will only occur if the EUID value is specified, changing just the real UID will have no effect on the MVS environment.

The `setreuid()` function invokes MVS SAF services to change the MVS identity of the address space. The MVS identity that is used is determined as follows:

- If an MVS user ID is already known by the kernel from a previous call to a kernel function (for example, `getpwnam()`) and the UID for this user ID matches the UID specified on the `setreuid()` call, then this user ID is used.
- For nonzero target UIDs, if there is no saved user ID or the UID for the saved user ID does not match the UID requested on the `setreuid()` call, the `setreuid()` function queries the security database (for example, using `getpwnam()`) to retrieve a user ID. The retrieved user ID is then used.
- If the target UID=0 and a user ID is not known, the `setreuid()` function always sets the MVS user ID to BPXROOT or the value specified on the SUPERUSER parm in sysparms. BPXROOT is set up during system initialization as a superuser with a UID=0. The BPXROOT user ID is not defined to the BPX.DAEMON FACILITY class profile. This special processing is necessary to prevent a superuser from gaining daemon authority.
- A nondaemon superuser that attempts to set a user ID to a daemon superuser UID fails with an EPERM.

When the MVS identity is changed, the auxiliary list of groups is also set to the list of groups for the new user ID.

If the `setreuid()` function is issued from multiple tasks within one address space, use synchronization to ensure that the `setreuid()` functions are not performed concurrently. The execution of `setreuid()` function concurrently within one address space can yield unpredictable results.

Returned value

If successful, `setreuid()` returns 0.

If unsuccessful, neither of the group IDs will be changed, `setreuid()` returns -1, and sets `errno` to one of the following values:

Error Code

Description

EINVAL

The value of the *rgid* or *egid* argument is invalid or out-of-range.

EMVSSAF2ERR

The SAF call IRRSSU00 incurred an error.

EPERM

The processes does not have appropriate privileges and a change other than changing the real group ID to the saved set-group-ID, or changing the effective group ID to the real group ID or the saved group ID, was requested.

setrlimit() — Control maximum resource consumption

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/resource.h>

int setrlimit(int resource, const struct rlimit *rlp);
```

General description

The `setrlimit()` function sets resource limits for the calling process. A resource limit is a pair of values; one specifying the current (soft) limit, the other a maximum (hard) limit.

The soft limit may be modified to any value that is less than or equal to the hard limit. For certain *resource* values, (RLIMIT_CPU, RLIMIT_NOFILE, RLIMIT_AS), the soft limit cannot be set lower than the existing usage.

The hard limit may be lowered to any value that is greater than or equal to the soft limit. The hard limit can be raised only by a process which has superuser authority. Both the soft limit and hard limit can be changed by a single call to `setrlimit()`.

The value `RLIM_INFINITY` defined in `<sys/resource.h>`, is considered to be larger than any other limit value. If a call to `getrlimit()` returns `RLIM_INFINITY` for a resource, it means the implementation does not enforce limits on that resource. Specifying `RLIM_INFINITY` as any resource limit values on a successful call to `setrlimit()` inhibits enforcement of that resource limit.

The *resource* argument specifies which resource to set the hard and/or soft limits for, and may be one of the following values:

RLIMIT_CORE

The maximum size of a dump of memory (in bytes) allowed for the process. A value of 0 (zero) prevents file creation. Dump file creation will stop at this limit.

RLIMIT_CPU

The maximum amount of CPU time (in seconds) allowed for the process. If the limit is exceeded, a SIGXCPU signal is sent to the process and the process is granted a small CPU time extension to allow for signal generation and delivery. If the extension is used up, the process is terminated with a SIGKILL signal. An attempt to set the CPU limit lower than that already used will result in an EINVAL errno.

RLIMIT_DATA

The maximum size of the break value for the process, in bytes. In this implementation, this resource always has a hard and soft limit value of `RLIM_INFINITY`. A call to `setrlimit()` to set this resource to any value other than `RLIM_INFINITY` will fail with an errno of EINVAL.

RLIMIT_FSIZE

The maximum file size (in bytes) allowed for the process. A value of 0 (zero) prevents file creation. If the size is exceeded, a SIGXFSZ signal is sent to the process. If the process is blocking, catching, or ignoring SIGXFSZ, continued attempts to increase the size of a file beyond the limit will fail with an errno of EFBIG.

RLIMIT_MEMLIMIT

The maximum amount of usable storage above the 2 gigabyte bar (in 1 megabyte segments) that can be allocated. Any attempt to extend the usable amount of virtual storage above the 2 gigabyte bar fails.

RLIMIT_NOFILE

The maximum number of open file descriptors allowed for the process. This number is one greater than the maximum value that may be assigned to a newly created descriptor. (That is, it is one-based.) Any function that attempts to create a new file descriptor beyond the limit will fail with an EMFILE errno. An attempt to set the open file descriptors limit lower than that already used will result in an EINVAL errno.

Restrictions: This value may not exceed 524288.

RLIMIT_STACK

The maximum size of the stack for a process, in bytes. Note that in z/OS UNIX services, the stack is a per-thread resource. In this implementation, this resource always has a hard and soft limit value of RLIM_INFINITY. A call to setrlimit() to set this resource to any value other than RLIM_INFINITY will fail with an errno of EINVAL.

RLIMIT_AS

The maximum address space size for the process, in bytes. If the limit is exceeded, malloc() and mmap() functions will fail with an errno of ENOMEM. Also, automatic stack growth will fail.

The *rlp* argument points to a `rlimit` structure. This structure contains the following members:

rlim_cur

The current (soft) limit

rlim_max

The maximum (hard) limit

Refer to the `<sys/resource.h>` header for more detail.

The resource limit values are propagated across exec and fork.

Special behavior for z/OS UNIX Services: An exception exists for exec processing in conjunction with daemon support. If a daemon process invokes exec and it had previously invoked setuid() before exec, the RLIMIT_CPU, RLIMIT_AS, RLIMIT_CORE, RLIMIT_FSIZE, and RLIMIT_NOFILE limit values are set based on the limit values specified in the kernel parmlib member BPXPRMxx.

For processes which are not the only process within an address space, the RLIMIT_CPU and RLIMIT_AS limits are shared with all the processes within the address space. For RLIMIT_CPU, when the soft limit is exceeded, action will be taken on the first process within the address space. If the action is termination, all processes within the address space will be terminated.

In addition to the RLIMIT_CORE limit values, the dump file defaults are set by SYSMDUMP defaults. Refer to *z/OS MVS Initialization and Tuning Reference* for more information on setting up SYSMDUMP defaults using the IEADMRO0 parmlib member.

Dumps of memory are taken in 4160 byte increments. Therefore, RLIMIT_CORE values affect the size of memory dumps in 4160 byte increments. For example, if the RLIMIT_CORE soft limit value is 4000, the dump will contain no data. If the RLIMIT_CORE soft limit value is 8000, the maximum size of a memory dump is 4160 bytes.

When setting RLIMIT_NOFILE, the hard limit cannot exceed the system defined limit of 524288.

Large file support for z/OS UNIX files: Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the [long long data type support](#) enabled and define the `_LARGE_FILES` feature test macro before any headers are included to enable this

function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the `_LARGE_FILES` feature test macro as well.

Returned value

If successful, `setrlimit()` returns 0.

If unsuccessful, `setrlimit()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

An invalid *resource* was specified, or the soft limit to set exceeds the hard limit to set, the soft limit to set is below the current usage, or the resource does not allow any value other than `RLIM_INFINITY`.

EPERM

The limit specified to `setrlimit()` would have raised the maximum limit value, and the calling process does not have appropriate privileges.

setservernt() — Open the network services information data set

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <netdb.h>

void setservernt(int stayopen);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <netdb.h>

void setservent(int stayopen);
```

General description

The `setservent()` function opens and rewinds the `/etc/services` or the `tcip.ETC.SERVICES` data set. For more information on `/etc/services` or the `tcip.ETC.SERVICES` data set, see [z/OS Communications Server: IP Configuration Guide](#). If the `stayopen` flag is nonzero, the `tcip.ETC.SERVICES` data set remains open after each call.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` 1 feature test macro.

Returned value

`setservent()` returns no values.

setsid() — Create session, set process group ID

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

pid_t setsid(void);
```

General description

Creates a new session with the calling process as its session leader. The caller becomes the process group leader of a new process group. The calling process must not be a process group leader already. The caller does not have a controlling terminal.

The process group ID (PGID) of the new process group is equal to the process ID (PID) of the caller. The caller starts as the only process in the new process group and in the new session.

Returned value

If successful, setsid() returns the value of the caller's new PGID.

If unsuccessful, setsid() returns -1 and sets errno to one of the following values:

Error Code

Description

EPERM

One of the following error conditions exists:

- The caller is already a process group leader.
- The caller's PID matches the PGID of some other process.

Example

CELEBS10

```
/* CELEBS10

   This example creates a new session.

*/
#define _POSIX_SOURCE
#include <unistd.h>
#include <sys/types.h>
#include <stdio.h>

main() {
    pid_t pid;
    int p[2];
    char c='?';

    if (pipe(p) != 0)
        perror("pipe() error");
    else
        if ((pid = fork()) == 0) {
            printf("child's process group id is %d\n", (int) getpgrp());
            write(p[1], &c, 1);
            setsid();
            printf("child's process group id is now %d\n", (int) getpgrp());
            exit(0);
        }
        else {
            printf("parent's process group id is %d\n", (int) getpgrp());
            read(p[0], &c, 1);
            sleep(5);
        }
}
```

Output

```
child's process group id is 262152
child's process group id is now 262150
parent's process group id is 262152
```

setsockopt() — Set options associated with a socket

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int setsockopt(int socket, int level, int option_name,
               const void *option_value, socklen_t option_length);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/types.h>
#include <sys/socket.h>

int setsockopt(int socket, int level, int option_name,
               char *option_value, int *option_length);
```

IPv6: To include support for IPv6 socket options, add the following code:

```
#define _OPEN_SYS_SOCK_IPV6 1
#include <netinet/in.h>
```

ip_mreq structure: To include the ip_mreq structure in your program, add the following code:

```
#define _XOPEN_SOURCE 500
#include <netinet/in.h>
```

or

```
#define _OPEN_SYS_SOCK_EXT3
#include <netinet/in.h>
```

group_req structure: To include the group_req structure in your program, add the following code:

```
#define _OPEN_SYS_SOCK_EXT3
#include <netinet/in.h>
```

group_source_req structure: To include the group_source_req structure in your program, add the following code:

```
#define _OPEN_SYS_SOCK_EXT3
#include <netinet/in.h>
```

ipv6_mreq structure: To include the ipv6_mreq structure in your program, add the following code:

```
#define _OPEN_SYS_SOCK_IPV6
#include <netinet/in.h>
```

icmp6_filter structure: To include the `icmp6_filter` structure in your program, add the following code:

```
#define _OPEN_SYS_SOCKET_IPV6
#include <netinet/icmp6.h>
```

General description

The `setsockopt()` function sets options associated with a socket. Options can exist at multiple protocol levels.

Parameter

Description

socket

The socket descriptor.

level

The level for which the option is being set.

option_name

The name of a specified socket option.

option_value

The pointer to option data.

option_length

The length of the option data.

When manipulating socket options, you must specify the level at which the option resides and the name of the option. To manipulate options at the socket level, the *level* parameter must be set to `SOL_SOCKET` as defined in `sys/socket.h`. To manipulate options at the IPv4 or IPv6 level, the *level* parameter must be set to `IPPROTO_IP` as defined in `sys/socket.h` or `IPPROTO_IPV6` as defined in `netinet/in.h`. To manipulate options at any other level, such as the TCP level, supply the appropriate protocol number for the protocol controlling the option. The `getprotobyname()` call can be used to return the protocol number for a named protocol.

The *option_value* and *option_length* parameters are used to pass data used by the particular set command. The *option_value* parameter points to a buffer containing the data needed by the set command. The *option_value* parameter is optional and can be set to the NULL pointer, if data is not needed by the command. The *option_length* parameter must be set to the size of the data pointed to by *option_value*.

All of the socket-level options except `SO_LINGER`, `SO_RCVTIMEO` and `SO_SNDTIMEO`, expect *option_value* to point to an integer and *option_length* to be set to the size of an integer. When the integer is nonzero, the option is enabled. When it is zero, the option is disabled. The `SO_LINGER` option expects *option_value* to point to a **linger** structure, as defined in `sys/socket.h`. This structure is defined in the following example:

```
struct linger
{
    int    l_onoff;           /* option on/off */
    int    l_linger;         /* linger time */
};
```

The *l_onoff* field is set to 0 if the `SO_LINGER` option is begin disabled. A nonzero value enables the option. The *l_linger* field specifies the amount of time to linger on close. The units of *l_linger* are seconds.

The following options are recognized at the IPv4 level:

Option

Description

IP_ADD_MEMBERSHIP

(RAW and UDP) This option is used to join a multicast group on a specific interface (an interface has to be specified with this option). Only applications that want to receive multicast datagrams need to join multicast groups. Applications that only transmit will not need to do so.

The multicast IP address and the interface IP address will be passed in the following structure available in `netinet/in.h`:

```
struct ip_mreq
{
    struct in_addr imr_multiaddr; /* IP multicast addr of group */
    struct in_addr imr_interface; /* local IP addr of interface */
};
```

If `INADDR_ANY` is specified on the interface address of the `mreq` structure passed a default interface will be chosen as follows:

- If the group address specified in the `mreq` structure was specified on a `GATEWAY` statement use that interface.
- If 224.0.0.0 was specified on `GATEWAY` statement use that interface.
- If `DEFAULTNET` was specified and is multicast capable use that interface.

IP_ADD_SOURCE_MEMBERSHIP

(RAW and UDP) This option is used to join a source-specific multicast group specified by the `ip_mreq_source` structure. The `ip_mreq_source` structure is defined in `netinet/in.h`.

IP_BLOCK_SOURCE

(RAW and UDP) This option is used to block from a given source to a given multicast group (for example, if the user "mutes" that source). The source multicast group is specified by the `ip_mreq_source` structure which is defined in `netinet/in.h`.

IP_DROP_MEMBERSHIP

(RAW and UDP) This option is used to leave a multicast group.

The multicast IP address and the interface IP address will be passed in the following structure available in `netinet/in.h`:

```
struct ip_mreq
{
    struct in_addr imr_multiaddr; /* IP multicast addr of group */
    struct in_addr imr_interface; /* local IP addr of interface */
};
```

If `INADDR_ANY` is specified on the interface address of the `mreq` structure passed the system will drop the first group that matches the group (class D) address without regard to the interface.

IP_DROP_SOURCE_MEMBERSHIP

(RAW and UDP) This option is used to leave a source-specific multicast group specified by the `ip_mreq_source` structure. The `ip_mreq_source` structure is defined in `netinet/in.h`.

IP_MULTICAST_IF

(RAW and UDP) Sets the interface for sending outbound multicast datagrams from this socket application. Multicast datagrams will be transmitted only on one interface at a time. An IP address is passed in an `in_addr` structure.

If `INADDR_ANY` is specified for the interface address passed a default interface will be chosen as follows:

- If 224.0.0.0 was specified on the `GATEWAY` statement use that interface.
- If `DEFAULTNET` was specified and is multicast capable use that interface.

IP_MULTICAST_LOOP

(RAW and UDP) Enables or disables loopback of outgoing multicast datagrams. Default is enable. When it is enabled, multicast applications that have joined the outgoing multicast group can receive a copy of the multicast datagrams destined for that address/port pair. The loopback indicator is passed as an `u_char`. The value 0 is specified to disable loopback. The value 1 is specified to enable loopback.

IP_MULTICAST_TTL

(RAW and UDP) Sets the IP time-to-live of outgoing multicast datagrams. Default value is 1 (that is, multicast only to the local subnet). The TTL value is passed as an `u_char`.

IP_RECVPKINFO

(RAW and UDP) Enables or disables returning the destination IP address of an incoming packet and the interface over which the packet was received as IP_PKTINFO ancillary data on recvmsg() function calls. The option value is specified as an int. A nonzero value enables the option; 0 disables the option.

This option is protected by the _OPEN_SYS SOCK_EXT4 feature test macro.

IP_UNBLOCK_SOURCE

(RAW and UDP) This option is used to undo the operation performed with the IP_BLOCK_SOURCE option (for example, if the user "mutes" that source). The source group is specified by the ip_mreq_source structure, which is defined in netinet/in.h.

IP_TTL

(TCP and UDP) This option is used to set the time-to-live field in the IP header for the SOCK_STREAM(TCP) and SOCK_DGRAM (UDP) sockets. This socket option allows the application to limit the lifetime of the packet in the network and prevent it from circulating indefinitely. This option is an IPv4-only socket option. Valid values are in the range 1–255. If not specified, the value is obtained from the TCP/IP stack and set via the IPCONFIG TTL configuration statement.

Note: IP_TTL can be used only when _XPLATFORM_SOURCE is defined.

MCAST_BLOCK_SOURCE

(RAW and UDP) This option is used to block data from a given source to a given group (for example, if the user "mutes" that source). The source is specified by the group_source_req structure, which is defined in netinet/in.h.

MCAST_JOIN_GROUP

(RAW and UDP) This option is used to join an any-source group. The group is specified by the group_req structure. The group_req structure is defined in netinet/in.h.

MCAST_JOIN_SOURCE_GROUP

(RAW and UDP) This option is used to join a source-specific group. The source is specified by the group_source_req structure which is defined in netinet/in.h.

MCAST_LEAVE_GROUP

(RAW and UDP) This option is used to leave an any-source group. The group is specified by the group_req structure. The group_req structure is defined in netinet/in.h.

MCAST_LEAVE_SOURCE_GROUP

(RAW and UDP) This option is used to leave a source-specific group. The source is specified by the group_source_req structure which is defined in netinet/in.h.

MCAST_UNBLOCK_SOURCE

(RAW and UDP) This option is used to undo the operation performed with the MCAST_BLOCK_SOURCE option (e.g., if the user then "unmutes" the source). The source is specified by the group_source_req structure which is defined in netinet/in.h.

The following options are recognized at IPv6 level:

Option**Description****IPv6_ADDR_PREFERENCES**

(TCP and UDP) Used to set the source address selection preference flags for a given socket. The socket option value (optval) is a 32-bit unsigned integer argument. The argument consists of a number of flags where each flag indicates a source address selection preference. These flags indicate the application's preferences for a source address, but will be ignored by the TCP stack if an IP address with the preferred address attributes is not available. For example, a preference flag of IPV6_PREFER_SRC_TMP tells the stack that the application would prefer to use a temporary IPv6 source address rather than a public source address. You can combine multiple flags with logical OR to express multiple preferences as long as the flags are not contradictory. The constants for the flag bit values are defined in netinet/in.h.

IPv6_CHECKSUM

(RAW) For a RAW (non-ICMPv6) socket, this option instructs the kernel to compute and store a checksum for output and verifies the received checksum on input. This prevents applications from

having to perform source address selection on the packets sent. This option specifies an integer value into the user data where the checksum is located. This option can be disabled by specifying an option value of -1.

IPV6_DONTFRAG

(RAW and UDP) This option turns off the automatic inserting of a fragment header in the packet for UDP and raw sockets.

IPV6_DSTOPTS

(RAW and UDP) The application can remove any sticky destination options header by calling `setsockopt()` for this option with a zero option length.

IPV6_HOPOPTS

(RAW and UDP) The application can remove any sticky hop-by-hop options header by calling `setsockopt()` for this option with a zero option length.

IPV6_JOIN_GROUP

(RAW and UDP) Controls the receipt of multicast packets by joining the multicast group specified by the `ipv6_mreq` structure that is passed. The `ipv6_mreq` structure is defined in `netinet/in.h`.

IPV6_LEAVE_GROUP

(RAW and UDP) Controls the receipt of multicast packets by leaving the multicast group specified by the `ipv6_mreq` structure that is passed. The `ipv6_mreq` structure is defined in `netinet/in.h`.

IPV6_MULTICAST_HOPS

(RAW and UDP) Sets the hop limit for outgoing multicast packets. The hop limit value is passed as an `int`.

IPV6_MULTICAST_IF

(RAW and UDP) Sets the interface for outgoing multicast packets. An interface index is used to specify the interface. It is passed as an `u_int`.

IPV6_MULTICAST_LOOP

(RAW and UDP) If a multicast datagram is sent to a group to which the sending host itself belongs (on the outgoing interface), a copy of the datagram is looped back by the IP layer for local delivery if this option is set to one. If this option is set to zero, a copy is not looped back. Other option values return an `errno` of `EINVAL`. The default is one (loopback). The option value is passed as an `int`.

IPV6_NEXTHOP

(RAW and UDP) Specifies the next hop for the datagram as a socket address structure.

IPV6_RECVDSTOPTS

(RAW and UDP) To receive destination options header this option must be enabled.

IPV6_RECVHOPLIMIT

(RAW, TCP, and UDP) When this option is enabled, the received hop limit from an incoming packet will be returned as `IPV6_HOPLIMIT` ancillary data on `recvmsg()` function calls. The option value is specified as an `int`. A nonzero value enables the option, zero disables the option.

IPV6_RECVHOPOPTS

(RAW and UDP) To receive a hop-by-hop options header this option must be enabled.

IPV6_RECVPATHMTU

(RAW and UDP) Enables the receipt of `IPV6_PATHMTU` ancillary data on `recvmsg()` function calls.

IPV6_RECVPKTINFO

(RAW and UDP) Enables or disables returning the destination IP address of an incoming packet and the interface over which the packet was received as `IPV6_PKTINFO` ancillary data on `recvmsg()` function calls. The option value is specified as an `int`. A nonzero value enables the option; 0 disables the option.

IPV6_RECVRTHDR

(RAW and UDP) To receive a routing header this option must be enabled.

IPV6_RECVTCLASS

(RAW, TCP, and UDP) To receive the traffic class this option must be enabled.

IPV6_RTHDR

(RAW and UDP) The application can remove any sticky routing header by calling `setsockopt()` for this option with a zero option length.

IPV6_RTHDRDSTOPTS

(RAW and UDP) The application can remove any sticky destination options header by calling `setsockopt()` for this option with a zero option length.

IPV6_TCLASS

(RAW, TCP, and UDP) To specify the traffic class value this option must be enabled.

IPV6_UNICAST_HOPS

(RAW and UDP) Used to control hop limit in outgoing unicast IPv6 packets. The hop limit value is passed as an int.

IPV6_USE_MIN_MTU

(RAW, TCP, and UDP) Indicates whether the IP layer will use the minimum MTU size (1280) for sending packets, bypassing path MTU discovery. The option value is passed as an int. A value of -1 causes the default values for unicast (disabled) and multicast (enabled) destinations to be used. A value of 0 disables this option for unicast and multicast destinations. A value of 1 enables this option for unicast and multicast destinations and the minimum MTU size will be used.

IPV6_V6ONLY

(RAW, TCP, and UDP) Used to determine whether a socket is restricted to IPv6 communications only. The default setting is off. The option value is passed as an int. A non-zero value means the option is enabled (socket can only be used for IPv6 communications). 0 means the option is disabled.

Note: To use these options, you must use the feature test macro `#define _OPEN_SYS_SOCKET_IPV6`.

The following options are recognized at the ICMPv6 level:

Option**Description****ICMP6_FILTER**

(RAW) Used to filter ICMPv6 messages. The option value is passed as an `icmp6_filter` structure. The `icmp6_filter` structure is defined in `netinet/icmp6.h`.

The following options are recognized at the socket level:

Option**Description****SO_BROADCAST**

Toggles the ability to broadcast messages. If enabled, this option allows the application program to send broadcast messages over *socket*, if the interface specified in the destination supports broadcasting of packets. This option has no meaning for stream sockets.

SO_DEBUG

Turns on recording of debugging information. This option enables or disables debugging in the underlying protocol modules. This option takes an int value.

SO_KEEPALIVE

Toggles the TCP keep-alive mechanism for a stream socket. When activated, the keep-alive mechanism periodically sends a packet on an otherwise idle connection. If the remote TCP does not respond to the packet or to retransmissions of the packet, the connection is terminated with the error ETIMEDOUT.

SO_LINGER

Lingers on close if data is present. When this option is enabled and there is unsent data present when `close()` is called, the calling application program is blocked during the `close()` call, until the data is transmitted or the connection has timed out. If this option is disabled, the TCP/IP address space waits to try to send the data. Although the data transfer is usually successful, it cannot be guaranteed, because the TCP/IP address space waits only a finite amount of time trying to send the data. The `close()` call returns without blocking the caller. This option has meaning only for stream sockets.

SO_OOBINLINE

Toggles the reception of out-of-band data. When this option is enabled, it causes out-of-band data to be placed in the normal data input queue as it is received, making it available to `recv()`, `recvfrom()`, and `recvmsg()` without having to specify the `MSG_OOB` flag in those calls. When this option is disabled, it causes out-of-band data to be placed in the priority data input queue as it is received, making it available to `recv()`, `recvfrom()`, and `recvmsg()` only by specifying the `MSG_OOB` flag in those calls. This option has meaning only for stream sockets.

_SO_PROPAGATEUSERID

Toggles propagating a user ID (UID) over an `AF_UNIX` stream socket. When enabled, user (UID) information is extracted from the system when the `connect()` function is invoked. Then, when the `accept()` function is invoked, the acceptor assumes the identity of the connector until the accepted socket is closed.

SO_RCVBUF

Sets receive buffer size. This option takes an `int` value. The value cannot be set after the socket is connected.

SO_RCVTIMEO

Sets the timeout specifying the maximum amount of time an input function waits until it completes.

It accepts a *timeval* structure with the number of seconds and microseconds specifying the limit on how long to wait for an input operation to complete. The *timeval* structure contains the number of seconds and microseconds specified as fullword binary numbers. The seconds can be a value in the range from 0 to 2,678,400 (equal to 31 days), and the microseconds can be a value in the range from 0 to 1,000,000 (equal to 1 second). While the *timeval* structure can be specified using microsecond granularity, the internal TCP/IP timers used to implement this function have a granularity of approximately 100 milliseconds.

If a receive operation has blocked for this much time without receiving additional data, it returns with a partial count or `errno` set to `EWOULDBLOCK` if no data is received. The default for this option is zero, which indicates that a receive operation does not time out.

SO_REUSEADDR

Toggles local address reuse. When enabled, this option allows local addresses that are already in use to be bound. This alters the normal algorithm used in the `bind()` call.

The system checks at connect time to ensure that the local address and port do not have the same foreign address and port. The error `EADDRINUSE` is returned if the association already exists.

After the `SO_REUSEADDR` option is active, the following situation is supported:

A server can `bind()` the same port multiple times as long as every invocation uses a different local IP address and the wildcard address `INADDR_ANY` is used only one time per port.

SO_SNDBUF

Sets send buffer size. This option takes an `int` value. The value cannot be set after the socket is connected.

SO_SNDTIMEO

Sets the timeout value specifying the amount of time that an output function blocks due to flow control preventing data from being sent.

It accepts a *timeval* structure with the number of seconds and microseconds specifying the limit on how long to wait for an input operation to complete. The *timeval* structure contains the number of seconds and microseconds specified as fullword binary numbers. The seconds can be a value in the range from 0 to 2,678,400 (equal to 31 days), and the microseconds can be a value in the range from 0 to 1,000,000 (equal to 1 second). While the *timeval* structure can be specified using microsecond granularity, the internal TCP/IP timers used to implement this function have a granularity of approximately 100 milliseconds.

If a send operation has blocked for this time, it returns with a partial count or with `errno` set to `EWouldBlock` if no data is sent. The default for this option is zero, which indicates that a send operation does not time out.

SO_SECINFO

Toggles receiving security information. When enabled on an `AF_UNIX` UDP socket, the `recvmsg()` function will return security information about the sender of each datagram as ancillary data. This information contains the sender's user ID, UID, GID, and job name and it is mapped by the `secsinfo` structure in `sys/socket.h`.

Note: To use these options, you must use the Feature Test Macro `#define _OPEN_SYS_SOCKET_IPV6`.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` 1 feature test macro.

Returned value

If successful, `setsockopt()` returns 0.

If unsuccessful, `setsockopt()` returns -1 and sets `errno` to one of the following values:

Error Code**Description****EADDRNOTAVAIL**

The `ip6_addr` is not available for use on the `ip6_ifindex` interface or the tuple consisting of socket, interface, and multicast group values does not exist..

EBADF

The *socket* parameter is not a valid socket descriptor.

EDOM

The send or receive timeout values exceed 31 days.

EFAULT

Using *option_value* and *option_length* parameters would result in an attempt to access storage outside the caller's address space.

EHOSTUNREACH

No route to the destination exists over the interface that is specified by `ip6_ifindex`.

EINVAL

The specified option is invalid at the specified socket level or the socket has been shut down.

ENETDOWN

The interface that is specified by `ip6_ifindex` is not enabled for IPv6 use.

ENOBUFS

Insufficient system resources are available to complete the call or a maximum of 64 source filters can be specified per multicast group, interface pair.

ENOPROTOPT

The *option_name* parameter is unrecognized, or the *level* parameter is not `SOL_SOCKET`.

ENOSYS

The function is not implemented. You attempted to use a function that is not yet available.

ENOTSOCK

The descriptor is for a file, not for a socket.

ENXIO

The interface that is specified by `ip6_ifindex` does not exist.

Example

The following are examples of the `setsockopt()` call. See [“getsockopt\(\) — Get the options associated with a socket” on page 778](#) for examples of how the `getsockopt()` options set are queried.

```
int rc;
int s;
int option_value;
struct linger l;
int setsockopt(int s, int level, int option_name,
char *option_value,
int option_len);
:
/* I want out of band data in the normal input queue */
option_value = 1;
rc = setsockopt(s, SOL_SOCKET, SO_OOBINLINE,
(char *) &option_value, sizeof(int));
:
/* I want to linger on close */
l.l_onoff = 1;
l.l_linger = 100;
rc = setsockopt(s, SOL_SOCKET, SO_LINGER,
(char *) &l, sizeof(l));
```

setsourcefilter() — Set source filter

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| RFC3678 | both | z/OS V1.9 |

Format

```
#define _XOPEN_SYS_SOCK_EXT3
#include <netinet/in.h>

int setsourcefilter(int s, uint32_t interface, struct sockaddr *group,
socklen_t grouplen, uint32_t fmode, uint32_t numsrc,
struct sockaddr_storage *slist);
```

General description

This function allow applications to set and replace the current multicast filtering state for a tuple consisting of socket, interface, and multicast group values.

A multicast filter is described by a filter mode, which is MCAST_INCLUDE or MCAST_EXCLUDE, and a list of source addresses which are filtered.

This function is protocol-independent. It can be on either AF_INET or AF_INET6 sockets of the type SOCK_DGRAM or SOCK_RAW.

If the function is unable to obtain the required storage, control will not return to the caller. Instead the application will terminate due to an out of memory condition (if the reserve stack is available and the caller is not XPLINK), or it will terminate with an abend indicating that storage could not be obtained.

Argument

Description

s

Identifies the socket.

interface

Holds the local the index of the interface.

group

Points to either a sockaddr_in structure for IPv4 or a sockaddr_in6 structure for IPv6 that holds the IP multicast address of the group.

grouplen

Gives the length of the sockaddr_in or sockaddr_in6 structure.

fmode

Identifies the filter mode. The value of this field will be either MCAST_INCLUDE or MCAST_EXCLUDE, which are likewise defined in <netinet/in.h>.

numsrc

Holds the number of source addresses in the slist array.

slist

Points to an array of IP addresses of sources to include or exclude depending on the filter mode.

Returned value

If successful, the function returns 0. Otherwise, it returns -1 and sets errno to one of the following values.

errno

Description

EBADF

s is not a valid socket descriptor.

EAFNOSUPPORT

The address family of the input sockaddr is not AF_INET or AF_INET6.

EPROTOTYPE

The socket s is not of type SOCK_DGRAM or SOCK_RAW.

EINVAL

Interface or group is not a valid address, or the socket s has already requested multicast setsockopt options (refer to z/OS Communications Server: IP Sockets Application Programming Interface Guide and Reference for details.) Or if the group address family is AF_INET and grouplen is not at least size of sockaddr_in or if the group address family is AF_INET6 and grouplen is not at least size of sockaddr_in6 or if grouplen is not at least size of sockaddr_in.

ENOBUFS

The number of the source addresses exceeds the allowed limit.

setstate() — Change generator for random()

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

char *setstate(const char *state);
```

General description

The `setstate()` function allows switching between state arrays used by the `random()` function once a state has been initialized. The array defined by the `state` argument is used for further random-number generation by the calling thread until `initstate()` is called or `setstate()` is called again. The `setstate()` function returns a pointer to the previous state array.

After initialization, a state array can be restarted at a different point by calling `setstate()` with the desired state, followed by `srandom()` with the desired seed.

Returned value

If successful, `setstate()` returns a pointer to the previous state array.

If unsuccessful, `setstate()` returns a NULL pointer. The function will fail and write a message to standard error if it detects that the state information has been damaged.

set_terminate() – Register a function for terminate()

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| ANSI/ISO C++ | C++ only | |

Format

```
#include <exception>

terminate_handler set_terminate(terminate_handler ph) throw();
```

General description

The `set_terminate()` function is part of the z/OS XL C++ error handling mechanism. The argument supplied to `set_terminate()` is of type `terminate_handler` as defined in the header `<exception>` (that is, a pointer to a function with a void return type and no arguments). The function specified will be called by the `terminate()` function.

Note that the function registered for `terminate()` must terminate execution of the program without returning to its caller(). If `set_terminate()` has not yet been called, then `terminate()` calls a system-defined default terminate handler, which calls `abort()`.

In a multithreaded environment, the terminate function created by the issuance of a `set_terminate()` call applies to all threads in the (POSIX) process. If a thread throws an exception which is not caught by that thread of execution, then `terminate()` is called. The default `terminate()` action calls `abort()` which by default cause a SIGABRT signal. If there is no signal handler, then SIGABRT terminates the process. You can override this with a thread-level termination by supplying a function which invokes `pthread_exit()` as a terminate function. This terminates the thread but not the process.

Returned value

`set_terminate()` returns the address of the previous `terminate_handler`.

Refer to [z/OS XL C/C++ Language Reference](#) for more information about z/OS XL C++ exception handling, including the `set_terminate()` function.

Related information

- [“exception – Exception handling”](#) on page 87

_SET_THLIIPADDR() – Set the client's IP address

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <sys/__ussos.h>

int _SET_THLIIPADDR(ln, ipaddr);
```

General description

The `_SET_THLIIPADDR()` macro provides a way for daemons to set a client's IP address.

`_SET_THLIIPADDR()` takes the following arguments:

ln

The length of the IP address as specified by *ipaddr*. The IP address length can be between 1 and 16 inclusive. The argument is specified as an unsigned int.

ipaddr

Pointer to the IP address.

Usage notes

The intent of the `_SET_THLIIPADDR()` macro is to provide a way for daemons to set the IP address of a client for Security Authorization Facility (SAF) exits when performing security related functions.

Restrictions

Results are unpredictable if `_SET_THLIIPADDR()` is issued outside of the z/OS UNIX environment.

Returned value

If the client's IP address is set, `_SET_THLIIPADDR()` returns nonzero.

`_SET_THLIIPADDR()` returns 0 and does not set the IP address of the client when:

- The base level of z/OS UNIX is not OS/390 R5.
- The setting of the IP address is not supported.
- The length of the IP address is less than 1 or greater than 16.

Related information

- [“sys/__ussos.h – Security facility authorization” on page 73](#)

setuid() – Set the effective user ID

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

int setuid(uid_t uid);
```

General description

Sets the real, effective, or saved set user IDs (UIDs) for the current process to *uid*.

If *uid* is the same as the real UID or the saved set-user-ID of the process, `setuid()` always succeeds and sets the effective UID. the real user ID and saved set-user-ID will remain unchanged.

The `setuid()` function will not affect the supplementary group list in any way.

If *uid* is not the same as the real UID of the process, `setuid()` succeeds only if the process has appropriate privileges. If the process has such privileges, `setuid()` sets the real group ID (UID), effective UID, and saved set UID to *uid*.

The `setuid()` function is not supported from an address space running multiple processes, since it would cause all processes in the address space to have their security environment changed unexpectedly.

`setuid()` can be used by daemon processes to change the identity of a process in order for the process to be used to run work on behalf of a user. In z/OS UNIX, changing the identity of a process is done by changing the real and effective UIDs and the auxiliary groups. In order to change the identity of the process on MVS completely, it is necessary to also change the MVS security environment. The identity change will only occur if the EUID value is specified, changing just the real UID will have no effect on the MVS environment.

The `setuid()` function invokes MVS SAF services to change the MVS identity of the address space. The MVS identity that is used is determined as follows:

- If an MVS user ID is already known by the kernel from a previous call to a kernel function (for example, `getpwnam()`) and the UID for this user ID matches the UID specified on the `setuid()` call, then this user ID is used.
- For nonzero target UIDs, if there is no saved user ID or the UID for the saved user ID does not match the UID requested on the `setuid()` call, the `setuid()` function queries the security database (for example, using `getpwnam()`) to retrieve a user ID. The retrieved user ID is then used.
- If the target UID is 0 and a user ID is not known, the `setuid()` function always sets the MVS user ID to BPXROOT or the value specified on the SUPERUSER parm in sysparms. BPXROOT is set up during system initialization as a superuser with a UID=0. The BPXROOT user ID is not defined to the BPX.DAEMON FACILITY class profile. This special processing is necessary to prevent a superuser from gaining daemon authority.

Note: When running under UID=0, some servers will issue `setuid(0)` in order to test whether they are running UID=0. The problem with this is that the `setuid` function will change the userid to BPXROOT which will likely cause the daemon to fail on subsequent function requests.

- When changing from a nonzero UID to a UID=0, the MVS user ID is not changed. When using the `su` shell command without specifying user name to become a superuser, the new shell retains the original MVS user ID.
- A nond daemon superuser that attempts to set a user ID to a daemon superuser UID fails with an EPERM.

When the MVS identity is changed, the daemon must make a call to `initgroups()` to set the auxiliary list of groups to the list of groups for the new user ID.

If the `setuid()` function is issued from multiple tasks within one address space, use synchronization to ensure that the `setuid()` functions are not performed concurrently. The execution of `setuid()` function concurrently within one address space can yield unpredictable results.

Returned value

If successful, `setuid()` returns 0.

If unsuccessful, `setuid()` returns -1 and sets `errno` to one of the following values:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

EAGAIN

The process is currently not able to change UIDs.

EINVAL

The value of *uid* is incorrect.

EPERM

The process does not have appropriate privileges to set the UID to *uid*.

Example**CELEBS11**

```
/* CELEBS11

   This example changes the effective UID.

   */
#define _POSIX_SOURCE
#include <sys/types.h>
#include <stdio.h>
#include <unistd.h>

main() {
    printf("prior to setuid(), uid=%d, effective uid=%d\n",
          (int) getuid(), (int) geteuid());
    if (setuid(25) != 0)
        perror("setuid() error");
    else
        printf("after setuid(), uid=%d, effective uid=%d\n",
              (int) getuid(), (int) geteuid());
}
```

Output

```
before setuid(), uid=0, effective uid=0
after setuid(), uid=25, effective uid=25
```

set_unexpected() — Register a function for unexpected()

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| ANSI/ISO C++ | C++ only | |

Format

```
#include <exception>

unexpected_handler set_unexpected(unexpected_handler ph) throw();
```

General description

The `set_unexpected()` function is part of the z/OS XL C++ error handling mechanism. The argument supplied to `set_unexpected()` is of type `unexpected_handler` as defined in the header `<exception>` (that is, a pointer to a function with a void return type and no arguments). The function specified will be called by the `unexpected()` function.

Note that the function registered for `unexpected()` must not return to its caller. It may terminate execution by:

- Throwing an object of a type listed in the exception specification (or an object of any type if the unexpected handler is called directly by the program).
- Throwing an object of type `bad_exception`.
- Calling `terminate()`, `abort()`, or `exit(int)`.

If `set_unexpected()` has not yet been called, then `unexpected()` calls `terminate()`.

In a multithreaded environment, the `unexpected()` function created by the issuance of a `set_unexpected()` call applies to all threads in the (POSIX) process.

Returned value

`set_unexpected()` returns the address of the previous `unexpected_handler`.

Refer to [z/OS XL C/C++ Language Reference](#) for more information about z/OS XL C++ exception handling, including the `set_unexpected()` function.

Related information

- [“exception — Exception handling” on page 87](#)
- [“unexpected\(\) — Handle exception not listed in exception specification” on page 1940](#)

setutxent() — Reset to start of utmpx database

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <utmpx.h>

void setutxent(void);
```

General description

The `setutxent()` function resets the input to the beginning of the `utmpx` database opened by previous calls to `getutxent()`/`getutxent64()`, `getutxid()`/`getutxid64()`, `getutxline()`/

`getutxline64()`, or `pututxline()/pututxline64()` calls from the current thread. This should be done before each `getutxid()` and `getutxline()` search for a new entry if it is desired that the entire database be examined.

Because the `setutxent()` function processes thread-specific data the `setutxent()` function can be used safely from a multithreaded application. If multiple threads in the same process open the database, then each thread opens the database with a different file descriptor. The thread's database file descriptor is closed when the calling thread terminates or the `endutxent()` function is called by the calling thread.

Returned value

`setutxent()` returns no values.

Related information

- [“utmpx.h — User accounting database” on page 78](#)

setvbuf() — Control buffering

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdio.h>

int setvbuf(FILE * __restrict__stream, char * __restrict__buf, int type, size_t
size);
```

General description

Controls the buffering strategy and buffer size for a specified stream. The *stream* pointer must refer to an open file, and `setvbuf()` must be the first operation on the file.

To provide an ASCII input/output format for applications using this function, define the feature test macro `__LIBASCII` as described in topic 2.1.

The location pointed to by *buf* designates an area that you provide that the z/OS XL C/C++ Runtime Library may choose to use as a buffer for the stream. A *buf* value of `NULL` indicates that no such area is supplied and that the z/OS XL C/C++ Runtime Library is to assume responsibility for managing its own buffers for the stream. If you supply a buffer, it must exist until the stream is closed.

If *type* is `_IOFBF` or `_IOLBF`, *size* is the size of the supplied buffer. If *buf* is `NULL`, the C library will take *size* as the suggested size for its own buffer. If *type* is `_IONBF`, both *buf* and *size* are ignored. Unbuffered I/O is allowed for memory files and z/OS UNIX files. However, it is not permitted for Hiperspace memory files. If the size of the supplied buffer for hiperspace memory files is greater than 4k, only the first 4k of the buffer will be used.

Value

Meaning

`_IONBF`

No buffer is used.

`_IOFBF`

Full buffering is used for input and output. Use *buf* as the buffer and *size* as the size of the buffer.

`_IOLBF`

Line buffering is used for text stream I/O and terminal I/O. The buffer is flushed when a newline character is used (text stream), when the buffer is full, or when input is requested (terminal). The value for *size* must be greater than 0.

The value for *size* must be greater than 0.

Note: If you use `setvbuf()` or `setbuf()` to define your own buffer for a stream, you must ensure that either the buffer is available after program termination, or the stream is closed or flushed, before you call `exit()`. This can be done by defining the array with file scope or by dynamically allocating the storage for the array using `malloc()`.

For example, if the buffer is declared within the scope of a function block, the *stream* must be closed before the function is terminated. This prevents the storage allocated to the buffer from being freed.

Returned value

If successful, even if it chooses not to use your buffer, `setvbuf()` returns 0.

If an invalid value was specified in the parameter list, or if the request cannot be performed, `setvbuf()` returns nonzero.

Example

```
/* This example sets up a buffer of buf for stream1 and specifies that
   input from stream2 is to be unbuffered.
*/
#include <stdio.h>
#define BUF_SIZE 1024

char buf[BUF_SIZE];

int main(void)
{
    FILE *stream1, *stream2;

    stream1 = fopen("myfile1.dat", "r");
    stream2 = fopen("myfile2.dat", "r");

    /* stream1 uses a user-assigned buffer of BUF_SIZE bytes */
    if (setvbuf(stream1, buf, _IOFBF, sizeof(buf)) != 0)
        printf("Incorrect type or size of buffer 1");

    /* stream2 is unbuffered */
    if (setvbuf(stream2, NULL, _IONBF, 0) != 0)
        printf("Incorrect type or size of buffer 2");

    ...
}
```

setxattr(), lsetxattr(), fsetxattr() — Set an extended attribute value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <sys/xattr.h>

int setxattr(const char *path, const char *name, const void *value, size_t size, int flags);
int lsetxattr(const char *path, const char *name, const void *value, size_t size, int flags);
int fsetxattr(int fd, const char *name, const void *value, size_t size, int flags);
```

General description

Extended attributes are extensions to the normal attributes that are associated with all inodes in the system. They are used as name: value pairs that are associated with files and directories to provide more functions to a file system.

`setxattr()` sets the value of the extended attribute that is identified by *name* and associated with the given *path* in the file system. The *size* argument specifies the size of value in bytes.

`lsetxattr()` is identical to `setxattr()` except that in the case of a symbolic link, the extended attribute is set on the link itself by `lsetxattr()`, not the file that it refers to.

`fsetxattr()` is identical to `setxattr()` except that the extended attribute is set on the open file that is referred to by *fd* by `fsetxattr()` in place of *path*.

If the value of *flags* is set to zero, the extended attribute is created if it does not exist, or the value is replaced if the attribute exists. To modify these semantics, one of the following values can be specified:

XATTR_CREATE

Perform a pure create, which fails if the named attribute exists.

XATTR_REPLACE

Perform a pure replace operation, which fails if the named attribute does not exist.

Table 56. Extended attribute name

| Extended attribute name | | Length | Value |
|--------------------------------|---------------------|--------|-----------|
| Modifiable extended attributes | trusted.apfauth | 0 | N/A |
| | trusted.sharelib | 0 | N/A |
| | trusted.progctl | 0 | N/A |
| | system.noshareas | 0 | N/A |
| | system.filefmt | 1 | Hex Value |
| | system.filetag | 4 | Hex Value |
| | system.seclabel | 8 | Character |
| | system.useraudit | 4 | Hex Value |
| | system.auditoraudit | 4 | Hex Value |
| Read-only extended attributes | system.auditid | 16 | Hex Value |
| | system.dmodelacl | 0 | N/A |
| | system.fmodelacl | 0 | N/A |
| | system.accessacl | 0 | N/A |
| | system.createtime | 8 | Hex value |

Restriction:

- trusted.apfauth, trusted.sharelib, trusted.progctl, and system.noshareas are general attributes. lsetxattr(), fsetxattr(), lremovexattr(), fremovexattr() cannot change the general attributes.
- The attributes system.filefmt, system.filetag, system.useraudit, system.auditoraudit cannot be set for symbolic links.

Returned value

If successful, 0 is returned.

If unsuccessful, -1 is returned and errno is set to one of the following values:

Error Code**Description****EEXIST**

XATTR_CREATE is specified and the attribute exists already.

EINVAL

The flag option is an invalid value.

Attempting to modify general attributes with fsetxattr().

ENAMETOOLONG

pathname is longer than PATH_MAX characters.

ENOATTR

XATTR_REPLACE is specified, and the attribute does not exist.

Attribute name is NULL or blank.

ENODATA

The specified attribute is not set.

Attribute name is NULL or blank.

ENOTSUP

Extended attributes are not supported by the file system.

Attempting to modify general attributes with `lsetxattr()`.

Attempting to modify a read only attribute.

ERANGE

The size of the value buffer is too small to hold the result.

The size of the value buffer is larger than 50000.

Attribute name is longer than `PATH_MAX` characters.

shmat() — Shared memory attach operation

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <sys/shm.h>

void *shmat(int shmid, const void *shmaddr, int shmflg);
```

General description

The `shmat()` function attaches the shared memory segment associated with the shared memory identifier, `shmid`, to the address space of the calling process. The segment is attached at the address specified by one of the following criteria:

- If `shmaddr` is a NULL pointer, the segment is attached at the first available address as selected by the system.
- If `shmaddr` is not a NULL pointer, and the flag, **SHM_RND** was specified, the segment is attached at the address given by `(shmaddr - ((ptrdiff_t)shmaddr % SHMLBA))` where `%` is the 'C' language remainder operator.
- If `shmaddr` is not a NULL pointer, and the flag, **SHM_RND** was not specified, the segment is attached at the address given by `shmaddr`.
- The segment is attached for reading if the flag, **SHM_RDONLY**, is specified with `shmflg` and the calling process has read permission. If the flag is not set and the process has both read and write permission, the segment is attached for reading and writing.

The first attach of newly created `__IPC_MEGA` segment, as well as subsequent attaches, will have write access to the segment, regardless of the **SHM_RDONLY** option.

- All attaches to an **__IPC_MEGA** shared memory segment have the same Write or Read access authority. If a segment is enabled for writes then all attaches have the ability to read and write to the segment. If the segment is disabled for writes, then all attaches have the ability to read from the segment and cannot write to the segment

The first attach of newly created **__IPC_MEGA** segment, as well as subsequent attaches, will have write access to the segment, regardless of the SHM_RDONLY option. Write/Read access can be changed by the shmctl() function, Shared Memory Control Operations.

An **__IPC_MEGA** shared memory segment is attached as follows:

- If shmaddr is zero and **__IPC_MEGA** segment, then the segment will be attached at the first available address selected by the system on a segment boundary.
- If shmaddr is not zero and SHM_RND is specified and **__IPC_MEGA** segment, the segment address will be truncated to the segment boundary (last 20 bits zero).
- If shmaddr is not zero and SHM_RND is not specified and **__IPC_MEGA** segment, the segment address must be a megabyte multiple (segment boundary).

Returned value

If successful, shmat() increments the value of shm_nattach in the data structure associated with the shared memory ID of the attached shared memory segment and returns the segment's starting address.

If unsuccessful, shmat() returns -1 and sets errno to one of the following values:

Error Code

Description

EACCES

Operation permission is denied to the calling process.

EINVAL

The value of *shmid* is not a valid shared memory identifier; the *shmaddr* is not a NULL pointer and the value of (*shmaddr* - ((ptrdiff_t)*shmaddr* % SHMLBA)) is an illegal address for attaching shared memory segments; or the *shmaddr* is not a NULL pointer, **SHM_RND** was specified, and the value of *shmaddr* is an illegal address for attaching shared memory segments.

The shared memory address, *shmaddr, is not zero, is not on a megabyte boundary, and SHM_RND was not specified.

EMFILE

The number of shared memory segments attached to the calling process would exceed the system-imposed limit.

ENOMEM

The available data space is not large enough to accommodate the shared memory segment.

shmctl(), shmctl64() – Shared memory control operations

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

shmctl:

```
#define _XOPEN_SOURCE
#include <sys/shm.h>

int shmctl(int shmid, int cmd, struct shmid_ds *buf);
```

shmctl64:

```
#define _LARGE_TIME_API
#define _XOPEN_SOURCE
#include <sys/shm.h>

int shmctl64(int shmid, int cmd, struct shmid_ds64 * buf);
```

Compile requirement: Use of the shmctl64() function requires the long long data type. For more information on how to make the long long data type available, see [z/OS XL C/C++ Language Reference](#).

General description

The shmctl() or shmctl64() function provides a variety of shared memory control operations on the shared memory segment identified by the argument, *shmid*.

The argument *cmd* specifies the shared memory control operation and may be any of the following values:

IPC_STAT

This command obtains status information for the shared memory segment specified by the shared memory identifier, *shmid*. It places the current value of each member of the shmid_ds or shmid_ds64 data structure associated with *shmid* into the structure pointed to by *buf*. The contents of this structure is defined in <sys/shm.h>. This command requires read permission.

IPC_SET

Set the value of the following members of the shmid_ds or shmid_ds64 data structure associated with *shmid* to the corresponding value in the structure pointed to by *buf*:

```
shm_perm.uid
shm_perm.gid
shm_perm.mode (only the low-order 9 bits)
```

This command can only be executed by a process that has an effective user ID equal to either that of a process with appropriate privileges or to the value of shm_perm.cuid or shm_perm.uid in the shmid_ds or shmid_ds64 data structure associated with *shmid*.

Using the IPC_SET function to change the IPC_MODE for an __IPC_MEGA shared memory segment will have an immediate effect on all attaches to the target segment. That is, the read and write access of all current attachers is immediately affected by the permissions specified in the new IPC_MODE. To determine how the new mode affects access, you must consider the effect of all three parts of the mode field (the owner permissions, group permissions and other permissions). If all three read and all three write permissions in the new mode are set off, then the access for all attachers is changed to read. If any of the three read permission bits is set on but the corresponding write permission bit

is off, then the access for all attachors is changed to read. Otherwise, the access of all attachors is changed to write.

IPC_RMID

Remove the shared memory identified specified by *shmid* from the system and destroy the shared memory segment and *shmid_ds* or *shmid_ds64* data structure associated with *shmid*. This command can only be executed by a process that has an effective user ID equal to either that of a process with appropriate privileges or to the value of *shm_perm.cuid* or *shm_perm.uid* in the *shmid_ds* or *shmid_ds64* data structure associated with *shmid*. The remove will be completed asynchronous to the return from the *shmctl()* function, when the last attachment is detached. When **IPC_RMID** is processed, no further attaches will be allowed.

The *IPC_STAT* option of *shmctl()* or *shmctl64()* returns a structure named *shmid_ds* or *shmid_ds64* (mapped in *shm.h*). *shmid_ds* or *shmid_ds64* contains status information for the requested shared memory segment.

As part of its own dump priority support, the z/OS UNIX kernel will be adding a new field to *shmid_ds* or *shmid_ds64*. This field will contain the dump priority of the requested shared memory segment. The new field will be added to the *shmid_ds* or *shmid_ds64* structure in *shm.h*.

The *shmctl64()* function behaves exactly like *shmctl()* except *shmctl64()* uses struct *shmid_ds64* instead of struct *shmid_ds* to support time beyond 03:14:07 UTC on January 19, 2038.

Returned value

If successful, *shmctl()* or *shmctl64()* returns 0.

If unsuccessful, *shmctl()* or *shmctl64()* returns -1 and sets *errno* to one of the following values:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

EACCES

The argument *cmd* is equal to **IPC_STAT** but the calling process does not have read permission.

EINVAL

The value of *shmid* is not a valid shared memory identifier or the value of *cmd* is not a valid command.

EPERM

The argument *cmd* is equal to either **IPC_RMID** or **IPC_SET** and the effective user ID of the calling process is not equal to that of a process with appropriate privileges and it is not equal to the value of *shm_perm.cuid* or *shm_perm.uid* in the data structure associated with *shmid*.

shmdt() — Shared memory detach operation

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <sys/shm.h>

int shmdt(const void *shmaddr);
```

General description

The `shmdt()` function detaches from the calling process's address space the shared memory segment located at the address specified by the argument *shmaddr*.

Storage in the user address space for a segment with the `__IPC_SHAREAS` attribute is not cleaned up unless the segment is no longer attached to by other processes in the address space.

Returned value

If successful, `shmdt()` decrements the value of `shm_nattach` in the data structure associated with the shared memory ID of the attached shared memory segment and returns 0.

If unsuccessful, `shmdt()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

The value of *shmaddr* is not the data segment start address of a shared memory segment.

shmget() — Get a shared memory segment

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <sys/shm.h>

int shmget(key_t key, size_t size, int shmflg);
```

General description

The `shmget()` function returns the shared memory identifier associated with *key*.

A shared memory identifier, associated data structure and shared memory segment of at least *size* bytes, see `<sys/shm.h>`, are created for *key* if one of the following is true:

1. Argument *key* has a value of **IPC_PRIVATE**
2. Argument *key* does not already have a shared memory identifier associated with it and the flag **IPC_CREAT** was specified

Specify **__IPC_MEGA** to request segment level sharing. The resulting shared memory segment will be allocated in units of segments instead of units of pages. The shared memory size parameter still reflects the number of bytes required but must be in megabyte multiples. A shared memory size parameter of 0 or one which is not a megabyte multiple will result in the request failing.

The first `shmget` to define the shared memory segment determines whether the segment has the **__IPC_MEGA** attribute or not. Subsequent `shmgets`, those that use existing shared memory segments, will use the **__IPC_MEGA** attribute defined by that segment. The **__IPC_MEGA** option will have no effect for these `shmgets` and will be ignored.

Specification of the **__IPC_MEGA** option for large segments will result in significant real storage savings and reduced ESQA usage, especially as the number of shares increases.

Valid values for the argument *shmflg* include any combination of the following constants defined in `<sys/ipc.h>` and `<sys/modes.h>`:

__IPC_SHAREAS

This flag enables the sharing of the same storage area from multiple processes in the same address space. When specified by an AMODE 31 application, this flag is only honored when **__IPC_MEGA** is also specified, otherwise it is ignored. When specified by an AMODE 64 application, this flag is honored for any type of shared memory segment that is obtained above the bar.

__IPC_BELOWBAR

Forces the memory object to be allocated from below the 2 gigabyte address range. This can be used to allow AMODE 64 applications to share objects with non-AMODE 64 applications. This option is mutually exclusive with the **__IPC_GIGA** option. If a 31-bit application specifies this option, then the request will be failed with `EINVAL`.

IPC_CREAT

Create a shared memory segment if the *key* specified does not already have an associated ID.

IPC_CREAT is ignored when **IPC_PRIVATE** is specified.

IPC_EXCL

Causes the `shmget()` function to fail if the *key* specified has an associated ID. **IPC_EXCL** is ignored when **IPC_CREAT** is not specified or **IPC_PRIVATE** is specified.

__IPC_GIGA

Requests a shared memory segment with a size in gigabyte multiples. Use of this option requires that the size parameter be specified as a gigabyte multiple. Failure to use a gigabyte multiple will result in a failure. [`EINVAL`] This option is mutually exclusive with the **__IPC_BELOWBAR** and **__IPC_MEGA** options.

__IPC_MEGA

Requests a shared memory segment with the size in megabyte multiples. Use of this option requires that the size parameter, *size_t*, be in a megabyte multiple. The **__IPC_MEGA** option is required to create the shared memory segment but the **__IPC_MEGA** option is not required to acquire access to a previously defined/created shared memory segment that has the **__IPC_MEGA** attribute. When specified by an AMODE 64 application, option **__IPC_BELOWBAR** is implied and megaroo sharing will be in effect. This option is mutually exclusive with the **__IPC_GIGA** option.

S_IRGRP

Permits read access when the effective group ID of the caller matches either `shm_perm.cgid` or `shm_perm.gid`.

S_IROTH

Permits other read access.

S_IRUSR

Permits read access when the effective user ID of the caller matches either `shm_perm.cuid` or `shm_perm.uid`.

S_IWGRP

Permits write access when the effective group ID of the caller matches either `shm_perm.cgid` or `shm_perm.gid`.

S_IWOTH

Permits other write access.

S_IWUSR

Permits write access when the effective user ID of the caller matches either `shm_perm.cuid` or `shm_perm.uid`.

When a shared memory segment associated with argument *key* already exists, setting **IPC_EXCL** and **IPC_CREAT** in argument *shmflg* will force `shmget()` to fail.

The following fields are initialized when a `shmid_ds` data structure is created:

- The fields `shm_perm.cuid` and `shm_perm.uid` are set equal to the effective user ID of the calling process
- The fields `shm_perm.cgid` and `shm_perm.gid` are set equal to the effective group ID of the calling process
- The low-order 9 bits of `shm_perm.mode` are set to the value in the low-order 9 bits of *shmflg*
- The field `shm_segsz` is set equal to the value of the argument *size*
- The field `shm_lpid`, `shm_nattach`, `shm_atime`, and `shm_dtime` are set equal to zero
- The value of `shm_ctime` is set equal to the current time

Usage notes

- Shared memory segments created with `__IPC_MEGA` will show this bit in `S_MODE` byte returned with `w_getipc`.

Special behavior for AMODE 64: Applications will not be allowed to change the address to which a shared memory segment allocated is attached, when it resides above the 2 gigabyte address range. The size parameter is rounded up to a megabyte multiple for AMODE 64 users.

Returned value

If successful, `shmget()` returns a nonnegative integer, namely a shared memory identifier.

If unsuccessful, `shmget()` returns -1 and sets `errno` to one of the following values:

Error Code**Description****EACCES**

A shared memory identifier exists for the argument *key*, but operation permission as specified by the low-order 9 bits of *shmflg* could not be granted

EEXIST

A shared memory identifier exists for the argument *key* and both **IPC_CREAT** and **IPC_EXCL** are specified in *shmflg*

EINVAL

A shared memory identifier does not exist for the argument *key* specified and the value of argument *size* is less than the system-imposed minimum or greater than the system-imposed maximum.

OR a shared memory identifier exists for the argument *key*, but the size of the segment associated with it is less than that specified by argument *size*.

OR `__IPC_MEGA` is specified and the segment size, `size_t`, is not in megabyte multiples.

ENOENT

A shared memory identifier does not exist for the argument, `key`, and **IPC_CREAT** is not specified.

ENOMEM

A shared memory identifier and associated shared memory segment are to be created but the amount of available system storage was insufficient to fill the request.

ENOSPC

A shared memory identifier is to be created but the system-imposed limit on the maximum number of allocated shared memory identifiers, system-wide, would be exceeded.

When `shmflg` equals 0, the following applies:

- If a shared memory identifier has already been created with `key` earlier, and the calling process of this `shmget()` has read and/or write permissions to it, then `shmget()` returns the associated shared memory identifier.
- If a shared memory identifier has already been created with `key` earlier, and the calling process of this `shmget()` does not have read and/or write permissions to it, then `shmget()` returns -1 and sets `errno` to `EACCES`.
- If a shared memory identifier has not been created with `key` earlier, then `shmget()` returns -1 and sets `errno` to `ENOENT`.

shutdown() — Shut down all or part of a duplex connection

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int shutdown(int socket, int how);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/socket.h>

long shutdown(int *s, int how);
```

General description

The `shutdown()` function shuts down all or part of a duplex connection.

Parameter Description

socket

The socket descriptor.

how

The condition of the shutdown. The values 0, 1, or 2 set the condition. *how* sets the condition for shutting down the connection to the socket indicated by *socket*.

how can have a value of:

- **SHUT_RD**, which ends communication from the socket indicated by *socket*.
- **SHUT_WR**, which ends communication to the socket indicated by *socket*.
- **SHUT_RDWR**, which ends communication both to and from the socket indicated by *socket*.

Note: You should issue a `shutdown()` call before you issue a `close()` call for a socket.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` 1 feature test macro.

Returned value

If successful, `shutdown()` returns 0.

If unsuccessful, `shutdown()` returns -1 and sets `errno` to one of the following values:

Error Code Description

EBADF

socket is not a valid socket descriptor.

EINVAL

The *how* parameter was not set to one of the valid values.

ENOBUFS

Insufficient system resources are available to complete the call.

ENOTCONN

The socket is not connected.

ENOTSOCK

The descriptor is for a file, not for a socket.

__shutdown_registration() – Register OMVS shutdown options

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R3 |

Format

```
#define _OPEN_SYS
#include <signal.h>

int __shutdown_registration(int regtype, int regscope, int regoptions);
```

General description

The `__shutdown_registration()` function is used to register OMVS Shutdown characteristics for the process. The process can be registered as one of the following:

- a shutdown blocking process
- a permanent process
- a shutdown notification process

These types are mutually exclusive. A shutdown blocking process will prevent OMVS shutdown from proceeding until it either de-registers as a blocking process or ends. A permanent process will survive across an OMVS shutdown. Most OMVS process attributes will be checkpointed during the shutdown and restored during the Restart. A shutdown notification process will be informed when an OMVS shutdown is initiated. It neither blocks Shutdown nor survives shutdown. Blocking and permanent processes can also register to be informed when OMVS shutdown is initiated. For more information on OMVS shutdown see *z/OS UNIX System Services Planning*.

Registration can be done for the invoking process only, or for all of the tasks in the job. The process can also modify the behavior of OMVS requests issued by permanent processes while OMVS shutdown and restart is in progress.

Checkpointed permanent process attributes include the following:

- process user and group identity
- process, session and process group identities
- process file mode creation mask
- zombie child processes
- signal registration, signal actions, signal mask data and pending signals
- current working directory
- open file and socket descriptors

Zombie child process ending status is checkpointed so that the permanent process can retrieve it after the restart.

If the current working directory path name cannot be resolved after restart, then the current working directory is set to a dummy root which will cause relative path name lookup to fail.

All of the checkpointed file descriptors will be marked invalid after restart, and any I/O requests other than `close()` will cause EIO errors.

Timer events are not checkpointed. Timer events which expire before the restart completes are lost. Timer events which have not expired after restart is complete will still be in effect.

Non-checkpointable permanent process attributes include the following:

- semaphores
- shared library programs
- __map() shared memory blocks
- message queues
- memory mapped files
- all other UNIX System Services resources

If any non-checkpointable resources are being used by a permanent process, the shutdown request will fail.

Registration is at the process level, not the thread level. For multithreaded applications, the SIGDANGER signal is sent to the process and not to any particular thread.

If a process is registered as a blocking process or a permanent process, the process must de-register before attempting to register with a different registration type. For example, a blocking process must de-register as a blocking process before attempting to register as a permanent process.

Registration remains in effect for the life of the process, or until the process de-registers. Registration remains in place across an exec() syscall because the new program image runs in the same process. Registration does not propagate to child processes as a result of fork() and spawn() syscalls.

regtype defines the type of registration. The possible values are listed below. These values are all mutually exclusive.

regtype **Description**

_SDR_BLOCKING

The process will prevent OMVS Shutdown from proceeding for as long as it the process remains registered as a blocking process. If the process exits or de-registers as a blocking process then OMVS Shutdown can proceed.

_SDR_PERMANENT

The process will not be terminated during OMVS Shutdown and Restart processing.

_SDR_NOBLOCKING

The process will no longer block an OMVS Shutdown.

_SDR_NOPERMANENT

The process will no longer be a permanent process.

_SDR_NOTIFY

The process will be notified by SIGDANGER signal delivery once OMVS Shutdown is initiated.

_SDR_NONOTIFY

The process will no longer be notified by SIGDANGER signal delivery if OMVS Shutdown is initiated.

The _SDR_BLOCKING and _SDR_PERMANENT registrations are restricted. The invoker must meet one of the following criteria in order for these two registration types to succeed:

- The calling address space is a system started task address space.
- The caller is running authorized (APF Authorized, System Key (0-7) or Supervisor State).
- The caller is a privileged UNIX process. It must either have a superuser identity or have read permission to BPX.SHUTDOWN.

regscope defines the registration scope. The possible values are listed below. The two values are mutually exclusive.

regscope **Definition**

_SDR_REGJOB

All the processes in the Job are registered.

_SDR_REGPROCESS

Only the calling process is registered.

__shutdown_registration()

regoptions defines various options for the registered process. The possible values are listed below. Multiple options may be specified by or'ing the values together. The default behavior for kernel calls issued by permanent processes while z/OS UNIX is not up is to fail the request with `errno` set to `EMVSERR` and the reason code (`__errno2()` value) set to `JrKernelReady`. Those kernel calls which do not return a return code will end with an EC6 abend and reason code `xxxx8039`.

regoptions

Definition

_SDR_NOOPTIONS

No options are requested. This request code is not valid for `_SDR_NOTIFY` registration.

_SDR_BLOCKSYSCALLS

Kernel calls issued from permanent processes while OMVS is not up will hang, and return to the caller once z/OS UNIX System Services is back up. This request is mutually exclusive with `_SDR_ABENDSYSCALLS`, and is valid only for permanent process registration.

_SDR_ABENDSYSCALLS

Kernel calls issued from permanent processes while OMVS is not up will ABEND. This request is mutually exclusive with `_SDR_BLOCKSYSCALLS`, and is valid only for permanent process registration.

_SDR_SENDSIGDANGER

Kernel sends SIGDANGER signal to the process when OMVS Shutdown is initiated. This option MUST be specified on `_SDR_NOTIFY` registration. This option may be specified for `_SDR_BLOCKING` and `_SDR_PERMANENT` registration. It may be combined with either `_SDR_BLOCK_SYSCALLS` or `_SDR_ABENDSYSCALLS` on `_SDR_PERMANENT` registration.

Returned value

If successful, `__shutdown_registration()` returns 0. the service completes without error, otherwise it returns

There are no documented `errno`s for this function.

If unsuccessful, `__shutdown_registration()` returns -1 and sets `errno` and `__errno2()` to indicate the cause of the failure. The `__errno2()` values are documented as reason codes in [z/OS UNIX System Services Messages and Codes](#).

The values of `errno` are:

Error Code

Description

EINVAL

Failed for one of the following reasons:

- The callable service is rejected because the job step process must be registered before registering a lower process of the job step process.
- The request to register a blocking process or job, or a request to register a permanent process or job cannot be performed as a shutdown is currently in progress.
- The request to register a blocking process or job, or a request to register a permanent process or job cannot be performed as the job can not be de-registered while a lowerprocess is still registered.
- The request to deregister a blocking process or job, or a request to deregister a permanent process or job cannot be performed because the job or the current process is not registered.
- One of the parameters was invalid.

EPERM

Failed for one of the following reasons:

- Invoker does not have superuser or equivalent authority.
- Caller must be given read permission to BPX.SHUTDOWN facility class profile in order to use `__shutdown_registration()` successfully.

EMVSSAF2ERR

Internal Security product error. Hexadecimal Reason code value contains the two byte security product return code xx and reason code yy.

Example

```
/*
Register the process as a blocking process and request notification
of shutdown initiation by way of SIGDANGER signal.
*/
#define _OPEN_SYS
#include <signal.h>
...
if (-1 == (rc = __shutdown_registration(_SDR_BLOCKING, _SDR_REGPROCESS,
    _SDR_SENDSIGDANGER)))
    printf("Error during __shutdown_registration errno=%d,
        errno2=0x%08x\n", errno, __errno2())

/*
Register the process as a permanent process and don't ask for
SIGDANGER signals.
*/
#define _OPEN_SYS
#include <sys>
if (-1 == (rc = __shutdown_registration(_SDR_PERMANENT, _SDR_REGPROCESS,
    _SDR_NOOPTIONS)))
    printf("Error during __shutdown_registration errno=%d,
        errno2=0x%08x\n", errno, __errno2())
```

```
#define _POSIX_SOURCE
#define _XOPEN_SOURCE_EXTENDED 1
#include <signal.h>

int sigaction(int sig, const struct sigaction *__restrict__ new,
    struct sigaction *__restrict__ old);
```

General description

Examines and changes the action associated with a specific signal.

int *sig* is the number of a recognized signal. `sigaction()` examines and sets the action to be associated with this signal. See [Table 57 on page 1606](#) for the values of *sig*, as well as the signals supported by z/OS UNIX services. The *sig* argument must be one of the macros defined in the `signal.h` header file.

`const struct sigaction *new` may be a NULL pointer. If so, `sigaction()` merely determines the action currently defined to handle `sig`. It does not change this action. If `new` is not NULL, it should point to a `sigaction` structure. The action specified in this structure becomes the new action associated with `sig`.

`struct sigaction *old` points to a memory location where `sigaction()` can store a `sigaction` structure. `sigaction()` uses this memory location to store a `sigaction` structure describing the action currently associated with `sig`. `old` can also be a NULL pointer, in which case `sigaction()` does not store this information.

This function is supported only in a POSIX program.

Special behavior for C++:

- The behavior when mixing signal-handling with C++ exception handling is undefined. Also, the use of signal-handling with constructors and destructors is undefined.
- C++ and C language linkage conventions are incompatible, and therefore `sigaction()` cannot receive C++ function pointers. If you attempt to pass a C++ function pointer to `sigaction()`, the compiler will flag it as an error. Therefore, to use the `sigaction()` function in the C++ language, you must ensure that signal handler routines established have C linkage, by declaring them as `extern "C"`.

Signals: Table 57 on page 1606 lists signal values and their default action and meaning.

Table 57. Signal values and signals supported by z/OS UNIX services

| Value | Default Action | Meaning |
|------------------|----------------|--|
| SIGABND | 1 | Abend. |
| SIGABRT | 1 | Abnormal termination (sent by <code>abort()</code>). |
| SIGALRM | 1 | A timeout signal (sent by <code>alarm()</code>). |
| SIGBUS | 1 | Bus error (available only when running on MVS 5.2 or higher). |
| SIGDSIOER | 1 | A data set file system I/O error occurred. |
| SIGFPE | 1 | Arithmetic exceptions that are not masked, for example, overflow, division by zero, and incorrect operation. |
| SIGHUP | 1 | A controlling terminal is suspended, or the controlling process ended. |
| SIGILL | 1 | Detection of an incorrect function image. |
| SIGINT | 1 | Interactive attention. |
| SIGKILL | 1 | A termination signal that cannot be caught or ignored. |
| SIGPIPE | 1 | A write to a pipe that is not being read. |
| SIGPOLL | 1 | Pollable event occurred (available only when running on MVS 5.2 or higher). |
| SIGPROF | 1 | Profiling timer expired (available only when running on MVS 5.2 or higher). |
| SIGQUIT | 1 | A quit signal for a terminal. |
| SIGSEGV | 1 | Incorrect access to memory. |
| SIGSYS | 1 | Bad system call issued (available only when running on MVS 5.2 or higher). |
| SIGTERM | 1 | Termination request sent to the program. |
| SIGTRAP | 1 | Internal for use by <code>dbx</code> or <code>ptrace</code> . |

Table 57. Signal values and signals supported by z/OS UNIX services (continued)

| Value | Default Action | Meaning |
|------------------|----------------|---|
| SIGURG | 2 | High bandwidth data is available at a socket (available only when running on MVS 5.2 or higher). |
| SIGUSR1 | 1 | Intended for use by user applications. |
| SIGUSR2 | 1 | Intended for use by user applications. |
| SIGVTALRM | 1 | Virtual timer has expired (available only when running on MVS 5.2 or higher). |
| SIGXCPU | 1 | CPU time limit exceeded (available only when running on MVS 5.2 or higher). If a process runs out of CPU time and SIGXCPU is caught or ignored, a SIGKILL is generated. |
| SIGXFSZ | 1 | File size limit exceeded. |
| SIGCHLD | 2 | An ended or stopped child process (SIGCLD is an alias name for this signal). |
| SIGIO | 2 | Completion of input or output. |
| SIGIOERR | 2 | A serious I/O error was detected. |
| SIGWINCH | 2 | Window size has changed (available only when running on MVS 5.2 or higher). |
| SIGSTOP | 3 | A stop signal that cannot be caught or ignored. |
| SIGTSTP | 3 | A stop signal for a terminal. |
| SIGTTIN | 3 | A background process attempted to read from a controlling terminal. |
| SIGTTOU | 3 | A background process attempted to write to a controlling terminal. |
| SIGCONT | 4 | If stopped, continue. |

The **Default Actions** in [Table 57 on page 1606](#) are:

- 1** Normal termination of the process.
- 2** Ignore the signal.
- 3** Stop the process.
- 4** Continue the process if it is currently stopped. Otherwise, ignore the signal.

If the main program abends in a way that is not caught or handled by the operating system or application, z/OS UNIX terminates the running application with a KILL -9. If z/OS UNIX gets control in EOT or EOM and the terminating status has not been set, z/OS UNIX sets it to appear as if a KILL -9 occurred.

If a signal catcher for a SIGABND, SIGFPE, SIGILL or SIGSEGV signal runs as a result of a program check or an ABEND, and the signal catcher executes a RETURN statement, the process will be terminated.

sigaction structure: The sigaction structure is defined as follows:

```
struct sigaction {
    void      (*sa_handler)(int);
    sigset_t  sa_mask;
    int       sa_flags;
```

```

        void      (*sa_sigaction)(int, siginfo_t *, void *);
    };

```

The following are members of the structure:

void (*)(int) sa_handler

A pointer to the function assigned to handle the signal. The value of this member can also be SIG_DFL (indicating the default action) or SIG_IGN (indicating that the signal is to be ignored).

Special behavior for XPG4.2: This member and sa_sigaction are mutually exclusive of each other. When the SA_SIGINFO flag is set in sa_flags then sa_sigaction is used. Otherwise, sa_handler is used.

sigset_t sa_mask

A signal set identifies a set of signals that are to be added to the signal mask of the calling process before the signal-handling function sa_handler or sa_sigaction (in XPG4.2) is invoked. For more on signal sets, see [“sigemptyset\(\) — Initialize a signal mask to exclude all signals” on page 1626](#). You cannot use this mechanism to block SIGKILL, SIGSTOP, or SIGTRACE. If sa_mask includes these signals, they will simply be ignored; sigaction() will not return an error.

sa_mask must be set by using one or more of the signal set manipulation functions: sigemptyset(), sigfillset(), sigaddset(), or sigdelset()

int sa_flags

A collection of flag bits that affect the behavior of signals. The following flag bits can be set in sa_flags:

_SA_IGNORE

This bit is output only and cannot be specified by the application. The handler value will be saved and returned on subsequent calls, but the signal is ignored.

SA_NOCLDSTOP

Tells the system not to issue a SIGCHLD signal when child processes stop. This is relevant only when the sig argument of sigaction() is SIGCHLD.

SA_NOCLDWAIT

Tells the system not to create 'zombie' processes when a child process dies. This is relevant only when the sig argument of sigaction() is SIGCHLD. If the calling process subsequently waits for its children, and the process has no unwaited for children that were transformed into zombie processes, it will block until all of its children terminate. The wait(), waitid(), or waitpid() will fail and set errno to **ECHILD**.

SA_NODEFER

Tells the system to bypass automatically blocking this signal when invoking a signal handler function.

_SA_OLD_STYLE

Tells the C runtime library to use ISO C/C++ signal delivery rules, instead of POSIX rules. It is supported for compatibility with applications that use signal() to set signal action. (See [“signal\(\) — Handle interrupts” on page 1635](#).) For a description of ISO C/C++ and POSIX.1 signal delivery rules, see [Handling error conditions, exceptions, and signals in z/OS XL C/C++ Programming Guide](#).

SA_ONSTACK

Tells the system to use the alternate signal stack (see [“sigaltstack\(\) — Set or get signal alternate stack context” on page 1622](#) or [“sigstack\(\) — Set or get signal stack context” on page 1652](#)) when invoking a signal handler function. If an alternate signal stack has not been declared, the signal handler function will be invoked with the current stack.

SA_RESETHAND

Tells the system to reset the signal's action to SIG_DFL and clear the SA_SIGINFO flag before invoking a signal handler function (Note: SIGILL and SIGTRAP cannot be automatically reset when delivered. However, no error will be generated should this situation exist). Otherwise, the disposition of the signal will not be modified on entry to the signal handler.

In addition, if this flag is set, sigaction() behaves as if the SA_NODEFER flag were also set.

SA_RESTART

Tells the system to restart certain library functions if they should be interrupted by a signal. The functions that this restartability applies to are all of those that are defined as interruptible by signals and set `errno` to **EINTR** (except `pause()`, `sigpause()`, and `sigsuspend()`).

Table 58 on page 1609 lists functions that are restartable if interrupted by a signal.

Table 58. Functions that are restartable if interrupted by a signal

| | | |
|-------------------|--------------------------|----------------------------|
| accept() | <code>fstatvfs()</code> | <code>recvmsg()</code> |
| catclose() | <code>fsync()</code> | <code>select()</code> |
| catgets() | <code>ftruncate()</code> | <code>semop()</code> |
| chmod() | <code>getgrgid()</code> | <code>send()</code> |
| chown() | <code>getgrnam()</code> | <code>sendmsg()</code> |
| close() | <code>getmsg()</code> | <code>sendto()</code> |
| closedir() | <code>getpass()</code> | <code>statvfs()</code> |
| connect() | <code>getpwnam()</code> | <code>tcdrain()</code> |
| creat() | <code>getpwuid()</code> | <code>tcflow()</code> |
| dup2() | <code>ioctl()</code> | <code>tcflush()</code> |

| fputc() | <code>read()</code> | <code>waitpid()</code> |
| fputwc() | <code>readv()</code> | <code>write()</code> |
| freopen() | <code>recv()</code> | |
| fseek() | <code>recvfrom()</code> | |

SA_SIGINFO

Tells the system to use the signal action specified by `sa_sigaction` instead of `sa_handler`.

When this flag is off and the action is to catch the signal, the signal handler function specified by `sa_handler` is invoked as:

```
void function(int signo);
```

where `signo` is the only argument to the signal handler and it specifies the type of signal that has caused the signal handler function to be invoked.

When this flag is on and the action is to catch the signal, the signal handler function specified by `sa_sigaction` is invoked as:

```
void function(int signo, siginfo_t *info, void *context);
```

where two additional arguments are passed to the signal handler function. If the second argument is not a NULL pointer, it will point to an object of type `siginfo_t` which provides additional information about the source of the signal. A `siginfo_t` object is a structure contains the following members:

si_signo

Contains the system-generated signal number

si_errno

Contains the implementation-specific error information (it is not used on this implementation)

si_code

Contains a code identifying the cause of the signal (refer to the `<signal.h>` include file for a list of these codes and for their meanings, see Table 59 on page 1637).

If `si_signo` contains `SIGPOLL` then `si_code` can be set to `SI_ASYNCIO`. Otherwise, if the value of `si_code` is less than or equal to zero then the signal was generated by another process and the `si_pid` and `si_uid` members respectively indicate the process ID and the real user ID of the sender of this signal.

If the value of `si_code` is less than or equal to zero, then the signal was generated by another process and the `si_pid` and `si_uid` members respectively indicate the process ID and the real user ID of the sender of this signal.

si_pid

If the value of `si_code` is less than or equal to zero, then this member will indicate the process ID of the sender of this signal. Otherwise, this member is meaningless.

si_uid

If the value of `si_code` is less than or equal to zero, then this member will indicate the real user ID of the sender of this signal. Otherwise, this member is meaningless.

si_value

If `si_code` is `SI_ASYNCIO`, `si_value` contains the application specified value. Otherwise, the contents of `si_value` are undefined

The third argument will point to an object of type `ucontext_t` (refer to the `<ucontext.h>` include file for a description of the contents of this object).

Note: The remaining flag bits are reserved for system use. There is no guarantee that the integer value of `int sa_flags` will be the same upon return from `sigaction()`. However, all flag bits defined above will remain unchanged.

void (*)(int, siginfo_t *, void *) sa_sigaction

A pointer to the function assigned to handle the signal, or `SIG_DFL`, or `SIG_IGN`. This function will be invoked passing three parameters. The first is of type `int` that contains the signal type for which this function is being invoked. The second is of type pointer to `siginfo_t` where the `siginfo_t` contain additional information about the source of the signal. The third is of type 'pointer to void' but will actually point to a `ucontext_t` containing the context information at the time of the signal interrupt.

Notes:

1. The user must cast `SIG_IGN` or `SIG_DFL` to match the `sa_sigaction` definition. (indicating that the signal is to be ignored).
2. **Special behavior for XPG4.2:** This member and `sa_handler` are mutually exclusive of each other. When the `SA_SIGINFO` flag is set in `sa_flags` then `sa_sigaction` is used. Otherwise, `sa_handler` is used.

When a signal handler installed by `sigaction()`, with the `_SA_OLD_STYLE` flag set off, catches a signal, the system calculates a new signal mask by taking the union of the current signal mask, the signals specified by `sa_mask`, and the signal that was just caught (if the `SA_NODEFER` flag is not set). This new mask stays in effect until the signal handler returns, or `sigprocmask()`, `sigsuspend()`, `siglongjmp()`, `sighold()`, `sigpause()`, or `sigrelse()` is called. When the signal handler ends, the original signal mask is restored.

After an action has been specified for a particular signal, using `sigaction()` or `signal()`, it remains installed until it is explicitly changed with another call to `sigaction()`, `signal()`, one of the `exec` functions, `bsd_signal()`, `sigignore()`, `sigset()`, or until the `SA_RESETHAND` flag causes it to be reset to `SIG_DFL`.

After an action has been specified for a particular signal, using `sigaction()` with the `_SA_OLD_STYLE` flag not set, it remains installed until it is explicitly changed with another call to `sigaction()`, `signal()`, or one of the `exec` functions.

After an action has been specified for a particular signal, using `sigaction()` with the `_SA_OLD_STYLE` flag set or using `signal()`, it remains installed until it is explicitly changed with another call to `sigaction()`, `signal()`, or one of the `exec` functions, or a signal catcher is driven, where it will be reset to `SIG_DFL`.

Successful setting of signal action to `SIG_IGN` for a signal that is pending causes the pending signal to be discarded, whether or not it is blocked. This provides the ability to discard signals that are found to be blocked and pending by `sigpending()`.

Special behavior for XPG4.2:

- If a process sets the action of the `SIGCHLD` signal to `SIG_IGN`, child processes of the calling process will not be transformed into 'zombie' processes when they terminate. If the calling process subsequently waits for its children, and the process has no unwaited for children that were transformed into 'zombie' processes, it will block until all of its children terminate. The `wait()`, `waitid()`, or `waitpid()` function will fail and set `errno` to **ECHILD**.
- If the **SA_SIGINFO** flag is set, the signal-catching function specified by `sa_sigaction` is invoked as:

```
void function(int signo, siginfo_t *info, void *context);
```

where *function* is the specified signal-catching function, *signo* is the signal number of the signal being delivered, *info* points to an object of type `siginfo_t` associated with the signal being delivered, and *context* points to an object of type `ucontext_t`.

Considerations for asynchronous signal-catching functions: Some of the functions have been restricted to be serially reusable with respect to asynchronous signals. That is, the library will not allow an asynchronous signal to interrupt the execution of one of these functions until it has completed.

This restriction needs to be taken into consideration when a signal-catching function is invoked asynchronously because it causes the behavior of some of the library functions to become unpredictable.

Thus, when you are producing a strictly compliant POSIX C or X/Open application, only the following functions should be assumed to be reentrant with respect to asynchronous signals. Use only these functions in your signal-catching functions:

| | | |
|----------------------|----------------------|----------------------|
| access() | alarm() | cfgetispeed() |
| cfgetospeed() | cfsetispeed() | cfsetospeed() |
| chdir() | chmod() | chown() |
| close() | creat() | dup() |
| dup2() | execle() | execve() |
| _exit() | fcntl() | fork() |
| fstat() | getegid() | geteuid() |
| getgid() | getgroups() | getpgrp() |
| getpid() | getppid() | getuid() |
| kill() | link() | lseek() |
| mkdir() | mkfifo() | open() |

| | | |
|---------------------------------|-----------------------|-------------------------|
| pathconf() | pause() | pipe() |
| pthread_cond_broadcast() | pthread_cond_signal() | pthread_mutex_trylock() |
| read() | rename() | rmdir() |
| setgid() | setpgid() | setsid() |
| setuid() | sigaction() | sigaddset() |
| sigdelset() | sigemptyset() | sigfillset() |
| sigismember() | sigpending() | sigprocmask() |
| sigsuspend() | sleep() | stat() |
| sysconf() | tcdrain() | tcflow() |
| tcflush() | tcgetattr() | tcgetpgrp() |
| tcsendbreak() | tcsetattr() | tcsetpgrp() |
| time() | times() | umask() |
| uname() | unlink() | utime() |
| utime64() | wait() | waitpid() |
| write() | | |

Special behavior for XPG4.2: Adds the following functions to the list of functions above that may be used in signal-catching functions in strictly compliant X/Open applications:

- `fpathconf()`
- `raise()`
- `signal()`

The macro versions of `getc()` and `putc()` are not reentrant, even though the library versions of these functions are.

For nonportable POSIX applications, most of the library functions can be used in a signal-catching function. However, do not use the following functions:

- `getenv()`
- `getgrent()`
- `getgrgid()`
- `getgrnam()`
- `getpwent()`
- `getpwnam()`
- `getpwuid()`
- `ttyname()`

Special behavior for XPLINK-compiled C++: Restrictions concerning `setjmp.h` and `ucontext.h`:

1. All XPLINK programs compiled with the V2R10 or later C compilers that are to run with Language Environment V2R10 or later libraries and use the **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** types must not be compiled with C headers from Language Environment V2R9 or earlier.
2. Non-XPLINK functions compiled with any level of Language Environment headers must not define **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** data items and pass them to XPLINK functions that call `getcontext()`, `longjmp()`, `_longjmp()`, `setjmp()`, `_setjmp()`, `setcontext()`, `sigsetjmp()`, or `swapcontext()` with these passed-in data items.
3. When `__XPLINK__` is defined, the Language Environment V2R10 and later headers define a larger **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** area that is required by `setjmp()`, `getcontext()`, and related functions when they are called from an XPLINK routine. If `__XPLINK__` is not defined, the Language

Environment V2R10 and later headers define a shorter **jmp_buf**, **sigjmp_buf** or **ucontext_t** area. The Language Environment headers before V2R10 also define the shorter version of these data areas. If an XPLINK function calls `setjmp()`, `getcontext()` or similar functions with a short **jmp_buf**, **sigjmp_buf** or **ucontext_t** area, a storage overlay or program check may occur when the C library tries to store past the end of the passed-in (too short) data area.

4. The `sigaction()` function supersedes the `signal()` interface, and should be the preferred usage. In particular, `sigaction()` and `signal()` must not be used in the same process to control the same signal.

Usage notes

The use of the `SIGTHSTOP` and `SIGTHCONT` signal is not supported with this function.

Returned value

If successful, `sigaction()` returns 0.

If unsuccessful, no new signal handler is installed, `sigaction()` returns -1, and sets `errno` to one of the following values:

Error Code

Description

EINVAL

The value of *sig* is not a valid signal for one of the following reasons:

- The *sig* is not recognized.
- The process tried to ignore a signal that cannot be ignored.
- The process tried to catch a signal that cannot be caught.

The default action for `SIGCHLD` and `SIGIO` is for the signal to be ignored. A `sigaction()` to set the action to `SIG_IGN` for `SIGIO` will result in an error, with `errno` equal to `EINVAL`.

Example

CELEBS13

```
/* CELEBS13

The first part of this example determines whether the SIGCHLD
signal is currently being ignored.
With a NULL pointer for the new argument, the current signal
handler action is not changed.

*/
#define _POSIX_SOURCE
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdio.h>
#include <signal.h>

void main(void) {
    struct sigaction info;

    if (sigaction(SIGCHLD, NULL, &info) != -1)
        if (info.sa_handler == SIG_IGN)
            printf("SIGCHLD being ignored.\n");
        else if (info.sa_handler == SIG_DFL)
            printf("SIGCHLD being defaulted.\n");
}
```

CELEBS14

```
/* CELEBS14

This fragment initializes a sigaction structure to specify
mysig as a signal handler and then sets the signal handler
for SIGCHLD.
Information on the previous signal handler for SIGCHLD is
```

```

    stored in info.

    */
#define _XOPEN_SOURCE_EXTENDED 1
#include <signal.h>
#include <stdio.h>
void mysig(int a) { printf("In mysig\n"); }

void main(void) {
    struct sigaction info, newhandler;

    if (sigaction(SIGCHLD, NULL, &info) != -1)
        if (info.sa_handler == SIG_IGN)
            printf("SIGCHLD being ignored.\n");
        else if (info.sa_handler == SIG_DFL)
            printf("SIGCHLD being defaulted.\n");

    newhandler.sa_handler = &mysig;
    sigemptyset(&(newhandler.sa_mask));
    newhandler.sa_flags = 0;
    if (sigaction(SIGCHLD, &newhandler, &info) != -1)
        printf("New handler set.\n"); }

```

__sigactionset() — Examine or change signal actions

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------------------|
| z/OS UNIX | both | POSIX(ON) OS/390 V2R6 |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <signal.h>

int __sigactionset(size_t newct, const __sigactionset_t new[],
                  size_t *oldct, __sigactionset_t old[],
                  int options);
```

General description

Examines and changes the actions associated with one or more signals. This function is equivalent to using `sigaction()` one or more times.

The parameters are:

size_t newct

newct is the number of `__sigactionset_t` structures to be processed in the *new* array. The value of *newct* must be from 0 to 64. If this parameter is 0, the *new* parameter is ignored, and may be NULL. If the *newct* parameter is not 0, *new* must be an array containing at least *newct* `__sigactionset_t` structures.

const __sigactionset_t new[]

new is an optional array of `__sigactionset_t` structures. When *newct* is 0, *new* may be NULL, and no signal actions will be changed.

When *newct* is not 0, the data in the *new* array of `__sigactionset_t` structures will cause the actions associated with one or more signals to be changed. The system will change the signal actions as if `sigaction()` were called multiple times. The first *newct* `__sigactionset_t` structures in the *new* array are processed in order, and may cause the actions for one or more signals to be set. For each array entry, the effect is the same as calling `sigaction()` once for each signal whose bit is on in the `__sa_signals` signal set. The fields `__sa_handler`, `__sa_mask`, `__sa_flags`, and `__sa_sigaction` correspond to the `sa_handler`, `sa_mask`, `sa_flags`, and `sa_sigaction` fields in the `sigaction` structure for `sigaction()`.

If a signal appears in more than one `__sa_signals` signal set in the *new* array, the last action specified for that signal will be in effect when `__sigactionset()` returns. If all bits in all `__sa_signals` signal sets in the *new* parameter are off, no signal actions will be changed.

size_t*oldct

oldct is both an input and output parameter. It points to a word containing the number of output entries allowed, used, or needed in the *old* array.

When `__sigactionset()` is called, **oldct* is the maximum number of `__sigactionset_t` structures in the *old* array that the system can fill in. The value of **oldct* must be from 0 to 64. If this parameter is 0, the *old* parameter is ignored, and may be NULL. If the **oldct* parameter is not 0, *old* must be an array of `__sigactionset_t` structures that the system can fill in. The number of array entries in *old* must be at least **oldct*. If not 0, **oldct* must be large enough to allow the system to pass back all the unique actions currently associated with all signals. If **oldct* is not large enough, `__sigactionset()` will fail and the `errno` will be set to `ENOMEM`.

If `__sigactionset()` returns with no error and `*oldct` was not 0, `*oldct` is set to the number of `__sigactionset_t` array entries in `old` that are filled in. If `*oldct` was too small, causing an ENOMEM error, `*oldct` is set to the number of `__sigactionset_t` structures the system would need in order to fill in all the distinct current signal actions. If `*oldct` was 0 when `__sigactionset()` was called, it is not updated.

__sigactionset_t old[]

`old` is an optional array of `__sigactionset_t` structures.

When `*oldct` is not 0, the structures in the `old` array will be filled in with the signal actions currently in effect before any changes are made. The `__sigactionset_t` structure entries in `old` are filled in with all the distinct signal actions currently in effect, starting with the first array entry. Each `__sigactionset_t` structure in the array will contain information about one or more signals. Bits in the `__sa_signals` signal set in each array entry will indicate which signals that entry applies to. The system will try to use as few array entries as possible when passing back the different signal actions. The signal actions for SIGKILL, SIGSTOP, or SIGTRACE will not be returned.

The output information in each array entry is similar to that returned from `sigaction()`. In the `__sigactionset_t` structure, the fields `__sa_handler`, `__sa_mask`, `__sa_flags`, and `__sa_sigaction` correspond to the `sa_handler`, `sa_mask`, `sa_flags`, and `sa_sigaction` fields in the `sigaction` structure filled in by `sigaction()`. The signal action as described by these fields applies to all signals whose bits are on in the `__sa_signals` signal set in the array entry.

If `old` is not large enough to contain information about all distinct signal actions currently in effect, `__sigactionset()` fails, and ENOMEM is returned. There is no way to obtain the current signal actions for a specified subset of signals.

When `old` is NULL, the system does not return any information about the current signal actions.

int options

`options` is a collection of flag bits that affects the operation `__sigactionset()`. The following flag bit can be set in `options`:

__SSET_IGINVALID

Tells the system to ignore invalid bits in the `__sa_signals` field in all `__sigactionset_t` array entries in the `new` parameter. Also, the system will ignore attempts to set SIGKILL, SIGSTOP or SIGTRACE to an action other than SIG_DFL, or SIGIO to SIG_IGN.

If this option bit is off, the system will fail the `__sigactionset()` request if any invalid bits are found in any `__sa_signals` signal set in any `new` array entry. Also, `__sigactionset()` will fail if an attempt it made to set SIGKILL, SIGSTOP, or SIGTRACE to something other than SIG_DFL, or to set SIGIO to SIG_IGN.

This function is supported only in a POSIX(ON) program.

Special behavior for C++: The behavior when mixing signal-handling with C++ exception handling is undefined. Also, the use of signal-handling with constructors and destructors is undefined.

C++ and C language linkage conventions are incompatible, and therefore `__sigactionset()` cannot receive C++ function pointers. If you attempt to pass a C++ function pointer to `__sigactionset()`, the compiler will flag it as an error. Therefore to use the `__sigactionset()` function in the C++ language, you must ensure that signal handler routines have C linkage, by declaring them as `extern "C"`.

Special behavior for XPLINK-compiled C++: Restrictions concerning `setjmp.h` and `ucontext.h`:

1. All XPLINK programs compiled with the V2R10 or later C compilers that are to run with Language Environment V2R10 or later libraries and use the **jmp_buf**, **sigjmp_buf** or **ucontext_t** types must not be compiled with C headers from Language Environment V2R9 or earlier.
2. Non-XPLINK functions compiled with any level of Language Environment headers must not define **jmp_buf**, **sigjmp_buf** or **ucontext_t** data items and pass them to XPLINK functions that call `getcontext()`, `longjmp()`, `_longjmp()`, `setjmp()`, `_setjmp()`, `setcontext()`, `sigsetjmp()`, or `swapcontext()` with these passed-in data items.

3. When `__XPLINK__` is defined, the Language Environment V2R10 and later headers define a larger **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** area that is required by `setjmp()`, `getcontext()`, and related functions when they are called from an XPLINK routine. If `__XPLINK__` is not defined, the Language Environment V2R10 and later headers define a shorter **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** area. The Language Environment headers before V2R10 also define the shorter version of these data areas. If an XPLINK function calls `setjmp()`, `getcontext()` or similar functions with a short **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** area, a storage overlay or program check may occur when the C library tries to store past the end of the passed-in (too short) data area.

Usage note

The use of the `SIGTHSTOP` and `SIGTHCONT` signal is not supported with this function.

__sigactionset_t type

The `__sigactionset_t` type is defined as follows:

```
typedef struct __sigactionset_s
{
    sigset_t    __sa_signals;
    int         __sa_flags;
    void        (*__sa_handler)(int);
    sigset_t    __sa_mask;

    void        (*__sa_sigaction)(int, siginfo_t *, void *);
} __sigactionset_t;
```

The following are members of the structure:

sigset_t __sa_signals

This is a signal set. It contains the signals whose actions are described by the other members in this structure. For more information on signal sets, see [“sigemptyset\(\) — Initialize a signal mask to exclude all signals” on page 1626](#).

In the *new* array of `__sigactionset_t` structures, the caller sets bits in this signal set. The signal action for each signal in the signal set will be set as described by the other members of the structure.

`__sa_signals` must be set using one or more of the signal set manipulation functions: `sigaddset()`, `sigdelset()`, `sigemptyset()`, or `sigfillset()`.

In the *old* array of `__sigactionset_t` structures, the system sets the bits in the `__sa_signals` field. The current signal action for each member of the signal set is described by the other members of the structure. All signals in the set have the same signal action.

int __sa_flags

A collection of flag bits that affect the behavior of the specified signal.

The flag bits in the `__sa_flags` field are the same as those in the `sa_flags` member of the `sigaction` structure. See [“sigaction\(\) — Examine or change a signal action” on page 1605](#) for a detailed description of these flag bits.

void (* __sa_handler)(int)

A pointer to the function assigned to handle the signals in the `__sa_signals` signal set. This function will be invoked passing one parameter of type `int` that contains the signal type for which this function is being invoked. The value of this member can also be `SIG_DFL` (indicating the default action) or `SIG_IGN` (indicating that the signal is to be ignored).

Note: This member and `__sa_sigaction` are mutually exclusive. When the `SA_SIGINFO` flag is set in `__sa_flags`, `__sa_sigaction` is used. Otherwise, `__sa_handler` is used.

sigset_t __sa_mask

This signal set identifies a set of signals that are to be added to the signal mask of the calling thread before the signal-handling function `__sa_handler` or `__sa_sigaction` is invoked. For more information on signal sets, see [“sigemptyset\(\) — Initialize a signal mask to exclude all signals” on page 1626](#). You cannot use this mechanism to block `SIGKILL`, `SIGSTOP`, or `SIGTRACE`. If

__sa_mask includes these signals, they will simply be ignored; __sigactionset() will not return an error.

__sa_mask must be set by using one or more of the signal set manipulation functions: sigaddset(), sigdelset(), sigemptyset(), or sigfillset().

void (*__sa_sigaction)(int, siginfo_t *, void *)

A pointer to the function assigned to handle the signal, or SIG_DFL, or SIG_IGN. This function will be invoked passing three parameters. The first is of type int that contains the signal type for which this function is being invoked. The second is of type siginfo_t* where the siginfo_t contain additional information about the source of the signal. The third is of type void* but will actually point to a ucontext_t_t containing the context information at the of time the signal interrupt.

Notes:

1. The user must cast SIG_DFL or SIG_IGN to match the __sa_sigaction definition.
2. This member and sa_handler are mutually exclusive. When the SA_SIGINFO flag is set in __sa_flags, __sa_sigaction is used. Otherwise, __sa_handler is used.

When a signal handler installed by __sigactionset(), with the _SA_OLD_STYLE flag set off, catches a signal, the system calculates a new signal mask by taking the union of the current signal mask at the time of the signal interrupt, the signals specified by __sa_mask, and the signal that was just caught (if the SA_NODEFER flag is not set). This new mask stays in effect until the signal handler returns, or sigprocmask(), sigsuspend(), siglongjmp(), sighold(), sigpause(), or sigrelse() is called. When the signal handler ends, the original signal mask is restored.

After an action has been specified for a particular signal, using __sigactionset() with the _SA_OLD_STYLE flag not set, it remains installed until it is explicitly changed with another call to __sigactionset(), sigaction(), signal(), bsd_signal(), sigset(), sigignore(), one of the exec functions, or until the SA_RESETHAND flag causes it to be reset to SIG_DFL.

After an action has been specified for a particular signal, using __sigactionset() with the _SA_OLD_STYLE flag set or using signal(), it remains installed until it is explicitly changed with another call to __sigactionset(), sigaction(), bsd_signal(), sigset(), signal(), sigignore(), one of the exec functions, or a signal catcher is driven, where it will be reset to SIG_DFL.

Successful setting of a signal action to SIG_IGN for a signal that is pending causes the pending signal to be discarded, whether or not it is blocked. This provides the ability to discard signals that are found to be blocked and pending by sigpending(). A signal is discarded across a call to __sigactionset() if any __sigactionset_t structure in the *new* array causes the action for that signal to be set to SIG_IGN. This happens even if a later __sigactionset_t structure in the *new* array sets the signal action to something other than SIG_IGN before __sigactionset() returns.

If a process sets the action of the SIGCHLD signal to SIG_IGN, child processes of the calling process will not be transformed into zombie processes when they terminate. If the calling process subsequently waits for its children, and the process has no unwaited from children that were transformed into zombie processes, it will block until all of its children terminate. The wait(), waitid(), or waitpid() function will fail and set errno to ECHILD.

If the SA_SIGINFO flag is set, the signal catching function specified by __sa_sigaction is invoked as:

```
void function(int signo, siginfo_t *info, void * context);
```

where *function* is the specified signal-catching function, *signo* is the signal number of the signal being delivered, *info* points to an object of type siginfo_t associated with the signal being delivered, and *context* points to an object of type ucontext_t.

For a signal catcher that has been loaded by fetch() or fetchep(), the address returned by __sigactionset() in the __sa_handler or __sa_sigaction fields may be different than the value originally passed in to sigaction() or __sigactionset() (when the signal action was first set). This signal catcher address can be passed in again to sigaction() or __sigactionset() to reestablish the same signal catcher. The effect will be similar to passing in the original catcher address obtained from fetch() or fetchep(). However, this

address should not be used for any other purpose, such as directly calling the signal catcher. Always use the original address obtained from `fetch()` or `fetchep()` when calling the catcher directly.

Considerations for asynchronous signal-catching functions

Some of the functions have been restricted to be serially reusable with respect to asynchronous signals. For more information on these functions, see [“sigaction\(\) — Examine or change a signal action”](#) on page 1605.

Returned value

If successful, `__sigactionset()` returns 0.

If unsuccessful, no signal actions are changed, `__sigactionset()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

This error can occur if:

- An unsupported signal bit was on in the `__sa_signals` signal set in the *new* parameter. This error will not be reported if the `__SSET_IGINVALID` flag is set in *options*. To obtain more information in this case, use `__errno2()`.
- An attempt was made to set the signal action for SIGSTOP, SIGKILL, or SIGTRACE to something other than SIG_DFL. This error will not be reported if the `__SSET_IGINVALID` flag is set in *options*. To obtain more information in this case, use `__errno2()`.
- The *newct* or *oldct* parameters are not in the range from 0 to 64.
- *newct* was not 0 and *new* was NULL.
- *oldct* was not 0 and *old* was NULL.

EMVSERR

An MVS environmental or internal error has occurred. Use `__errno2()` to obtain more information about this error.

ENOMEM

The input value in *oldct* was not 0, and was too small to let the system pass back all distinct current signal actions. When `__sigactionset()` returns, **oldct* will be set to the number of array entries needed by the system.

Example

```
/*
 * Note: This is just a code fragment
 */

void catch_sigchld(int, siginfo_t *, void *);

...

__sigactionset_t new[2], old[64];
int options;
int rc;
size_t oldct = 64;

/*
 * Set SIGUSR1 and SIGUSR2 to SIG_IGN
 * Set SIGCHLD to new-style catcher catch_sigchld()
 * Save original signal setup in variable old
 */

bzero(new, sizeof new);

(void)sigemptyset(&(new[0].__sa_signals) );
```

```

(void)sigaddset (&(new[0].__sa_signals), SIGUSR1);
(void)sigaddset (&(new[0].__sa_signals), SIGUSR2);

(void)sigemptyset(&(new[1].__sa_signals) );
(void)sigaddset (&(new[1].__sa_signals), SIGCHLD);

new[0].__sa_handler = SIG_IGN;
new[1].__sa_sigaction = &catch_sigchld;
new[1].__sa_flags = SA_SIGINFO;

rc = __sigactionset((size_t)2, new, &oldct, old, __SSET_IGINVALID);

```

sigaddset() — Add a signal to the signal mask

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <signal.h>

int sigaddset(sigset_t *set, int signal);
```

General description

Adds a signal to the set of signals already recorded in *set*.

`sigaddset()` is part of a family of functions that manipulate signal sets. *Signal sets* are data objects that let a process keep track of groups of signals. For example, a process can create one signal set to record which signals it is blocking, and another signal set to record which signals are pending. In general, signal sets are used to manipulate groups of signals used by other functions (such as `sigprocmask()`) or to examine signal sets returned by other functions (such as `sigpending()`).

Applications should call either `sigemptyset()` or `sigfillset()` at least once for each object of type `sigset_t` prior to any other use of that object. If such an object is not initialized in this way, but is nonetheless supplied as an argument to any of `pthread_sigmask()`, `sigaction()`, `sigaddset()`, `sigdelset()`, `sigismember()`, `sigpending()`, `sigprocmask()`, `sigsuspend()`, `sigtimedwait()`, `sigwait()`, or `sigwaitinfo()`, the results are undefined.

Usage note

The use of the `SIGTHSTOP` and `SIGTHCONT` signal is not supported with this function.

Returned value

If the signal is successfully added to the signal set, `sigaddset()` returns 0.

If *signal* is not supported, `sigaddset()` returns -1 and sets `errno` to `EINVAL`.

Example

CELEBS15

```
/* CELEBS15
   This example adds a set of signals.
*/
#define _POSIX_SOURCE
#include <stdio.h>
#include <signal.h>
#include <unistd.h>

void catcher(int signum) {
    puts("catcher() has gained control");
}
```

```
main() {
    struct sigaction sact;
    sigset_t sigset;

    sigemptyset(&sact.sa_mask);
    sact.sa_flags = 0;
    sact.sa_handler = catcher;
    sigaction(SIGUSR1, &sact, NULL);

    puts("before first kill()");
    kill(getpid(), SIGUSR1);
    puts("before second kill()");

    sigemptyset(&sigset);
    sigaddset(&sigset, SIGUSR1);
    sigprocmask(SIG_SETMASK, &sigset, NULL);

    kill(getpid(), SIGUSR1);
    puts("after second kill()");
}
```

Output

```
before first kill()
catcher() has gained control
before second kill()
after second kill()
```

sigaltstack() — Set or get signal alternate stack context

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <signal.h>

int sigaltstack(const stack_t *__restrict__ ss, stack_t *__restrict__ oss);
```

General description

The `sigaltstack()` function allows a thread to define and examine the state of an alternate stack for signal handlers. Signals that have been explicitly declared to execute on the alternate stack will be delivered on the alternate stack.

Note: To explicitly declare that a signal catcher is to run on the alternate signal stack, the `SA_ONSTACK` flag must be set in the `sa_flags` when the signal action is set using `sigaction()`.

If `ss` is not a NULL pointer, it points to a `stack_t` structure that specifies the alternate signal stack that will take effect upon return from `sigaltstack()`. The `ss_flags` member specifies the new stack state. If it is set to `SS_DISABLE`, the stack is disabled and `ss_sp` and `ss_size` are ignored. Otherwise the stack will be enabled, and the `ss_sp` and `ss_size` members specify the new address and size of the stack.

AMODE 64 considerations: Storage for this stack must be above the 2GB bar. It may not be storage acquired with the `__malloc24()` or `__malloc31()` functions.

The range of addresses starting at `ss_sp`, up to but not including `ss_sp + ss_size`, is available to the implementation for use as the stack. This interface makes no assumptions regarding which end is the stack base and in which direction the stack grows as items are pushed.

If `oss` is not a NULL pointer, on successful completion it will point to a `stack_t` structure that specifies the alternate signal stack that was in effect before the call to `sigaltstack()`. The `ss_sp` and `ss_size` members specify the address and size of that stack. The `ss_flags` member specifies the stack's state, and may contain one of the following values:

SS_ONSTACK

The thread is currently executing on the alternate signal stack. Attempts to modify the alternate signal stack while the thread is executing on it fails. This flag must not be modified by threads.

SS_DISABLE

The alternate signal stack is currently disabled.

The value `SIGSTKSZ` is a system default specifying the number of bytes that would be used to cover the usual case when manually allocating an alternate stack area. The value `MINSIGSTKSZ` is defined to be the minimum stack size for a signal handler. In computing an alternate signal stack size, a program should add that amount to its stack requirements to allow for the system implementation overhead. The constants `SS_ONSTACK`, `SS_DISABLE`, `SIGSTKSZ`, and `MINSIGSTKSZ` are defined in `<signal.h>`.

After a successful call to one of the `exec` functions, there are no alternate signal stacks in the new process image.

Notes:

1. If a signal handler is enabled to run on an alternate stack, then all functions called by that signal handler must be compiled with the same linkage. For example, if the signal handler is compiled with `XPLINK`, then all functions it calls must also be compiled `XPLINK`. Since only one alternate stack can be supplied, no mixing of linkages (which would require both upward and downward-growing alternate stacks) is allowed. The type of stack created will be based on the attributes of the signal handler to be given control. If the signal handler has been compiled with `XPLINK`, then a downward-growing stack will be created in the alternate stack, including, in `AMODE 31`, using enough storage in the user stack to create a 4k read-only guard page (aligned on a 4k boundary).
2. If a new signal is received while a signal handler is running on an alternate stack, and that new signal specified a signal handler that also runs on the alternate stack, then both signal handlers must have been compiled with the same linkage (`XPLINK` versus non-`XPLINK`).

Returned value

If successful, `sigaltstack()` returns 0.

If unsuccessful, `sigaltstack()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

ss argument is not a NULL pointer, and the ss_flags member pointed to by ss contains flags other than SS_DISABLE.

ENOMEM

The size of the alternate stack area is less than MINSIGSTKSZ.

EPERM

An attempt was made to modify an active stack.

sigdelset() — Delete a signal from the signal mask

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <signal.h>

int sigdelset(sigset_t *set, int signal);
```

General description

Removes the specified *signal* from the list of signals recorded in *set*.

The sigdelset() function is part of a family of functions that manipulate signal sets. *Signal sets* are data objects that let a process keep track of groups of signals. For example, a process can create one signal set to record which signals it is blocking, and another signal set to record which signals are pending. In general, signal sets are used to manipulate groups of signals used by other functions (such as sigprocmask()) or to examine signal sets returned by other functions (such as sigpending()).

Applications should call either sigemptyset() or sigfillset() at least once for each object of type sigset_t prior to any other use of that object. If such an object is not initialized in this way, but is nonetheless supplied as an argument to any of pthread_sigmask(), sigaction(), sigaddset(), sigdelset(), sigismember(), sigpending(), sigprocmask(), sigsuspend(), sigtimedwait(), sigwait(), or sigwaitinfo(), the results are undefined.

Usage note

The use of the SIGTHSTOP and SIGTHCONT signal is not supported with this function.

Returned value

If the signal is successfully deleted from the signal set, sigdelset() returns 0.

If *signal* is not supported, `sigdelset()` returns -1 and sets `errno` to `EINVAL`.

Example

CELEBS16

```
/* CELEBS16

   This example deletes specific signals.

   */
#define _POSIX_SOURCE
#include <stdio.h>
#include <signal.h>
#include <unistd.h>

void catcher(int signum) {
    puts("catcher() has gained control");
}

main() {
    struct sigaction sact;
    sigset_t sigset;

    sigemptyset(&sact.sa_mask);
    sact.sa_flags = 0;
    sact.sa_handler = catcher;
    sigaction(SIGUSR1, &sact, NULL);

    sigfillset(&sigset);
    sigprocmask(SIG_SETMASK, &sigset, NULL);

    puts("before kill()");
    kill(getpid(), SIGUSR1);

    puts("before unblocking SIGUSR1");
    sigdelset(&sigset, SIGUSR1);
    sigprocmask(SIG_SETMASK, &sigset, NULL);
    puts("after unblocking SIGUSR1");
}
```

Output

```
before kill()
before unblocking SIGUSR1
catcher() has gained control
after unblocking SIGUSR1
```

sigemptyset() — Initialize a signal mask to exclude all signals

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <signal.h>

int sigemptyset(sigset_t *set);
```

General description

Initializes a signal set *set* to the empty set. All recognized signals are excluded.

`sigemptyset()` is part of a family of functions that manipulate signal sets. *Signal sets* are data objects that let a process keep track of groups of signals. For example, a process can create one signal set to record which signals it is blocking, and another signal set to record which signals are pending. Signal sets are used to manipulate groups of signals used by other functions (such as `sigprocmask()`) or to examine signal sets returned by other functions (such as `sigpending()`).

Returned value

If successful, `sigemptyset()` returns 0.

There are no documented `errno` values.

Example

CELEBS17

```
/* CELEBS17

   This example initializes a set of signals to an empty set.

*/
#define _POSIX_SOURCE
#include <stdio.h>
#include <signal.h>
#include <unistd.h>

main() {
    struct sigaction sact;

    sigemptyset(&sact.sa_mask);
    sact.sa_flags = 0;
    sact.sa_handler = SIG_IGN;

    sigaction(SIGUSR2, &sact, NULL);

    puts("before kill()");
    kill(getpid(), SIGUSR2);
    puts("after kill()");
}
```

Output

```
before kill()
after kill()
```

sigfillset() — Initialize a signal mask to include all signals

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <signal.h>

int sigfillset(sigset_t *set);
```

General description

Initializes a signal set *set* to the complete set of supported signals.

`sigfillset()` is part of a family of functions that manipulate signal sets. *Signal sets* are data objects that let a process keep track of groups of signals. For example, a process can create one signal set to record which signals it is blocking, and another signal set to record which signals are pending. Signal sets are used to manipulate groups of signals used by other functions (such as `sigprocmask()`) or to examine signal sets returned by other functions (such as `sigpending()`).

Returned value

If successful, `sigfillset()` returns 0.

There are no documented `errno` values.

Example

CELEBS18

```
/* CELEBS18

   This example initializes a set of signals to a complete set.

*/
#define _POSIX_SOURCE
#include <stdio.h>
#include <signal.h>
#include <unistd.h>

main() {
    sigset_t sigset;

    sigfillset(&sigset);

    sigprocmask(SIG_SETMASK, &sigset, NULL);

    puts("before kill()");
    kill(getpid(), SIGSEGV);
    puts("after kill()");
}
```

Output

```
before kill()
after kill()
```

sighold() — Add a signal to a thread

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <signal.h>

int sighold(int sig);
```

General description

The sighold() function provides a simplified method for adding the signal specified by the argument *sig* to the calling thread's signal mask.

Usage note

The use of the SIGTHSTOP and SIGTHCONT signal is not supported with this function.

Returned value

If successful, sighold() returns 0.

If unsuccessful, sighold() returns -1 and sets errno to one of the following values:

Error Code

Description

EINVAL

The value of the argument *sig* is not a valid signal type or it is SIGKILL, SIGSTOP, or SIGTRACE.

sigignore() — Set disposition to ignore a signal

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <signal.h>

int sigignore(int sig);
```

General description

The sigignore() function provides a simplified method for setting the signal action of the signal specified by the argument *sig* to SIG_IGN.

Usage note

The use of the SIGTHSTOP and SIGTHCONT signal is not supported with this function.

Returned value

If successful, sigignore() returns 0.
If unsuccessful, sigignore() returns -1 and sets errno to one of the following values:

| Error Code | Description |
|------------|-------------|
| EINVAL | |

The value of the argument *sig* is not a valid signal type or it is SIGKILL, SIGSTOP, or SIGTRACE.

siginterrupt() — Allow signals to interrupt functions

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <signal.h>

int siginterrupt(int sig, int flag);
```

General description

The siginterrupt() function provides a simplified method for changing the restart behavior when a function is interrupted by the signal specified in the argument *sig*.
The argument *flag* serves as a binary switch to enable or disable restart behavior. When *flag* is nonzero, restart behavior will be disabled. Otherwise it is enabled.

Returned value

If successful, siginterrupt() returns 0.
If unsuccessful, siginterrupt() returns -1 and sets errno to one of the following values:

| Error Code | Description |
|------------|-------------|
| EINVAL | |

The value of the argument *sig* is not a valid signal type.

Related information

sigismember() — Test if a signal is in a signal mask

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <signal.h>

int sigismember(const sigset_t *set, int signal);
```

General description

Tests whether a specified signal number *signal* is a member of a signal set *set*.

`sigismember()` is part of a family of functions that manipulate signal sets. *Signal sets* are data objects that let a process keep track of groups of signals. For example, a process can create one signal set to record which signals it is blocking, and another signal set to record which signals are pending. Signal sets are used to manipulate groups of signals used by other functions (such as `sigprocmask()`) or to examine signal sets returned by other functions (such as `sigpending()`).

Applications should call either `sigemptyset()` or `sigfillset()` at least once for each object of type `sigset_t` prior to any other use of that object. If such an object is not initialized in this way, but is nonetheless supplied as an argument to any of `pthread_sigmask()`, `sigaction()`, `sigaddset()`, `sigdelset()`, `sigismember()`, `sigpending()`, `sigprocmask()`, `sigsuspend()`, `sigtimedwait()`, `sigwait()`, or `sigwaitinfo()`, the results are undefined.

Usage note

The use of the `SIGTHSTOP` and `SIGTHCONT` signal is not supported with this function.

Returned value

`sigismember()` returns 1 if *signal* is in *set*, and it returns 0 if it is not.

If unsuccessful, `sigismember()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

The value of *signal* is not one of the supported signals.

Example

CELEBS19

```

/* CELEBS19

   This example tests signals.

*/
#define _POSIX_SOURCE
#include <stdio.h>
#include <signal.h>

void check(sigset_t set, int signum, char *signame) {
    printf("%-8s is ", signame);
    if (!sigismember(&set, signum))
        printf("not ");
    puts("in the set");
}

main() {
    sigset_t sigset;

    sigemptyset(&sigset);
    sigaddset(&sigset, SIGUSR1);
    sigaddset(&sigset, SIGKILL);
    sigaddset(&sigset, SIGCHLD);

    check(sigset, SIGUSR1, "SIGUSR1");
    check(sigset, SIGUSR2, "SIGUSR2");
    check(sigset, SIGFPE, "SIGFPE");
    check(sigset, SIGKILL, "SIGKILL");
}

```

Output

```

SIGUSR1  is in the set
SIGUSR2  is not in the set
SIGFPE   is not in the set
SIGKILL  is in the set

```

siglongjmp() — Restore the stack environment and signal mask

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <setjmp.h>

void siglongjmp(sigjmp_buf env, int val);
```

General description

For a stack environment previously saved in *env* by `sigsetjmp()`, the `siglongjmp()` function restores all the stack environment and, optionally, the signal mask, depending on whether it was saved by `sigsetjmp()`. The `sigsetjmp()` and `siglongjmp()` functions provide a way to perform a nonlocal goto.

env is an address for a `sigjmp_buf` structure.

val is the return value from `siglongjmp()`.

`siglongjmp()` is similar to `longjmp()`, except for the optional capability of restoring the signal mask. The `sigsetjmp()`—`siglongjmp()` pair, the `setjmp()`—`longjmp()` pair, the `_setjmp()`—`_longjmp()` pair, and the `getcontext()`—`setcontext()` pair cannot be intermixed. A stack environment and signal mask saved by `sigsetjmp()` can be restored only by `siglongjmp()`.

A call to `sigsetjmp()` causes the current stack environment including, optionally, the signal mask to be saved in *env*. A subsequent call to `siglongjmp()` restores the saved environment and signal mask (if saved by `sigsetjmp()`) and returns control to a point in the program corresponding to the `sigsetjmp()` call. Execution resumes as if the `sigsetjmp()` call had just returned the given *value*. All variables (except register variables) that are accessible to the function that receives control contain the values they had when you called `siglongjmp()`. The values of register variables are unpredictable. Nonvolatile auto variables that are changed between calls to `sigsetjmp()` and `siglongjmp()` are also unpredictable.

Notes:

1. If you call `siglongjmp()`, the function in which the corresponding call to `sigsetjmp()` was made must not have returned first. After the function calling `sigsetjmp()` returns, calling `siglongjmp()` causes unpredictable program behavior.
2. If `siglongjmp()` is used to jump back into an XPLINK routine, any `alloca()` requests issued by the XPLINK routine after the earlier `sigsetjmp()` (or `getcontext()`, and so on.) was called and before `siglongjmp()` is called are backed out. All storage obtained by these `alloca()` requests is freed before the XPLINK routine is resumed.
3. If `siglongjmp()` is used to jump back into a non-XPLINK routine, `alloca()` requests made after `sigsetjmp()` and before `siglongjmp()` are not backed out.

The *value* argument passed to `siglongjmp()` must be nonzero. If you give a zero argument for *value*, `siglongjmp()` substitutes the value 1 in its place.

`siglongjmp()` does not use the normal function call and return mechanisms. `siglongjmp()` restores the saved signal mask only if the *env* parameter was initialized by a call to `sigsetjmp()` with a nonzero *savemask* argument.

Special behavior for C++: If `sigsetjmp()` and `siglongjmp()` are used to transfer control, the behavior is undefined whether the destruction of automatic C++ objects is done. Additionally, if any automatic objects would be destroyed by a thrown exception transferring control to another (destination) point in the program, then a call to `siglongjmp()` at the throw point that transfers control to the same (destination) point has undefined behavior. The use of `sigsetjmp()` and `siglongjmp()` in conjunction with `try()`, `catch()`, and `throw()` is also undefined.

Special behavior for XPLINK-compiled C++: Restrictions concerning `setjmp.h` and `ucontext.h`:

1. All XPLINK programs compiled with the V2R10 or later C compilers that are to run with Language Environment V2R10 or later libraries and use the **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** types must not be compiled with C headers from Language Environment V2R9 or earlier.
2. Non-XPLINK functions compiled with any level of Language Environment headers must not define **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** data items and pass them to XPLINK functions that call `getcontext()`, `longjmp()`, `_longjmp()`, `setjmp()`, `_setjmp()`, `setcontext()`, `sigsetjmp()`, or `swapcontext()` with these passed-in data items.
3. When `__XPLINK__` is defined, the Language Environment V2R10 and later headers define a larger **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** area that is required by `setjmp()`, `getcontext()`, and related functions when they are called from an XPLINK routine. If `__XPLINK__` is not defined, the Language Environment V2R10 and later headers define a shorter **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** area. The Language Environment headers before V2R10 also define the shorter version of these data areas. If an XPLINK function calls `setjmp()`, `getcontext()` or similar functions with a short **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** area, a storage overlay or program check may occur when the C library tries to store past the end of the passed-in (too short) data area.

Returned value

`siglongjmp()` returns no values.

There are no documented `errno` values.

Example

This example saves the stack environment and signal mask at the statement:

```
if(sigsetjmp(mark,1) != 0) ...
```

When the system first performs the `if` statement, it saves the environment and signal mask in *mark* and sets the condition to false, because `sigsetjmp()` returns 0 when it saves the environment. The program prints the message: `sigsetjmp() has been called`

The subsequent call to function `p()` tests for a local error condition, which can cause it to perform `siglongjmp()`. Then control returns to the original `sigsetjmp()` function using the environment saved in *mark* and restores the signal mask. This time the condition is true because -1 is the return value from `siglongjmp()`. The example then performs the statements in the block and prints: `siglongjmp() has been called` Then it performs your `recover()` function and leaves the program.

```
#define _POSIX_SOURCE
#include <stdio.h>
#include <setjmp.h>

sigjmp_buf mark;

void p(void);
void recover(void);

int main(void)
{
    if (sigsetjmp(mark) != 0) {
        printf("siglongjmp() has been called\n");
        recover();
        exit(1);
    }
    printf("sigsetjmp() has been called\n");
    :
    p();
```

```

:
}

void p(void) {
    int error = 0;
:
    error = 9;
:
    if (error != 0)
        siglongjmp(mark, -1);
:
}

void recover(void) {
:
:
}

```

signal() — Handle interrupts

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 POSIX.4a XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```

#include <signal.h>

void(*signal(int sig, void(*func)(int)))(int);

```

General description

Allows a process to choose one of several ways to handle an interrupt signal *sig* from the operating system or from the `raise()` function.

The *sig* argument must be one of the macros defined in the `signal.h` header file. See [Table 59 on page 1637](#).

The *func* argument must be one of the macros, `SIG_DFL` or `SIG_IGN`, defined in the `signal.h` header file, or a function address.

If the value of *func* is `SIG_DFL`, default handling for that signal will occur. If the value of *func* is `SIG_IGN`, the signal will be ignored. Otherwise, *func* points to a function to be called when that signal occurs. Such a function is called a *signal handler*.

When a signal occurs, if *func* points to a function:

1. First the equivalent of `signal(sig, SIG_DFL)`; is executed or an implementation-defined blocking of the system is performed. (If the value of *sig* is `SIGILL`, the occurrence of the reset to `SIG_DFL` is implementation-defined.)
2. Next, the equivalent of `(*func)(sig)`; is executed. The function *func* may terminate by executing a `return` statement or by calling the `abort()`, `exit()`, or `longjmp()` function. If *func* executes a `return` statement and the value of *sig* was `SIGFPE` or any other implementation-defined value corresponding to a computational exception, the behavior is undefined. Otherwise, the program will resume execution at the point it was interrupted.

If a signal occurs for a reason other than having called the `abort()` or `raise()` function, the behavior is undefined if the signal handler calls any function in the standard library other than the `signal()` function itself (with a first argument of the signal number corresponding to the signal that caused the invocation of the handler). Behavior is also undefined if the signal handler refers to any object with static storage duration other than by assigning a value to a static storage duration variable of type `volatile sig_atomic_t`. Furthermore, if such a call to the `signal()` function returns `SIG_ERR`, the value of `errno` is indeterminate.

At program startup, the equivalent of `signal(sig, SIG_IGN)`; may be executed for some selected signals. The equivalent of `signal(sig, SIG_DFL)`; is executed for all other signals.

The action taken when the interrupt signal is received depends on the value of *func*.

Value

Meaning

SIG_DFL

Default handling for the signal will occur.

SIG_IGN

The signal is to be ignored.

As of Language Environment Release 3, the defaults for `SIGUSR1`, `SIGUSR2`, `SIGINT`, and `SIGTERM` are changed from the signal being ignored to abnormal termination. To compensate for this change, you would explicitly register that the signal is to be ignored, using a call sequence such as:

```
signal(SIGUSR1, SIG_IGN);
signal(SIGUSR2, SIG_IGN);
signal(SIGINT, SIG_IGN);
signal(SIGTERM, SIG_IGN);
```

These calls may be made either in the source or they can be made from the HLL user exit `CEEBCINT`, which will require a re-link.

Special behavior for POSIX: For a z/OS UNIX C application running `POSIX(ON)`, the interrupt signal can also come from `kill()` or from another process. A program can use `sigaction()` to establish a signal handler; `sigaction()` blocks the signal while the signal handler has control. If you use `signal()` to establish a signal handler, the signal reverts back to the default action. If you want the signal handler to get control for the next signal of this type, you must reissue `signal()`.

`signal(sig, func)` is equivalent to `sigaction(sig, &act, NULL)`, where *act* points to a `sigaction` structure containing an `sa_action` of *func*, an `sa_mask` by `sigemptyset()`, and an `sa_flags` containing `_SA_OLD_STYLE`.

Note: The `sigaction()` function supersedes the `signal()` interface, and should be the preferred usage. In particular, `sigaction()` and `signal()` must not be used in the same process to control the same signal.

For a list of considerations for coding signal-catching functions that will support asynchronous signals, refer to “[sigaction\(\) — Examine or change a signal action](#)” on page 1605.

The `sig` argument must be one of the macros defined in the `signal.h` header file.

Special behavior for C++:

- The behavior when mixing signal-handling with C++ exception handling is undefined. Also, the use of signal-handling with constructors and destructors is undefined.
- C++ and C language linkage conventions are incompatible, and therefore `signal()` cannot receive C++ function pointers. If you attempt to pass a C++ function pointer to `signal()`, the compiler will flag it as an error. Therefore, to use the `signal()` function in the C++ language, you must ensure that signal handler routines established have C linkage, by declaring them as `extern "C"`.

The signals supported are listed below.

Table 59. Signals Supported by C or C++ — POSIX(OFF)

| Value | Default Action | Meaning |
|----------|----------------|---|
| SIGABND | 1 | Abend |
| SIGABRT | 1 | Abnormal termination (sent by <code>abort()</code>) |
| SIGFPE | 1 | Arithmetic exceptions that are not masked, for example, overflow, division by zero, and incorrect operation |
| SIGILL | 1 | Detection of an incorrect function image |
| SIGINT | 1 | Interactive attention |
| SIGSEGV | 1 | Incorrect access to memory |
| SIGTERM | 1 | Termination request sent to the program |
| SIGUSR1 | 1 | Intended for use by user applications |
| SIGUSR2 | 1 | Intended for use by user applications |
| SIGIOERR | 2 | A serious I/O error was detected. |

In [Table 59 on page 1637](#), the **Default Actions** are:

- 1 Normal termination of the process.
- 2 Ignore the signal.

When the runtime option `POSIX(ON)` is specified, if a signal catcher for a `SIGABND`, `SIGFPE`, `SIGILL` or `SIGSEGV` signal runs as a result of a program check or an `ABEND`, and the signal catcher executes a `RETURN` statement, the process will be terminated.

Returned value

If successful, `signal()` returns the most recent value of *func*.

If unsuccessful, `signal()` returns a value of `SIG_ERR` and a positive value in `errno`.

There are no documented `errno` values. If an error occurs, issue `perror()` using the `errno` value.

Example

CELEBS20

```

/* CELEBS20

   This example shows you how to establish a signal handler.

   */
#include <signal.h>
#include <stdio.h>
#include <stdlib.h>
#define ONE_K 1024

#define OUT_OF_STORAGE      (SIGUSR1)

/* The SIGNAL macro does a signal() checking the return code */
#define SIGNAL(handler, StrCln) { \
    if (signal((handler), (StrCln)) == SIG_ERR) { \
        perror("Could not signal user signal"); \
        abort(); \
    } \
}

#ifdef __cplusplus          /* the __cplusplus macro      */
extern "C" void StrCln(int); /* is automatically defined */
#else                      /* by the C++/MVS compiler  */
void StrCln(int);
#endif

void DoWork(char **, int);

int main(int argc, char *argv[]) {
    int size;
    char *buffer;

    signal(OUT_OF_STORAGE, StrCln);

    if (argc != 2) {
        printf("Syntax: %s size \n", argv[0]);
        return(-1);
    }

    size = atoi(argv[1]);

    DoWork(&buffer, size);
    return(0);
}

void StrCln(int SIG_TYPE) {
    printf("Failed trying to malloc storage\n");
    signal(SIG_TYPE, SIG_DFL);
    exit(0);
}

void DoWork(char **buffer, int size) {
    int rc;

    while (*buffer != NULL)
        *buffer = (char *)malloc(size*ONE_K);
    if (*buffer == NULL) {
        if (raise(OUT_OF_STORAGE)) {
            perror("Could not raise user signal");
            abort();
        }
    }
    return;
}

```

signbit() — Determines whether the sign of its argument is negative

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| C99 Single UNIX Specification, Version 3 | both | z/OS V1R8 |

Format

```
#define _ISOC99_SOURCE
#include <math.h>

int signbit(real-floating x);

#define __STDC_WANT_DEC_FP__
#include <math.h>

int signbit(real-floating x); /* C only */
int signbit(decimal-floating x); /* C only */
bool signbit(real-floating x); /* C++ only */
bool signbit(decimal-floating x); /* C++ only */

#define _TR1_C99
#include <math.h>

bool signbit(real-floating x); /* C++ only */
```

General description

The `signbit()` macro or function template determines whether the sign of its argument value is negative.

| Function | Hex | IEEE |
|----------|-----|------|
| signbit | X | X |

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. This function works in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

The `signbit()` macro returns 1 if the sign of its argument value is negative, else returns 0. The C++ function template returns true if the sign of its argument value is negative, else returns false.

`__signgam()` — Return `signgam` reference

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XOPEN_SOURCE
#include <math.h>

int *__signgam(void);
#define signgam (*__signgam())
```

General description

The `__signgam()` function returns the address of the calling thread's storage for the `signgam` external variable used by the `gamma()` and `lgamma()` functions. This extended mechanism is necessary for multithreaded processes which use either of these two functions, since each thread has its own instance of `signgam`. The `<math.h>` header defines `signgam` to an invocation of `__signgam()`, so generally, all references to `signgam` will be mapped to calls to `__signgam()`. If the user eliminates this definition, either by not including the header, or by using `#undef`, then references to `signgam` will refer to the actual `signgam` external variable, which contains the `signgam` value for the IPT only. In the absence of the definition of `signgam` to a call to `__signgam()`, `signgam` values in threads other than the IPT are inaccessible.

Returned value

`__signgam()` is always successful.

`sigpause()` — Unblock a signal and wait for a signal

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <signal.h>

int sigpause(int sig);
```

General description

The `sigpause()` function provides a simplified method for removing a signal, specified by the argument *sig*, from the calling thread's signal mask and suspending this thread until a signal is received whose action is either to execute a signal catcher function or to terminate the process.

Usage notes

The use of the `SIGTHSTOP` and `SIGTHCONT` signal is not supported with this function.

Returned value

If successful, `sigpause()` returns -1 and sets `errno` to `EINTR`.

If unsuccessful, `sigpause()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

The value of the argument *sig* is not a valid signal type or it is `SIGKILL`, or `SIGTRACE`.

Related information

- [“signal.h — Exception handling” on page 58](#)
- [“pause\(\) — Suspend a process pending a signal” on page 1182](#)

sigpending() — Examine pending signals

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <signal.h>

int sigpending(sigset_t *set);
```

General description

Returns the union of the set of signals that are blocked from delivery and pending for the calling thread and the set that are pending for the process. If there is only one thread, it does the same for the calling

process. This information is represented as a signal set stored in *set*. For more information on examining the signal set pointed to by *set*, see [“sigismember\(\) — Test if a signal is in a signal mask”](#) on page 1631.

Usage notes

The use of the SIGTHSTOP and SIGTHCONT signal is not supported with this function.

Returned value

If successful, sigpending() returns 0.

If unsuccessful, sigpending() returns -1.

There are no documented errno values.

Example

CELEBS22

```
/* CELEBS22

   This example returns blocked or pending signals.

*/
#define _POSIX_SOURCE
#include <signal.h>
#include <stdio.h>
#include <unistd.h>

void catcher(int signum) {
    puts("inside catcher!");
}

void check_pending(int signum, char *signame) {
    sigset_t sigset;

    if (sigpending(&sigset) != 0)
        perror("sigpending() error");
    else if (sigismember(&sigset, signum))
        printf("a %s signal is pending\n", signame);
    else
        printf("no %s signals are pending\n", signame);
}

main() {
    struct sigaction sigact;
    sigset_t sigset;

    sigemptyset(&sigact.sa_mask);
    sigact.sa_flags = 0;
    sigact.sa_handler = catcher;
    if (sigaction(SIGUSR1, &sigact, NULL) != 0)
        perror("sigaction() error");
    else {
        sigemptyset(&sigset);
        sigaddset(&sigset, SIGUSR1);
        if (sigprocmask(SIG_SETMASK, &sigset, NULL) != 0)
            perror("sigprocmask() error");
        else {
            puts("SIGUSR1 signals are now blocked");
            kill(getpid(), SIGUSR1);
            printf("after kill: ");
            check_pending(SIGUSR1, "SIGUSR1");
            sigemptyset(&sigset);
            sigprocmask(SIG_SETMASK, &sigset, NULL);
            puts("SIGUSR1 signals are no longer blocked");
            check_pending(SIGUSR1, "SIGUSR1");
        }
    }
}
```

Output

```
SIGUSR1 signals are now blocked
after kill: a SIGUSR1 signal is pending
inside catcher!
SIGUSR1 signals are no longer blocked
no SIGUSR1 signals are pending
```

sigprocmask() — Examine or change a thread

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <signal.h>

int sigprocmask(int option, const sigset_t *__restrict__ new_set,
                sigset_t *__restrict__ old_set);
```

General description

Examines, changes, or examines and changes the signal mask of the calling thread. If there is only one thread, it does the same for the calling process.

Typically, `sigprocmask(SIG_BLOCK, ..., ...)` is used to block signals during a critical section of code. At the end of the critical section of code, `sigprocmask(SIG_SETMASK, ..., ...)` is used to restore the mask to the previous value returned by `sigprocmask(SIG_BLOCK, ..., ...)`.

option

Indicates the way in which the existing set of blocked signals should be changed. The following are the possible values for *option*, defined in the `signal.h` header file:

SIG_BLOCK

Indicates that the set of signals given by *new_set* should be blocked, in addition to the set currently being blocked.

SIG_UNBLOCK

Indicates that the set of signals given by *new_set* should not be blocked. These signals are removed from the current set of signals being blocked.

SIG_SETMASK

Indicates that the set of signals given by *new_set* should replace the old set of signals being blocked.

new_set

Points to a signal set giving the new signals that should be blocked or unblocked (depending on the value of *option*) or it points to the new signal mask if the option was *sig_setmask*. Signal sets are

described in “sigemptyset() — Initialize a signal mask to exclude all signals” on page 1626. If *new_set* is a NULL pointer, the set of blocked signals is not changed. sigprocmask() determines the current set and returns this information in **old_set*. If *new_set* is NULL, the value of *option* is not significant.

The signal set manipulation functions: sigemptyset(), sigfillset(), sigaddset(), and sigdelset() must be used to establish the new signal set pointed to by *new_set*.

old_set

Points to a memory location where sigprocmask() can store a signal set. If *new_set* is NULL, *old_set* returns the current set of signals being blocked. When *new_set* is not NULL, the set of signals pointed to by *old_set* is the previous set.

If there are any pending unblocked signals, either at the process level or at the current thread's level after sigprocmask() has changed the signal mask, then at least one of those signals is delivered to the thread before sigprocmask() returns.

The signals SIGKILL, SIGSTOP, or SIGTRACE cannot be blocked. If you attempt to use sigprocmask() to block these signals, the attempt is simply ignored. sigprocmask() does not return an error status.

SIGFPE, SIGILL, and SIGSEGV signals that are not artificially generated by kill(), killpg(), raise(), sigqueue(), or pthread_kill() (that is, were generated by the system as a result of a hardware or software exception) will not be blocked.

If an artificially raised SIGFPE, SIGILL, or SIGSEGV signal is pending and blocked when an exception causes another SIGFPE, SIGILL, or SIGSEGV signal, both the artificial and exception-caused signals may be delivered to the application.

If sigprocmask() fails, the signal mask of the thread is not changed.

Usage notes

The use of the SIGTHSTOP and SIGTHCONT signal is not supported with this function.

Returned value

If successful, sigprocmask() returns 0.

If unsuccessful, sigprocmask() returns -1 and sets errno to one of the following values:

Error Code**Description****EINVAL**

option does not have one of the recognized values.

Example**CELEBS23**

```
/* CELEBS23
   This example changes the signal mask.
*/
#define _POSIX_SOURCE
#include <signal.h>
#include <stdio.h>
#include <time.h>
#include <unistd.h>

void catcher(int signum) {
    puts("inside catcher");
}

main() {
    time_t start, finish;
    struct sigaction sact;
    sigset_t new_set, old_set;
    double diff;
```

```

sigemptyset(&sact.sa_mask);
sact.sa_flags = 0;
sact.sa_handler = catcher;
if (sigaction(SIGALRM, &sact, NULL) != 0)
    perror("sigaction() error");
else {
    sigemptyset(&new_set);
    sigaddset(&new_set, SIGALRM);
    if (sigprocmask(SIG_BLOCK, &new_set, &old_set) != 0)
        perror("1st sigprocmask() error");
    else {
        time(&start);
        printf("SIGALRM signals blocked at %s", ctime(&start));
        alarm(1);

        do {
            time(&finish);
            diff = difftime(finish, start);
        } while (diff < 10);
        if (sigprocmask(SIG_SETMASK, &old_set, NULL) != 0)
            perror("2nd sigprocmask() error");
        else
            printf("SIGALRM signals unblocked at %s", ctime(&finish));
    }
}
}

```

Output

```

SIGALRM signals blocked at Fri Jun 16 12:24:19 2006
inside catcher
SIGALRM signals unblocked at Fri Jun 16 12:24:29 2006

```

sigqueue() – Queue a signal to a process

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 | both | OS/390 V2R9 |

Format

```
#define _XOPEN_SOURCE 500
#include <sys/types.h>
#include <signal.h>

int sigqueue(pid_t pid, int signo, const union sigval value);
```

General description

Causes the signal specified by *signo* to be sent with the value specified by *value* to the process specified by *pid*. If *signo* is zero (the null signal), error checking is performed but no signal is actually sent. The null signal can be used to check the validity of *pid*. The conditions required for a process to have permission to queue a signal to another process are the same as for the `kill()` function.

The `sigqueue()` function returns immediately. If the resources were available to queue the signal, the signal is queued and sent to the receiving process. The fact that `SA_SIGINFO` is not set for *signo* does not effect this processing and queueing of the signal.

If the value of *pid* causes *signo* to be generated for the sending process, and if *signo* is not blocked for the calling thread and if no other thread has *signo* unblocked or is waiting in a `sigwait()` function for *signo*, either *signo* or at least the pending, unblocked signal will be delivered to the calling thread before `sigqueue()` returns.

Usage notes

The use of the `SIGTHSTOP` and `SIGTHCONT` signal is not supported with this function.

Since in AMODE 64 programs, `sigval` is 64 bits long, and in AMODE 31 programs `sigval` is only 32 bits long, when passing signal data between an AMODE 31 and AMODE 64 process, there are the following restrictions:

- In AMODE 64, the `sival_int` field covers only the first 4 bytes of the `sigval` field -- only the `sival_ptr` field can access all 8 bytes of the `sigval` field.
- When an AMODE 64 program passes a `sival_ptr` value to an AMODE 31 program, the AMODE 31 program receives only the low 32 bits of the original `sival_ptr`.
- When an AMODE 31 program passes a `sival_ptr` value to an AMODE 64 program, the original `sival_ptr` value is received in the low 32 bits of the AMODE 64 `sival_ptr`.
- When an AMODE 64 program tries to pass a value to an AMODE 31 program using the `sival_int` field, the AMODE 31 program will receive 0 in `sigval`.
- When an AMODE 31 program sends a value to an AMODE 64 program using `sival_int`, the AMODE 64 program will receive a 0 value in `sival_int`, but it can access the original value as the low 32 bits of the AMODE 64 `sival_ptr` field.

Returned value

If successful, `sigqueue()` returns 0.

If unsuccessful, `sigqueue()` returns -1 and sets `errno` to one of the following values:

Error Code
Description

EAGAIN
No resources available to queue the signal or the system-wide resource limit, defined by `MAXQUEUEDSIGS`, has been exceeded.

EINVAL
The value of the *signo* argument is an invalid or unsupported signal number.

EPERM
The process does not have the appropriate privilege to send the signal to the receiving process.

ESRCH
The process *pid* does not exist.

sigrelse() — Remove a signal from a thread

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <signal.h>

int sigrelse(int sig);
```

General description

The `sigrelse()` function provides a simplified method for removing the signal specified by the argument *sig* from the calling thread's signal mask.

Usage notes

The use of the `SIGTHSTOP` and `SIGTHCONT` signal is not supported with this function.

Returned value

If successful, `sigrelse()` returns 0.

If unsuccessful, `sigrelse()` returns -1 and sets `errno` to one of the following values:

Error Code
Description

EINVAL
The value of the argument *sig* is not a valid signal type or it is `SIGKILL`, `SIGSTOP`, or `SIGTRACE`.

sigset() — Change a signal action or a thread

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <signal.h>

void (*sigset(int sig, void (*disp)(int)))(int);
```

General description

The `sigset()` function provides a simplified method for changing the action associated with a specific signal and unblock the signal, or to block this signal.

sig

The number of a recognized signal. `sigset()` sets the action associated with this signal and unblock this signal, or adds this signal to the calling thread's signal mask (thus blocking this signal). Refer to [Table 57 on page 1606](#) for a list of the supported values of *sig*.

The value of *sig* can be any valid signal type except SIGKILL, SIGSTOP, or SIGTRACE.

disp

There are four possible value that *disp* can have. Three are actions that can be associated with the signal, *sig*: SIG_DFL, SIG_IGN, or a pointer to a function. The fourth value is not a signal action, but a flag to `sigset()` that affects whether the signal action is changed.

The values that *disp* is permitted to have are:

SIG_DFL

Set the signal action to the signal-specific default.

- The default actions for each signal is shown in [Table 57 on page 1606](#).
- If *disp* is set to SIG_DFL, `sigset()` will change the signal action associated with *sig* and remove this signal from the calling thread's signal mask (thus unblocking this signal).
- If the default action is to stop the process, the execution of that process is temporarily suspended. When a process stops, a SIGCHLD signal will be generated for its parent process, unless the parent process has set the **SA_NOCLDSTOP** flag. While a process is stopped, any additional signals that are sent to the process will not be delivered until the process is continued, except SIGKILL which always terminates the receiving process. A process that is a member of an orphaned process group will not be allowed to stop in response to the SIGTSTP, SIGTTIN, or SIGTTOU signals. In cases where delivery of one of these signals would stop such a process, the signal will be discarded.

- Setting a signal action to SIG_DFL for a signal that is pending, and whose default action is to ignore the signal (for example SIGCHLD), will cause the pending signal to be discarded.

SIG_IGN

Set the signal action to ignore the signal.

- Delivery of the signal will have no effect on the process.
- If *disp* is set to SIG_IGN, sigset() will change the signal action associated with *sig* and remove this signal from the calling thread's signal mask (thus unblocking this signal).
- Setting a signal action to SIG_IGN for a signal that is pending will cause the pending signal to be discarded. This provides the ability to discard signals that are found to be blocked and pending by sigpending().
- If *sig* is SIGCHLD, child processes of the calling process will not be transformed into 'zombie' processes when they terminate. If the calling process subsequently waits for its children, and the process has no unwaited from children that were transformed into 'zombie' processes, it will block until all of its children terminate. The wait(), waitid(), or waitpid() function will fail and set errno to **ECHILD**.

SIG_HOLD

Set the calling thread's signal mask to block signal, *sig*.

- The signal action associated with *sig* is not changed.

Pointer to function

Set the signal action to catch the signal.

- sigset() will change the signal action associated with *sig* and remove this signal from the calling thread's signal mask (thus unblocking this signal).
- On delivery of the signal, the receiving process is to execute the signal-catching function at the specified address. After returning from the signal-catching function, the receiving process will resume execution at the point at which it was interrupted.
- The signal-catching function specified by *disp* is invoked as:

```
void function(int signo);
```

Where *function* is the specified signal-catching function and *signo* is the signal number of the signal being delivered.

After an action has been specified for a particular signal, using sigset(), it remains installed until it is explicitly changed with another call to sigset(), sigaction(), signal(), one of the exec functions, bsd_signal(), or sigignore().

Special behavior for C++:

- The behavior when mixing signal-handling with C++ exception handling is undefined. Also, the use of signal-handling with constructors and destructors is undefined.
- C++ and C language linkage conventions are incompatible, and therefore sigaction() cannot receive C++ function pointers. If you attempt to pass a C++ function pointer to sigaction(), the compiler will flag it as an error. Therefore, to use the sigaction() function in the C++ language, you must ensure that signal handler routines established have C linkage, by declaring them as `extern "C"`.

Usage notes

The use of the SIGTHSTOP and SIGTHCONT signal is not supported with this function.

Returned value

If successful, sigset() returns SIG_HOLD if the signal had been blocked and the signal's previous action if it had not been blocked.

If unsuccessful, sigset() returns SIG_ERR and sets errno to one of the following values:

Error Code
Description

EINVAL
The value of the argument *sig* was not a valid signal type, or it was SIGKILL, SIGSTOP, or SIGTRACE.

sigsetjmp() — Save stack environment and signal mask

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <setjmp.h>

int sigsetjmp(sigjmp_buf env, int savemask);
```

General description

Saves the current stack environment including, optionally, the current signal mask. The stack environment and signal mask saved by sigsetjmp() can subsequently be restored by siglongjmp().

env is an address for a sigjmp_buf structure. *savemask* is a flag used to determine if the signal mask is to be saved. If it has a value of 0, the current signal mask is not to be saved or restored as part of the environment. Any other value means the current signal mask is saved and restored.

sigsetjmp() is similar to setjmp() and _setjmp(), except for the optional capability of saving the signal mask. Like setjmp() and longjmp(), the sigsetjmp() and siglongjmp() functions provide a way to perform a nonlocal goto.

The sigsetjmp()—siglongjmp() pair, the setjmp()—longjmp() pair, the _setjmp()—_longjmp() pair and the getcontext()—setcontext() pair cannot be intermixed. A stack environment and signal mask saved by sigsetjmp() can be restored only by siglongjmp().

A call to sigsetjmp() causes it to save the current stack environment in *env*. If the value of the *savemask* parameter is nonzero, it will also save the current signal mask in *env*. A subsequent call to siglongjmp() restores the saved environment and signal mask (if saved by sigsetjmp()), and returns control to a point corresponding to the sigsetjmp() call. The values of all variables (except register variables) accessible to the function receiving control contain the values they had when siglongjmp() was called. The values of register variables are unpredictable. Nonvolatile auto variables that are changed between calls to sigsetjmp() and siglongjmp() are also unpredictable.

Note: Ensure that the function that calls `sigsetjmp()` does not return before you call the corresponding `siglongjmp()` function. Calling `siglongjmp()` after the function calling `sigsetjmp()` returns causes unpredictable program behavior.

Special behavior for C++: If `sigsetjmp()` and `siglongjmp()` are used to transfer control, the behavior is undefined whether the destruction of automatic C++ objects is done. The use of `sigsetjmp()` and `siglongjmp()` in conjunction with `try()`, `catch()`, and `throw()` is also undefined.

Special behavior for XPLINK-compiled C++: Restrictions concerning `setjmp.h` and `ucontext.h`:

1. All XPLINK programs compiled with the V2R10 or later C compilers that are to run with Language Environment V2R10 or later libraries and use the **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** types must not be compiled with C headers from Language Environment V2R9 or earlier.
2. Non-XPLINK functions compiled with any level of Language Environment headers must not define **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** data items and pass them to XPLINK functions that call `getcontext()`, `longjmp()`, `_longjmp()`, `setjmp()`, `_setjmp()`, `setcontext()`, `sigsetjmp()`, or `swapcontext()` with these passed-in data items.
3. When `__XPLINK__` is defined, the Language Environment V2R10 and later headers define a larger **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** area that is required by `setjmp()`, `getcontext()`, and related functions when they are called from an XPLINK routine. If `__XPLINK__` is not defined, the Language Environment V2R10 and later headers define a shorter **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** area. The Language Environment headers before V2R10 also define the shorter version of these data areas. If an XPLINK function calls `setjmp()`, `getcontext()` or similar functions with a short **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** area, a storage overlay or program check may occur when the C library tries to store past the end of the passed-in (too short) data area.

Returned value

`sigsetjmp()` returns 0 when it is invoked to save the stack environment and signal mask.

`sigsetjmp()` returns the value *val*, specified on `siglongjmp()` (or 1 if the value of *val* is zero), when `siglongjmp()` causes control to be transferred to the place in the user's program where `sigsetjmp()` was issued.

There are no documented `errno` values.

Example

The following saves the stack environment and signal mask at the statement:

```
if(sigsetjmp(mark,1) != 0) ...
```

When the system first performs the `if` statement, it saves the environment and signal mask in *mark* and sets the condition to false because `sigsetjmp()` returns 0 when it saves the environment. The program prints the message:

```
sigsetjmp() has been called
```

The subsequent call to function `p()` tests for a local error condition, which can cause it to perform `siglongjmp()`. Then control returns to the original `sigsetjmp()` function using the environment saved in *mark* and the restored signal mask. This time the condition is true because -1 is the return value from `siglongjmp()`. The program then performs the statements in the block and prints:

```
siglongjmp() has been called
```

Then the program performs the `sample_recover()` function and exits.

```
#define _POSIX_SOURCE
#include <stdio.h>
#include <setjmp.h>

sigjmp_buf mark;
```

```
void p(void);
void recover(void);

int main(void)
{
    if (sigsetjmp(mark,1) != 0) {
        printf("siglongjmp() has been called\n");
        recover();
        exit(1);
    }
    printf("sigsetjmp() has been called\n");
    :
    p();
    :
    :
}

void p(void)
{
    int error = 0;
    :
    error = 9;
    :
    if (error != 0)
        siglongjmp(mark, -1);
    :
    :
}

void recover(void)
{
    :
    :
}
```

sigstack() – Set or get signal stack context

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | POSIX(ON) |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <signal.h>

int sigstack(struct sigstack *ss, struct sigstack *oss);
```

General description

The `sigstack()` function allows the calling thread to indicate, to the system, an area of its address space to be used for processing signals received by this thread.

Note: To explicitly declare that a signal catcher is to run on the alternate signal stack, the `SA_ONSTACK` flag must be set in the `sa_flags` when the signal action is set using `sigaction()`.

If the `ss` argument is not a NULL pointer, it must point to a `sigstack` structure. The length of the application-supplied stack must be at least `SIGSTKSZ` bytes. If the alternate signal stack overflows, the resulting behavior is undefined.

- The value of the `ss_onstack` member indicates whether the thread wants the system to use an alternate signal stack when delivering signals.
- The value of the `ss_sp` member indicates the desired location of the alternate signal stack area in the process's address space.

AMODE 64: Storage for this stack must be above the 2GB bar. It may not be storage acquired with the `__malloc24()` or `__malloc31()` functions.

- If the `ss` argument is a NULL pointer, the current alternate signal stack context is not changed.

If the `oss` argument is not a NULL pointer, it must point to a `sigstack` structure into which the current alternate signal stack context is placed. The value stored in the `ss_onstack` member of this `sigstack` structure will be nonzero if the thread is currently executing on the alternate signal stack. If the `oss` argument is a NULL pointer, the current alternate signal stack context is not returned.

When a signal's action indicates its handler should execute on the alternate signal stack (specified by calling `sigaction()`), the implementation checks to see if the thread is currently executing on the alternate signal stack. If it is not, the system will switch to the alternate signal stack for the duration of the signal handler's execution.

After a successful call to one of the `exec` functions, there are no alternate signal stacks in the new process image.

Notes:

1. If a signal handler is enabled to run on an alternate stack, then all functions called by that signal handler must be compiled with the same linkage. For example, if the signal handler is compiled with `XPLINK`, then all functions it calls must also be compiled `XPLINK`. Since only one alternate stack can be supplied, no mixing of linkages (which would require both upward and downward-growing alternate stacks) is allowed. The type of stack created will be based on the attributes of the signal handler to be given control. If the signal handler has been compiled with `XPLINK`, then a downward-growing stack will be created in the alternate stack, including, in `AMODE 31`, using enough storage in the user stack to create a 4k read-only guard page (aligned on a 4k boundary).
2. If a new signal is received while a signal handler is running on an alternate stack, and that new signal specified a signal handler that also runs on the alternate stack, then both signal handlers must have been compiled with the same linkage (`XPLINK` versus non-`XPLINK`).
3. This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. New applications should use `sigaltstack()` instead of `sigstack()`.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

If successful, `sigstack()` returns 0.

If unsuccessful, `sigstack()` returns -1 and sets `errno` to one of the following values:

Error Code
Description

EPERM
An attempt was made to modify an active stack.

sigsuspend() — Change mask and suspend the thread

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _POSIX_SOURCE
#include <signal.h>

int sigsuspend(const sigset_t *mask);
```

General description

Replaces the current signal mask of a thread with the signal set given by **mask* and then suspends execution of the calling thread. The thread does not resume running until a signal is delivered whose action is either to execute a signal-handling function or to end the process. (Signal sets are described in more detail in [“sigemptyset\(\) — Initialize a signal mask to exclude all signals” on page 1626.](#))

The signal mask indicates a set of signals that should be blocked. Such signals do not “wake up” the suspended function. The signals SIGKILL, SIGSTOP, or SIGTRACE cannot be blocked or ignored; they are delivered to the thread no matter what the *mask* argument specifies.

If an incoming unblocked signal ends the thread, sigsuspend() never returns to the caller. If an incoming signal is handled by a signal-handling function, sigsuspend() returns after the signal-handling function returns. The signal mask of the thread is restored to whatever it was before sigsuspend() was called, unless the signal-handling functions explicitly changed the mask.

This function is supported only in a POSIX program.

Usage notes

The use of the SIGTHSTOP and SIGTHCONT signal is not supported with this function.

Returned value

If sigsuspend() returns, it always returns -1.

If unsuccessful, sigsuspend() sets errno to one of the following values:

Error Code

Description

EINTR

A signal was received and handled successfully.

Example

CELEBS25

```

/* CELEBS25

   This example replaces the signal mask and then suspends execution.

*/
#define _POSIX_SOURCE
#include <stdio.h>
#include <signal.h>
#include <time.h>
#include <unistd.h>

void catcher(int signum) {
    switch (signum) {
        case SIGUSR1: puts("catcher caught SIGUSR1");
                     break;
        case SIGUSR2: puts("catcher caught SIGUSR2");
                     break;
        default:      printf("catcher caught unexpected signal %d\n",
                           signum);
    }
}

main() {
    sigset_t sigset;
    struct sigaction sact;
    time_t t;

    if (fork() == 0) {
        sleep(10);
        puts("child is sending SIGUSR2 signal - which should be blocked");
        kill(getppid(), SIGUSR2);
        sleep(5);
        puts("child is sending SIGUSR1 signal - which should be caught");
        kill(getppid(), SIGUSR1);
        exit(0);
    }

    sigemptyset(&sact.sa_mask);
    sact.sa_flags = 0;
    sact.sa_handler = catcher;
    if (sigaction(SIGUSR1, &sact, NULL) != 0)
        perror("1st sigaction() error");

    else if (sigaction(SIGUSR2, &sact, NULL) != 0)
        perror("2nd sigaction() error");

    else {
        sigfillset(&sigset);
        sigdelset(&sigset, SIGUSR1);
        time(&t);
        printf("parent is waiting for child to send SIGUSR1 at %s",
               ctime(&t));
        if (sigsuspend(&sigset) == -1)
            perror("sigsuspend() returned -1 as expected");
        time(&t);
        printf("sigsuspend is over at %s", ctime(&t));
    }
}

```

Output

```

parent is waiting for child to send SIGUSR1 at Fri Jun 16 12:30:57 2006
child is sending SIGUSR2 signal - which should be blocked
child is sending SIGUSR1 signal - which should be caught
catcher caught SIGUSR2
catcher caught SIGUSR1

```

```
sigsuspend() returned -1 as expected: Interrupted function call
sigsuspend is over at Fri Jun 16 12:31:12 2006
```

sigtimedwait() — Wait for queued signals

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 | both | OS/390 V2R7 |

Format

```
#define _XOPEN_SOURCE 500
#include <signal.h>

int sigtimedwait(const sigset_t *set, siginfo_t *info
                 const struct timespec *timeout);
```

General description

The `sigtimedwait()` function selects a pending signal from the `sigset_t` object (signal set) pointed to by `set`, automatically clearing it from the system's set of pending signals, and returning that signal number. If there are multiple pending signals, the lowest numbered signal will be selected.

If no signal in the signal set is pending at the time of the call to `sigtimedwait()`, the thread is suspended until one or more of the signals specified in the signal set become pending or until it is interrupted by an unblocked, caught signal. The signals defined in the `sigset_t` object (signal set) pointed to by `set` may

be unblocked during the call to this routine and will be blocked when the thread returns from the call unless some other thread is currently waiting for one of those signals.

If more than one thread is using sigtimedwait() to wait for the same signal, only one of these threads will return from this routine with the signal number, until a second signal of the same type is received.

The function sigtimedwait() behaves the same as the sigwait() function if the *info* argument is NULL. If the *info* argument is not NULL, then in addition to behaving the same as sigwait(), sigtimedwait() places the selected signal number in the *si_signo* member, places the cause of the signal in the *si_code* member, and, if any value is queued to the selected signal, sigtimedwait() will place it in the *si_value* member of *info*. However, if there is no value queued for the selected signal then the content of *si_value* is undefined.

If the sigtimedwait() function finds that none of the signals specified by *set* are pending, it waits for the time interval specified in the *timespec* structure referenced by *timeout*. If the *timespec* structure pointed to by *timeout* is zero-valued and if none of the signals specified by *set* are pending, then sigtimedwait() returns immediately with an error. A *timespec* with the *tv_sec* field set with *INT_MAX*, as defined in <limits.h>, will cause the sigtimedwait() service to wait until a signal is received. If *timeout* is the NULL pointer, the behavior is not necessarily the same on all platforms but for this platform it will be treated the same as when *timespec* structure was supplied with the *tv_sec* field set with *INT_MAX*.

Usage notes

The use of the SIGTHSTOP and SIGTHCONT signal is not supported with this function.

Returned value

If successful, sigtimedwait() returns the signal number.

If unsuccessful, sigtimedwait() returns -1 and sets *errno* to one of the following values:

Error Code

Description

EAGAIN

No signal specified by *set* was generated within the specified time out period.

EINTR

The wait was interrupted by an unblocked, caught signal. No further waiting will occur for this call. sigtimedwait() can be reissued to begin waiting again.

EINVAL

set points to a **sigset_t** that contains a signal number that is either not valid or not supported.

sigwait() — Wait for an asynchronous signal

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 Single UNIX Specification, Version 3 | both | |

Format

```
#define _OPEN_THREADS
#include <signal.h>

int sigwait(sigset_t *set);
```

SUSV3:

```
#define _POSIX_C_SOURCE 200112L
#include <signal.h>
int sigwait(const sigset_t *__restrict__ set, int *__restrict__ sig);
```

General description

Causes a thread to wait for an asynchronous signal by choosing a pending signal from *set*, automatically clearing it from the system's set of pending signals, and returning that signal number in the return code.

If no signal in *set* is pending at the time of the call, the thread is suspended until one or more of the signals in *set* become pending. The signals defined by *set* may be unblocked during the call to this routine, and will be blocked when the thread returns from the call unless some other thread is currently waiting for one of those signals.

If more than one thread is using this routine to wait for the same signal, only one of these threads will return from this routine with the signal number.

Special behavior for SUSV3: The `sigwait()` function selects a pending signal from *set*, atomically clear it from the system's set of pending signals, and return that signal number in the location referenced by *sig*.

| Argument | Description |
|------------|--|
| <i>sig</i> | location reference where the signal number is stored |

Usage notes

The use of the `SIGTHSTOP` and `SIGTHCONT` signal is not supported with this function.

Returned value

If successful, `sigwait()` returns the signal number.

If unsuccessful, `sigwait()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

The *set* argument contains an invalid or unsupported signal number.

Special behavior for SUSV3: Upon successful completion, `sigwait()` stores the signal number of the received signal at the location referenced by `sig` and return 0. Otherwise, an error number is returned to indicate the error.

Example

CELEBS26

```
/* CELEBS26 */
#define _OPEN_THREADS

#include <stdio.h>
#include <errno.h>
#include <signal.h>
#include <pthread.h>
#include <unistd.h>

void          *threadfunc(void *parm)
{
    int          threadnum;
    int          *tnum;
    sigset_t      set;

    tnum = parm;
    threadnum = *tnum;

    printf("Thread %d executing\n", threadnum);
    sigemptyset(&set);
    if(sigaddset(&set, SIGUSR1) == -1) {
        perror("Sigaddset error");
        pthread_exit((void *)1);
    }

    if(sigwait(&set) != SIGUSR1) {
        perror("Sigwait error");
        pthread_exit((void *)2);
    }

    pthread_exit((void *)0);
}

main() {
    int          status;
    int          threadparm = 1;
    pthread_t      threadid;
    int          thread_stat;

    status = pthread_create( &threadid, NULL,
                            threadfunc,
                            (void *)&threadparm);

    if ( status < 0 ) {
        perror("pthread_create failed");
        exit(1);
    }

    sleep(5);

    status = pthread_kill( threadid, SIGUSR1);
    if ( status < 0 )
        perror("pthread_kill failed");

    status = pthread_join( threadid, (void *)&thread_stat);
    if ( status < 0 )
        perror("pthread_join failed");

    exit(0);
}
```

CELEBP73

```
/* CELEBS73

This example demonstrates the use of the sigwait() function.
The program will wait until a SIGINT signal is received from the
command line.
```

```
Expected output:
SIGINT was received

*/

#define _POSIX_C_SOURCE 200112L
#include <signal.h>
#include <stdio.h>
#include <errno.h>

void main() {
    sigset_t set;
    int sig;
    int *sigptr = &sig;
    int ret_val;
    sigemptyset(&set);
    sigaddset(&set, SIGINT);
    sigprocmask( SIG_BLOCK, &set, NULL );

    printf("Waiting for a SIGINT signal\n");

    ret_val = sigwait(&set,sigptr);
    if(ret_val == -1)
        perror("sigwait failed\n");
    else {
        if(*sigptr == 2)
            printf("SIGINT was received\n");
        else
            printf("sigwait returned with sig: %d\n", *sigptr);
    }
}

sigwaitinfo() — Wait for queued signals

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 | both | OS/390 V2R7 |

Format

```
#define _XOPEN_SOURCE 500
#include <signal.h>

int sigwaitinfo(const sigset_t *set, siginfo_t *info);
```

General description

The `sigwaitinfo()` function selects a pending signal from the `sigset_t` object (signal set) pointed to by *set*, automatically clearing it from the system's set of pending signals, and returning that signal number. If there are multiple pending signals, the lowest numbered signal will be selected.

If no signal in the signal set is pending at the time of the call to `sigwaitinfo()`, the thread is suspended until one or more of the signals specified in the signal set become pending or until it is interrupted by an unblocked, caught signal. The signals defined in the `sigset_t` object (signal set) pointed to by *set* may be unblocked during the call to this routine and will be blocked when the thread returns from the call unless some other thread is currently waiting for one of those signals.

If more than one thread is using `sigwaitinfo()` to wait for the same signal, only one of these threads will return from this routine with the signal number, until a second signal of the same type is received.

The function `sigwaitinfo()` behaves the same as the `sigwait()` function if the *info* argument is `NULL`. If the *info* argument is not `NULL`, then in addition to behaving the same as `sigwait()`, `sigwaitinfo()` places the selected signal number in the `si_signo` member, places the cause of the signal in the `si_code` member, and, if any value is queued to the selected signal, `sigwaitinfo()` will place it in the `si_value` member of *info*. However, if there is no value queued for the selected signal then the content of *si_value* is undefined.

Usage notes

The use of the `SIGTSTOPS` and `SIGTCONT` signal is not supported with this function.

Returned value

If successful, `sigwaitinfo()` returns the signal number.

If unsuccessful, `sigwaitinfo()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINTR

The wait was interrupted by an unblocked, caught signal. No further waiting will occur for this call. `sigwaitinfo()` can be reissued to begin waiting again.

EINVAL

set points to a `sigset_t` that contains a signal number that is either not valid or not supported.

sin(), sinf(), sinl() – Calculate sine

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#include <math.h>

double sin(double x);
float sin(float x);           /* C++ only */
long double sin(long double x); /* C++ only */
float sinf(float x);
long double sinl(long double x);
```

General description

Calculates the sine of x, with x expressed in radians.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

Returned value

If successful, the function returns the calculated value, expressed as a double, float, or long double. Otherwise, if the result is an underflow, the function returns 0 and sets the errno to ERANGE.

Special Behavior for XPG4.2: The following error is added:

Error Code

Description

EDOM

The argument exceeded an internal limit for the function (approximately 2⁵⁰).

Example

CELEBS27

```
/* CELEBS27

   This example computes y as the sine of &pi.&slr.2.

*/
#include <math.h>
#include <stdio.h>

int main(void)
{
    double pi, x, y;

    pi = 3.1415926535;
    x = pi/2;
    y = sin(x);
```

```
printf("sin( %lf ) = %lf\n", x, y);
}
```

Output

```
sin( 1.570796 ) = 1.000000
```

sind32(), sind64(), sind128() — Calculate sine

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 sind32(_Decimal32 x);
_Decimal64 sind64(_Decimal64 x);
_Decimal128 sind128(_Decimal128 x);
_Decimal32 sin(_Decimal32 x); /* C++ only */
_Decimal64 sin(_Decimal64 x); /* C++ only */
_Decimal128 sin(_Decimal128 x); /* C++ only */
```

General description

Calculates the sine of x, with x expressed in radians.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, the function returns the calculated value, expressed as a _Decimal32, _Decimal64, or _Decimal128.

If x is outside prescribed limits, the value is not calculated. Instead, the function returns 0 and sets errno to EDOM.

Example

```
/* CELEBS69

   This example illustrates the sind32() function.
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal32 pi, x, y;

    pi = 3.141593DF;
    x = pi/2.0DF;
    y = sind32(x);

    printf("sind32(%Hf) = %Hf\n", x, y);
}
```

Related information

sinh(), sinhf(), sinhl() — Calculate hyperbolic sine

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#include <math.h>

double sinh(double x);
float sinh(float x);
long double sinh(long double x);
float sinhf(float x);
long double sinhl(long double x);

/* C++ only */
/* C++ only */
```

General description

Calculates the hyperbolic sine of x , with x expressed in radians.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

Returned value

If successful, the function returns the calculated value.

Otherwise, if the result is too large, the function sets `errno` to `ERANGE` and returns $\pm\text{HUGE_VAL}$, depending on the value of x . If the value underflows, the function returns 0 and sets `errno` to `ERANGE`.

Special behavior for IEEE: If successful, the function returns the hyperbolic sine of x with x expressed in radians.

If the result would overflow, the function returns $\pm\text{HUGE_VAL}$, according to the value of x , and sets `errno` to `ERANGE`. No other errors can occur.

Example

CELEBS28

```
/* CELEBS28
   This example computes y as the hyperbolic sine of &pi.&slr.2.
*/
#include <math.h>
#include <stdio.h>

int main(void)
{
    double pi, x, y;

    pi = 3.1415926535;
    x = pi/2;
    y = sinh(x);

    printf("sinh( %lf ) = %lf\n", x, y);
}
```

Output

```
sinh( 1.570796 ) = 2.301299
```

sinhd32(), sinhd64(), sinhd128() - Calculate hyperbolic sine

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.10 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 sinhd32(_Decimal32 x);
_Decimal64 sinhd64(_Decimal64 x);
_Decimal128 sinhd128(_Decimal128 x);
_Decimal32 sinh(_Decimal32 x);    /* C++ only */
_Decimal64 sinh(_Decimal64 x);    /* C++ only */
_Decimal128 sinh(_Decimal128 x);  /* C++ only */
```

General description

Calculates the hyperbolic sine of x , with x expressed in radians.

These functions work in IEEE decimal floating-point format. See [“IEEE decimal floating-point” on page 97](#) for more information.

Note: To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

If successful, the function returns the hyperbolic sine of x with x expressed in radians.

If the result would overflow, the function returns $\pm\text{HUGE_VAL_D32}$, $\pm\text{HUGE_VAL_D64}$, or $\pm\text{HUGE_VAL_D128}$ according to the value of x , and sets `errno` to `ERANGE`. No other errors can occur.

Example

CELEBS75

```
/* CELEBS75

   This example illustrates the sinhd64() function.

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal64 pi, x, y;

    pi = 3.1415926535DD;
    x = pi/2.0DD;
    y = sinhd64(x);

    printf("sinhd64( %Df ) = %Df\n", x, y);
}

__sinpid32(), __sinpid64(), __sinpid128() — Calculate sine of $\pi * x$

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 __sinpid32(_Decimal32 x);
_Decimal64 __sinpid64(_Decimal64 x);
_Decimal128 __sinpid128(_Decimal128 x);
```

General description

Calculates the sine of $\pi * x$, with x expressed in radians.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, the function returns the calculated value, expressed as a `_Decimal32`, `_Decimal64`, or `_Decimal128` number.

If x is outside prescribed limits, the value is not calculated. Instead, the function returns 0 and sets `errno` to `EDOM`.

Example

```
/* CELEBS70
   This example illustrates the __sinpid64() function.
```

```
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal64 x, y;

    x = 0.5DD;
    y = __sinpid64(x);

    printf("__sinpid64(%Df) = %Df\n", x, y);
}
```

Related information

sleep() — Suspend execution of a thread

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

unsigned int sleep(unsigned int seconds);
```

General description

Suspends thread execution for a specified number of *seconds*. Because of processor delays, the thread can sleep slightly longer than this specified time. An unblocked signal received during this time (for which the action is to invoke a signal handler function or to end the thread) “wakes up” the thread prematurely. When that function returns, sleep() returns immediately even if there is sleep time remaining.

This function is supported only in a POSIX program.

Returned value

If the thread slept for the full specified time, sleep() returns 0.

If the thread awoke prematurely because of a signal whose action is to invoke a signal-handling function or to end the thread, sleep() returns the number of seconds remaining in its sleep time (that is, the value of *seconds* minus the actual number of seconds that the thread was suspended).

sleep() always succeeds, so there is no failure return. An abend is generated when any failures are encountered that prevent this function from completing successfully.

There are no documented errno values.

Example

CELEBS29

```

/* CELEBS29

   This example suspends execution for a specified time.

   */
#define _POSIX_SOURCE
#include <stdio.h>
#include <time.h>
#include <unistd.h>

main() {
    unsigned int ret;
    time_t t;
    time(&t);
    printf("starting sleep at %s", ctime(&t));
    ret = sleep(10);
    time(&t);
    printf("naptime over at %s", ctime(&t));
    printf("sleep() returned %d\n", ret);
}

```

Output

```

starting sleep at Fri Jun 16 07:44:47 2006
naptime over at Fri Jun 16 07:44:58 2006
sleep() returned 0

```

__smf_record() — Record an SMF record

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <unistd.h>

int __smf_record(int smf_record_type,
                 int smf_record_subtype,
                 int smf_record_length,
                 char *smf_record);
```

General description

The `__smf_record()` function writes an SMF record pointed to by `smf_record` of length `smf_record_length` for SMF record type `smf_record_type` and subtype `smf_record_subtype` to the SMF data set.

The service can also be used to determine if a particular type or subtype of SMF record is being recorded to avoid the overhead of data collection if the SMF record is not going to be recorded. See [z/OS MVS System Management Facilities \(SMF\)](#) for more information on SMF record types and layout.

The caller of this service must be APF-authorized or permitted to either the BPX.SMF facility class profile or the BPX.SMF.type.subtype resource profile in the FACILITY class where type is the SMF record type to be written and subtype is the SMF record subtype to be written. For more information about creating and using these profiles and the restrictions on their use, refer to [z/OS UNIX System Services Planning](#).

Returned value

If successful, `__smf_record()` returns 0.

If unsuccessful, `__smf_record()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

The value specified on the length operand was incorrect. Use `__errno2()` to retrieve the reason code that is associated with the error. The following reason codes can accompany the return code: JRSMFBadRecordLength, JrSMFTypeSubtypeMismatch, or JrSMFRecordLenMismatch.

EMVSERR

The SMF service returned a nonzero return code. Use `__errno2()` to determine why the error occurred. The following reason codes can accompany the return code: JRSMFNotAccepting, JRSMFError, JRBadAddress, or JRInternalError.

ENOMEM

Not enough storage.

EPERM

The calling process is not permitted to the BPX.SMF resource in the FACILITY class and the calling processes are not APF-authorized, or the calling process is permitted to the BPX.SMF.xxx.yyy FACILITY class resource but the environment is dirty. The following reason codes can accompany the return code: JRSMFNotAuthorized and JREnvDirty.

Related information

None.

__smf_record2() – Record an SMF record with exit control

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1.12 |

Format

```
#include <unistd.h>

int __smf_record2 (int smf_record_type,
                  int smf_record_subtype,
                  int smf_record_length,
                  char *smf_record
                  unsigned int smf_exit );
```

General description

The `__smf_record2()` function writes an SMF record pointed to by `smf_record` of length `smf_record_length` for SMF record type `smf_record_type` and subtype `smf_record_subtype` to the SMF data set.

The `smf_exit` argument defines which user exit is to take control when the SMF record is written. Acceptable values for this argument are as follows:

`_SMF_IUFU83` Cause SMF exit IEFU83 to gain control.
`_SMF_IUFU84` Cause SMF exit IEFU84 to gain control.

and are defined in `<unistd.h>`

The service can also be used to determine if a particular type or subtype of SMF record is being recorded to avoid the overhead of data collection if the SMF record is not going to be recorded. See [z/OS MVS System Management Facilities \(SMF\)](#) for more information on SMF record types and layout.

The caller of this service must be APF-authorized or permitted to either the BPX.SMF facility class profile or the BPX.SMF.type.subtype resource profile in the FACILITY class where type is the SMF record type to be written and subtype is the SMF record subtype to be written. For more information about creating and using these profiles and the restrictions on their use, see [z/OS UNIX System Services Planning](#).

This function is supported under CICS Transaction Server for z/OS only when run in an open transaction environment (OTE).

Note: To determine if a particular SMF record type or subtype is being recorded, specify NULL for the `smf_record` argument. If the return value is 0, the type or subtype is being recorded. If the return value is -1 and `errno` is EMVSERR with a reason code of JRSMFNotAccepting, SMF is not recording this type or subtype.

Returned value

If successful, `__smf_record2()` returns 0.

If unsuccessful, `__smf_record2()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

The value that was specified for an argument was incorrect. Use `__errno2()` to retrieve the reason code that is associated with the error. The following reason codes can accompany the return code: JRSMFBadRecordLength, JrSMFTypeSubtypeMismatch, or JrSMFRecordLenMismatch.

EMVSERR

The SMF service returned a nonzero return code. Use `__errno2()` to retrieve the reason code associated with the error. The following reason codes can accompany the return code: JRSMFNotAccepting, JRSMFError, JRBadAddress, or JRInternalError.

ENOMEM

Not enough storage is available.

EPERM

The calling process is not permitted to the BPX.SMF resource in the FACILITY class and the calling processes are not APF-authorized, or the calling process is permitted to the BPX.SMF.xxx.yyy

FACILITY class resource but the environment is dirty. The following reason codes can accompany the return code: JRSMFNotAuthorized and JREnvDirty.

snprintf() — Format and write data

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R6 |

Format

```
#define _ISOC99_SOURCE
#include <stdio.h>

int snprintf(char *__restrict__ s, size_t n, const char *__restrict__ format, ...);
```

Note: The snprintf() function is also available under the alternate name __snprtf(). The __snprtf() function is accessible in the open name space.

```
#include <stdio.h>

int __snprtf(char *__restrict__ s, size_t n, const char *__restrict__ format, ...);
```

General description

Equivalent to fprintf(), except that the output is written into an array (specified by argument s) rather than to a stream. If n is zero, nothing is written, and s may be a null pointer. Otherwise, output characters beyond the n-1st are discarded rather than being written to the array, and a null character is written at the end of the characters actually written into the array. If copying takes place between objects that overlap, the behavior is undefined.

Returned value

Returns the number of characters that would have been written had n been sufficiently large, not counting the terminating null character, or a negative value if an encoding error occurred. Thus, the null-terminated output has been completely written if and only if the returned value is nonnegative and less than n.

Errors

Function fails if:

- The value of n is greater than {INT_MAX} or the number of bytes needed to hold the output excluding the terminating null is greater than {INT_MAX}. In this case, the function returns a negative value and sets errno to EOVERFLOW

socketmark() — Determine whether a socket is at the out-of-band mark

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|--------------|
| Single UNIX Specification, Version 3 | both | z/OS V1R9 |

Format

SUSV3:

```
#define _POSIX_C_SOURCE 200112L
#include <sys/socket.h>

int socketmark(int s);
```

General description

The `socketmark()` function determines whether the socket specified by the descriptor `s` is at the out-of-band data mark. If the protocol for the socket supports out-of-band data by marking the stream with an out-of-band data mark, the `socketmark()` function returns 1 when all data preceding the mark has been read and the out-of-band data mark is the first element in the receive queue. The `socketmark()` function does not remove the mark from the stream.

| Argument | Description |
|----------------|--|
| <code>s</code> | The descriptor used to determine if the socket is at the out-of-band data mark |

Returned value

Upon successful completion, the `socketmark()` function returns a value indicating whether the socket is at an out-of-band data mark. If the protocol has marked the data stream and all data preceding the mark has been read, the return value is 1; if there is no mark, or if data precedes the mark in the receive queue, the `socketmark()` function returns 0. Otherwise, it returns a value of -1 and set `errno` to indicate the error.

Error Code

Description

EBADF

The `s` argument is not a valid file descriptor.

ENOTTY

The `s` argument does not specify a descriptor for a socket.

Example

CELEBS74

```
/* CELEBS74

This example demonstrates the use of the socketmark() function.

Expected output:
C: Sending regular data
C: Sending OOB data
S: Received "123a"
S: At the mark
S: Received "b"
```

```

*/

#define _POSIX_C_SOURCE 200112L
#include <sys/socket.h>

sock_do_teststor() — Check for attempt to access storage outside

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _OPEN_SYS_SOCK_EXT
#include <sys/socket.h>

void sock_do_teststor(int onoff);
```

General description

The sock_do_teststor call is used to check for calls that attempt to access storage outside the caller's address space.

Parameter Description

onoff

A parameter that can be set to zero or nonzero.

If *onoff* is set to a nonzero value, for either inbound or outbound sockets, both the address of the message buffer and the message buffer are checked for addressability for each bulk mode socket call. The EFAULT error condition is set if there is an addressing problem. If *onoff* is set to 0, address checking is not done by the socket library program. If an error occurs when *onoff* is 0, normal runtime error handling reports the exception condition.

To improve response time, you can disable this checking when your program has been tested.

As an alternative to calling `sock_do_teststor`, with *onoff* set to a nonzero value, you can include the statement `SOCKTESTSTOR` in the file `/etc/resolv.conf` or data set `tcpip.TCPIP.DATA`. When the process is started, all the programs using bulk mode sockets for this process will validate the storage for the caller's parameters.

Returned value

`sock_do_teststor()` returns no values.

socket() — Create a socket

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format**X/Open:**

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int socket(int domain, int type, int protocol);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/socket.h>

int socket(int *domain, int type, int protocol);
```

General description

The `socket()` function creates an endpoint for communication and returns a socket descriptor representing the endpoint. Different types of sockets provide different communication services.

Parameter**Description*****domain***

The address domain requested, either `AF_INET`, `AF_INET6`, `AF_UNIX`, or `AF_RAW`.

type

The type of socket created, either `SOCK_STREAM`, `SOCK_DGRAM`, or `SOCK_RAW`. With the `_XPLATFORM_SOURCE` feature test macro, the bitwise OR of the `SOCK_NONBLOCK` flag and `SOCK_CLOEXEC` flag can be specified with the socket type.

protocol

The protocol requested. Some possible values are 0, `IPPROTO_UDP`, or `IPPROTO_TCP`.

The *domain* parameter specifies a communication domain within which communication is to take place. This parameter selects the address family (format of addresses within a domain) that is used. The families supported are `AF_INET` and `AF_INET6`, which is the Internet domain, and `AF_UNIX`, which is the local socket domain. These constants are defined in the **sys/socket.h** include file.

The *type* parameter specifies the type and flags of the created socket. The type is analogous with the semantics of the communication requested. These socket type constants are defined in the `sys/socket.h` include file. The types supported are:

Socket Type**Description****SOCK_DGRAM**

Provides datagrams, which are connectionless messages of a fixed maximum length whose reliability is not guaranteed. Datagrams can be corrupted, received out of order, lost, or delivered multiple times. This type is supported in the `AF_INET`, `AF_INET6`, and `AF_UNIX` domains.

SOCK_RAW

Provides the interface to internal protocols (such as IP and ICMP). This type is supported in the `AF_INET` and `AF_INET6` domains. You must be a superuser to use this type.

SOCK_STREAM

Provides sequenced, two-way byte streams that are reliable and connection-oriented. They support a mechanism for out-of-band data. This type is supported in the `AF_INET`, `AF_INET6`, and `AF_UNIX` domains.

Socket Flag**Description****SOCK_NONBLOCK**

Set the `O_NONBLOCK` file status flag on the open file description.

SOCK_CLOEXEC

Provides the interface to internal protocols (such as IP and ICMP). This type is supported in the `AF_INET` and `AF_INET6` domains. You must be a superuser to use this type.

Understanding the socket() parameters: The *protocol* parameter specifies a particular protocol to be used with the socket. In most cases, a single protocol exists to support a particular type of socket in a particular address family. If the *protocol* parameter is set to 0, the system selects the default protocol number for the domain and socket type requested. Protocol numbers are found in the *tcpip.ETC.PROTO* data set. Alternatively, the `getprotobyname()` call can be used to get the protocol number for a protocol with a known name.

Note: The *protocol* field *must* be set to 0, if the *domain* parameter is set to `AF_UNIX`.

`SOCK_STREAM` sockets model duplex-byte streams. They provide reliable, flow-controlled connections between peer application programs. Stream sockets are either active or passive. Active sockets are used by clients who start connection requests with `connect()`. By default, `socket()` creates active sockets. Passive sockets are used by servers to accept connection requests with the `connect()` call. You can transform an active socket into a passive socket by binding a name to the socket with the `bind()` call and by indicating a willingness to accept connections with the `listen()` call. After a socket is passive, it cannot be used to start connection requests.

In the `AF_INET` and `AF_INET6` domains, the `bind()` call applied to a stream socket lets the application program specify the networks from which it is willing to accept connection requests. The application program can fully specify the network interface by setting the *Internet address* field in the **address** structure to the Internet address of a network interface. Alternatively, the application program can use a *wildcard* to specify that it wants to receive connection requests from any network. For `AF_INET` sockets,

this is done by setting the *Internet address* field in the **address** structure to the constant `INADDR_ANY`, as defined in `<netinet/in.h>`. For `AF_INET6` sockets, this is done by setting the *Internet address* field in the address structure to `in6addr_any` as defined in `<netinet/in.h>`.

After a connection has been established between stream sockets, any of the data transfer calls can be used: `read()`, `readv()`, `recv()`, `recvfrom()`, `recvmsg()`, `send()`, `sendmsg()`, `sendto()`, `write()`, and `writev()`. Usually, the `read()`-`write()` or `send()`-`recv()` pairs are used for sending data on stream sockets. If out-of-band data is to be exchanged, the `send()`-`recv()` pair is normally used.

`SOCK_DGRAM` sockets model datagrams. They provide connectionless message exchange without guarantees of reliability. Messages sent have a maximum size. Datagram sockets are supported in the `AF_UNIX` domain.

There is no active or passive analogy to stream sockets with datagram sockets. Servers must still call `bind()` to name a socket and to specify from which network interfaces it wishes to receive packets. Wildcard addressing, as described for stream sockets, applies for datagram sockets also. Because datagram sockets are connectionless, the `listen()` call has no meaning for them and must not be used with them.

After an application program has received a datagram socket, it can exchange datagrams using the `sendto()` and `recvfrom()`, or `sendmsg()` and `recvmsg()` calls. If the application program goes one step further by calling `connect()` and fully specifying the name of the peer with which all messages will be exchanged, then the other data transfer calls `read()`, `write()`, `readv()`, `writev()`, `send()`, and `recv()` can also be used. For more information on placing a socket into the connected state, see [“connect\(\) — Connect a socket” on page 312](#).

Datagram sockets allow messages to be broadcast to multiple recipients. Setting the destination address to be a broadcast address is network-interface-dependent (it depends on the class of address and whether *subnets*—logical networks divided into smaller physical networks to simplify routing—are used). The constant `INADDR_BROADCAST`, defined in `netinet/in.h`, can be used to broadcast to the primary network if the primary network configured supports broadcast.

Outgoing packets have an IP header prefixed to them. IP options can be set and inspected using the `setsockopt()` and `getsockopt()` calls, respectively. Incoming packets are received with the IP header and options intact.

Sockets are deallocated with the `close()` call.

Note: For `AF_UNIX`, when closing sockets that were bound, you should also use `unlink()` to delete the file created at `bind()` time.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` 1 feature test macro.

Returned value

If successful, `socket()` returns a nonnegative socket descriptor.

If unsuccessful, `socket()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

Permission to create a socket of the specified type or protocol is denied.

EAFNOSUPPORT

The address family is not supported (it is not `AF_UNIX`, `AF_INET`, or `AF_INET6`).

EAGAIN

Resource temporarily unavailable.

EINVAL

The request is invalid or not supported.

EIO

There has been a network or transport failure.

ENOBUFS

Insufficient system resources are available to complete the call.

ENOENT

There was no NETWORK statement in the parmlib member to match the specified domain.

EPROTONOSUPPORT

The protocol is not supported in this domain or this protocol is not supported for this socket type.

EPROTOTYPE

The socket type is not supported by the protocol.

Example

The following are examples of the socket() call.

```
int s;
char *name;
int socket(int domain, int type, int protocol);
:
/* Get stream socket in Internet
domain with default protocol */
s = socket(AF_INET, SOCK_STREAM, 0);
:
/* Get stream socket in local socket
domain with default protocol */
s = socket(AF_UNIX, SOCK_STREAM, 0);
```

socketpair() — Create a pair of sockets

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/socket.h>

int socketpair(int *domain, int type, int protocol, int socket_vector[2]);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/socket.h>

int socketpair(int *domain, int type, int protocol, int sv[2]);
```

General description

The `socketpair()` function acquires a pair of sockets of the type specified that are unnamed and connected in the specified domain and using the specified protocol. For socket pairs in the `AF_UNIX` domain, the protocol *must* be 0.

Parameter

Description

domain

The domain in which to open the socket. Although socket pairs can be obtained for `AF_INET` domain sockets, it is recommended that `AF_UNIX` domain sockets be used for socket pairs.

type

The type of socket created, either `SOCK_STREAM`, or `SOCK_DGRAM`. With the `_XPLATFORM_SOURCE` feature test macro, the bitwise OR of the `SOCK_NONBLOCK` flag and `SOCK_CLOEXEC` flag can be specified with the socket type.

protocol

The protocol requested *must* be 0.

sv

The descriptors used to refer to the obtained sockets.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

Returned value

If successful, `socketpair()` returns a nonnegative socket descriptor.

If unsuccessful, `socketpair()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

Permission to create a socket of the specified type or protocol is denied.

EFAULT

sv is not in the writable part of the user's address space.

EINVAL

The request is invalid or not supported.

EMFILE

Too many files are open for this process.

ENFILE

Too many files are open in the system.

ENOBUFS

Insufficient system resources are available to complete the call.

EOPNOSUPPORT

The protocol does not allow for the creation of socket pairs.

EPROTONOSUPPORT

The protocol is not supported in this domain or this protocol is not supported for this socket type.

EPROTOTYPE

The socket type is not supported by the protocol.

Example

The following are examples of the socketpair() call.

```
#include <types.h>
#include <sys/socket.h>

int sv[2];
...
/* Get stream socket in UNIX
domain with default protocol */
if (socketpair(AF_UNIX, SOCK_STREAM, 0, sv) < 0)
printf ("Error occurred while trying to get a socket pair.\n");
else
...
;
```

spawn(), spawnp() – Spawn a new process

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------|----------|--------------|
| POSIX.4b z/OS UNIX | both | |

Format

```
#define _POSIX_SOURCE
#include <spawn.h>

pid_t spawn(const char *path,
            const int fd_count,
            const int fd_map[],
            const struct inheritance *inherit,
            const char *argv[],
            const char *envp[]);
```

```
pid_t spawnp(const char *file,
             const int fd_count,
             const int fd_map[],
             const struct inheritance *inherit,
             const char *argv[],
             const char *envp[]);
```

General description

The `spawn()` and `spawnp()` functions create a new process from the specified process image. `spawn()` and `spawnp()` create the new process image from a regular executable file called the new process image file.

To execute a C program as a result of this call, enter the function call as follows:

```
int main (int argc, char *argv[]);
```

Where *argc* is the argument count and *argv* is an array of character pointers to the arguments themselves. In addition, the following variable:

```
extern char **environ;
```

is initialized as a pointer to an array of character pointers to the environment strings. The *argv* and *environ* arrays are each terminated by a NULL pointer. The NULL pointer terminating the *argv* array is not counted in *argc*.

Supported parameters are:

Parameter Description

path

Path name used by `spawn()` that identifies the new process image file to execute.

file

Used by `spawnp()` to construct path name that identifies the new process image file. If the file parameter contains a slash character, `spawnp()` uses the file parameter as a path name for the new process image file. Otherwise, `spawnp()` obtains the path prefix for this file by a search of the directories passed as the environment variable `PATH`.

fd_count

Specifies the number of file descriptors the child process inherits. It may take values from zero to **OPEN_MAX**. Except for those file descriptors designated by `SPAWN_FDCLOSED`, each of the child's file descriptors, *x*, in the range zero to *fd_count*-1 inherits descriptor *fd_map*[*x*] from the parent process.

The files from *fd_count* through **OPEN_MAX** are closed in the child process, as are any elements of *fd_map* designated as `SPAWN_FDCLOSED`.

fd_map

If the *fd_map* parameter is NULL, *fd_count* and *fd_map* are ignored. All file descriptors except those with the `FD_CLOEXEC` or `FD_CLOFORK` attribute are inherited without reordering. File descriptors with the `FD_CLOEXEC` or `FD_CLOFORK` attribute are closed under simple inheritance.

For those file descriptors that remain open, all other attributes of the associated file descriptor object and open file description remain unchanged by this operation.

Directory streams open in the calling process are closed in the new process image.

If an element of *fd_map* refers to an invalid file descriptor, then the (EBADF) `spawn()` or `spawnp()` posts the error status.

The `FD_CLOEXEC` and `FD_CLOFORK` file descriptor attributes are never inherited.

The `FD_CLOEXEC` and `FD_CLOFORK` file descriptor attributes have no effect on inheritance when the *fd_map* parameter is not NULL.

Note: For XTI endpoints, *fd_map* must not map to a number greater than 65535 in the child process.

inherit

The name of a data area that contains the inheritance structure.

The 'struct inheritance' is defined as follows:

```
struct inheritance {
    short flags;           //Flags
    pid_t pgroup;         //Process group
    sigset_t sigmask;      //Signal mask
    sigset_t sigdefault;   //Signals set to SIG_DFL
    int ctltyfd;          //Cntl tty FD for tcsetpgrp()
}
```

The `inherit.flags` effect `spawn()` and `spawnp()` as follows:

SPAWN_SETGROUP

If the `SPAWN_SETGROUP` flag is set in `inherit.flags`, then the child's process group is as specified in `inherit.pgroup`.

If the `SPAWN_SETGROUP` flag is set in `inherit.flags` and `inherit.pgroup` is set to `SPAWN_NEWPGROUP`, then the child is in a new process group with a process group ID equal to its process ID.

If the `SPAWN_SETGROUP` flag is not set in `inherit.flags`, the new child process inherits the parent's process group ID.

SPAWN_SETSIGMASK

If the `SPAWN_SETSIGMASK` flag is set in `inherit.flags`, the child process initially has the signal mask specified in `inherit.sigmask`.

SPAWN_SETSIGDEF

If the `SPAWN_SETSIGDEF` flag is set in `inherit.flags`, the signals specified in `inherit.sigdefault` are set to their default actions in the child process. Signals set to the default action in the parent process, are set to the default action in the new process.

Signals set to be caught by the calling process are set to the default action in the child process.

Signals set to be ignored by the calling process are set to be ignored by the new process, unless otherwise specified by the `SPAWN_SETSIGDEF` flag being set in `inherit.flags` and the signal being indicated in `inherit.sigdefault`.

SPAWN_SETTCPGRP

If the `SPAWN_SETTCPGRP` flag is set in `inherit.flags`, the file descriptor specified in `inherit.ctltyfd` is used to set the controlling terminal file descriptor (`tcsetpgrp()`) for the child's foreground process group. The child's foreground process group is inherited from the parent, unless the `SPAWN_SETGROUP` flag in `inherit.flags` is set, indicating that the value specified in `inherit.pgroup` is to be used to determine the child's process group.

SPAWN_PROCESS_INITTAB

If this flag is set, `spawn` attempts to read the `/etc/inittab` file and process the entries found there. This processing involves the spawning of child shell processes to run each of the commands identified in the file. Only the `SPAWN_SETSIGMASK` flag can be set in combination with this flag. All other flags will be ignored. Use of this flag implies that only file descriptors 0, 1, and 2 will be initially opened in the child process. File descriptor 0 will be initially opened as `/dev/null`, while file descriptors 1 and 2 will initially opened as `/etc/log`. The `fd_count` and `fd_map` parameters will be ignored. This flag is currently restricted to the `/usr/sbin/init` process. See [z/OS UNIX System Services Planning](#) for more information on the `/etc/inittab` support.

argv

The value in the first element of `argv` should point to a file name that is associated with the process being started by the `spawn()` or `spawnp()` operation.

The number of bytes available for the new process's combined argument and environment lists is **ARG_MAX**.

envp

The value *envp* contains the list of environmental variables that is to be passed to the specified program.

If the `set-user-ID` mode bit of the new process image file is set, the effective user ID of the new process image is set to the owner id of the new process image file. Similarly, if the `set-group-ID` mode bit of the new process image file is set, the effective group ID of the new process image is set to the group id of the new process image file. The real user ID, real group ID, and supplementary group IDs of the new process image remain the same as those of the calling process image. The effective user ID and effective group ID of the new process image are saved (as the saved `set-user-ID` and the saved `set-group-ID`) for use by the `setuid()` function.

The new process image inherits the following attributes from the calling process image:

- Process group ID (unless the **SPAWN_SETGROUP** flag is set in `inherit.flags`)
- Session membership
- Real user ID
- Real group ID
- Supplementary group IDs
- Priority
- Current working directory
- Root directory
- File creation mask
- Signal mask (unless the **SPAWN_SETSIGMASK** flag is set in `inherit.flags`)
- Signal actions specified as default (`SIG_DFL`)
- Signal actions specified as ignore (`SIG_IGN`) (except as modified by `inherit.sigdefault` and the **SPAWN_SETSIGDEF** flag set in `inherit.flags`)

The following are differences between the parent process and the child process:

- Signals set to be caught by the calling process are set to the default action (`SIG_DFL`).
- The process and system utilization times for the child are set to zero.
- Any file locks previously set by the parent are not inherited by the child.
- The child process has no alarms set.
- The child process has no interval timers set.
- The child has no pending signals.
- Memory mappings established by the parent are not inherited by the child.

If the process image was read from a writable file system, then upon successful completion, the `spawn()` or `spawnp()` function mark for update the `st_atime` field of the new process image file.

If the `spawn()` or `spawnp()` function is successful, the new child process image file is opened, with all the effects of the `open()` function.

Special behavior for z/OS UNIX Services:

Note: If an application spawns a shell command or utility that performs terminal I/O, the command may fail due to the fact that the shell file descriptors are not initialized. The Shell file descriptors must be defined. An example of how these can be defined in a C application are as follows:

```
stdin = fopen("/tmp/sys.stdin","r");
stdout = fopen("/tmp/sys.stdout","w");
stderr = fopen("/tmp/sys.stderr","w");
```

Aspects of `spawn` processing are controlled by environment variables. The environment variables that affect `spawn` processing are the ones that are passed into the `spawn` syscall and not the environment

variables of the calling process. The environment variables of the calling process do not affect spawn processing unless they are the same as those that are passed in *envp*.

The `_BPXK_JOBLOG` environment variable can be used to specify that WTO messages are to be written to an open job log file. The following are the allowable values:

Value

Description

nn

Job log messages are to be written to open file descriptor nn.

STDERR

Job log messages are to be written to the standard error file descriptor, 2.

None

Job log messages are not to be written. This is the default.

The file that is used to capture messages can be changed at any time by calling the `oe_env_np` service (BPX1ENV) and specifying `_BPXK_JOBLOG` with a different file descriptor.

Message capturing is turned off if the specified file descriptor is marked for close on a fork or exec.

Message capturing is process-related. All threads under a given process share the same job log file. Message capturing may be initiated by any thread under that process.

Multiple processes in a single address space can each have different files active as the JOBLOG file; some or all of them can share the same file; and some processes can have message capturing active while others do not.

Only files that can be represented by file descriptors may be used as job log files; MVS data sets are not supported.

Message capturing will be propagated on a `fork()` or `spawn()`. In the case where a file descriptor was specified, the physical file must be the same for message capturing to continue in the forked or spawned process. If `STDERR` was specified, the file descriptor may be re-mapped to a different physical file.

Message capturing may be overridden on `exec()` or `spawn()` by specifying the `_BPXK_JOBLOG` environment variable as a parameter to the `exec()` or `spawn()`.

Message capturing will only work in forked (BPXAS) address spaces.

Note: This is not true joblog support, messages that would normally go to the JESYSMSG data set are captured, but messages that go to JESMSGLOG are not captured.

For more information on the use of environment variables, see [z/OS UNIX System Services Programming: Assembler Callable Services Reference](#).

Security information from the parent's address space is propagated to the child's address space, unless the `_BPX_USERID` environment variable specifies otherwise. As a result, the child has a security environment equivalent to that of the parent.

The TASKLIB, STEPLIB, or JOBLIB DD data set allocations that are active for the current task are propagated to the child's address space, unless the STEPLIB environment variable specifies otherwise. This causes the child address space to have the same exact MVS program search order as the calling parent task.

The accounting information of the parent's address space is propagated to the child's address space. See [z/OS UNIX System Services Planning](#).

The jobname of the parent is propagated to the child and appended with a numeric value in the range of 1-9 if the jobname is 7 characters or less. If the jobname is 8 characters, then it is propagated as-is. When a jobname is appended with a numeric value, the count wraps back to 1 when it exceeds 9.

If the calling parent task is in a WLM enclave, the child is joined to the same WLM enclave. This allows WLM to manage the parent and child as one "business unit of work" entity for system accounting and management purposes.

To allow the caller to control whether the spawned child process runs in a separate address space from the parent address space or in the same address space, the spawn service allows for the specification of the `_BPX_SHAREAS` environment variable. The following are the accepted values for the `_BPX_SHAREAS` environment variable, and the actions taken for each value:

1. `_BPX_SHAREAS=YES` - Indicates that the child process that is to be created is to run in the same address space as the parent. In the following circumstances, the `_BPX_SHAREAS=YES` value cannot be honored, and the child process is created in its own address space:
 - If the program to be run is a set-user-ID or set-group-ID program that would cause the effective user-ID or group-ID of the child process to be different from that of the parent process.
 - If the program to be run is an APF-authorized z/OS UNIX or MVS program and the caller is not running APF authorized.
 - If the program to be run is an unauthorized z/OS UNIX or MVS program and the caller is running APF authorized.
 - If the specified file name represents an external link or a sticky bit file. However, if the program that is to be run is a shell script and `_BPX_SPAWN_SCRIPT=YES` is set, the process runs in the same address space. `_BPX_SPAWN_SCRIPT` only has an effect while running in the z/OS shell (`/bin/sh...` NOT `/bin/tcsh`).
 - If the address space of the parent lacks the necessary resources to create another process within the address space.

Note that only one local spawned process per TSO address space is supported at a given time. This is done to reduce conflict among multiple shells running in the same address space.

2. `_BPX_SHAREAS=MUST` - Indicates that the child process that is to be created must run in the same address space as the parent, or the spawn request will fail. In the following circumstances, the `_BPX_SHAREAS=MUST` value cannot be honored, and the spawn invocation fails:
 - If the program to be run is a set-user-ID or set-group-ID program that would cause the effective user ID or group ID of the child process to be different from that of the parent process.
 - If the program to be run is an APF-authorized z/OS UNIX or MVS program and the caller is not running APF authorized.
 - If the program to be run is an unauthorized z/OS UNIX or MVS program and the caller is running APF authorized.
 - If the address space of the parent lacks the necessary resources to create another process within the address space.
3. `_BPX_SHAREAS=REUSE` - Indicates that the child process to be created is to run in the same address space as the parent; also, that it will be created as a medium-weight process. Specifying `REUSE` allows the caller to indicate that it wants to reuse the existing process structure for locally spawned processes.

The same rules that apply to the creation of a local spawn process apply to the specification of a local spawn medium-weight process. In addition, in the following circumstances, the `_BPX_SHAREAS=REUSE` value cannot be honored, and the child process will be created as a non-medium weight local spawn process:

- If `PTRACE` is active for the process.
- If the program to execute is a REXX exec.

For performance reasons, the `STEPLIB` that is specified for each medium-weight process that is created for the address space should be the same.

4. `_BPX_SHAREAS=NO` - Indicates that the child process that is to be created is to run in a separate address space from the address space of the parent. This is the default behavior for the spawn service if the `_BPX_SHAREAS` environment variable is not specified, or if it contains an unsupported value.

If you specify the `_BPX_USERID` environment variable, then `spawn()` creates the new address space and image with the specified userid's identity. The invoker of `spawn()` must be authorized to change MVS

identity. The resulting spawn() image will emerge as if a program had done a fork(), setgid(), initgroups(), setuid(), and exec.

The value of _BPX_USERID can be any 1-to-8-character XPG4 compliant username. If you specify both _BPX_USERID and _BPX_SHAREAS, then spawn() ignores _BPX_SHAREAS, and creates a new address space with the new identity.

If the caller of the spawn() function is the z/OS UNIX shell (that is, /bin/sh), then the setting of the _BPX_SPAWN_SCRIPT= environment variable to YES is recommended. The setting of this variable to YES provides a more efficient mechanism to invoke z/OS UNIX shell scripts.

To support the creation and propagation of a STEPLIB environment to the new process image, spawn() and spawnp() allow for the specification of a STEPLIB environment variable. The following are the accepted values for the STEPLIB environment variable and the actions taken for each:

- STEPLIB=NONE. No Steplib DD is to be created for the new process image.
- STEPLIB=CURRENT. The TASKLIB, STEPLIB, or JOBLIB DD data set allocations that are active for the calling task at the time of the call to spawn() and spawnp() are propagated to the new process image, if found to be cataloged. Uncataloged data sets are not propagated to the new process image.
- STEPLIB=Dsn1:Dsn2;...DsnN. The specified data sets, Dsn1:Dsn2:...DsnN, are built into a STEPLIB DD in the new process image.

Note: The actual name of the DD is not STEPLIB, but is a system-generated name that has the same effect as a STEPLIB DD.

The data sets are concatenated in the order specified. The specified data sets must follow standard MVS data set naming conventions. Data sets found to be in violation of this standard are ignored. If the data sets do follow the standard, but:

- The caller does not have the proper security access to a data set.
- A data set is uncataloged or is not in load library format.

then the data set is ignored. Because the data sets in error are ignored, the executable file may run without the proper STEPLIB environment. If a data set is in error due to improper security access a X'913' abend is generated. The dump for this abend can be suppressed by your installation.

If the STEPLIB environment variable is not specified, spawn() and spawnp() default behavior is the same as if STEPLIB=CURRENT were specified.

If the program to be invoked is a set-user-ID or set-group-ID file and the user-ID or group-ID of the file is different from that of the current process image, then the data sets to be built into the STEPLIB environment for the new process image must be found in the system sanction list for set-user-id and set-group-id programs. Only those data sets that are found in the sanction list are built into the STEPLIB environment for the new process image. For detailed information regarding the sanction list, and for information on STEPLIB performance considerations, see *z/OS UNIX System Services Planning*.

Notes:

1. A prior loaded copy of an HFS program in the same address space is reused under the same circumstances that apply to the reuse of a prior loaded MVS unauthorized program from an unauthorized library by the MVS XCTL service with the following exceptions:
 - If the calling process is in Ptrace debug mode, a prior loaded copy is not reused.
 - If the calling process is not in Ptrace debug mode, but the only prior loaded usable copy found of the HFS program is in storage modifiable by the caller, the prior copy is not reused.
2. If the specified file name represents an external link or a sticky bit file, the program is loaded from the caller's MVS load library search order. For an external link, the external name is only used if the name is eight characters or less, otherwise the caller receives an error from the loadhfs service. For a sticky bit program, the file name is used if it is eight characters or less. Otherwise, the program is loaded from the z/OS UNIX file system and the following restriction exists for sticky bit programs that have the set-user-ID or set-group-ID attribute:

If the program is found in the MVS program search order, the MVS program name must have a BPX.STICKYSUG.program_name resource profile defined in the RACF FACILITY class. See [z/OS UNIX System Services Planning](#) for details on defining the resource profile. Failure to follow this restriction will cause the abend EC6 with code xxxxEO55.

3. If the calling task is in a WLM enclave, the resulting task in the new process image is joined to the same WLM enclave. This allows WLM to manage the old and new process images as one "business unit of work" entity for system accounting and management purposes.

Note: If you are expecting this function to take advantage of the z/OS UNIX magic number support, the Language Environment runtime option to POSIX(ON) must have been set when the process was initialized. Attempting to use magic number support with a process initialized with POSIX(OFF) may produce undesirable effects. See [z/OS UNIX System Services Planning](#) and [z/OS UNIX System Services User's Guide](#) for details and uses of the z/OS UNIX magic number.

Returned value

If successful, `spawn()` and `spawnp()` return the value of the process ID of the child process to the parent process.

If unsuccessful, `spawn()` and `spawnp()` return -1, no child process is created, and they set `errno` to one of the following values:

Error Code

Description

E2BIG

The number of bytes used by the argument and environment list of the new process image is greater than the system-imposed limit of **ARG_MAX** bytes.

EACCES

Search permission is denied for a directory in the path of the new process image file or the new process image file denies execution permission, or the new process image file is not a regular file and the implementation does not support execution of files of its type.

EAGAIN

The system lacked the necessary resources to create another process or the system-imposed limit on the total number of processes or UIDs under execution by a single user would be exceeded.

EBADF

An entry in the `fd_map` array refers to an invalid file descriptor or the controlling terminal file descriptor specified in the `inherit.ctltyfd` is not valid.

EFAULT

The system detected an invalid address in attempting to use a parameter of the call.

EINVAL

One or more of the following conditions were detected:

- The username that was specified on the `_BPX_USERID` environment variable has an incorrect length.
- An attribute that was specified in the inheritance structure (BPXYINHE) is not valid or contains an unsupported value.
- The version number that was specified for the inheritance structure (BPXYINHE) is not valid.
- The inheritance structure length that was specified by the `Inherit_area_len` parameter or within the inheritance structure does not contain a length that is appropriate for the BPXYINHE version.
- The process group ID that was specified in the inheritance structure is less than zero or has some other unsupported value.

The following reason codes can accompany the return code: JR0K, JRUserNameLenError, JRJsRacXtr, JRInheUserid, JRInheRegion, JRInheCPUTime, JRInheDynamber, JRInheAccountData, JRInheCWD, JRInheSetPgrp, JRInheVersion, and JRInheLength.

ELOOP

A loop exists in symbolic links encountered during resolution *file* argument. This error is issued if more than 8 symbolic links are detected in the resolution of file name.

EMVSERR

An MVS internal error has occurred. This may indicate a problem with security permissions for the user calling spawn() or spawnp().

EMVSSAF2ERR

The executable file is a set-user-ID or set-group-ID file and the file owner's UID or GID is not defined to the Security Authorization Facility (SAF), or _BPX_USERID was specified and the specified username was not defined to SAF with a z/OS UNIX segment.

ENAMETOOLONG

The length of the *path* or *file* arguments, or an element of the environment variable PATH prefixed to *file* exceeds PATH_MAX, or a path name component is longer than NAME_MAX and {_POSIX_NO_TRUNC} is in effect for that file.

ENOENT

One or more components of the path name of the new process image file do not exist or the *path* or *file* argument is empty.

ENOEXEC

The new process image file has the appropriate access permission but is not in the proper format.

Note: Reason codes further qualify the errno. For most of the reason codes, see [z/OS UNIX System Services Messages and Codes](#).

For ENOEXEC, the reason codes are:

| Reason Code | Explanation |
|-------------|---|
| X'xxxx0C27' | The target file is not in the correct format to be an executable file. |
| X'xxxx0C31' | The target file is built at a level that is higher than that supported by the running system. |

ENOMEM

The new process requires more memory than is permitted by the hardware or the operating system.

ENOTDIR

A component of the path prefix of the new process image file is not a directory.

ENOTTY

The tcsetpgrp() failed for the specified controlling terminal file descriptor in inherit.ctltyfd. The failure occurred because the calling process does not have a controlling terminal, or the specified file descriptor is not associated with the controlling terminal, or the controlling terminal is no longer associated with the session of the calling process.

EPERM

The spawn failed for one of the following reasons:

- The spawned process is not a process group leader.
- The _BPX_USERID environment variable was specified, but the invoker does not have appropriate privileges to change the MVS identity.
- The invoker does not have the appropriate privileges to change one or more of the attributes specified in the inheritance structure (BPXYINHE).

The following reason codes can accompany the return code: JROK, JRNoChangeIdentity, JRInheUserid, JRInheRegion, JRInheCPUTime, JRInheUmask, and JRInheCWD.

ESRCH

The process group ID specified in inherit.pgroup is not that of a process group in the session of the calling process.

Example of a parent program that uses spawn to create a child process

The following is an example of a parent program that uses spawn to create a child process.

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>
#include <spawn.h>
#include <stdio.h>
#include <errno.h>
#include <sys/types.h>

/* This program uses spawn instead of fork/exec to create a child
 * process and uses unnamed pipes to allow the parent and child to
 * exchange communication.
 */

void main(int argc, char *argv[]) {
    pid_t child;
    int fd_count, fd_map[10];
    struct inheritance inherit;
    const char *c_argv[10], *c_envp[10];
    char buf[256];
    int nbytes;

    int c_stdin[2], c_stdout[2], c_stderr[2]; /* Pipes for child
        * communication */

    /* Create pipes to communicate with child via stdin/stdout/stderr */
    if(pipe(c_stdin) ||
        pipe(c_stdout) ||
        pipe(c_stderr) ) {
        perror("Bad pipe");
        exit(-1);
    }

    /* Set up file descriptor map for child process */
    fd_map[0]=dup(c_stdin[0]); /* child stdin is read end of pipe */
    fd_map[1]=dup(c_stdout[1]); /* child stdout is write end of pipe */
    fd_map[2]=dup(c_stderr[1]); /* child stderr is write end of pipe */
    fd_count=3;

    /* Close unused end of pipes for the parent */
    close(c_stdin[0]); close(c_stdout[1]); close(c_stderr[1]);

    /* Build the argument structure for child arguments.
     * [0] is the program name */
    c_argv[0]="spawnc";
    c_argv[1]="arg1"; c_argv[2]="arg2"; c_argv[3]=NULL;

    /* Build the environment structure which defines the child's
     * environment variables */
    c_envp[0]="TEST_ENV=YES"; c_envp[1]="BPX_SHAREAS=NO"; c_envp[2]=NULL;

    /* Spawn the child process */
    child=spawnp("spawnc", fd_count, fd_map, &inherit, c_argv, c_envp);
    if(child==-1) {
        perror("Error on spawn");
        exit(-1);
    }
    else printf("Spawned %i\n", child);

    /* Test interaction with the child process */
    printf("parent: Asking child, \"what are you doing?\\n\\n\\n");
    strcpy(buf, "child from parent: what are you doing?\\n");
    if(write(c_stdin[1], buf, sizeof(buf))== -1) {
        perror("write stdout");
        exit(-1);
    }

    memset(buf, 0, 255); /* Just zeroing out the buffer */
    printf("parent: reading from child now\\n");
    if((nbytes=read(c_stdout[0], buf, 255))== -1) {
        perror("read error:");
        exit(-1);
    }
    printf("parent: child says, \"%s\\n\\n", buf);

    /* Cleanup pipes before exiting */
    close(c_stdin[1]); close(c_stdout[0]); close(c_stderr[0]);
}
```

```

    exit(0);
}

```

Example of a child program used by spawn

The following is an example of a child program used by spawn.

```

#include <stdlib.h>
#include <stdio.h>

/* This is a sample child program used by spawn. This program will
 * work stand-alone as well as from spawn or fork/exec. */

extern char ** environ; /* External used to access the environment
                        directly instead of using getenv */

void main(int argc, char *argv[]) {
    char *e, **env=environ; /* Used to step through the environment
                           * to write out to file. */
    char buf[256]={0};
    FILE *fp=fopen("spawntest.out","w");
    int i;

    /* Print out the environment variables */
    i=0;
    fprintf(fp, "Environment:\n");
    while(e=env[i++]) fprintf(fp, "%s\n", e);
    fprintf(fp, "\n\n");

    /* Just to prove getenv works */
    fprintf(fp, "TEST_ENV envvar = %s", getenv("TEST_ENV"));

    /* Print out the command line arguments */
    i=0;
    fprintf(fp, "Args:\n");
    while(e=argv[i++]) fprintf(fp, "%s\n", e);
    fprintf(fp, "\n\n");

    /* Print out what was sent on stdin */
    fprintf(fp, "Child/parent\n");
    if(!gets(buf)) {
        perror(stdin);
        exit(-1);
    }
    fprintf(fp, "child from parent: %i bytes, [%s]\n", strlen(buf), buf);

    /* Send something to stdout */
    printf("nothing");

    fclose(fp);
    exit(0);
}

```

__spawn2(), __spawnp2() — Spawn a new process using enhanced inheritance structure

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4 XPG4.2 | both | POSIX(ON) |

Format

```
#include <spawn.h>

pid_t __spawn2(const char *path,
               const int fd_count,
               const int fd_map[],
               const struct __inheritance *inherit,
               const char *argv[],
               const char *envp[]);

pid_t __spawnp2(const char *file,
                const int fd_count,
                const int fd_map[],
                const struct __inheritance *inherit,
                const char *argv[],
                const char *envp[]);
```

General description

The `__spawn2()` and `__spawnp2()` functions create a new process from the specified process image. The new process image is constructed from a regular executable file called the new process image file.

To execute a C program as a result of this call, enter the function call as follows:

```
int main (int argc, char *argv[]);
```

Where `argc` is the argument count and `argv` is an array of character pointers to the arguments themselves. In addition, the following variable:

```
extern char **environ;
```

is initialized as a pointer to an array of character pointers to the environment strings. The `argv` and `environ` arrays are each terminated by a NULL pointer. The NULL pointer terminating the `argv` array is not counted in `argc`.

Supported parameters are:

Parameter Description

path

Path name used by `__spawn2()` that identifies the new process image file to execute.

file

Used by __spawnp2() to construct a path name that identifies the new process image file. If the file parameter contains a slash character, the file parameter shall be used as a path name for the new process image file. Otherwise, the path prefix for this file shall be obtained by a search of the directories passed as the environment variable PATH.

fd-count

Specifies the number of file descriptors the child process shall inherit. It may take values from zero to **OPEN_MAX**. Except those file descriptors designated by SPAWN_FDCLOSED, each of the child's file descriptors, x, in the range zero to *fd_count*-1 shall inherit descriptor *fd_map*(x) from the parent process.

The files from *fd_count* through **OPEN_MAX** are closed in the child process, as are any elements of *fd_map* designated as SPAWN_FDCLOSED.

fd-map

If the *fd_map* parameter is NULL, *fd_count* and *fd_map* are ignored. All file descriptors except those with the FD_CLOEXEC or FD_CLOFORK attribute are inherited without reordering. File descriptors with the FD_CLOEXEC or FD_CLOFORK attribute are closed under simple inheritance.

For those file descriptors that remain open, all other attributes of the associated file descriptor object and open file description shall remain unchanged by this operation.

Directory streams open in the calling process image shall be closed in the new process image, with the effect of the closedir() operation.

If an element of *fd_map* refers to an invalid file descriptor, then the (EBADF) error status shall be posted by __spawn2() or __spawnp2().

The FD_CLOEXEC and FD_CLOFORK file descriptor attributes are never inherited.

The FD_CLOEXEC and FD_CLOFORK file descriptor attributes have no effect on inheritance when the *fd_map* parameter is not NULL.

Note: For XTI endpoints, *fd_map* must not map to a number greater than 65535 in the child process.

inherit

The name of a data area that contains the inheritance structure.

The 'struct __inheritance' is defined as follows:

```
struct __inheritance {
    short    flags;           -- Flags
    pid_t    pgroup;         -- Process group
    sigset_t sigmask;        -- Signal mask
    sigset_t sigdefault;     -- Signals set to SIG_DFL
    int      ctltyfd;        -- Cntl tty FD for tcsetpgrp()
    char     *cwdptr;        -- Pointer to the users CWD
    int      cwdlen;         -- Length of the users CWD
    int      acctdatalen;    -- Length of account data area
    char     *acctdataptr;   -- Ptr to account data area
    int      umask;          -- Users UMASK
    char     userid[9];      -- New A.S. user identity
    char     jobname[9];     -- New A.S. jobname
    int      regionsize;     -- New A.S. region size
    int      timelimit;      -- New A.S. time limit
    union {
        #ifdef _LP64
        unsigned long    memlimit;
        #define __memlimit    memlimit_u.memlimit
        #endif
        #ifdef __LL
        unsigned long long    memlimit_ll;
        #define __memlimit_ll    memlimit_u.memlimit_ll
        #endif
        unsigned int        memlimit_i[2];
        #define __memlimit_h    memlimit_u.memlimit_i[0]
        #define __memlimit_l    memlimit_u.memlimit_i[1]
        double              memlimit_d;
    } memlimit_u;
}
```

The `inherit.flags` effect `spawn()` and `spawnp()` as follows:

SPAWN_SETGROUP

If the `SPAWN_SETGROUP` flag is set in *inherit.flags*, then the child's process group shall be as specified in *inherit.pgroup*.

If the `SPAWN_SETGROUP` flag is set in *inherit.flags* and *inherit.pgroup* is set to `SPAWN_NEWPGROUP`, then the child shall be in a new process group with a process group ID equal to its process ID.

If the `SPAWN_SETGROUP` flag is not set in *inherit.flags*, the new child shall inherit the parent's process group ID.

SPAWN_SETSIGMASK

If the `SPAWN_SETSIGMASK` flag is set in *inherit.flags*, the child process shall initially have the signal mask specified in *inherit.sigmask*.

SPAWN_SETSIGDEF

If the `SPAWN_SETSIGDEF` flag is set in *inherit.flags*, the signals specified in *inherit.sigdefault* shall be set to their default actions in the child process. Signals set the default action in the parent process shall be set to the default action in the new process.

Signals set to be caught by the calling process shall be set to the default action in the child process.

Signals set to be ignored by the calling process shall be set to be ignored by the new process, unless otherwise specified by the `SPAWN_SETSIGDEF` flag being set in *inherit.flags* and the signal being indicated *inherit.sigdefault*.

SPAWN_SETCPPGRP

If the `SPAWN_SETCPPGRP` flag is set in *inherit.flag*, the file descriptor specified in *inherit.clttyfd* is used to set the controlling terminal file descriptor (`tcsetpgrp()`) for the child's foreground process group. The child's foreground process group is inherited from the parent, unless the `SPAWN_SETGROUP` flag in *inherit.flags* is set, indicating that the value specified in *inherit.pgroup* is to be used to determine the child's process group.

argv

The value in the first element of *argv* should point to a file name that is associated with the process being started by the `spawn2()` or `spawnp2()` operation.

The number of bytes available for the new process's combined argument and environment lists is **ARG_MAX**.

envp

The value *envp* contains the list of environmental variables that is to be passed to the specified program.

If the set-user-ID mode bit of the new process image file is set, the effective user ID of the new process image shall be set to the owner ID of the new process image file. Similarly, if the set-group-ID mode bit of the new process image file is set, the effective group ID of the new process image shall be set to the group ID of the new process image file. The real user ID, real group ID, and supplementary group IDs of the new process image shall remain the same as those of the calling process image. The effective user ID and effective group ID of the new process image shall be saved (as the saved set-user-ID and set-group-ID) for use by the `setuid()` function.

The new process image shall inherit the following attributes of the calling process image:

- Process group ID (unless the `SPAWN_SETGROUP` flag is set in *inherit.flags*).
- Session membership.
- Real user ID.
- Real group ID.
- Supplementary group IDs.
- Priority.

- Current working directory.
- File creation mask.
- Signal mask (unless the SPAWN_SETSIGMASK flag is set in *inherit.flags*).
- Signal actions specified as default (SIG_DFL).
- Signal actions specified as ignore (SIG_IGN) (except as modified by *inherit.sigdefault* and the SPAWN_SETSIGDEF flag set in *inherit.flags*).

The following are differences between the parent process and child:

- Signals set to be caught by the calling process shall be set to the default action (SIG_DFL).
- The process and system utilization times for the child are set to zero.
- Any file locks previously set by the parent are not inherited by the child.
- The child process has no alarms set and has no interval timers set.
- The child has no pending signals.
- Memory mappings established by the parent are not inherited by the child.

If the process image was read from a writable file system, then upon successful completion, the `__spawn2()` and `__spawnp2()` functions will mark for update the *st_time* field of the new process image file.

If the `__spawn2()` or `__spawnp2()` function is successful, the new child process image file shall be opened with all the effects of the `open()` function.

All the following inherit flags are used by `__spawn2()` and `__spawnp2()`:

SPAWN_SETCWD

Specifies the Current Working Directory that the child process will run when first created. This will override the CWD that would normally be set up or propagated by the child process.

SPAWN_SETUMASK

Specifies the UMASK that the child process will run when first created. This will override the UMASK that would normally be set up in the child process. The invoker must have superuser privileges to specify UMASK.

SPAWN_SETUSERID

When this flag is set, this attribute will be the equivalent of the `_BPX_USERID` environment variable. If specified, the invoking userid will be checked for daemon authority. If the invoker is authorized and the userid is valid, the child process will be created with RACF identity and POSIX permissions associated with the input USERID. If not authorized or the userid is invalid, the `__spawn2()` or `__spawnp2()` function will fail. If the USERID value is specified, any value in `_BPX_USERID` will be ignored.

SPAWN_SETREGIONSZ

Specifies the number of megabytes the child process will have available for private storage. The authority/ranges required will be as per RLIMIT_AS rules. Unless the invoker has superuser privileges, the region size range will be checked and if it exceeds the hard limit, the `__spawn2()` or `__spawnp2()` function will fail. This value will override RLIMIT_AS or the normal spawn propagation rules.

SPAWN_SETTIMELIMIT

Specifies the number of seconds of CPU time that is allowed by the child process before receiving a SIGXCPU signal. Unless the invoker has superuser privileges, the time limit range will be checked and if it exceeds the hard limit, the `__spawn2()` or `__spawnp2()` function will fail. This value will override the RLIMIT_CPU or the normal spawn propagation rules.

SPAWN_SETACCTDATA

Specifies account data of the child process. The format and length will be as per the `_BPX_ACCT_DATA` environmental variable. No special authority is needed to change account data. This will override the target userid's default account data and any value specified on the `_BPX_ACCT_DATA` will be ignored.

SPAWN_SETJOBNAME

When this flag is set, it is the equivalent of the `_BPX_JOBNAME` environment variable. If specified, the invoking userid will be checked for superuser authority. If the invoker is authorized and the jobname is valid, the child process will be created with the specified jobname. If not authorized or the jobname is invalid, `__spawn2()` or `__spawnp2()` will ignore the `JOBNAME` attribute and continue. If the `JOBNAME` value is specified, any value in `_BPX_JOBNAME` will be ignored.

SPAWN_MUSTBELOCAL

When this flag is set, it is the equivalent of the `_BPX_SHAREAS=MUST` environment variable. If specified, the system will attempt a local spawn, otherwise the request will fail.

SPAWN_SETMEMLIMIT

When this flag is set and not doing a local spawn, `inherit.memlimit_u` determines the maximum amount of bytes the child address space is allowed to obtain above the 2-gigabyte bar. If the specified value exceeds the current hard limit, the invoking userid must have appropriate privileges, otherwise the request will fail.

SPAWN_PROCESS_INITTAB

If this flag is set, spawn attempts to read the `/etc/inittab` file and process the entries found there. This processing involves the spawning of child shell processes to run each of the commands identified in the file. Only the `SPAWN_SETSIGMASK` flag can be set in combination with this flag. All other flags will be ignored. Use of this flag implies that only file descriptors 0, 1, and 2 will be initially opened in the child process. File descriptor 0 will be initially opened as `/dev/null`, while file descriptors 1 and 2 will initially be opened as `/etc/log`. The `fd_count` and `fd_map` parameters will be ignored. This flag is currently restricted to the `/usr/sbin/init` process. See *z/OS UNIX System Services Planning* for more information on the `/etc/inittab` support.

For more information on the use of inheritance structure flags, see *z/OS UNIX System Services Programming: Assembler Callable Services Reference*.

Returned value

If successful, `__spawn2()` or `__spawnp2()` returns the process ID of the child process to the parent.

If unsuccessful, `__spawn2()` or `__spawnp2()` returns -1 to the parent process, no child is created, and they set `errno` to one of the following values:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

E2BIG

The number of bytes used by the argument and environment list of the new process image is greater than the system-imposed limit of **ARG_MAX** bytes.

EACCES

Search permission is denied for a directory in the path of the new process image file or the new process image file denies execution permission, or the new process image file is not a regular file and the implementation does not support execution of files of its type.

EAGAIN

The system lacked the necessary resources to create another process, or the system-imposed limit on the total number of processes under execution by a single user would be exceeded. The resources required to let another process be created are not available, or you have already reached the maximum number of processes or UIDs you are allowed to create. This error will also be generated if `_BPX_USERID` or `INHEUSERID` was specified and the username was not defined to SAF with a segment.

EBADF

An entry in the `fd_map` array refers to an invalid file descriptor or the controlling terminal file descriptor specified in the `__inheritance` structure.

EFAULT

The system detected an invalid address while attempting to use a parameter of the call.

EINVAL

One or more of the following conditions were detected:

- The username that was specified on the `_BPX_USERID` environment variable has an incorrect length.
- An attribute that was specified in the inheritance structure (BPXYINHE) is not valid or contains an unsupported value.
- The version number that was specified for the inheritance structure (BPXYINHE) is not valid.
- The inheritance structure length that was specified by the `Inherit_area_len` parameter or within the inheritance structure does not contain a length that is appropriate for the BPXYINHE version.
- The process group ID that was specified in the inheritance structure is less than zero or has some other unsupported value.

The following reason codes can accompany the return code: JR0K, JRUserNameLenError, JRJsRacXtr, JRInheUserid, JRInheRegion, JRInheCPUTime, JRInheDynamber, JRInheAccountData, JRInheCWD, JRInheSetPgrp, JRInheVersion, and JRInheLength.

ELOOP

A loop exists in symbolic links encountered during resolution of the file name argument. This error is issued if more than 8 symbolic links are detected.

EMVSERR

The spawn failed for the following reason: Local spawn not allowed. Either the environment variable `_BPX_SHAREAS` was set to MUST (`_BPX_SHAREAS=MUST`), or the `__inheritance` structure specified `SPAWN_MUSTBELOCAL`.

The following reason code can accompany the return code: JRLocalSpawnNotAllowed.

EMVSSAF2ERR

The executable file is a set-user-ID or set-group-ID file and the owner's UID or GID is not defined to the Security Authorization Facility (SAF).

ENAMETOOLONG

The length of the path or file parameter, or an element of the environmental variable `PATH` prefixed to a file, exceeds **PATH_MAX**, or a path name component is longer than **NAME_MAX** and `{_POSIX_N_TRUNC_}` is in effect for that file.

ENOENT

One or more components of the path name of the new process image file do not exist or the path or file parameter is empty.

ENOEXEC

The new process image file has the appropriate access permission, but is not in the proper format.

Note:

Reason codes further qualify the `errno`. For most of the reason codes, see [z/OS UNIX System Services Messages and Codes](#).

For ENOEXEC, the reason codes are:

| Reason Code | Explanation |
|-------------|---|
| X'xxxx0C27' | The target file is not in the correct format to be an executable file. |
| X'xxxx0C31' | The target file is built at a level that is higher than that supported by the running system. |

ENOMEM

The new process requires more memory than is permitted by the hardware or operating system.

ENOTDIR

A component of the path prefix of the new process image file is not a directory.

ENOTTY

tcsetpgrp() failed for the specified controlling terminal file descriptor in `__inheritance` structure. The failure occurred because the calling process does not have a controlling terminal, or the specified file descriptor is not associated with the controlling terminal, or the controlling terminal is no longer associated with the session of the calling process.

EPERM

The spawn failed for one of the following reasons:

- The spawned process is not a process group leader.
- The `_BPX_USERID` environment variable was specified, and the invoker does not have appropriate privileges to change the MVS identity.
- The invoker does not have the appropriate privileges to change one or more of the attributes specified in the inheritance structure (BPXYINHE).

The following reason codes can accompany the return code: JROK, JRNoChangeIdentity, JRInheUserid, JRInheRegion, JRInheCPUTime, JRInheUmask, JRInheCWD and JRInheMemLimit.

ESRCH

The process group ID specified in the `__inheritance` structure is not that of a process group in the calling process's session.

sprintf() — Format and write data to buffer

The information for this function is included in [“fprintf\(\), printf\(\), sprintf\(\) — Format and write data” on page 593](#).

sqrt(), sqrtf(), sqrtl() – Calculate square root

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#include <math.h>

double sqrt(double x);
float sqrt(float x);           /* C++ only */
long double sqrt(long double x); /* C++ only */
float sqrtf(float x);
long double sqrtl(long double x);
```

General description

Calculates the square root of x .

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

Returned value

If successful, returns the square root of x .

If x is negative, the function sets `errno` to `EDOM`, and returns 0. If the correct value would cause underflow, zero is returned and the value `ERANGE` is stored in `errno`.

Special behavior for IEEE

If $x < -0$, the function returns `NaNQ` and sets `errno` to `EDOM`.

If x is a NaN, a NaN will be returned.

If x is ± 0 or $+\text{INF}$, x will be returned.

If x is $-\text{INF}$, a `EDOM` will be set, and `NaNQ` will be returned.

Example

CELEBS30

```
/* CELEBS30

   This example computes the square root of the quantity passed
   as the first argument to main.
   It prints an error message if you pass a negative value.

*/
#include <stdio.h>
#include <stdlib.h>
#include <math.h>
```

```
int main(int argc, char ** argv)
{
    char * rest;
    double value;

    if ( argc != 2 )
        printf( "Usage: %s value\n", argv[0] );
    else
    {
        value = strtod( argv[1], &rest );
        if ( value < 0.0 )
            printf( "sqrt of a negative number\n" );
        else
            printf("sqrt( %f ) = %f\n", value, sqrt( value ));
    }
}
```

Output

If the input is 45, then the output should be:

```
sqrt( 45.000000 ) = 6.708204
```

sqrtd32(), sqrtd64(), sqrtd128() — Calculate square root

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 sqrtd32(_Decimal32 x);
_Decimal64 sqrtd64(_Decimal64 x);
_Decimal128 sqrtd128(_Decimal128 x);
_Decimal32 sqrt(_Decimal32 x);          /* C++ only */
_Decimal64 sqrt(_Decimal64 x);          /* C++ only */
_Decimal128 sqrt(_Decimal128 x);        /* C++ only */
```

General description

Calculates the square root of x.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

If successful, returns the square root of x .

If the correct value would cause underflow, zero is returned and the value ERANGE is stored in `errno`.

If $x < -0$, the function returns NaNQ and sets `errno` to EDOM.

If x is a NaN, a NaN will be returned.

If x is ± 0 or $+\text{INF}$, x will be returned.

If x is $-\text{INF}$, the function returns NaNQ and sets `errno` to EDOM.

Example

```
/* CELEBS71

   This example illustrates the sqrt32() function, along with
   the strtod32() function.

   This example computes the square root of the quantity passed
   as the first argument to main.
   It prints an error message if you pass a negative value.

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>
#include <stdlib.h>

int main(int argc, char ** argv)
{
    char      *rest;
    _Decimal32 value;

    if (argc != 2)
    {
        printf("Usage: %s value\n", argv[0]);
    }
    else
    {
        value = strtod32(argv[1], &rest);

        if (value < 0.0DF)
            printf("sqrt of a negative number\n");
        else
            printf("sqrt(%Hf) = %Hf\n", value, sqrt32(value));
    }
}
```

srand() — Set seed for rand() function

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdlib.h>

void srand(unsigned int seed);
```

General description

srand() uses its argument *seed* as a seed for a new sequence of pseudo-random numbers to be returned by subsequent calls to rand(). If srand() is not called, the rand() seed is set as if srand(1) was called at program start. Any other value for *seed* sets the generator to a different starting point. The rand() function generates pseudo-random numbers.

Some people find it convenient to use the return value of the time() function as the argument to srand(), as a way to ensure random sequences of random numbers.

Returned value

srand() returns no values.

Example

CELEBS31

```
/* CELEBS31

   This example first calls &srand. with a value other than 1 to
   initiate the random value sequence.
   Then the program computes 5 random values for the array of
   integers called ranvals.
   If you repeat this code exactly, then the same sequence of
   random values will be generated.

*/
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    int i, ranvals[5];

    srand(17);
    for (i = 0; i < 5; i++)
    {
        ranvals[i] = rand();
        printf("Iteration %d ranvals [%d] = %d\n", i+1, i, ranvals[i]);
    }
}
```

Output

```
Iteration 1 ranvals [0] = 24107
Iteration 2 ranvals [1] = 16552
Iteration 3 ranvals [2] = 12125
```

```
Iteration 4 ranvals [3] = 9427
Iteration 5 ranvals [4] = 13152
```

srandom() — Use seed to initialize generator for random()

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

void srandom(unsigned seed);
```

General description

The `srandom()` function initializes the calling thread's current state array for the `random()` function using the value of *seed*.

Returned value

`srandom()` returns no values.

srand48() – Pseudo-random number initializer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <stdlib.h>

void srand48(long int seedval);
```

General description

The drand48(), erand48(), jrand48(), lrand48(), mrand48() and nrand48() functions generate uniformly distributed pseudo-random numbers using a linear congruential algorithm and 48-bit integer arithmetic.

The lcong48(), seed48(), and srand48() functions are initialization functions, one of which should be invoked before either the drand48(), lrand48() or mrand48() function is called.

The drand48(), lrand48() and mrand48() functions generate a sequence of 48-bit integer values, X(i), according to the linear congruential formula:

$$X(n+1) = (aX(n) + c) \bmod (2^{**}48) \qquad n \geq 0$$

The initial values of X, a, and c are:

```
X(0)= 1
a  = 5deece66d (base 16)
c  = b          (base 16)
```

C/370 provides storage to save the most recent 48-bit integer value of the sequence, X(i). This storage is shared by the drand48(), lrand48() and mrand48() functions. The srand48() function is used to reinitialize the most recent 48-bit value in this storage. The srand48() function replaces the high-order (leftmost) 32 bits of this storage with *seedval* argument value. The srand48() function replaces the low-order 16 bits of this storage with the value **330E** (base 16).

The values a and c, may be changed by calling the lcong48() function. The srand48()function restores the initial values of a and c.

Special behavior for z/OS UNIX Services: You can make the srand48() function and other functions in the drand48 family thread-specific by setting the environment variable `_RAND48` to the value `THREAD` before calling any function in the drand48 family.

If you do not request thread-specific behavior for the drand48 family, C/370 serializes access to the storage for X(n), a and c by functions in the drand48 family when they are called by a multithreaded application.

If thread-specific behavior is requested, calls to the drand48(), lrand48() and mrand48() functions from thread *t* generate a sequence of 48-bit integer values, X(t,i), according to the linear congruential formula:

$$X(t,n+1) = (a(t)X(t,n) + c(t)) \bmod (2^{**}48) \qquad n \geq 0$$

C/370 provides thread-specific storage to save the most recent 48-bit integer value of the sequence, X(t,i). When the srand48()function is called from thread *t*, it reinitializes the most recent 48-bit value in this storage. The srand48() function replaces the high-order (leftmost) 32 bits of this storage with *seedval*

argument value. The `srand48()` function replaces the low-order 16 bits of this storage with the value **330E** (base 16).

The values of `a(t)` and `c(t)` may be changed by calling the `lcong48()` function from thread `t`. When the `srand48()` function is called from this thread it restores the initial values of `a(t)` and `c(t)` for the thread which are:

```
a(t) = 5deece66d (base 16)
c(t) = b         (base 16)
```

Returned value

`srand48()` returns no values.

`srand48()` returns after it has used the value of the argument *seedval* to reinitialize storage for the most recent 48-bit integer value in the sequence, `X(i)`, and has restored the initial values of `a` and `c`.

Special behavior for z/OS UNIX Services: If thread-specific behavior is requested for the `drand48` family and the `srand48()` function is called on thread `t`, it uses the value of the argument *seedval* to reinitialize storage for the most recent 48-bit integer value in the sequence, `X(t,i)`, for the thread. It also restores the initial values of `a(t)` and `c(t)` for the thread. Then it returns.

sscanf() – Read and format data from buffer

The information for this function is included in [“fscanf\(\), scanf\(\), sscanf\(\) – Read and format data” on page 626](#).

stat(), stat64() – Get file information

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

stat:

```
#define _POSIX_SOURCE
#include <sys/stat.h>
```

```
int stat(const char *__restrict__ pathname, struct stat *__restrict__ info);
```

stat64:

```
#define _LARGE_TIME_API
#define _POSIX_SOURCE
#include <sys/stat.h>

int stat64(const char *__restrict__ pathname, struct stat64 *__restrict__ info);
```

Compile requirement: Use of the `stat64()` function requires the `long long` data type. For more information on how to make the `long long` data type available, see [z/OS XL C/C++ Language Reference](#).

General description

Gets status information about a specified file that is pointed to by the *pathname* argument and places it in the area of memory pointed to by the *info* argument. The process does not need permissions on the file itself, but must have search permission on all directory components of the *pathname*. If the named file is a symbolic link, `stat()` resolves the symbolic link. It also returns information about the resulting file.

The `stat64()` function behaves exactly like `stat()` except `stat64()` uses structure `stat64` instead of `struct stat` to support time beyond 03:14:07 UTC on January 19, 2038.

The information is returned as shown in the following table for the `stat` and `stat64` structures, as defined in the `sys/stat.h` header file.

| Table 60. Values Returned in stat and stat64 Structures | | |
|---|-------------------|---|
| Value for stat | Value for stat64 | Description |
| mode_t st_mode | mode_t st_mode | A bit string indicating the permissions and privileges of the file. Symbols are defined in the <code>sys/stat.h</code> header file to refer to bits in a <code>mode_t</code> value; these symbols are listed in “ chmod() – Change the mode of a file or directory ” on page 274. |
| ino_t st_ino | ino_t st_ino | The serial number of the file. |
| dev_t st_dev | dev_t st_dev | The numeric ID of the device containing the file. |
| nlink_t st_nlink | nlink_t st_nlink | The number of links to the file. |
| uid_t st_uid | uid_t st_uid | The numeric user ID (UID) of the file's owner. |
| gid_t st_gid | gid_t st_gid | The numeric group ID (GID) of the file's group. |
| off_t st_size | long long st_size | For regular files, the file's size in bytes. For other kinds of files, the value of this field is unspecified. |
| time_t st_atime | time64_t st_atime | The most recent time the file was accessed. |
| time_t st_ctime | time64_t st_ctime | The most recent time the status of the file was changed. |
| time_t st_mtime | time64_t st_mtime | The most recent time the contents of the file were changed. |

Values for `time_t` and `time64_t` are given in terms of seconds since epoch.

`stat()` updates the time-related fields before putting information in the `stat` structure.

You can examine properties of a `mode_t` value from the `st_mode` field using a collection of macros defined in the `sys/modes.h` header file. If *mode* is a `mode_t` value, and *genvalue* is an unsigned `int` value from the `stat` structure, then:

S_ISBLK(*mode*)

Is nonzero for block special files.

S_ISCHR(*mode*)

Is nonzero for character special files.

S_ISDIR(*mode*)

Is nonzero for directories.

S_ISEXTL(*mode*,*genvalue*)

Is nonzero for external links.

S_ISFIFO(*mode*)

Is nonzero for pipes and FIFO special files.

S_ISLNK(*mode*)

Is nonzero for symbolic links.

S_ISREG(*mode*)

Is nonzero for regular files.

S_ISSOCK(*mode*)

Is nonzero for sockets.

If `stat()` successfully determines this information, it stores it in the area indicated by the *info* argument. The size of the buffer determines how much information is stored; data that exceeds the size of the buffer is truncated.

Large file support for z/OS UNIX files: `stat64()` automatically supports large z/OS UNIX files for both AMODE 31 and AMODE 64 C/C++ applications, which means there is no need for `_LARGE_FILES` feature test macro to be defined. As for `stat()`, the automatic support is only for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the [long long data type support](#) enabled and define the `_LARGE_FILES` feature test macro before any headers are included to enable `stat()` to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the `_LARGE_FILES` feature test macro as well.

Returned value

If successful, `stat()` returns 0.

If unsuccessful, `stat()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

The process does not have search permission on some component of the *pathname* prefix.

EINVAL

info is a NULL pointer.

EIO

Added for XPG4.2: An error occurred while reading from the file system.

ELOOP

A loop exists in symbolic links encountered during resolution of the *pathname* argument. This error is returned if more than `POSIX_SYMLINK` (defined in the `limits.h` header file) symbolic links are encountered during resolution of the *pathname* argument.

ENAMETOOLONG

pathname is longer than `PATH_MAX` characters, or some component of *pathname* is longer than `NAME_MAX` characters while `_POSIX_NO_TRUNC` is in effect. For symbolic links, the length of the path name string substituted for a symbolic link exceeds `PATH_MAX`. The `PATH_MAX` and `NAME_MAX` values can be determined with `pathconf()`.

ENOENT

There is no file named *pathname*, or *pathname* is an empty string.

ENOTDIR

A component of the *pathname* prefix is not a directory.

EOverflow

The file size in bytes or the number of blocks allocated to the file or the file serial number cannot be represented correctly in the structure pointed to by *info*.

Note: Environment variable `_EDC_EOverflow` can be used to control behavior of the `stat()` function with respect to detecting an `EOverflow` condition for z/OS UNIX files. By default, the `stat()` function will not set `EOverflow` when the file size can not be represented correctly in structure pointed to by *buf*. When `_EDC_EOverflow` is set to YES, the `stat()` function will check for an overflow condition.

Example**CELEBS33**

```
/* CELEBS33

   This example gets status information about a file.

*/
#define _POSIX_SOURCE
#include <sys/types.h>
#include <sys/stat.h>
#undef _POSIX_SOURCE
#include <stdio.h>
#include <time.h>

main() {
    struct stat info;

    if (stat("/", &info) != 0)
        perror("stat() error");
    else {
        puts("stat() returned the following information about root f/s:");
        printf("  inode:   %d\n",    (int) info.st_ino);
        printf(" dev id:  %d\n",    (int) info.st_dev);
        printf("  mode:   %08x\n",    info.st_mode);
        printf(" links:  %d\n",    info.st_nlink);
        printf("   uid:   %d\n",    (int) info.st_uid);
        printf("   gid:   %d\n",    (int) info.st_gid);
        printf("created:  %s",      ctime(&info.st_createtime));
    }
}
```

Output

`stat()` returned the following information about root `f/s`:

```
inode:   0
dev id:  1
mode:    010001ed
links:   11
uid:     0
gid:     500
created:  Fri Jun 16 10:07:55 2006
```

statfs() — Get file system statistics

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFOM_SOURCE
#include <sys/statfs.h>

int statfs(const char *path, struct statfs *buf);
```

General description

The `statfs()` system call returns information about a mounted file system. *path* is the path name of any file within the mounted file system. *buf* is a pointer to a structure of `statfs` as defined in the `sys/statfs.h` header file.

Values that are returned in the `statfs` structure are summarized in the following table. Fields that are undefined for a particular file system are set to 0.

Table 61. Values that are returned in the *statfs* structure

| Value | Description |
|-------------------------------------|--|
| unsigned long <code>f_type</code> | Type of file system ¹ |
| unsigned long <code>f_bsize</code> | Optimal transfer block size |
| unsigned long <code>f_blocks</code> | Total data blocks in file system |
| unsigned long <code>f_bfree</code> | Free blocks in file system |
| unsigned long <code>f_bavail</code> | Free blocks available to unprivileged user |

Table 61. Values that are returned in the *statfs* structure (continued)

| Value | Description |
|---------------------------------|---------------------------------------|
| unsigned long <i>f_files</i> | Total inodes in file system |
| unsigned long <i>f_ffree</i> | Free inodes in file system |
| unsigned long <i>f_fsid</i> | File system ID |
| unsigned long <i>f_namelen</i> | Maximum length of file names |
| unsigned long <i>f_frsize</i> | Fragment size |
| unsigned long <i>f_flags</i> | Mount flags of file system |
| 2 | |
| unsigned long <i>f_spare[4]</i> | Padding bytes reserved for future use |

Notes:

1. *f_type* supports the following file system types:

Table 62. *f_type* value and file system type

| f_type value | File system type |
|---------------------|-------------------------|
| ZOSDSFS_SUPER_MAGIC | /* zOS DSFS */ |
| ZOSHFS_SUPER_MAGIC | /* zOS UNIX */ |
| NFS_SUPER_MAGIC | /* NFS */ |
| PROC_SUPER_MAGIC | /* /proc FS */ |
| ZOSUFS_SUPER_MAGIC | /* zOS UFS */ |
| ZOSZFS_SUPER_MAGIC | /* zOS ZFS */ |

2. The *f_flags* field is a bit mask indicating mount options for the file system. It contains zero or more of the following bits:

ST_NOSUID

The set-user-ID and set-group-ID bits are ignored by exec.

ST_RDONLY

This file system is mounted read-only.

ST_OEEXPORTED

The file system is exported.

ST_NOSECURITY

Security checks are not enforced for files in this file system.

Returned value

If successful, *statfs()* returns 0.

If unsuccessful, *statfs()* returns -1 and sets *errno* to one of the following values:

Error Code**Description****EACCES**

The process does not have search permission on some components of the *pathname* prefix.

EINTR

A signal is caught during the function execution.

EIO

An I/O error occurs while reading the file system.

ELOOP

A loop exists in symbolic links that are encountered during resolution of the *pathname* argument.

ENAMETOOLONG

The length of *pathname* exceeds PATH_MAX or a component of *pathname* is longer than NAME_MAX.

ENOENT

There is no file that is named *pathname*, or *pathname* is an empty string.

ENOTDIR

A component of the *pathname* prefix is not a directory.

EINVAL

A parameter is specified incorrectly.

ERANGE

The result is too large to fit in the available buffer space.

Related information

- [“sys/statfs.h — File system status” on page 71](#)

statvfs() – Get file system information

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/statvfs.h>

int statvfs(const char *_restrict_ pathname, struct statvfs *_restrict_ fsinfo);
```

General description

The statvfs() function obtains information about the file system containing the file named by *pathname* and stores it in the area of memory pointed to by the *fsinfo* argument. The process does not need permissions on the file itself, but must have search permission on all directory components of the *pathname*.

The information is returned in the following statvfs structure, as defined in the sys/statvfs.h header file.

| Table 63. Values Returned in statvfs Structure | |
|--|--------------------------------------|
| Value | Description |
| char f_OEcbid[4] | The structure acronym (eye catcher). |
| int f_OEcblen | The length of the structure. |
| unsigned long f_bsize | The file system block size. |

Table 63. Values Returned in statvfs Structure (continued)

| Value | Description |
|---------------------------------|--|
| unsigned long f_blocks | The total number of blocks on the file system in units of f_frsize. |
| unsigned long f_OEusedspace | The allocated space in block size units. |
| unsigned long f_bavail | The number of free blocks available to non-privileged process. |
| unsigned long f_fsid | The file system ID. |
| unsigned long f_flag | A bit string indicating file system status. |
| int f_OEmaxfilesizehw | The high word of maximum file size. |
| unsigned long f_OEmaxfilesizelw | The low word of maximum file size. |
| unsigned long f_frsize | The fundamental file system block size. |
| unsigned long f_bfree | The total number of free blocks. |
| unsigned long f_files | The total number of file serial numbers. |
| unsigned long f_ffree | The total number of free file serial numbers. |
| unsigned long f_favail | The number of file serial numbers available to non-privileged process. |
| unsigned long f_namemax | The maximum file name length. |
| unsigned long f_OEinvarsec | The number of seconds the file system will remain unchanged. |

The following flags can be returned in the `f_flag` member:

ST_RDONLY

read-only file system

ST_NOSUID

setuid/setgid bits ignored by exec

ST_OEEXPORTED

file system is exported

If `statvfs()` successfully determines this information, it stores in the area indicated by the *fsinfo* argument. The size of the buffer determines how much information is stored; data that exceeds the size of the buffer is truncated.

Returned value

If successful, `statvfs()` returns 0.

If unsuccessful, `statvfs()` returns -1 and sets `errno` to one of the following values:

Error Code**Description****EACCES**

The process does not have search permission on some component of the *pathname* prefix.

EINTR

A signal was caught during the execution of the function.

EIO

An I/O error has occurred while reading the file system.

ELOOP

A loop exists in symbolic links encountered during resolution of the *pathname* argument. This error is issued if more than the system-defined limit of symbolic links, 8, are detected in the resolution of *pathname*.

ENAMETOOLONG

The length of the *pathname* exceeds **PATH_MAX** or a component of *pathname* is longer than **NAME_MAX**.

ENOENT

There is no file named *pathname*, or *pathname* is an empty string.

ENOTDIR

A component of the *pathname* prefix is not a directory.

Example

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/statvfs.h>
#include <stdio.h>

main() {
    int fd;
    struct statvfs buf;

    if (statvfs(".", &buf) == -1)
        perror("statvfs() error");
    else {
        printf("each block is %d bytes big\n", fs,
            buf.f_frsize);
        printf("there are %d blocks available out of a total of %d\n",
            buf.f_bavail, buf.f_blocks);
        printf("in bytes, that's %.0f bytes free out of a total of %.0f\n",
            ((double)buf.f_bavail * buf.f_frsize),
            ((double)buf.f_blocks * buf.f_frsize));
    }
}
```

Output

```
each block is 4096 bytes big
there are 2089 blocks available out of a total of 2400
in bytes, that's 8556544 bytes free out of a total of 9830400
```

step() — Pattern match with regular expression

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4 XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE
#include <regex.h>

int step(const char *string, const char *expbuf);

extern char *loc1, *loc2;
```

General description

Restriction: This function is not supported in AMODE 64.

The `step()` function attempts to match an input string of characters with the compiled regular expression which was obtained by an earlier call to `compile()`.

The first parameter *string* is a pointer to a string of characters to be checked for a match.

expbuf is the pointer to the regular expression which was previously obtained by a call to `compile()`.

Usage notes

1. The external variables *cirf*, *sed*, and *nbra* are reserved.
2. The application must provide the proper serialization for the `compile()`, `step()`, and `advance()` functions if they are run under a multithreaded environment.
3. The `compile()`, `step()` and `advance()` functions are provided for historical reasons. These functions were part of the Legacy Feature in Single UNIX Specification, Version 2. They have been withdrawn and are not supported as part of Single UNIX Specification, Version 3. New applications should use the newer functions `fnmatch()`, `glob()`, `regcomp()`, and `regexexec()`, which provide full internationalized regular expression functionality compatible with ISO POSIX.2 standard.

Returned value

If some substring of *string* matches the regular expression in *expbuf*, `step()` returns nonzero.

If there is no match, `step()` returns 0.

If there is a match, `step()` sets two external pointers, as follows:

- The variable *loc1* points to the first character that matched the regular expression.
- The variable *loc2* points to the character after the last character that matched the regular expression.

For example, if the regular expression matches the entire input *loc1* will point to the first character of *string* and *loc2* will point to the NULL at the end of *string*.

stpcpy() — Copy string, returning pointer to its end

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1-2008 Single UNIX Specification, Version 4 | Both | z/OS 3.2 |

Format

```
#define _POSIX_C_SOURCE 200809L
#include <string.h>

char *stpcpy(char *__restrict__ string1, const char *__restrict__ string2);
```

General description

The `stpcpy()` function copies *string2*, including the terminating NULL character (`\0`), to the location that is specified by *string1*.

The string that is pointed to by *string1* must have the space of at least `strlen(string2)+1` characters to receive the copy.

You cannot use a string literal for a *string1* value, although *string2* may be a string literal.

string2 and *string1* must not overlap. Otherwise, the behavior is undefined.

Returned value

`stpcpy()` returns a pointer to the end of *string1*.

Note: No return values are reserved to indicate an error. To check for error situations, set `errno` to 0, call this function, then check `errno`.

Example

```
/* This example copies the contents of source to dest,
   returning a pointer to the end of dest.
*/

#define _POSIX_C_SOURCE 200809L
#include <stdio.h>
#include <string.h>

#define SIZE    40

int main(void)
```

```

{
    char source[ SIZE ] = "test string";
    char dest[ SIZE ];
    char * result;

    result = stpcpy( dest, source );

    /* use strlen() to calculate length of source string */
    printf( "result: \"%s\\", result - strlen(source): \"%s\\\"\\n",
           result, result - strlen(source) );
}

```

Output

```
result: "", result - strlen(source): "test string"
```

stpncpy() — Copy fixed-size string, returning pointer to its end

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1-2008 Single UNIX Specification, Version 4 | both | z/OS 3.2 |

Format

```

#define _POSIX_C_SOURCE 200809L
#include <string.h>

char *stpncpy(char *__restrict__ string1, const char *__restrict__ string2, size_t n);

```

General description

The `stpncpy()` function copies at most *n* characters (bytes) before and including the terminating NULL character (`\0`) from the string that is pointed to by *string2* to the location that is specified by *string1*.

If the string that is pointed to by *string2* is smaller than *n* characters, the remaining characters in the string that is pointed to by *string1* are filled with terminating NULL characters (`\0`).

You cannot use a string literal for a *string1* value, although *string2* may be a string literal.

string2 and *string1* must not overlap. Otherwise, the behavior is undefined.

Returned value

`stpncpy()` returns a pointer to the terminating NULL character (`\0`) in *string1* if *string1* is null-terminated. Otherwise, `stpncpy()` returns `&string1[n]`.

Note: No return values are reserved to indicate an error. To check for error situations, set `errno` to 0, call this function, then check `errno`.

Example

```

/*
 * This example copies at most max_len characters from source to dest,
 * returning a pointer to the end of dest.
 */

#define _POSIX_C_SOURCE
#include <stdio.h>
#include <string.h>

```

```

#define SIZE    40

int main(void)
{
    char source[ SIZE ] = "test string";
    char dest[ SIZE ];
    size_t max_len = 9;
    char * result;

    result = stpncpy( dest, source, max_len );

    /* use strlen() to calculate length of source string */
    printf( "result: \"%s\\", "
            "result - strlen(source, max_len): \"%s\\\"\\n",
            result, result - strlen(source, max_len) );
}

```

Output

```

result: "", result - strlen(source, max_len): "test stri"

```

strcasecmp() – Case-insensitive string comparison

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```

#define _XOPEN_SOURCE_EXTENDED 1
#include <strings.h>

int strcasecmp(const char *string1, const char *string2);

```

General description

The `strcasecmp()` function compares, while ignoring differences in case, the string pointed to by *string1* to the string pointed to by *string2*.

The string arguments to the function must contain a NULL character (`\0`) marking the end of the string.

The `strcasecmp()` function is locale-sensitive.

Returned value

`strcasecmp()` returns a value indicating the relationship between the strings, while ignoring case, as follows:

Value**Meaning****< 0**

String pointed to by *string1* is less than string pointed to by *string2*.

= 0

String pointed to by *string1* is equal to string pointed to by *string2*.

> 0

String pointed to by *string1* is greater than string pointed to by *string2*.

There are no `errno` values defined.

strcat() — Concatenate strings

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <string.h>

char *strcat(char * __restrict__string1, const char * __restrict__string2);
```

General description

The `strcat()` built-in function concatenates *string2* with *string1* and ends the resulting string with the NULL character. In other words, `strcat()` appends a copy of the string pointed to by *string2*—including the terminating NULL byte—to the end of a string pointed to by *string1*, with its last byte (that is, the terminating NULL byte of *string1*) overwritten by the first byte of the appended string.

Do not use a literal string for a *string1* value, although *string2* may be a literal string.

If the storage of *string1* overlaps the storage of *string2*, the behavior is undefined.

Returned value

Returns the value of *string1*, the concatenated string.

Example

CELEBS34

```
/* CELEBS34

   This example creates the string "computer program" using strcat().

*/
#include <stdio.h>
#include <string.h>

#define SIZE 40

int main(void)
{
    char buffer1[SIZE] = "computer";
    char * ptr;

    ptr = strcat( buffer1, " program" );
```

```
printf( "buffer1 = %s\n", buffer1 );
}
```

Output

```
buffer1 = computer program
```

strchr() — Search for character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

C:

```
#include <string.h>

char *strchr(const char *string, int c);
```

C++:

```
#include <string.h>

const char *strchr(const char *string, int c);
char *strchr(char *string, int c);
```

General description

The `strchr()` built-in function finds the first occurrence of `c` converted to `char`, in the string **string*. The character `c` can be the NULL character (`\0`); the ending NULL character of *string* is included in the search.

The `strchr()` function operates on NULL-terminated strings. The string argument to the function *must* contain a NULL character (`\0`) marking the end of the string.

Returned value

If successful, `strchr()` returns a pointer to the first occurrence of `c` (converted to a character) in *string*.

If the character is not found, `strchr()` returns a NULL pointer.

Example

CELEBS35

```

/* CELEBS35

   This example finds the first occurrence of the character p in
   "computer program".

   */
#include <stdio.h>
#include <string.h>

#define SIZE 40

int main(void)
{
    char buffer1[SIZE] = "computer program";
    char * ptr;
    int    ch = 'p';

    ptr = strchr( buffer1, ch );
    printf( "The first occurrence of %c in '%s' is '%s'\n",
           ch, buffer1, ptr );
}

```

Output

```
The first occurrence of p in 'computer program' is 'puter program'
```

strchrnul() — Find first occurrence of character in string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```

#define _XPLATFROM_SOURCE 1
#include <string.h>

char * strchrnul(const char *string, int c);

```

General description

The `strchrnul()` function finds the first occurrence of `c`, which is converted to a `char` in the string `*string`. The character `c` can be the NULL character (`\0`). The ending NULL character of `string` is included in the search.

The `strchrnul()` function operates on NULL-terminated strings. The string argument to the function must contain a NULL character (`\0`) that represents the end of the string.

Returned value

If successful, `strchrnul()` returns a pointer to the first occurrence of `c`, which is converted to a `char` in the string `*string`.

If the character is not found, `strchrnul()` returns a pointer to the null byte at the end of `string`.

strcmp() – Compare strings

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <string.h>

int strcmp(const char *string1, const char *string2);
```

General description

The `strcmp()` built-in function compares the string pointed to by `string1` to the string pointed to by `string2`. The string arguments to the function must contain a NULL character (`\0`) marking the end of the string.

The relation between the strings is determined by subtracting: $string1[i] - string2[i]$, as i increases from 0 to $strlen$ of the smaller string. The sign of a nonzero return value is determined by the sign of the difference between the values of the first pair of bytes (both interpreted as type unsigned char) that differ in the strings being compared. This function is *not* locale-sensitive.

Returned value

strcmp() returns a value indicating the relationship between the strings, as listed below.

Value

Meaning

< 0

String pointed to by *string1* less than string pointed to by *string2*

= 0

String pointed to by *string1* equivalent to string pointed to by *string2*

> 0

String pointed to by *string1* greater than string pointed to by *string2*

Example

CELEBS36

```
/* CELEBS36

   This example compares the two strings passed to main using
   &strcmp..

   */
#include <stdio.h>
#include <string.h>

int main(int argc, char ** argv)
{
    int result;

    if ( argc != 3 )
    {
        printf( "Usage: %s string1 string2\n", argv[0] );
    }
    else
    {
        result = strcmp( argv[1], argv[2] );

        if ( result == 0 )
            printf( "\"%s\" is identical to \"%s\"\n", argv[1], argv[2] );
        else if ( result < 0 )
            printf( "\"%s\" is less than \"%s\"\n", argv[1], argv[2] );
        else
            printf( "\"%s\" is greater than \"%s\"\n", argv[1], argv[2] );
    }
}
```

Output

If the input is the strings "is this first?" and "is this before that one?" then the expected output is:

```
"is this first?" is greater than "is this before that one?"
```

strcoll() — Compare strings

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <string.h>

int strcoll(const char *string1, const char *string2);
```

General description

Compares the string pointed to by *string1* against the string pointed to by *string2*, both interpreted according to the information in the LC_COLLATE category of the current locale.

Returned value

strcoll() returns a value indicating the relationship between the strings, as listed below.

Value

Meaning

< 0

string pointed to by *string1* less than string pointed to by *string2*

= 0

string pointed to by *string1* equivalent to string pointed to by *string2*

> 0

string pointed to by *string1* greater than string pointed to by *string2*

Notes:

1. The strcoll() function may need to allocate additional memory to perform the comparison algorithm specified in the LC_COLLATE. If the memory request cannot be satisfied (by malloc()), strcoll() fails.
2. If the locale supports double-byte characters (MB_CUR_MAX specified as 4), the strcoll() function validates the multibyte characters, whereas previously the strcoll() function did not validate the string. The strcoll() function will fail if the string contains invalid multibyte characters.
3. If MB_CUR_MAX is specified as 4, but the charmap file does not specify the DBCS characters, the DBCS characters will collate after the single-byte characters.

Example

CELEBS37

```

/* CELEBS37

   This example compares the two strings passed to main.

*/
#include <stdio.h>
#include <string.h>

int main(int argc, char ** argv)
{
    int result;

    if ( argc != 3 ) {
        printf( "Usage: %s string1 string2\n", argv[0] );
    }
    else {
        result = strcoll( argv[1], argv[2] );

        if ( result == 0 )
            printf( "\"%s\" is identical to \"%s\"\n", argv[1], argv[2] );
        else if ( result < 0 )
            printf( "\"%s\" is less than \"%s\"\n", argv[1], argv[2] );
        else
            printf( "\"%s\" is greater than \"%s\"\n", argv[1], argv[2] );
    }
}

```

Output

If the input is the strings “firststring” and “secondstring”, then the expected output is:

```
"firststring" is less than "secondstring"
```

Related information

- [“string.h – String manipulation functions” on page 66](#)
- [“setlocale\(\) – Set locale” on page 1547](#)

strcpy() – Copy string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```

#include <string.h>

char *strcpy(char * __restrict__string1, const char * __restrict__string2);

```

General description

The `strcpy()` built-in function copies *string2*, including the ending NULL character, to the location specified by *string1*. The *string2* argument to `strcpy()` must contain a NULL character (`\0`) marking the end of the string. You cannot use a literal string for a *string1* value, although *string2* may be a literal string. If the two objects overlap, the behavior is undefined.

Returned value

`strcpy()` returns the value of *string1*.

Example

CELEBS38

```
/* CELEBS38

   This example copies the contents of source to destination.

*/
#include <stdio.h>
#include <string.h>

#define SIZE    40

int main(void)
{
    char source[ SIZE ] = "This is the source string";
    char destination[ SIZE ] = "And this is the destination string";
    char * return_string;

    printf( "destination is originally = \"%s\\n", destination );
    return_string = strcpy( destination, source );
    printf( "After strcpy, destination becomes \"%s\\n", destination );
}
```

Output

```
destination is originally = "And this is the destination string"
After strcpy, destination becomes "This is the source string"
```

strcspn() — Compare strings

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <string.h>

size_t strcspn(const char *string1, const char *string2);
```

General description

Computes the length of the initial portion of the string pointed to by *string1* that contains no characters from the string pointed to by *string2*.

Returned value

strcspn() returns the calculated length of the initial portion found.

Example

CELEBS39

```
/* CELEBS39

   This example uses &strcspn. to find the first occurrence of
   any of the characters a, x, l or e in string.

*/
#include <stdio.h>
#include <string.h>

#define SIZE    40

int main(void)
{
    char string[ SIZE ] = "This is the source string";
    char * substring = "axle";

    printf( "The first %i characters in the string \"%s\"\\
are not in the " "string \"%s\" \\n",
           strcspn(string, substring), string, substring);
}
```

Output

```
The first 10 characters in the string "This is the source string"
are not in the string "axle"
```

strdup() — Duplicate a string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <string.h>

char *strdup(const char *string);
```

General description

The `strdup()` function creates a duplicate of the string pointed to by *string*.

Returned value

If successful, `strdup()` returns a pointer to a new string which is a duplicate of *string*.

Otherwise, `strdup()` returns a NULL pointer.

Note: The caller of `strdup()` should free the storage obtained for the string.

Error Code

Description

ENOMEM

Insufficient storage space is available.

Related information

- [“string.h — String manipulation functions” on page 66](#)
- [“free\(\) — Free a block of storage” on page 620](#)
- [“malloc\(\) — Reserve storage block” on page 1035](#)

strerror() — Get pointer to runtime error message

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <string.h>

char *strerror(int errnum);
```

General description

Maps the error number in *errnum* to an error message string. The *errnum* must be a valid *errno* value. This function does not produce a locale-dependent error message string.

Returned value

`strerror()` returns a pointer to the string, which may be overwritten by a subsequent call to `strerror()`.

Note: Do not allow the content of this string to be modified by the program.

Example

```
/* This example opens a file and prints a runtime error message if an
   error occurs.
   */
#include <stdio.h>
#include <string.h>
#include <errno.h>

int main(void)
{
    FILE *stream;
    :
    if ((stream = fopen("myfile.dat", "r")) == NULL)
        printf(" %s \n", strerror(errno));
}
```

Related information

- [“string.h — String manipulation functions” on page 66](#)
- [“clearerr\(\) — Reset error and end of file \(EOF\)” on page 285](#)
- [“ferror\(\) — Test for read and write errors” on page 512](#)
- [“perror\(\) — Print error message” on page 1184](#)

strerror_r() – Get copy of runtime error message

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|--------------|
| Single UNIX Specification, Version 3 | both | z/OS V1R7 |

Format

```
#define _UNIX03_SOURCE
#include <string.h>

int strerror_r(int errnum, char *strerrbuf, size_t buflen);
```

General description

`strerror_r()` maps the error number in *errnum* to an error message string and copies the message string into the buffer pointed to by *strerrbuf* with length *buflen*. If the length of the message string is greater than or equal to *buflen*, `strerror_r()` copies the first *buflen*-1 characters of the message string into *strerrbuf*, terminates *strerrbuf* with a null character (`\0`) and returns `ERANGE`. The error number must be a valid `errno` value.

This function does not produce a locale-dependent error message string.

Returned value

If successful, `strerror_r()` returns 0.

If unsuccessful, `strerror_r()` returns an error number to indicate the error.

- `EINVAL` – The value of *errnum* is not a valid error number.
- `ERANGE` – Insufficient storage was supplied via *strerrbuf* and *buflen* to contain the generated message string.

Related information

- `errno.h`
- `string.h`
- `clearerr()`
- `ferror()`
- `perror()`
- `strerror()`
- `unsetenv()`

strfmon() – Convert monetary value to string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <monetary.h>

ssize_t strfmon(char * __restrict__ s, size_t maxsize,
                const char * __restrict__ format, ...);
```

General description

strfmon() produces a formatted monetary output string from a double argument. It has been extended to determine floating-point argument format (hexadecimal floating-point or IEEE Binary Floating-Point) using the __isBFP() function.

Note: In IEEE Binary Floating-Point mode, denormal, infinity and NaN argument values are out of range.

Places characters into the array pointed to by *s* as controlled by the string pointed to by *format*. No more than *maxsize* characters are placed into the array.

The character string *format* contains two types of objects: plain characters, which are copied to the output array, and directives, each of which results in the fetching of zero or more arguments that are converted and formatted. The results are undefined if there are insufficient arguments for the *format*. If the *format* is exhausted while arguments remain, the excess arguments are simply ignored. If objects pointed to by *s* and *format* overlap, the behavior is undefined.

The directive (conversion specification) consists of the following sequence:

1. A % character
2. Optional flags: =f, ^, !, then +, C, or (
3. Optional field width (may be preceded by w
4. Optional left precision: #n
5. Optional right precision: .p
6. Required conversion character to indicate what conversion should be performed: i or n

Each directive is replaced by the appropriate characters, as described in the following list:

%i

The double argument is formatted according to the locale's international currency format (for example, in USA: USD 1,234.56). An @euro codeset modifier can be used to request "EUR" instead of a national 4-character monetary string.

%n

The double argument is formatted according to the locale's national currency format (for example, in USA: \$1,234.56). An @euro codeset modifier can be used to get <euro-sign> instead of <currency>.

%% is replaced by %. No argument is converted.

The following optional conversion specifications may immediately follow the initial % of a directive:

=f

A flag, used in conjunction with the maximum digits specification #n (see below), specifies that the character *f* should be used as the numeric fill character. The default numeric fill character is the space character. This option does not affect the other fill operations that always use space as the fill character.

^

A flag. Do not format the currency amount with thousands grouping characters. The default is to insert the grouping characters if defined for the current locale.

Note: The code point for the ^ character will be determined according to the current LC_SYNTAX category.

+ | C | (

A flag, specifies the style of representing positive and negative currency amounts. Only one of +, C, or (may be specified. If + is specified, the locale's equivalent of + and - are used (for example, in USA: the empty (NULL) string if positive and - if negative). If C is specified, the locale's equivalent of DB for negative and CR for positive are used. If (is specified, the locale's equivalent of enclosing negative amounts within parentheses is used. If this option is not included, a default specified by the current locale is used.

[-]w

The field width. The decimal digit string *w* specifies a minimum field width in which the result of the conversion is right-justified (or left-justified if the optional flag “-” is specified).

#n

The left precision. The decimal digit string *n* specifies the maximum number of digits expected to be formatted to the left of the radix character. This option can be used to keep the formatted output from multiple calls to the strfmon() aligned in the same columns. It can also be used to fill unused positions with a special character as in \$***123.45. This option causes an amount to be formatted as if it has the number of digits specified by *n*. If more digit positions are required than the number specified, conversion specification is ignored. Digit positions in excess of those actually required are filled with the numeric fill character. (See the =f specification above.)

If the thousands grouping is enabled, the behavior is:

1. Format the number as if it is an *n* digit number.
2. Insert fill characters to the left of the leftmost digit (for example, \$0001234.56 or \$***1234.56)
3. Insert the separator character (for example, \$0,001,234.56 or \$*,**1,234.56)
4. If the fill character is not the digit zero, the separators are replaced by the fill character (for example, \$****1,234.56).

To ensure alignment, any characters appearing before or after the number in the formatted output such as currency or sign symbols are padded as necessary with space characters to make their positive and negative formats an equal length.

Note: The code point for the # character (in #n) will be determined according to the current LC_SYNTAX category.

.p

The right precision. The decimal digit string *p* specifies the number of digits after the radix character. If the value of the precision *p* is zero, no radix character appears. If this option is not included, a default specified by the current locale is used. The amount being formatted is rounded to the specified number of digits before formatting.

!

A flag used to suppress the currency symbol from the output conversion.

Note: The code point for the ! character is determined according to the current LC_SYNTAX category.

The LC_MONETARY category of the program's locale affects the behavior of this function including the monetary radix character (which is different from the numeric radix character affected by the LC_NUMERIC category), the thousands (or alternative grouping) separator, the currency symbols and formats. The international currency symbol must be in accordance with those specified in ISO4217 Codes for the representation of currencies and funds.

Formatting choices are indicated in the LC_MONETARY category for the output of both national and international monetary quantities. The national format is determined by the settings of p_cs_precedes, n_cs_precedes, p_sign_posn, n_sign_posn, p_sep_by_space, and n_sep_by_space. An equivalent set of members for international formats are added to conform with the ISO/IEC standard. See [“locale.h — Locale settings” on page 36](#) for more information on international formats.

The following tables show expected results for the various combinations of sep_by_space and sign_posn. All examples are based on a positive monetary quantity of 123.00, positive sign of '+', and currency

symbol of '\$'. Note that formatting rules are equivalent for negative and non-negative values as well as for national and international formats.

| Table 64. Monetary formats when <i>cs_precedes</i> = 1 | | | | | |
|--|-------------|------------|------------|------------|------------|
| sep_by_space | sign_posn | | | | |
| | 0 | 1 | 2 | 3 | 4 |
| 0 | (\$123.00) | +\$123.00 | \$123.00+ | +\$123.00 | \$+123.00 |
| 1 | (\$ 123.00) | +\$ 123.00 | \$ 123.00+ | +\$ 123.00 | \$+ 123.00 |
| 2 | (\$123.00) | + \$123.00 | \$123.00 + | + \$123.00 | \$ +123.00 |

| Table 65. Monetary formats when <i>cs_precedes</i> = 0 | | | | | |
|--|-------------|------------|------------|------------|------------|
| sep_by_space | sign_posn | | | | |
| | 0 | 1 | 2 | 3 | 4 |
| 0 | (123.00\$) | +123.00\$ | 123.00\$+ | 123.00+\$ | 123.00\$+ |
| 1 | (123.00 \$) | +123.00 \$ | 123.00 \$+ | 123.00 +\$ | 123.00 \$+ |
| 2 | (123.00\$) | + 123.00\$ | 123.00\$ + | 123.00+ \$ | 123.00\$ + |

cs_precedes

0

The currency symbol follows the value.

1

The currency symbol precedes the value.

sep_by_space

0

No space separates the currency symbol and value.

1

If the currency symbol and sign string are adjacent, a space separates them from the value; otherwise, a space separates the currency symbol from the value.

2

If the currency symbol and sign string are adjacent, a space separates them; otherwise, a space separates the sign string from the value.

sign_posn

0

Parentheses surround the quantity and currency_symbol or int_curr_symbol.

1

The sign string precedes the quantity and currency_symbol or int_curr_symbol.

2

The sign string succeeds the quantity and currency_symbol or int_curr_symbol.

3

The sign string immediately precedes the currency_symbol or int_curr_symbol.

4

The sign string immediately succeeds the currency_symbol or int_curr_symbol.

Returned value

If the total number of resulting bytes including the terminating NULL character is not more than *maxsize*, strfmon() returns the number of bytes placed into the array pointed to by *s*, not including the terminating NULL character.

If unsuccessful, the contents of the array are indeterminate, strfmon() returns -1, and sets *errno* to one of the following values:

Error Code

Description

E2BIG

Conversion stopped due to lack of space in the buffer

Example

CELEBS41

```
/* CELEBS41 */
#include <localdef.h>
#include <monetary.h>
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    char    string[100];    /* hold the string returned from strfmon() */
    double money = 1234.56;

    if (setlocale(LC_ALL, "En_US") == NULL) {
        printf("Unable to setlocale().\n");
        exit(1);
    }

    strfmon(string, 100, "%i", money);
    printf("%s\n", string);
    strfmon(string, 100, "%n", money);
    printf("%s\n", string);
}
```

Example

The following example shows euro currency support:

```
/* EUROSAMP
   This example sets the locale to Fr_BE.IBM-1148
   and Fr_BE.IBM-1148@euro and prints a value with
   the locales national and international currency
   format.
*/

#include <localdef.h>
#include <locale.h>
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    char string[100];
    double money = 1234.56;

    if (setlocale(LC_ALL, "Fr_BE.IBM-1148") == NULL) {
        printf("Unable to setlocale().\n");
        exit(1);
    }

    strfmon(string, 100, "%i", money);
    printf("%s\n", string);
    strfmon(string, 100, "%n", money);
    printf("%s\n", string);

    if (setlocale(LC_ALL, "Fr_BE.IBM-1148@euro") == NULL) {
        printf("Unable to setlocale().\n");
        exit(1);
    }
}
```

```
strfmon(string,100,"%i",money);
printf("%s\n",string);
strfmon(string,100,"%n",money);
printf("%s\n",string);
}
```

Output

```
1.234,56 BEF
1.234,56 BF
1.234,56 EUR
1.234,56 <euro-sign>
```

strftime() — Convert to formatted time

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | Both | |

Format

```
#include <time.h>

size_t strftime(char * __restrict__ dest, size_t maxsize,
                const char * __restrict__ format, const struct tm * __restrict__ timeptr);
```

General description

Places characters into the array pointed to by *dest* according to the string pointed to by *format*. The format string is a multibyte character string which contains:

- Conversion specification characters
- Ordinary multibyte characters, which are copied into an array unchanged.

The characters that are converted are determined by the LC_CTYPE category of the current locale and by the values in the time structure pointed to by *timeptr*. The time structure pointed to by *timeptr* is usually obtained by calling the `gmtime()` or `localtime()` function.

Table 66. Conversion Specifiers Used by strftime()

| Specifier | Meaning |
|-----------|--|
| %a | Replace with abbreviated weekday name of locale. |
| %A | Replace with full weekday name of locale. |
| %b | Replace with abbreviated month name of locale. |

Table 66. Conversion Specifiers Used by *strptime()* (continued)

| Specifier | Meaning |
|------------------|--|
| %B | Replace with full month name of locale. |
| %c | Replace with date and time of locale. |
| %C | Replace with locale's century number (year divided by 100 and truncated). |
| %d | Replace with day of the month (01-31). |
| %D | Insert date in mm/dd/yy form, regardless of locale. |
| %e | Insert day of the month as a decimal number (01–31). Under C POSIX only, it's a 2-character, right-justified, blank-filled field. |
| %E[cCxyY] | If the alternative date/time format is not available, the %E descriptors are mapped to their unextended counterparts. For example, %EC is mapped to %C. |
| %Ec | Replace with the locale's alternative date and time representation. |
| %EC | Replace with the name of the base year (period) in the locale's alternative representation. |
| %Ex | Replace with the locale's alternative date representation. |
| %EX | Replace with the locale's alternative time representation. |
| %Ey | Replace with the offset from %EC (year only) in the locale's alternative representation. |
| %EY | Replace with the full alternative year representation. |
| %F | Replace with the ISO 8601:2000 standard date format, equivalent to %Y-%m-%d. Values are taken from struct tm members, tm_year, tm_mon, and tm_mday. |
| %g | Replace with the last two digits of the week-based year as a decimal number (00-99). |
| %G | Replace with the week-based year as a four digit decimal. |
| %h | Replace with locale's abbreviated month name. This is the same as %b. %b. |
| %H | Replace with hour (24-hour clock) as a decimal number (00-23). |
| %I | Replace with hour (12-hour clock) as a decimal number (01-12). |
| %j | Replace with day of the year (001-366). |
| %m | Replace with month (01-12). |
| %M | Replace with minute (00-59). |
| %n | Replace with a newline. |
| %O[deHIImMSUwWy] | If the alternative date/time format is not available, the %E descriptors are mapped to their unextended counterparts. For example, %Od is mapped to %d. |
| %Od | Replace with the day of month, using the locale's alternative numeric symbols, filled as needed with leading zeros if there is any alternative symbol for zero, otherwise with leading spaces. |

Table 66. Conversion Specifiers Used by `strftime()` (continued)

| Specifier | Meaning |
|-----------|--|
| %Oe | Replace with the day of the month, using the locale's alternative symbols, filled as needed with leading spaces. |
| %OH | Replace with the hour (24-hour clock) using the locale's alternative symbols. |
| %OI | Replace with the hour (12-hour clock) using the locale's alternative symbols. |
| %Om | Replace with the month using the locale's alternative numeric symbols. |
| %OM | Replace with the minutes using the locale's alternative numeric symbols. |
| %OS | Replace with the seconds using the locale's alternative numeric symbols. |
| %Ou | Replace with the weekday as a number in the locale's alternative representation (Monday=1). |
| %OU | Replace with the week number of the year (Sunday as the first day of the week, rules corresponding to %U) using the locale's alternative numeric symbols. |
| %OV | Replace with the week number of the year (Monday as the first day of the week, rules corresponding to %V) using the locale's alternative numeric symbols. |
| %Ow | Replace with the weekday (Sunday=0) using the locale's alternative numeric symbols. |
| %OW | Replace with the week number of the year (Monday as the first day of the week) using the locale's alternative numeric symbols. |
| %Oy | Replace with the year (offset from %C) in the locale's alternative representation and using the locale's alternative numeric symbols. |
| %p | Replace with the locale's equivalent of AM or PM. |
| %r | Replace with a string equivalent to %I:%M:%S %p; or use <code>t_fmt_ampm</code> from <code>LC_TIME</code> , if present. |
| %R | Replace with time in 24 hour notation (%H:%M). |
| %s | Replace with the number of seconds since the Epoch, 1970-01-01 00:00:00 +0000 (UTC). (Calculated from <code>mktime64(tm)</code> .) |
| %S | Replace with seconds as a decimal number (00-60). |
| %t | Replace with a tab. |
| %T | Replace with a string equivalent to %H:%M:%S. |
| %u | Replace with the weekday as a decimal number (1 to 7), with 1 representing Monday. |
| %U | Replace with week number of the year (00-53) where Sunday is the first day of the week. The first Sunday of January is the first day of week 1; days in the new year before this are in week 0. |
| %V | Replace with week number of the year (01-53) where Monday is the first day of the week. If the week containing 1 January has four or more days in the new year, then it is considered week 1. Otherwise, it is the last week of the previous year, and the next week is week 1. Both January 4th and the first Thursday of January are always in week 1. |

Table 66. Conversion Specifiers Used by *strptime()* (continued)

| Specifier | Meaning |
|-----------|--|
| %w | Replace with weekday (0-6) where Sunday is 0. |
| %W | Replace with week number of the year (00-53) where Monday is the first day of the week. |
| %x | Replace with date representation of locale. |
| %X | Replace with time representation of locale. |
| %y | Replace with year without the century (00-99). |
| %Y | Replace with year with century. |
| %z | Replace with the offset from UTC in ISO8601:2000 standard format (+hhmm or -hhmm). For example, "-0430" means 4 hours 30 minutes behind UTC (west of Greenwich). If tm_isdst is zero, the standard time offset is used. If tm_isdst is greater than zero, the daylight savings time offset is used. If tm_isdst is negative, or if no timezone can be determined, then no characters are returned. |
| %Z | Replace with name of time zone, or no characters if time zone is not available. |
| %% | Replace with %. |

If data has the form of a directive, but is not one of the above, the characters following the % are copied to the output.

The behavior is undefined when objects being copied overlap. *maxsize* specifies the maximum number of characters that can be copied into the array.

If *strptime()* is called by a non-POSIX application, it obtains appropriate time zone name information from LC_TOD locale category. Time zone name defaults to STD for Standard time name, DST for Daylight Savings time name, or UTC for Coordinated Universal Time (UTC), name, as appropriate, if time zone name information is unspecified in the current LC_TOD locale category.

Note: The *strptime()* function requires time zone name information to convert the %Z conversion specifier. It is obtained as follows:

- The *strptime()* functions calls the *tzset()* function to obtain time zone information by parsing the TZ (POSIX) or _TZ (non_POSIX) environment variable or from the current LC_TOD locale category. If the tm structure input to *strptime()* was produced by calling *localtime()*, *strptime()* converts %Z to the Standard or Daylight Savings name characters specified by the TZ environment variable or LC_TOD category (if TZ cannot be found or parsed).
- When neither TZ nor _TZ is defined, the current locale is interrogated for time zone information. If neither TZ nor _TZ is defined and LC_TOD time zone information is not present in the current locale, a default value is applied to local time. POSIX programs simply default to Coordinated Universal Time (UTC), while non-POSIX programs establish an offset from UTC based on the setting of the system clock. For more information about customizing a time zone to work with local time, see “Customizing a time zone” in [z/OS XL C/C++ Programming Guide](#).

The *tm_isdst* flag in the time structure input to *strptime()* determines whether %Z is replaced by the Standard or Daylight Savings name characters. If Standard or Daylight Savings name characters are not available in the current LC_TOD locale category or from parsing TZ, *strptime()* uses the characters STD for Standard or DST for Daylight Savings time name.

If the tm structure input to *strptime()* was produced by the *gmtime()* function, *strptime()* replaces %Z by UCTNAME characters specified in the current LC_TOD locale category or by UTC if UCTNAME is not specified.

Returned value

If successful, `strptime()` returns the number of characters (bytes) placed into the array, not including the terminating NULL character.

If unsuccessful, `strptime()` returns 0 and the content of the string is indeterminate.

Example

CELEBS42

```
/* CELEBS42

   This example places characters into the array dest and prints
   the resulting string.

*/
#include <stdio.h>
#include <time.h>

int main(void)
{
    char dest[70];
    int ch;
    time_t temp;
    struct tm *timeptr;

    temp = time(NULL);
    timeptr = localtime(&temp);
    ch = strptime(dest, sizeof(dest)-1, "Today is %A,"
                  " %b %d. \n Time: %I:%M %p", timeptr);
    printf("%d characters placed in string to make: \n \n %s", ch, dest);
}
```

Output

```
44 characters placed in string to make:

Today is Friday, Jun 16.
Time: 03:07 PM
```

strlen() — Determine string length

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <string.h>

size_t strlen(const char *string);
```

General description

The `strlen()` built-in function determines the length of string pointed to by *string*, excluding the terminating NULL character.

Returned value

`strlen()` returns the length of *string*.

Example

CELEBS43

```
/* CELEBS43

   This example determines the length of the string that is
   passed to main.

*/
#include <stdio.h>
#include <string.h>

int main(int argc, char **argv)
{
    if ( argc != 2 )
        printf( "Usage: %s string\n", argv[0] );
    else
        printf( "Input string has a length of %i\n", strlen( argv[1] ) );
}
```

Output

If the input is the string: "How long is this string?", then the expected output is:

```
Input string has a length of 24
```

strnlen() — Determine fixed-size string length

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1-2008 Single UNIX Specification, Version 4 | both | z/OS 3.2 |

Format

```
#define _POSIX_C_SOURCE 200809L
#include
<string.h>

size_t strnlen(const char *string, size_t n);
```

General description

The `strnlen()` function computes the number of characters (bytes) in the string that is pointed to by *string*, not including the terminating NULL character (`\0`), up to a maximum of *n* characters.

Returned value

`strnlen()` returns the smaller value between *n* and the number of characters that precede the terminating NULL character (`\0`) in the string that is pointed to by *string*.

Example

```
/* This example determines the length of a string, up to SIZE bytes. */

#define _POSIX_C_SOURCE 200809L
#include <stdio.h>
#include <string.h>

#define SIZE 40
int main(void)
{
    char string[ SIZE ] = "abcdefghijklmnopqrstuvwxyz";
    size_t result;

    result = strnlen( string, SIZE );

    printf( "String \"%s\" has a length of %d\n", string, result );
}
```

Output

```
String "abcdefghijklmnopqrstuvwxyz" has a length of 26
```

strncasecmp() — Case-insensitive string comparison

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <strings.h>

int strncasecmp(const char *string1, const char *string2, size_t n);
```

General description

The `strncasecmp()` function compares, while ignoring differences in case, the string pointed to by *string1* to the string pointed to by *string2*. At most *n* characters will be compared.

The string arguments to the function should contain a NULL character (`\0`) marking the end of the string.

The `strncasecmp()` function is locale-sensitive.

Returned value

`strncasecmp()` returns a value indicating the relationship between the strings, while ignoring case, as follows:

Value

Meaning

< 0

String pointed to by *string1* is less than string pointed to by *string2*.

= 0

String pointed to by *string1* is equal to string pointed to by *string2*.

> 0

String pointed to by *string1* is greater than string pointed to by *string2*.

There are no `errno` values defined.

Related information

- [“strings.h — String operations” on page 67](#)
- [“strcasecmp\(\) — Case-insensitive string comparison” on page 1718](#)
- [“strcspn\(\) — Compare strings” on page 1727](#)
- [“strncmp\(\) — Compare strings” on page 1744](#)

strncat() — Concatenate strings

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <string.h>

char *strncat(char * __restrict__string1, const char * __restrict__string2, size_t count);
```

General description

The `strncat()` built-in function appends the first *count* characters of *string2* to *string1* and ends the resulting string with a NULL character (`\0`). If *count* is greater than the length of *string2*, `strncat()` appends only the maximum length of *string2* to *string1*. The first character of the appended string overwrites the terminating NULL character of the string pointed to by *string1*.

If copying takes place between overlapping objects, the behavior is undefined.

Returned value

`strncat()` returns the value *string1*, the concatenated string.

Example

CELEBS44

```
/* CELEBS44

   This example demonstrates the difference between &strcat. and
   &strncat..
   &strcat. appends the entire second string to the first,
   whereas &strncat. appends only the specified number of
   characters in the second string to the first.

   */
#include <stdio.h>
#include <string.h>

#define SIZE 40

int main(void)
{
    char buffer1[SIZE] = "computer";
    char * ptr;

    /* Call strcat with buffer1 and " program" */

    ptr = strcat( buffer1, " program" );
    printf( "strcat : buffer1 = \"%s\"\n", buffer1 );

    /* Reset buffer1 to contain just the string "computer" again */

    memset( buffer1, '\0', sizeof( buffer1 ) );
    ptr = strcpy( buffer1, "computer" );
```

```
/* Call strncat with buffer1 and " program" */
ptr = strncat( buffer1, " program", 3 );
printf( "strncat: buffer1 = \"%s\\n\", buffer1 );
}
```

Output

```
strncat : buffer1 = "computer program"
strncat: buffer1 = "computer pr"
```

strncmp() – Compare strings

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <string.h>

int strncmp(const char *string1, const char *string2, size_t count);
```

General description

The strncmp() built-in function compares at most the first *count* characters of the string pointed to by *string1* to the string pointed to by *string2*.

The string arguments to the function should contain a NULL character (\0) marking the end of the string.

The relation between the strings is determined by the sign of the difference between the values of the leftmost first pair of characters that differ. The values depend on character encoding. This function is *not* locale sensitive.

Returned value

strncmp() returns a value indicating the relationship between the substrings, as follows:

| Value | Meaning |
|-------|---------|
|-------|---------|

< 0

String pointed to by *substring1* less than string pointed to by *substring2*

= 0

String pointed to by *substring1* equivalent to string pointed to by *substring2*

> 0

String pointed to by *substring1* greater than string pointed to by *substring2*

Example

CELEBS45

```

/* CELEBS45

   This example demonstrates the difference between &strcmp.
   and &strncmp..

*/
#include <stdio.h>
#include <string.h>

#define SIZE 10

int index = 3;

int main(void)
{
    int result;
    char buffer1[SIZE] = "abcdefg";
    char buffer2[SIZE] = "abcfg";
    void print_result( int, char *, char * );

    result = strcmp( buffer1, buffer2 );
    printf( " strcmp: compares each character\n");
    print_result( result, buffer1, buffer2 );

    result = strncmp( buffer1, buffer2, index);
    printf( "\nstrncmp: compares only the first %i characters\n", index );
    print_result( result, buffer1, buffer2 );
}

void print_result( int res, char * p_buffer1, char * p_buffer2 )
{
    if ( res == 0 )
        printf( "first %i characters of \"%s\" is identical to \"%s\"\n",
                index, p_buffer1, p_buffer2 );
    else if ( res < 0 )
        printf( "\"%s\" is less than \"%s\"\n", p_buffer1, p_buffer2 );
    else
        printf( "\"%s\" is greater than \"%s\"\n", p_buffer1, p_buffer2 );
}

```

Output

```

strcmp: compares each character
"abcdefg" is less than "abcfg"

strncmp: compares only the first 3 characters
first 3 characters of "abcdefg" is identical to "abcfg"

```

strncpy() — Copy string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <string.h>

char *strncpy(char * __restrict__string1, const char * __restrict__string2, size_t count);
```

General description

The `strncpy()` built-in function copies at most *count* characters of *string2* to *string1*. If *count* is less than or equal to the length of *string2*, a NULL character (`\0`) is *not* appended to the copied string. If *count* is greater than the length of *string2*, the *string1* result is padded with NULL characters (`\0`) up to length *count*.

If copying takes place between objects that overlap, the behavior is undefined.

Returned value

`strncpy()` returns *string1*.

Example

CELEBS46

```
/* CELEBS46

   This example demonstrates the difference between &strcpy.
   and &strncpy..

*/
#include <stdio.h>
#include <string.h>

#define SIZE    40

int main(void)
{
    char source[ SIZE ] = "123456789";
    char source1[ SIZE ] = "123456789";
    char destination[ SIZE ] = "abcdefg";
    char destination1[ SIZE ] = "abcdefg";
    char * return_string;
    int    index = 5;

    /* This is how strcpy works */
    printf( "destination is originally = '%s'\n", destination );
    return_string = strcpy( destination, source );
    printf( "After strcpy, destination becomes '%s'\n\n", destination );
```

```

/* This is how strncpy works */
printf( "destination1 is originally = '%s'\n", destination1 );
return_string = strncpy( destination1, source1, index );
printf( "After strncpy, destination1 becomes '%s'\n", destination1 );
}

```

Output

```

destination is originally = 'abcdefg'
After strcpy, destination becomes '123456789'

destination1 is originally = 'abcdefg'
After strncpy, destination1 becomes '12345fg'

```

strlen() – Determine fixed-size string length

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|--------------|
| POSIX.1-2008 | both | z/OS 3.2 |
| Single UNIX Specification, Version 4 | | |

Format

```

#define _POSIX_C_SOURCE 200809L
#include
<string.h>

size_t strlen(const char *string, size_t n);

```

General description

The `strlen()` function computes the number of characters (bytes) in the string that is pointed to by *string*, not including the terminating NULL character (`\0`), up to a maximum of *n* characters.

Returned value

`strlen()` returns the smaller value between *n* and the number of characters that precede the terminating NULL character (`\0`) in the string that is pointed to by *string*.

Example

```
/* This example determines the length of a string, up to SIZE bytes. */
#define _POSIX_C_SOURCE 200809L
#include <stdio.h>
#include <string.h>

#define SIZE    40
int main(void)
{
    char string[ SIZE ] = "abcdefghijklmnopqrstuvwxyz";
    size_t result;

    result = strlen( string, SIZE );

    printf( "String \"%s\" has a length of %d\n", string, result );
}
```

Output

String "abcdefghijklmnopqrstuvwxyz" has a length of 26

strpbrk() — Find characters in string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <string.h>

char *strpbrk(const char *string1, const char *string2);
```

General description

Locates the first occurrence in the string pointed to by *string1* of any character from the string pointed to by *string2*.

Returned value

If successful, strpbrk() returns a pointer to the character.
If *string1* and *string2* have no characters in common, strpbrk() returns a NULL pointer.

Example

CELEBS47

```
/* CELEBS47

   This example returns a pointer to the first occurrence in the
   array string of either a or b.

*/
```

```
#include <stdio.h>
#include <string.h>

int main(void)
{
    char *result, *string = "A Blue Danube";
    char *chars = "ab";

    result = strpbrk(string, chars);
    printf("The first occurrence of any of the characters \"%s\" in \"
          \"%s\" is \"%s\"\\n", chars, string, result);
}
```

Output

```
The first occurrence of any of the characters "ab" in "A Blue Danube"
is "anube"
```

strptime() — Date and time conversion

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <time.h>

char *strptime(const char * __restrict__ buf, const char * __restrict__ fmt,
               struct tm * __restrict__ tm);
```

General description

The `strptime()` function converts the character string pointed to by *buf* to values that are stored in the `tm` structure pointed to by *tm*, using the format specified by *fmt*. Only the fields in the `tm` structure for which there is a corresponding format item in *fmt* are updated by the `strptime()` function. Therefore, for a valid and conforming `tm` structure, provide `strptime()` with a format and data that completely specify the date and time being converted.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

The format is composed of zero or more directives. Each directive is composed of one of the following: one or more white space characters (as specified by the `isalnum()` to `isdigit()` function), an ordinary character other than a percent sign (%) or white space character, or a conversion specification. Each conversion specification is composed of a percent sign followed by a conversion character that specifies the replacement required. There must be a white space character or other nonalphanumeric character between any two conversion specifications.

Table 67. Conversion Specifiers Used by `strptime()`

| Specifier | Meaning |
|-----------|--|
| %a | Day of week, using locale's abbreviated or full weekday name. |
| %A | Day of week, using locale's abbreviated or full weekday name. |
| %b | Month, using locale's abbreviated or full month name. |
| %B | Month, using locale's abbreviated or full month name. |
| %c | Date and time, using locale's date and time. |
| %C | Century number (year divided by 100 and truncated to an integer). |
| %d | Day of the month (1 - 31; leading zeros permitted but not required; day will not be checked for correctness for the month specified). |
| %D | Date as %m/%d/%y. |
| %e | Day of the month (1 - 31; leading zeros permitted but not required; day will not be checked for correctness for the month specified). |
| %h | Month, using locale's abbreviated or full month name. |
| %H | Hour (0 - 23; leading zeros permitted but not required). |
| %I | Hour (0 - 12; leading zeros permitted but not required). |
| %j | Day number of the year (001 - 366). |
| %m | Month number (1 - 12; leading zeros are permitted but not required). |
| %M | Minute (0 - 59; leading zeros are permitted but not required). |
| %n | Newline character. |
| %p | Locale's equivalent of AM or PM. |
| %r | 12-hour clock time using the AM/PM notation if <code>t_fmt_ampm</code> is not an empty string in the <code>LC_TIME</code> portion of the current locale; in the POSIX locale, this is equivalent to %I : %M : %S %p. |
| %R | Time in 24 hour notation (11/19/01M). |
| %S | Seconds (0 - 60; leading zeros are permitted but not required). |
| %t | Tab character. |
| %T | Time as %H:%M:%S. |
| %U | Week number of the year (0 - 53; where Sunday is the first day of the week; leading zeros are permitted but not required). |
| %w | Weekday (0 - 6; where Sunday is 0; leading zeros are permitted but not required). |
| %W | Week number of the year (0 - 53; where Monday is the first day of the week; leading zeros are permitted but not required). |
| %x | Date, using locale's date format. |

Table 67. Conversion Specifiers Used by `strptime()` (continued)

| Specifier | Meaning |
|-----------|--|
| %X | Time, using locale's time format. |
| %y | Year within century. When a century is not otherwise specified, values in the range 69 - 99 refer to years in the twentieth century (1969 to 1999 inclusive); values in the range 00 - 68 refer to years in the twenty-first century (2000 to 2068 inclusive). Leading zeros are permitted but not required. |
| %Y | Year, including century. When the value of the <code>_EDC_STRPTM_STD</code> environment variable is set to 1, at most 4 digits will be consumed. When the value of <code>_EDC_STRPTM_STD</code> is set to other values or unset, more than 4 digits might be consumed, and if the generated value is greater than 9999, this function fails. |
| %Z | Time zone name. |
| %% | Replace with %. |

Modified directives: Some directives can be modified by the E or O modifier characters to indicate that an alternative format or specification should be used rather than the one normally used by the unmodified directive. If the alternative format or specification does not exist in the current locale, the behavior will be as if the unmodified directive were used.

Table 68. Modified Directives Used by `strptime()`

| Specifier | Meaning |
|-----------|--|
| %Ec | Replace with the locale's alternative date and time representation. |
| %EC | Replace with the name of the base year (period) in the locale's representation. |
| %Ex | Replace with the locale's alternative date representation. |
| %EX | Replace with the locale's alternative time representation. |
| %Ey | Replace with the offset from %EC (year only) in the locale's representation. |
| %EY | Replace with the full alternative year representation. |
| %Od | Replace with the day of month, using the locale's alternative numeric symbols, filled as needed with leading zeros if there is any alternative symbol for zero, otherwise with leading spaces. |
| %Oe | Replace with the day of the month, using the locale's alternative numeric symbols, filled as needed with leading spaces. |
| %OH | Replace with the hour (24-hour clock) using the locale's alternative numeric symbols. |
| %OI | Replace with the hour (12-hour clock) using the locale's alternative numeric symbols. |
| %Om | Replace with the month using the locale's alternative numeric symbols. |
| %OM | Replace with the minutes using the locale's alternative numeric symbols. |
| %OS | Replace with the seconds using the locale's alternative numeric symbols. |
| %OU | Replace with the week number of the year (Sunday as the first rules corresponding to %U) using the locale's alternative numeric symbols. |
| %Ow | Replace with the weekday (Sunday=0) using the locale's alternative numeric symbols. |
| %OW | Replace with the week number of the year (Monday as the first day of the week) using the locale's alternative numeric symbols. |

Table 68. Modified Directives Used by *strptime()* (continued)

| Specifier | Meaning |
|-----------|---|
| %Oy | Replace with the year (offset from %C) in the locale's alternative representation and using the locale's alternative numeric symbols. |

A directive composed of white space characters is executed by scanning input up to the first character that is not white space (which remains unscanned) or until no more characters can be scanned.

A directive that is an ordinary character is executed by scanning the next character from the buffer. If the character scanned from the buffer differs from the one comprising the directive, the directive fails, and the differing and subsequent characters remain unscanned.

A series of directives composed or %n, %t, white space characters or any combination is executed by scanning up to the first character that is not white space (which remains unscanned), or until no more characters can be scanned.

Any other conversion specification is executed by scanning characters until a character matching the next directive is scanned, or until no more characters can be scanned. These characters, excepting the one matching the next directive, are then compared to the locale values associated with the conversion specifier. If a match is found, values for the appropriate *tm* structure members are set to values corresponding to the locale information. Case is ignored when matching items in *buf*, such as month or weekday names. If no match is found, *strptime()* fails and no more characters are scanned.

Returned value

If successful, *strptime()* returns a pointer to the character following the last character parsed.

If unsuccessful, *strptime()* returns a NULL pointer.

Example

CELEBS48

```
/* CELEBS48 */
#include <stdio.h>
#include <stdlib.h>
#include <time.h>
#include <localdef.h>

int main(void)
{
    struct tm xmas;

    if (strptime("12/25/93 13:30:00", "%D %T", &xmas) == NULL) {
        printf("strptime() failed.\n");
        exit(1);
    }

    printf("tm_sec  =%3d\n", xmas.tm_sec );
    printf("tm_min  =%3d\n", xmas.tm_min );
    printf("tm_hour  =%3d\n", xmas.tm_hour );
    printf("tm_mday =%3d\n", xmas.tm_mday );
    printf("tm_mon   =%3d\n", xmas.tm_mon );
    printf("tm_year  =%3d\n", xmas.tm_year );
    printf("tm_wday  =%3d\n", xmas.tm_wday );
    printf("tm_yday  =%3d\n", xmas.tm_yday );
}
```

Output

```
tm_sec  = 0
tm_min  = 30
tm_hour  = 13
tm_mday = 25
tm_mon   = 11
tm_year  = 93
```

```
tm_wday = 0
tm_yday =358
```

strchr() – Find last occurrence of character in string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <string.h>

char *strchr(const char *string, int c);
```

General description

The `strchr()` function finds the last occurrence of `c` (converted to a `char`) in *string*. The ending NULL character is considered part of the *string*.

Returned value

If successful, `strchr()` returns a pointer to the last occurrence of `c` in *string*.

If the given character is not found, `strchr()` returns a NULL pointer.

Example

CELEBS49

```
/* CELEBS49

   This example compares the use of &strchr. and &strrchr..
   It searches the string for the first and last occurrence of
   p in the string.

*/
#include <stdio.h>
#include <string.h>

#define SIZE 40

int main(void)
{
    char buf[SIZE] = "computer program";
    char * ptr;
    int   ch = 'p';

    /* This illustrates strchr */
    ptr = strchr( buf, ch );
    printf( "The first occurrence of %c in '%s' is '%s'\n", ch, buf, ptr );

    /* This illustrates strrchr */
```

```
ptr = strrchr( buf, ch );
printf( "The last occurrence of %c in '%s' is '%s'\n", ch, buf, ptr );
}
```

Output

```
The first occurrence of p in 'computer program' is 'puter program'
The last occurrence of p in 'computer program' is 'program'
```

strsignal() – Return string describing signal

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|--------------|
| POSIX.1-2008 | both | z/OS 3.2 |
| Single UNIX Specification, Version 4 | | |

Format

```
#define _POSIX_C_SOURCE 200809L
#include <string.h>

char *strsignal(int signal);
```

General description

The `strsignal()` function maps the signal number *signal* to an implementation-defined string and returns a pointer to it. `strsignal()` uses the same set of messages as `psignal()`.

The application must not modify the string that is returned by `strsignal()`. The returned string might be invalidated or the string content might be overwritten by subsequent calls to `strsignal()` or `setlocale()`. The returned string might also be invalidated if the calling thread is terminated.

The content of the message string that is returned by `strsignal()` is determined by the setting of the `LC_MESSAGES` category in the current locale.

Returned value

`strsignal()` returns a pointer to the appropriate description string if *signal* is a valid signal number. Otherwise, `strsignal()` returns the string: `Unknown signal signal`.

Note: No return values are reserved to indicate an error. To check for error situations, set `errno` to 0, call this function, then check `errno`.

Example

```
/* This example calls strsignal() with valid
   and invalid signal values.
*/

#define _POSIX_C_SOURCE 200809L
#include <stdio.h>
#include <string.h>

int main(void)
{
    int first_signum = 14; /* timeout */
    int second_signum = -5; /* INVALID value */

    char * first_signal;
    first_signal = strsignal( first_signum );

    printf( "strsignal(14): \"%s\"\n", first_signal);

    char * second_signal;
    second_signal = strsignal( second_signum );

    printf( "strsignal(-5): \"%s\"\n", second_signal );
}
```

Output

```
strsignal(14): "Timeout"
strsignal(-5): "Unknown signal -5"
```

strspn() – Search string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| Language Environment ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <string.h>

size_t strspn(const char *string1, const char *string2);
```

General description

Calculates the length of the maximum initial portion of the string pointed to by *string1* that consists entirely of the characters contained in the string pointed to by *string2*.

Returned value

strspn() returns the length of the substring found.

Example

CELEBS50

```
/* CELEBS50

This example finds the first occurrence in the array string
of a character that is neither an a, b, nor c. Because the
string in this example is cabbage, &strspn. returns 5, the
length of the segment of cabbage before a character that is
not an a, b or c.

*/
#include <stdio.h>
#include <string.h>

int main(void)
{
    char * string = "cabbage";
    char * source = "abc";
    int index;

    index = strspn( string, "abc" );
    printf( "The first %d characters of \"%s\" are found in \"%s\"\\n",
            index, string, source );
}
```

Output

The first 5 characters of "cabbage" are found in "abc"

strstr() — Locate substring

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <string.h>

char *strstr(const char *string1, const char *string2);
```

General description

Finds the first occurrence of the string pointed to by *string2* (excluding the NULL character) in the string pointed to by *string1*.

Returned value

If successful, `strstr()` returns a pointer to the beginning of the first occurrence of *string2* in *string1*.

If *string2* does not appear in *string1*, `strstr()` returns NULL.

If *string2* points to a string with zero length, `strstr()` returns *string1*.

Example

CELEBS51

```
/* CELEBS51

   This example locates the string haystack in the string "needle in a
   haystack".

   */
#include <stdio.h>
#include <string.h>

int main(void)
{
    char *string1 = "needle in a haystack";
    char *string2 = "haystack";
    char *result;

    result = strstr(string1, string2);
    /* Result = a pointer to "haystack" */
    printf("%s\n", result);
}
```

Output

```
haystack
```

strtolcoll() – Return collating element for string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <collate.h>

collat_t strtocoll(char *s);
```

General description

Determines whether the string pointed to by *s* represents the valid element as defined in the LC_COLLATE category of the current locale.

If a string pointed to by *s* contains only one character, the collating element representing this character always exists. Otherwise, a valid collating element exists if the LC_COLLATE category contains the definition of a sequence of characters that collate as one for the purpose of culture-sensitive string comparison. This many-characters-to-one-collating element relation is also called *many-to-one* mapping.

Returned value

The type `collat_t` represents the collating elements.

If many-to-one mapping is not defined in the LC_COLLATE of the current locale, `strtolcoll()` returns `(collat_t)-1`.

Also, if the string is not a valid collating element or is of zero length, `strtolcoll()` returns `(collat_t)-1`.

Example

CELEBS52

```
/* CELEBS52

   This example uses the strtocoll() function to get the
   collat_t value for the start and end collating-elements for
   the collrange() function.

*/
#include <stdio.h>
#include <stdlib.h>
#include <locale.h>
#include <collate.h>
#include <wchar.h>
#include <wctype.h>

main(int argc, char *argv[]) {
    collat_t s, e, *rp;
    int i;

    setlocale(LC_ALL, "");
    if ((s = strtocoll(argv[1])) == (collat_t)-1) {
        printf("%s collating element not defined\n", argv[1]);
        exit(1);
    }
    if ((e = strtocoll(argv[2])) == (collat_t)-1) {
        printf("%s collating element not defined\n", argv[2]);
        exit(1);
    }
    if ((i = collrange(s, e, &rp)) == -1) {
        printf("Invalid range for %s to %s\n", argv[1], argv[2]);
        exit(1);
    }
    for (; i-- > 0; rp++) {
        if (ismccollat(*rp))
            printf("%s' ", colltostr(*rp));
        else if (iswprint(*rp))
            printf("%lc' ", *rp);
        else
            printf("%x' ", *rp);
    }
}
```

strtod() — Convert character string to double

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdlib.h>

double strtod(const char * __restrict__nptr, char ** __restrict__endptr);
```

General description

Converts a part of a character string, pointed to by *nptr*, to a double. The parameter *nptr* points to a sequence of characters that can be interpreted as a numerical value of the type *double*.

See the “*fscanf* Family of Formatted Input Functions” on [fscanf\(\)](#), [scanf\(\)](#), [sscanf\(\)](#) — Read and format data for a description of special infinity and NaN sequences recognized by z/OS formatted input functions, including [atof\(\)](#) and [strtod\(\)](#) in IEEE Binary Floating-Point mode.

The [strtod\(\)](#) function breaks the string into three parts:

1. A sequence of white space characters (as specified for the current locale, see [isspace\(\)](#))
2. A subject sequence interpreted as a floating-point constant or representing infinity or a NaN.
3. A sequence of unrecognized characters (including a NULL character).

The subject string is the longest string that matches the expected form.

The expected form of the subject sequence is an optional plus or minus sign, then one of the following:

- A non-empty sequence of decimal digits optionally containing a radix character, then an optional exponent part. Where radix character is the character that separates the integer part of a number from the fractional part.

- A 0x or 0X, then a non-empty sequence of hexadecimal digits optionally containing a radix character, then an optional binary exponent part. Where radix character is the character that separates the integer part of a number from the fractional part.
- One of INF or INFINITY, ignoring case.
- One of NANQ or NANQ(n-char-sequence), ignoring case.
- One of NANS or NANS(n-char-sequence), ignoring case.
- One of NAN or NAN(n-char-sequence), ignoring case.

The pointer to the last string successfully converted is stored in the object pointed to by *endptr*, provided that *endptr* is not a NULL pointer. If the subject string is empty or it does not have the expected form, then no conversion is performed. The value of *nptr* is stored in the object pointed to by *endptr*.

Returned value

If successful, `strtod()` returns the value of the floating-point number.

The double value is hexadecimal floating-point or IEEE Binary Floating-Point format depending on the floating-point mode of the thread invoking the `strtod()` function. This function uses `__isBFP()` to determine the floating-point mode of the invoking thread.

In an overflow, `strtod()` returns \pm HUGE_VAL. In an underflow, it returns 0. If no conversion is performed, `strtod()` returns 0. In both cases, `errno` is set to `ERANGE`, depending on the base of the value.

Example

CELEBS53

```
/* CELEBS3

   This example converts a string to a double value.
   It prints out the converted value and the substring that
   stopped the conversion.

*/
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    char *string, *stopstring;
    double x;

    string = "3.1415926This stopped it";
    x = strtod(string, &stopstring);
    printf("string = %s\n", string);
    printf("    strtod = %f\n", x);
    printf("    Stopped scan at %s\n\n", stopstring);

    string = "100ergs";
    x = strtod(string, &stopstring);
    printf("string = \"%s\"\n", string);
    printf("    strtod = %f\n", x);
    printf("    Stopped scan at \"%s\"\n\n", stopstring);
}
```

Output

```
string = 3.1415926This stopped it
    strtod = 3.141593
    Stopped scan at This stopped it

string = 100ergs
    strtod = 100.000000
    Stopped scan at ergs
```

strtod32(), strtod64(), strtod128() — Convert character string to decimal floating point

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <stdlib.h>

_Decimal32 strtod32(const char * __restrict__ nptr, char ** __restrict__ endptr);
_Decimal64 strtod64(const char * __restrict__ nptr, char ** __restrict__ endptr);
_Decimal128 strtod128(const char * __restrict__ nptr, char ** __restrict__ endptr);
```

General description

The `strtod32()`, `strtod64()`, and `strtod128()` functions convert the initial portion of the string pointed to by *nptr* to `_Decimal32`, `_Decimal64`, and `_Decimal128` representation, respectively.

First, they decompose the input string into three parts:

1. An initial, possibly empty, sequence of white-space characters (as specified by the `isspace()` function) .
2. A subject sequence resembling a floating-point constant or representing an infinity or NaN.
3. A final string of one or more unrecognized characters, including the terminating null character of the input string.

Then, they attempt to convert the subject sequence to a floating-point number, and return the result.

The expected form of the subject sequence is an optional plus or minus sign, then one of the following:

- a nonempty sequence of decimal digits optionally containing a decimal-point character, then an optional exponent part
- INF or INFINITY, ignoring case
- NAN, NAN(n-char-sequence), NANQ, NANQ(n-char-sequence), NANS, or NANS(n-char-sequence), ignoring case in the NAN, NANQ, or NANS part, where n-char-sequence is one or more decimal numeric digits.

Note: If the input string is not one of these forms (for example "INFINITE"), the output results are undefined.

The subject sequence is defined as the longest initial subsequence of the input string, starting with the first non-white-space character, that is of the expected form. The subject sequence contains no characters if the input string is not of the expected form.

A character sequence NAN, NANQ, NAN(n-char-sequence), or NANQ(n-char-sequence) is interpreted as a quiet NaN. A character sequence of NANS, or NANS(n-char-sequence), is interpreted as a signalling NaN. A character sequence INF or INFINITY is interpreted as an infinity. A character sequence NAN, NAN(), or NAN(n-char-sequence) is interpreted as a quiet NaN. A character sequence of NANS, NANS(), or NANS(n-char-sequence), is interpreted as a signalling NaN.

A pointer to the final string is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

The converted value keeps the same precision as the input if possible, and the value may be denormalized. Otherwise, rounding may occur. Rounding happens after any negation.

In other than the "C" locale, additional locale-specific subject sequence forms are accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *nptr* is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

| Argument | Description |
|---------------|--|
| <i>nptr</i> | Input pointer to start of the string to be converted |
| <i>endptr</i> | NULL, or a pointer to a output pointer field that is filled in with the address of the first character in the input string that is not used in the conversion. |

Note: To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

These functions return the converted value, if any. If no conversion could be performed, the value +0.E0DF, +0.E0DD, or +0.E0DL is returned. If the correct value is outside the range of representable values, plus or minus HUGE_VAL_D32, HUGE_VAL_D64, or HUGE_VAL_D128 is returned (according to the return type and sign of the value), and *errno* is set to ERANGE. If the result underflows, these functions return a value whose magnitude is no greater than the smallest normalized positive number in the return type. No signal is raised at the point of returning a signaling NaN.

| errno | Description |
|--------|---|
| ERANGE | The input string represents a value too large to fit in the output Decimal Floating Point type. |

Example

See [“strtod\(\) — Convert character string to double”](#) on page 1759 for an example.

strtouf() – Convert character string to float

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _ISOC99_SOURCE
#include <stdlib.h>

float strtouf(const char *__restrict__ nptr, char **__restrict__ endptr);
```

General description

strtouf() converts a part of a character string, pointed to by *nptr*, to float. The parameter *nptr* points to a sequence of characters that can be interpreted as a numerical value of the type float.

The strtouf() function breaks the string into three parts:

1. An initial, possibly empty, sequence of white-space characters (as specified by isspace()).
2. A subject sequence interpreted as a floating-point constant or representing infinity or a NaN.
3. A final string of one or more unrecognized characters, including the terminating null byte of the input string.

The function then attempts to convert the subject string into the floating-point number, and returns the result.

The expected form of the subject sequence is an optional plus or minus sign, then one of the following:

- A non-empty sequence of decimal digits optionally containing a radix character, then an optional exponent part. A radix character is the character that separates the integer part of a number from the fractional part.
- A 0x or 0X, a non-empty sequence of hexadecimal digits optionally containing a radix character, then a base 2 decimal exponent part with a p or P as prefix, a plus or minus sign, then a sequence of at least one decimal digit. (Example [-]0xh.hhhhp+/-d). A radix character is the character that separates the integer part of a number from the fractional part.
- One of INF or INFINITY, ignoring case.
- One of NANQ or NANQ(n-char-sequence), ignoring case.
- One of NANS or NANS(n-char-sequence), ignoring case.
- One of NAN or NAN(n-char-sequence), ignoring case.

See the "scanf Family of Formatted Input Functions" for a description of special infinity and NaN sequences recognized by z/OS formatted input functions in IEEE Binary Floating-Point mode.

The pointer to the last string successfully converted is stored in the object pointed to by *endptr*, provided that *endptr* is not a NULL pointer. If the subject string is empty or it does not have the expected form, then no conversion is performed. The value of *nptr* is stored in the object pointed to by *endptr*.

Returned value

If successful, strtouf() returns the value of the floating-point number.

The float value is hexadecimal floating-point or IEEE Binary Floating-Point format depending on the floating-point mode of the thread invoking the strtod() function. This function uses __isBFP() to determine the floating-point mode of the invoking thread.

In an overflow, strtod() returns +/-HUGE_VALF. In an underflow, it returns 0. If no conversion is performed, strtod() returns 0. In both cases, errno is set to ERANGE, depending on the base of the value.

strtoimax() — Convert character string to intmax_t integer type

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _ISOC99_SOURCE
#include <inttypes.h>

intmax_t strtoimax(const char * __restrict__ nptr, char ** __restrict__ endptr, int
base);
```

Compile requirement: Function strtoimax() requires LONGLONG to be available.

General description

The strtoimax() function converts the string nptr to an intmax_t integer type. Valid input values for base are 0 and in the range 2-36. The strtoimax() function is equivalent to strtol() and strtoll() with the only difference being that the return value is of type intmax_t. See strtoll() for more information.

Returned value

If successful, strtoimax() returns the converted intmax_t value represented in the string.

If unsuccessful, strtoimax() returns 0 if no conversion could be performed. If the correct value is outside the range of representable values, strtoimax() returns INTMAX_MAX or INTMAX_MIN, according to the sign of the value. If the value of base is not supported, strtoimax() returns 0.

If unsuccessful strtoimax() sets errno to one of the following values:

Error Code Description

EINVAL

The value of *base* is not supported.

ERANGE

The conversion caused an overflow.

Example

```
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    intmax_t j;
    int base = 10;
    char *nptr, *endptr;
    nptr = "10345134932abc";
    printf("nptr = %s\n", nptr);
    j = strtoumax(nptr, &endptr, base);
    printf("strtoumax = %jd (base %d)\n", j, base);
    printf("Stopped scan at %s\n\n", endptr);
}
```

Output

```
nptr = 10345134932abc
strtoumax = 10345134932(base 10)
Stopped scan at abc
```

strtok() — Tokenize string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <string.h>

char *strtok(char * __restrict__string1, const char * __restrict__string2);
```

General description

Breaks a character string, pointed to by *string1*, into a sequence of tokens. The tokens are separated from one another by the characters in the string pointed to by *string2*.

The token starts with the first character not in the string pointed to by *string2*. If such a character is not found, there are no tokens in the string. `strtok()` returns a NULL pointer. The token ends with the first character contained in the string pointed to by *string2*. If such a character is not found, the token ends at the terminating NULL character. Subsequent calls to `strtok()` will return the NULL pointer. If such a character *is* found, then it is overwritten by a NULL character, which terminates the token.

If the next call to `strtok()` specifies a NULL pointer for *string1*, the tokenization resumes at the first character following the found and overwritten character from the previous call. For example:

```
/* Here are two calls */
strtok(string, " ")
strtok(NULL, " ")

/* Here is the string they are processing */
      abc defg hij
first call finds  ↑
                  ↑ second call starts
```

Returned value

The first time `strtok()` is called, it returns a pointer to the first token in *string1*. In later calls with the same token string, `strtok()` returns a pointer to the next token in the string. A NULL pointer is returned when there are no more tokens. All tokens are NULL-terminated.

Example

CELEBS54

```
/* CELEBS54
 *
 * strtok() example:
 *
 * This example parses tokens separated by commas, blanks and semicolons,
 * from a string until no tokens are left. As the string is parsed,
 * pointers to the the following tokens are returned by strtok(),
 * and these tokens are written to stdout:
 *
 * a
 * string
 * of
 * tokens
 *
 * The final call to strtok() returns NULL indicating that
 * there are no more tokens.
 *
 * Note that as the string is tokenized, it will be overwritten.
 *
 */

#include <stdio.h>
#include <string.h>

int main(void)
{
    char *token, string[] = "a string, of,; ,,,;tokens\0,after null terminator";

    token = strtok(string, ", ;");
    do
```

```
{
    printf("token: \"%s\"\n", token);
}
while (token = strtok(NULL, " ;"));
}
```

Output

```
token: "a string"
token: " of"
token: " "
token: "tokens"
```

strtok_r() — Split string into tokens

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 | both | OS/390 V2R8 |

Format

```
#define _XOPEN_SOURCE 500
#include <string.h>

char *strtok_r(char *s, const char *sep, char **lasts);
```

General description

The function `strtok_r()` considers the NULL-terminated string `s` as a sequence of zero or more text tokens separated by spans of one or more characters from the separator string `sep`. The argument `lasts` points to a user-provided pointer which points to stored information necessary for `strtok_r()` to continue scanning the same string.

In the first call to `strtok_r()`, `s` points to a NULL-terminated string, `sep` to a NULL-terminated string of separator characters and the value pointed to by `lasts` is ignored. The function `strtok_r()` returns a pointer to the first character of the first token, writes a NULL character into `s` immediately following the returned token, and updates the pointer to which `lasts` points.

In subsequent calls, `s` is a NULL pointer and `lasts` will be unchanged from the previous call so that subsequent calls will move through the string `s`, returning successive tokens until no tokens remain. The separator string `sep` may be different from call to call. When no token remains in `s`, a NULL pointer is returned.

Returned value

If successful, strtok_r() returns a pointer to the token found.
When no token is found, strtok_r() returns a NULL pointer.

strtol() – Convert character string to long

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdlib.h>

long int strtol(const char * __restrict__nptr, char ** __restrict__endptr, int base);
```

General description

Converts *nptr*, a character string, to a long int value.

The function decomposes the entire string into three parts:

1. A sequence of characters, which in the current locale are defined as white space characters. This part may be empty.
2. A sequence of characters interpreted as integer in some base notation. This is the *subject sequence*.
3. A sequence of unrecognized characters.

The base notation is determined by *base*, if *base* is greater than zero. If *base* is zero, the base notation is determined by the format of the sequence of characters that follow an optional plus—or optional minus—sign.

10

Sequence starts with nonzero decimal digit.

8

Sequence starts with 0, followed by a sequence of digits with values from 0 to 7.

16

Sequence starts with either 0x or 0X, followed by digits, and letters A through F or a through f.

If the base is greater than zero, the subject sequence contains decimal digits and letters, possibly preceded by either a plus or a minus sign. The letters a (or A) through z (or Z) represent values from 10 through 36, but only those letters whose value is less than the value of the base are allowed.

When you use the `strtol()` function, *nptr* should point to a string with the following form:

The pointer to the converted characters, even if conversion was unsuccessful, is stored in the object pointed to by *endptr*, as long as *endptr* is not a NULL pointer.

Returned value

If successful, `strtol()` returns the converted long int value.

If unsuccessful, `strtol()` returns 0 if no conversion could be performed. If the correct value is outside the range of representable values, `strtol()` returns `LONG_MAX` or `LONG_MIN`, according to the sign of the value. If the value of base is not supported, `strtol()` returns 0.

If unsuccessful `strtol()` sets `errno` to one of the following values:

Error Code**Description****EINVAL**

The value of *base* is not supported.

ERANGE

The conversion caused an overflow.

Example**CELEBS55**

```

/* CELEBS55

This example converts the strings to a long.
It prints out the converted value and the substring that
stopped the conversion.

*/
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    char *string, *stopstring;
    long l;
    int bs;

    string = "10110134932";
    printf("string = %s\n", string);
    for (bs = 2; bs <= 8; bs *= 2)
    {
        l = strtol(string, &stopstring, bs);
        printf("    strtol = %ld (base %d)\n", l, bs);
        printf("    Stopped scan at %s\n\n", stopstring);
    }
}

```

Output

```
string = 10110134932
  strtol = 45 (base 2)
  Stopped scan at 34932

  strtol = 4423 (base 4)
  Stopped scan at 4932

  strtol = 2134108 (base 8)
  Stopped scan at 932
```

strtold() — Convert character string to long double

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _ISOC99_SOURCE
#include <stdlib.h>

long double strtold(const char *__restrict__ nptr, char **__restrict__ endptr);
```

General description

strtold() converts a part of a character string, pointed to by *nptr*, to long double. The parameter *nptr* points to a sequence of characters that can be interpreted as a numerical value of the type long double.

The strtold() function breaks the string into three parts:

1. An initial, possibly empty, sequence of white-space characters (as specified by isspace()).
2. A subject sequence interpreted as a floating-point constant or representing infinity or NaN.
3. A final string of one or more unrecognized characters, including the terminating null byte of the input string.

The function then attempts to convert the subject string into the floating-point number, and returns the result.

The expected form of the subject sequence is an optional plus or minus sign, then one of the following:

- A non-empty sequence of decimal digits optionally containing a radix character, then an optional exponent part. A radix character is the character that separates the integer part of a number from the fractional part.
- A 0x or 0X, a non-empty sequence of hexadecimal digits optionally containing a radix character, then a base 2 decimal exponent part with a p or P as prefix, a plus or minus sign, then a sequence of at least one decimal digit. (Example [-]0xh.hhhhp+/-d). A radix character is the character that separates the integer part of a number from the fractional part.
- One of INF or INFINITY, ignoring case.
- One of NANQ or NANQ(n-char-sequence), ignoring case.
- One of NANS or NANS(n-char-sequence), ignoring case.
- One of NAN or NAN(n-char-sequence), ignoring case.

See the "scanf Family of Formatted Input Functions" for a description of special infinity and NaN sequences recognized by z/OS formatted input functions in IEEE Binary Floating-Point mode.

The pointer to the last string successfully converted is stored in the object pointed to by *endptr*, provided that *endptr* is not a NULL pointer. If the subject string is empty or it does not have the expected form, then no conversion is performed. The value of *nptr* is stored in the object pointed to by *endptr*.

Returned value

If successful, strtold() returns the value of the floating-point number.

The long double value is hexadecimal floating-point or IEEE Binary Floating-Point format depending on the floating-point mode of the thread invoking the strtold() function. This function uses __isBFP() to determine the floating-point mode of the invoking thread.

In an overflow, strtold() returns +/-HUGE_VALL. In an underflow, it returns 0. If no conversion is performed, strtold() returns 0. In both cases, errno is set to ERANGE, depending on the base of the value.

strtoll() – Convert string to signed long long

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| Language Environment C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | OS/390 V2R9 |

Format

```
#include <stdlib.h>

long long strtoll(const char * __restrict__ nptr, char ** __restrict__ endptr, int
base);
```

Compile requirement: Use of this function requires the long long data type. See [z/OS XL C/C++ Language Reference](#) for information on how to make long long available.

General description

Converts *nptr*, a character string, to a signed long long value.

The function decomposes the entire string into three parts:

- 1. A sequence of characters, which in the current locale are defined as white space characters. This part may be empty.
- 2. A sequence of characters interpreted as an unsigned integer in some base notation. This is the *subject sequence*.
- 3. A sequence of unrecognized characters.

The base notation is determined by *base*, if *base* is greater than zero. If *base* is zero, the base notation is determined by the format of the sequence of characters that follow an optional plus or optional minus sign.

10 Sequence starts with nonzero decimal digit.

8 Sequence starts with 0, followed by a sequence of digits with values from 0 to 7.

16 Sequence starts with either 0x or 0X, followed by digits, and letters A through F or a through f.

If the base is greater than zero, the subject sequence contains decimal digits and letters, possibly preceded by either a plus or a minus sign. The letters a (or A) through z (or Z) represent values from 10 through 36, but only those letters whose value is less than the value of the base are allowed.

When you are using strtoll(), *nptr* should point to a string with the following form:

The pointer to the converted characters, even if conversion was unsuccessful, is stored in the object pointed to by *endptr*, as long as *endptr* is not a NULL pointer.

Returned value

If successful, `strtoll()` returns the converted signed long long value, represented in the string.

If unsuccessful, `strtoll()` returns 0 if no conversion could be performed. If the correct value is outside the range of representable values, `strtoll()` returns `LLONG_MAX` (`LONGLONG_MAX`) or `LLONG_MIN` (`LONGLONG_MIN`), according to the sign of the value. If the value of *base* is not supported, `strtoll()` returns 0.

If unsuccessful `strtoll()` sets `errno` to one of the following values:

Error Code Description

EINVAL

The value of *base* is not supported.

ERANGE

The conversion caused an overflow.

strtoul() – Convert string to unsigned integer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| Language Environment ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdlib.h>

unsigned long int strtoul(const char * __restrict__ string1,
                        char ** __restrict__ string2, int base);
```

General description

Converts *string1*, a character string, to an unsigned long int value.

The function decomposes the entire string into three parts:

- 1. A sequence of characters, which in the current locale are defined as white space characters. This part may be empty.
- 2. A sequence of characters interpreted as an unsigned integer in some base notation. This is the *subject sequence*.
- 3. A sequence of unrecognized characters.

The base notation is determined by *base*, if *base* is greater than zero. If *base* is zero, the base notation is determined by the format of the sequence of characters that follow an optional plus or optional minus sign.

10

Sequence starts with nonzero decimal digit.

8

Sequence starts with 0, followed by a sequence of digits with values from 0 to 7.

16

Sequence starts with either 0x or 0X, followed by digits, and letters A through F or a through f.

If the base is greater than zero, the subject sequence contains decimal digits and letters, possibly preceded by either a plus or a minus sign. The letters a (or A) through z (or Z) represent values from 10 through 36, but only those letters whose value is less than the value of the base are allowed. The function stops reading the string at the first character that it cannot recognize as part of a number. This character can be the first numeric character greater than or equal to the *base*. The strtoul() function sets *string2* to point to the end of the resulting output string if a conversion is performed and provided that *string2* is not a NULL pointer.

When you are using the strtoul() function, *string1* should point to a string with the following form:

If *base* is in the range of 2-36, it becomes the base of the number. If *base* is 0, the prefix determines the base (8, 16, or 10): the prefix 0 means base 8; the prefix 0x or 0X means base 16; using any other digit without a prefix means decimal.

The pointer to the converted characters, even if conversion was unsuccessful, is stored in the object pointed to by *string2*, as long as *string2* is not a NULL pointer.

Returned value

If successful, strtoul() returns the converted unsigned long int value, represented in the string.

If unsuccessful, strtoul() returns 0 if no conversion could be performed. If the correct value is outside the range of representable values, strtoul() returns ULONG_MAX. If the value of base is not supported, strtoul() returns 0.

If unsuccessful strtoul() sets errno to one of the following values:

Error Code

Description

EINVAL

The value of *base* is not supported.

ERANGE

The conversion caused an overflow.

Example

CELEBS56

```

/* CELEBS56

   This example converts the string to an unsigned long value.
   It prints out the converted value and the substring that
   stopped the conversion.

*/
#include <stdio.h>
#include <stdlib.h>

#define BASE 2

int main(void)
{
    char *string, *stopstring;
    unsigned long ul;

    string = "1000e13 e";
    printf("string = %s\n", string);
    ul = strtoul(string, &stopstring, BASE);
    printf("    strtoul = %ld (base %d)\n", ul, BASE);
    printf("    Stopped scan at %s\n\n", stopstring);
}

```

Output

```

string = 1000e13 e
    strtoul = 8 (base 2)
    Stopped scan at e13 e

```

strtoull() — Convert string to unsigned long long

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| Language Environment C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | OS/390 V2R9 |

Format

```

#include <stdlib.h>

unsigned long long strtoull(register const char * __restrict__ nptr,
                           char ** __restrict__ endptr, int base);

```

Compile requirement: Use of this function requires the long long data type. See [z/OS XL C/C++ Language Reference](#) for information on how to make long long available.

General description

Converts *nptr*, a character string, to an unsigned long long value.

The function decomposes the entire string into three parts:

- 1. A sequence of characters, which in the current locale are defined as white space characters. This part may be empty.
- 2. A sequence of characters interpreted as an unsigned integer in some base notation. This is the *subject sequence*.
- 3. A sequence of unrecognized characters.

The base notation is determined by *base*, if *base* is greater than zero. If *base* is zero, the base notation is determined by the format of the sequence of characters that follow an optional plus or optional minus sign.

10

Sequence starts with nonzero decimal digit.

8

Sequence starts with 0, followed by a sequence of digits with values from 0 to 7.

16

Sequence starts with either 0x or 0X, followed by digits, and letters A through F or a through f.

If the base is greater than zero, the subject sequence contains decimal digits and letters, possibly preceded by either a plus or a minus sign. The letters a (or A) through z (or Z) represent values from 10 through 36, but only those letters whose value is less than the value of the base are allowed. The function stops reading the string at the first character that it cannot recognize as part of a number. This character can be the first numeric character greater than or equal to the *base*. The strtoull() function sets *endptr* to point to the end of the resulting output string if a conversion is performed and provided that *endptr* is not a NULL pointer.

When you are using the strtoull() function, *nptr* should point to a string with the following form:

If *base* is in the range of 2-36, it becomes the base of the number. If *base* is 0, the prefix determines the base (8, 16 or 10): the prefix 0 means base 8; the prefix 0x or 0X means base 16; using any other digit without a prefix means decimal.

The pointer to the converted characters, even if conversion was unsuccessful, is stored in the object pointed to by *endptr*, as long as *endptr* is not a NULL pointer.

Returned value

If successful, strtoull() returns the converted unsigned long long value, represented in the string.

If unsuccessful, strtoull() returns 0 if no conversion could be performed. If the correct value is outside the range of representable values, strtoull() returns ULLONG_MAX (ULONGLONG_MAX). If the value of *base* is not supported, strtoull() returns 0.

If unsuccessful strtoull() sets *errno* to one of the following values:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

EINVAL

The value of *base* is not supported.

ERANGE

The conversion caused an overflow.

strtoumax() — Convert character string to uintmax_t integer type

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _ISOC99_SOURCE
#include <inttypes.h>

uintmax_t strtoumax(const char * __restrict__ nptr,
                    char ** __restrict__ endptr, int base);
```

Compile requirement: Function strtoumax() requires long long to be available.

General description

The strtoumax() function converts the string nptr to an uintmax_t integer type. Valid input values for base are 0 and in the range 2-36. The strtoumax() function is equivalent to strtoul() and strtoull(). The only difference being that the return value is of type uintmax_t. See strtoull for more information.

Returned value

If successful, strtoumax() returns the converted uintmax_t value, represented in the string.

If unsuccessful, strtoumax() returns 0 if no conversion could be performed. If the correct value is outside the range of representable values, strtoumax() returns UINTMAX_MAX. If the value of base is not supported, strtoumax() returns 0.

If unsuccessful strtoumax() sets errno to one of the following values:

Error Code**Description****EINVAL**

The value of *base* is not supported.

ERANGE

The conversion caused an overflow.

Example

```
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    uintmax_t j;
    int base = 10;
    char *nptr, *endptr;
    nptr = "20690239864abc";
    printf("string = %s\n", nptr);
    j = strtoumax(nptr, &endptr, base);
    printf("strtoumax = %ju (base %d)\n", j, base);
    printf("Stopped scan at %s\n", endptr);
}
```

Output

```
string = 20690239864abc
strtoumax = 20690239864 (base 10)
Stopped scan at abc
```

strxfrm() – Transform string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <string.h>

size_t strxfrm(char * __restrict__ s1, const char * __restrict__ s2, size_t n);
```

General description

Transforms the string pointed to by *s2* and places the resulting string into the array pointed to by *s1*. The transformation is determined by the program's locale. The transformed string is not necessarily readable, but can be used with the `strcmp()` or `strncmp()` functions.

The transformation is such that, if `strcmp()` or `strncmp()` were applied to the two transformed strings, the results would be the same as applying the `strcoll()` function to the two corresponding untransformed strings.

No more than *n* bytes are placed into the area pointed to by *s1*, including the terminating NULL byte. If *n* is zero, *s1* is allowed to be a NULL pointer.

Returned value

If successful, `strxfrm()` returns the length of the transformed string (excluding the NULL byte). When *n* is zero and *s1* is a NULL pointer, the length returned is the number of bytes minus one required to contain the transformed string.

If unsuccessful, `strxfrm()` returns `(size_t)-1` and sets `errno` to indicate the error.

Notes:

1. The string returned by `strxfrm()` contains the weights for each order of the characters within the string. As a result, the string returned may be longer than the input string, and does not contain printable characters.
2. `strxfrm()` issues a `malloc()` when the `LC_COLLATE` category specifies *backward* on the *order_start* keyword, the *substitute* keyword is specified, or the locale has one-to-many mapping. The `strxfrm()` function will fail if the `malloc()` fails.
3. If the locale supports double-byte characters (`MB_CUR_MAX` specified as 4), the `strxfrm()` function validates the multibyte characters, whereas previously the `strxfrm()` function did not validate the string. The `strxfrm()` function will fail if the string contains invalid multibyte characters.
4. If `MB_CUR_MAX` is defined as 4, and no collation is defined for DBCS chars in the current locale, the DBCS characters will collate after the single-byte characters.

Example

CELEBS57

```
/* CELEBS57

   This example prompts the user to input a string of characters, then
   uses strxfrm() to transform the string and return its length.

*/
#include <collate.h>
#include <stdlib.h>
#include <stdio.h>
#include <string.h>
int main(void)
{
    char *string1="string1", *string2="string2";
    char *newstring1, *newstring2;
    int length1, length2;

    length1=strxfrm(NULL, string1, 0);
    length2=strxfrm(NULL, string2, 0);
    if (((newstring1=(char *)calloc(length1+1, 1))==NULL) ||
        ((newstring2=(char *)calloc(length2+1, 1))==NULL))
    {
        printf("insufficient memory\n");
        exit(99);
    }
    if ((strxfrm(newstring1, string1, length1+1) != length1) ||
        (strxfrm(newstring2, string2, length2+1) != length2))
    {
        printf("error in string processing\n");
        exit(99);
    }
}
```

```

    }
    if (strcoll(string1, string2) != strcmp(newstring1, newstring2))
    {
        printf("wrong results\n");
        exit(99);
    }
    printf("correct results\n");
    exit(0);
}

```

__superkill() – Sends "super" SIGKILL to terminate target process

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|---------------------|
| z/OS UNIX | both | z/OS V1R6 POSIX(ON) |

Format

```

#define _POSIX_SOURCE
#include <signal.h>

int __superkill(pid_t pid);

```

General description

The `__superkill()` function generates a more robust version of the SIGKILL signal to the process with `pid` as the process ID. The SIGKILL will be able to break through almost all of the current signal deterrents that can be an obstacle to the normal delivery of a SIGKILL and the resulting termination of the target process.

Function restrictions include:

- Cannot do a `__superkill()` to a group or specifying PID -1. An attempt to do so will result in a EINVAL/JrNoGroups.
- The superkill will be ignored if the target process has blocked all signals, in which case the `__superkill()` will not fail but simply be ignored (refer to BPX1SDD syscall in Chapter 2 . Callable services descriptions, *z/OS UNIX System Services Programming: Assembler Callable Services Reference*). Under a multithread environment, as long as BPX1SDD is called on the initial thread, `__superkill()` will be ignored. The `sigprocmask()` function cannot be used to block `__superkill()`.
- A regular SIGKILL must be sent, at least 3 seconds, to a process before a superkill. Otherwise the attempt will result in EINVAL/JRSigkillNotSent.
- Runtime option POSIX(ON) is required to be set for this function to work properly.

If the environment is valid, then the target process will be abended with a '422'x abend reason code x'0109' reason code. The abend code will be sent to the first dubbed thread in the process. Under Language Environment, this is almost always the initial processing thread (IPT).

Returned value

When successful, the target process is terminated. Upon failure, `__superkill()` returns -1 and sets `errno` to one of the following values:

Value

Description

ENIVAL

PID is -1 or a group process ID or the superkill was not sent 3 seconds after the regular SIGKILL.

EPERM

The caller does not have the permission to send the signal to any process that was specified by the process ID parameter.

ESRCH

No process or process groups that correspond to the process ID are found.

svc99() — Access supervisor call

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <stdio.h>

int svc99(__S99parms *string);
```

General description

Provides access to SVC99 on z/OS, which provides ability to:

- Dynamically allocate or deallocate a resource
- Dynamically concatenate or deconcatenate data sets
- Dynamically retrieve information on data sets

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

The `__S99parms` structure must be in 31-bit addressable storage. A call to `svc99()` with 64-bit addressable storage will result in -1 return code.

The `__S99TXTPP` element needs to be a 32-bits wide pointer to 31-bit addressable storage containing an array of text unit pointers. Each of the text unit pointers must be a 32-bits wide pointer, each pointing to 31-bit addressable storage containing a text unit, or can be a NULL pointer. The last text unit pointer must have its high bit (traditional 31-bit amode high bit) turned on to denote the end of text units has been reached.

The `__S99S99X` element needs to be a 32-bits wide pointer to 31-bit addressable storage containing the `__S99rbx` structure, when needed. This is consistent with the `__dyn_t` structure element `__rbx` requirement outlined above.

The `__S99parms` structure is defined in `stdio.h`. It has been changed to include the address of the Request Block Extension. The Request Block Extension and the Error Message Parameter list can be used to process the messages returned by SVC99 when an error occurs. To use this feature, you must allocate and initialize these structures.

Table 69. Elements Contained by __S99parms Structure

| Field | Type | Value Stored |
|------------|----------------|---|
| __S99RBLN | unsigned char | SVC99 length of request block |
| __S99VERB | unsigned char | SVC99 verb code |
| __S99FLAG1 | unsigned short | SVC99 Flags 1 field |
| __S99ERROR | unsigned short | SVC99 error code field |
| __S99INFO | unsigned short | SVC99 information code |
| __S99TXTPP | void * __ptr32 | SVC99 pointer to a list of text unit pointers |
| __S99S99X | void * __ptr32 | SVC99 pointer to the Request Extension Block |
| __S99FLAG2 | unsigned int | SVC99 Flags 2 field for APF authorized programs |

Returned value

If the input pointer is NULL, svc99() returns 0 if running under CICS and nonzero otherwise. The nonzero value indicates that svc99() is supported under the current operating system (that is, z/OS non-CICS). If the input is not NULL, svc99() returns -1 if running under CICS (to indicate an error), otherwise it returns a code that results from svc99().

If the input is not NULL, and svc99() is not supported on the system, it returns -1.

Example

CELEBS58

```

/* CELEBS58

   This example uses the svc99() function to dynamically allocate a data
   set called USERID.EXAMPLE.

   */
#define MASK 0x80000000
#define _EXT

#include <stdio.h>
#include <string.h>

int main(void)
{
    int rc;
    struct __S99struc parmlist;
    char *s[10] = {                /* array of text pointers */
        /* text units follow */
        "\0\02\0\01\0\0E" "USERID.EXAMPLE", /* DSN=EXAMPLE */
        "\0\05\0\01\0\01\02",              /* DISP=(,CATLG) */
        "\0\07\0\0",                          /* SPACE=(TRK,.. */
        "\0\0A\0\01\0\03\0\0\014",          /* primary=20 */
        "\0\0B\0\01\0\03\0\0\01",           /* secondary=1 */
        "\0\015\0\01\0\05SYSDA",             /* UNIT=SYSDA */
        "\0\030\0\01\0\02\0\050",           /* BLKSIZE=80 */
        "\0\03C\0\01\0\02\040",             /* DSORG=PS */
        "\0\042\0\01\0\02\0\050",           /* LRECL=80 */
        "\0\049\0\01\0\01\080"};            /* RECFM=F */

    memset(&parmlist, 0, sizeof(parmlist));
    parmlist.__S99RBLN = 20;
    parmlist.__S99VERB = 1;                  /* verb for dsname allocation */
    parmlist.__S99FLAG1 = 0x4000;           /* do not use existing allocation */
    parmlist.__S99TXTPP = s;                /* pointer to pointer to text units */
    s[9] = (char *)((long unsigned) (s[9]) | MASK);

```

```

rc = svc99(&parmlist);
if (rc != 0)
    printf(" Error code = %d    Information code = %d\n",
           parmlist.__S99ERROR, parmlist.__S99INFO);
}

```

If your user ID starts with one of the letters A-F, you must add two double quotation marks (") before the user ID so that the first letter of the user ID is interpreted as a character rather than as a hexadecimal digit.

The preceding example can be made more readable by using symbolic names and data structures as demonstrated in the example below. The members IEFZB4DB, IEFZB4D0 and IEFZB4D2 of SYS1.MACLIB contain symbolic names that will be familiar to most assembler language programmers.

This next example uses symbolic names taken from these members to define, in z/OS XL C/C++ the text unit representing primary=20 or s[3]. Similar definitions can be made for the remaining text units but will not be given here.

```

#include <stdio.h>
#include <string.h>

#define MASK 0x80000000
#define CHAR_BIT 4
/* Defines one text unit with an integer of size 'bytes' */

#define __S99TUNIT_INT(bytes) struct {
    short unsigned __S99TUKEY;      /* KEY */

swab() — Copy and swap bytes

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <unistd.h>

void swab(const void *__restrict__src, void *__restrict__dest, ssize_t nbytes);
```

General description

The `swab()` function copies *nbytes* bytes, which are pointed to by *src* to the object pointed to by *dest*, exchanging adjacent bytes. The *nbytes* argument should be even. If *nbytes* is odd, `swab()` copies and exchanges *nbytes*-1 bytes and the disposition of the last byte is left unchanged in the target area. If *nbytes* is zero or negative, no copying is performed.

Returned value

`swab()` returns no values.

Related information

- “[unistd.h — Implementation-specific functions](#)” on page 77

swapcontext() — Save and restore user context

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <ucontext.h>

int swapcontext(ucontext_t *__restrict__ oucp, const ucontext_t *__restrict__ ucp);
```

General description

The `swapcontext()` function saves the current user context in the context structure pointed to by *oucp* and restores the user context structure pointed to by *ucp*. `swapcontext()` is equivalent to `getcontext()` with the *oucp* argument followed by `setcontext()` with the *ucp* argument.

Control does not return from the initial invocation of `swapcontext()`. However, if the saved context is not modified using `makecontext()`, and a subsequent `setcontext()` or `swapcontext()` is issued using the saved context, `swapcontext()` returns with a 0 return value.

Notes:

1. If the *ucontext* pointed to by *ucp* that is input to `swapcontext()`, has not been modified by `makecontext()`, you must ensure that the function that saved that context by calling either `getcontext()` or `swapcontext()` does not return before you call `swapcontext()` to restore that context. Calling `swapcontext()` after the function that saved the context returns causes unpredictable program behavior.
2. If `swapcontext()` is used to jump back into an XPLINK routine, any `alloca()` requests issued by the XPLINK routine after the earlier `getcontext()` was called and before `swapcontext()` is called are backed out. All storage obtained by these `alloca()` requests is freed before the XPLINK routine is resumed.
3. If `swapcontext()` is used to jump back into a non-XPLINK routine, `alloca()` requests made after `getcontext()` and before `swapcontext()` are not backed out.
4. Do not issue `swapcontext()` from any type of condition handling routine (for example, a signal catcher, a Language Environment user condition handler or an exception handler).
5. If *ucp* is pointing to a user context of a different execution stack from the current, the user context should be either a freshly modified one (by `makecontext()`) or the most recently saved one (by `getcontext()` or `swapcontext()`) when running on its stack.
6. If *ucp* is pointing to a user context of a different execution stack from the current, the current stack is never collapsed and any resource associated with it is never freed after `swapcontext()` being called.

This function is supported only in a POSIX program.

The `<ucontext.h>` header file defines the `ucontext_t` type as a structure that includes the following members:

| | | |
|-------------------------|--------------------------|--|
| <code>mcontext_t</code> | <code>uc_mcontext</code> | A machine-specific representation of the saved context. |
| <code>ucontext_t</code> | <code>*uc_link</code> | Pointer to the context that will be resumed when this context returns. |
| <code>sigset_t</code> | <code>uc_sigmask</code> | The set of signals that are blocked when this context is active. |
| <code>stack_t</code> | <code>uc_stack</code> | The stack used by this context. |

Special behavior for C++: If `getcontext()` and `swapcontext()` are used to transfer control, the behavior is undefined whether the destruction of automatic C++ objects is done. The use of `getcontext()` and `swapcontext()` in conjunction with `try()`, `catch()`, and `throw()` is also undefined.

Do not issue `getcontext()` in a C++ constructor or destructor, since the saved context would not be usable in a subsequent `setcontext()` or `swapcontext()` after the constructor or destructor returns.

Special behavior for XPLINK-compiled C/C++: Restrictions concerning `setjmp.h` and `ucontext.h`:

1. All XPLINK programs compiled with the V2R10 or later C compilers that are to run with Language Environment V2R10 or later libraries and use the **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** types must not be compiled with C headers from Language Environment V2R9 or earlier.
2. Non-XPLINK functions compiled with any level of Language Environment headers must not define **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** data items and pass them to XPLINK functions that call `getcontext()`, `longjmp()`, `_longjmp()`, `setjmp()`, `_setjmp()`, `setcontext()`, `sigsetjmp()`, or `swapcontext()` with these passed-in data items.
3. When `__XPLINK__` is defined, the Language Environment V2R10 and later headers define a larger **`jmp_buf`**, **`sigjmp_buf`** or **`ucontext_t`** area that is required by `setjmp()`, `getcontext()`, and related functions when they are called from an XPLINK routine. If `__XPLINK__` is not defined, the Language

Environment V2R10 and later headers define a shorter **jmp_buf**, **sigjmp_buf** or **ucontext_t** area. The Language Environment headers before V2R10 also define the shorter version of these data areas. If an XPLINK function calls `setjmp()`, `getcontext()` or similar functions with a short **jmp_buf**, **sigjmp_buf** or **ucontext_t** area, a storage overlay or program check may occur when the C library tries to store past the end of the passed-in (too short) data area.

Returned value

If successful, `swapcontext()` does not return from the initial invocation. If the unmodified saved context is later restored, `swapcontext()` returns 0.

If unsuccessful, `swapcontext()` returns -1.

There are no `errno` values defined.

Example

This example uses two contexts. It creates the first, *fcontext*, in `main` with the `getcontext()` statement, and invokes the function *func*. It invokes the function with the `swapcontext()` statement, saving the context at that point in the second context, *mcontext*. The function returns to the point of the `swapcontext()` using the `setcontext()` statement and specifying *mcontext* as the context.

```
/* This example shows the usage of swapcontext(). */

#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>
#include <stdio.h>
#include <ucontext.h>
#include <errno.h>

#ifdef _LP64
#define STACK_SIZE 2097152+16384 /* large enough value for AMODE 64 */
#else
#define STACK_SIZE 16384 /* AMODE 31 addressing*/
#endif
void func(int);

ucontext_t fcontext,mcontext;
int x = 0;

int main(void) {
    int value = 1;

    getcontext(&fcontext);
    if ((fcontext.uc_stack.ss_sp = (char *) malloc(STACK_SIZE)) != NULL) {
        fcontext.uc_stack.ss_size = STACK_SIZE;
        fcontext.uc_stack.ss_flags = 0;
        errno = 0;
        makecontext(&fcontext,func,1,value);
        if (errno != 0){
            perror("Error reported by makecontext()");
            return -1; /* Error occurred exit */
        }
    }
    else {
        perror("not enough storage for stack");
        abort();
    }
    printf("context has been built\n");
    swapcontext(&mcontext,&fcontext);
    if (!x) {
        perror("incorrect return from swapcontext");
        abort();
    }
    else {
        printf("returned from function\n");
    }
}

void func(int arg) {
    printf("function called with value %d\n",arg);
```

```

x++;
printf("function returning to main\n");
setcontext(&mcontext);

}

```

Output

```

context has been built
function called with value 1
function returning to main
returned from function

```

symlink() — Create a symbolic link to a path name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1a XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```

#define _POSIX1_SOURCE 2
#include <unistd.h>

int symlink(const char *pathname, const char *slink);

```

General description

Creates the symbolic link named by *slink* with the file specified by *pathname*. File access checking is not performed on the file *pathname*, and the file need not exist. In addition, a symbolic link can cross file system boundaries.

A symbolic link path name is resolved in this fashion:

- When a component of a path name refers to a symbolic link rather than to a directory, the path name contained in the symbolic link is resolved.
- If the path name in the symbolic link begins with / (slash), the symbolic link path name is resolved relative to the process root directory.

If the path name in the symbolic link does not start with / (slash), the symbolic link path name is resolved relative to the directory that contains the symbolic link.

- If the symbolic link is the last component of a path name, it may or may not be resolved. Resolution depends on the function using the path name. For example, `rename()` does not resolve a symbolic link when it appears as the final component of either the new or old path name. However, `open` does resolve a symbolic link when it appears as the last component.
- If the symbolic link is not the last component of the original path name, remaining components of the original path name are resolved relative to the symbolic link.
- When a / (slash) is the last component of a path name and it is preceded by a symbolic link, the symbolic link is always resolved.

Because the mode of a symbolic link cannot be changed, its mode is ignored during the lookup process. Any files and directories to which a symbolic link refers are checked for access permission.

Returned value

If successful, `symlink()` returns 0.

If unsuccessful, `symlink()` returns -1, does not affect any file it names, and sets `errno` to one of the following values:

Error Code

Description

EACCES

A component of the *slink* path prefix denies search permission, or write permission is denied in the parent directory of the symbolic link to be created.

EEXIST

The file named by *slink* already exists.

EINVAL

There is a NULL character in *pathname*.

EIO

Added for XPG4.2: An I/O error occurred while reading from the file system.

ELOOP

A loop exists in symbolic links. This error is issued if more than `POSIX_SYMLINK_LOOP` symbolic links are encountered during resolution of the *slink* argument.

ENAMETOOLONG

pathname is longer than **PATH_MAX** characters, or some component of *pathname* is longer than **NAME_MAX** characters while `_POSIX_NO_TRUNC` is in effect. For symbolic links, the length of the path name string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values can be determined with `pathconf()`.

ENOENT

Added for XPG4.2: A component of *slink* does not name an existing file or *slink* is an empty string. This might be also returned for the following reason:

slink has a slash as its last component, which indicates that the preceding component is a directory. A symbolic link cannot be a directory.

ENOSPC

The new symbolic link cannot be created because there is no space left on the file system that will contain the symbolic link.

ENOTDIR

A component of the path prefix of *slink* is not a directory.

EROFS

The file *slink* cannot reside on a read-only system.

Example

```
/* This example works only under z/OS XL C, not z/OS XL C++ */
#define _POSIX1_SOURCE 2
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#include <stdlib.h>
#include <stdio.h>

main() {
    char fn[]="test.file";
    char sln[]="test.symlink";
    int fd;

    if ((fd = creat(fn, S_IWUSR)) < 0)
        perror("creat() error");
    else {
        close(fd);
        puts("before symlink()");
        system("ls -il test.*");
        if (symlink(fn, sln) != 0) {
            perror("symlink() error");
            unlink(fn);
        }
        else {
            puts("after symlink()");
            system("ls -il test.*");
            unlink(fn);
            puts("after first unlink()");
            system("ls -il test.*");
            unlink(sln);
        }
    }
}
```

Output

```
before symlink()
4030 --w----- 1 MVSUSR1 SYS1    0 Apr 20 13:57 test.file

after symlink()
4030 --w----- 1 MVSUSR1 SYS1    0 Apr 20 13:57 test.file
4031 l----- 1 MVSUSR1 SYS1    9 Apr 20 13:57 test.symlink -> test.file
after first unlink()
4031 l----- 1 MVSUSR1 SYS1    9 Apr 20 13:57 test.symlink -> test.file
```

symlinkat() – Create a symbolic link to a path name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1-2008 Single UNIX Specification, Version 4 | both | |

Format

```
#define _POSIX_C_SOURCE 200809L
#include <unistd.h>

int symlinkat(const char *pathname, int newdirfd, const char *slink);
```

General description

symlinkat() operates in the same way as symlink() except for the following differences.

- If the path name that is given in *slink* is relative, it is interpreted relative to the directory that is referred to by the file descriptor *newdirfd* (rather than relative to the current working directory of the calling process, as is done by symlink() for a relative path name).
- If *slink* is relative and *newdirfd* is the special value AT_FDCWD, *slink* is interpreted relative to the current working directory of the calling process (like symlink()).
- If *slink* is absolute, *newdirfd* is ignored.

Returned value

If successful, symlinkat() returns 0.

If unsuccessful, symlinkat() returns -1 and sets errno to one of the following values:

Error Code

Description

EACCES

A component of the *slink* path prefix denies search permission, or write permission is denied in the parent directory of the symbolic link to be created.

EEXIST

The file that is named by *slink* exists.

EINVAL

There is a NULL character in *pathname*.

EIO

Added for XPG4.2: An I/O error occurs while reading from the file system.

ELOOP

A loop exists in symbolic links. This error is issued if more than POSIX_SYMLINK_MAX symbolic links are encountered during the resolution of the *slink* argument.

ENAMETOOLONG

pathname is longer than PATH_MAX characters, or some component of *pathname* is longer than NAME_MAX characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the path name string that is substituted for a symbolic link exceeds PATH_MAX. The PATH_MAX and NAME_MAX values can be determined with pathconf().

ENOENT

Added for XPG4.2: A component of *slink* does not name an existing file or *slink* is an empty string.

slink has a slash as its last component, which indicates that the preceding component is a directory. A symbolic link cannot be a directory.

ENOSPC

The new symbolic link cannot be created because there is no space left on the file system to contain the symbolic link.

ENOTDIR

slink is relative and *newdirfd* is a file descriptor that refers to a file other than a directory.

EROFS

The file *slink* cannot reside on a read-only system.

EBADF

newdirfd is not a valid file descriptor.

EFBIG

A request to create a symbolic link is prohibited because the file size limit for the process is set to 0.

sync() — Schedule file system updates

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

void sync(void);
```

General description

The `sync()` function causes all information in memory that updates file systems to be scheduled for writing out to all file systems.

The writing, although scheduled, is not necessarily complete upon return from `sync()`.

Returned value

`sync()` returns no values.

No errors are defined.

Related information

- [“unistd.h — Implementation-specific functions” on page 77](#)
- [“fsync\(\) — Write changes to direct-access storage” on page 655](#)

syncfs() – Schedule specific file system updates

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <unistd.h>

int syncfs(int fd);
```

General description

`syncfs()` is similar to `sync()` but synchronizes the file system that contains the files that are referred to by the open file descriptor `fd`.

Returned value

If successful, `syncfs()` returns 0.

If unsuccessful, `syncfs()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

`fd` is not a valid file descriptor.

EIO

An error occurs during synchronization. This error might relate to data that is written to any file on the file system or on metadata that is related to the file system itself.

ENOSPC

Disk space is exhausted while synchronizing.

Related information

- [“unistd.h – Implementation-specific functions” on page 77](#)
- [“fsync\(\) – Write changes to direct-access storage” on page 655](#)
- [“sync\(\) – Schedule file system updates” on page 1791](#)

syscall() – Invokes indirect system calls

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX __XPLAT | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <unistd.h>
```

```
long syscall(long number, ...);
```

General description

The `syscall()` invokes the system call whose assembly language interface has the specified number with the specified arguments. Employing `syscall()` is useful, for example, when invoking a system call that has no wrapper function in the C library.

Symbolic constants for system call numbers can be found in `/usr/include/zos/syscalls.h` (and `SYS1.SIEAHDR.H(BPXYSYSC)`).

Returned value

The return value is defined by the system call that is invoked.

Example

```
#define _XPLATFORM_SOURCE
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>
#include <errno.h>

int main (void) {
    int i;
    int dirlen = 10;
    char dirname[10]= "/u/userexample";
    int buflen = 1023;
    char *bufferc;
    char bufferout[1024];
    int retval = 0;
    int retcod = 0;
    int reascod = 0;

    int fd;
    int alet = 0;

    bufferc = (char *)malloc(1024);
    memset(bufferc,0x00,1024);

    /* opendir */
    i = syscall(37,&dirlen,dirname,&retval,&retcod,&reascod);
    if (retval > 0) {
        fd = retval;
        retval = 0;
        /* readdir */
        i = syscall(41,&fd,&bufferc,&alet,&buflen,&retval,&retcod,&reascod);
    }

    printf("fd = %d\n", fd);
    printf("errno = %d, errno2 = %x\n", errno, __errno2());
    memcpy(bufferout,bufferc,1024);
    printf("***bufferc start***\n");
    for (i=0; i<1024; i++) {
        printf("%c", bufferout[i]);
    }
    printf("\n***bufferc end***\n");

    return 0;
}
```

sysconf() — Determine system configuration options

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

long sysconf(int name);
```

General description

Determines the value of a configurable system option.

int *name*

Specifies the system configuration option to be obtained. The value of *name* can be any one of the following set of symbols defined in the `unistd.h` header file, each corresponding to a system configuration option:

The following are available when `_POSIX_SOURCE` is defined.

_SC_ARG_MAX

Represents **ARG_MAX**, as defined by the values returned by `sysconf()`, the maximum number of bytes of arguments and environment data that can be passed in an `exec` function.

_SC_CHILD_MAX

Represents `CHILD_MAX`, as defined by the values returned by `sysconf()`, the maximum number of processes that a real user ID (UID) may have running simultaneously.

_SC_CLK_TCK

Represents the `CLK_TCK` macro defined in the `time.h` header file: the number of clock ticks in a second.

_SC_JOB_CONTROL

Represents the `_POSIX_JOB_CONTROL` macro that can be defined in the `unistd.h` header file. This indicates that certain job control operations are implemented by this version of the operating system. If `_POSIX_JOB_CONTROL` is defined, various functions (for example, `setpgid()`) have more functionality than when the macro is not defined.

_SC_NGROUPS_MAX

Represents **NGROUPS_MAX**, as defined by the values returned by `sysconf()`, the maximum number of supplementary group IDs (GIDs) that can be associated with a process.

_SC_OPEN_MAX

Represents **OPEN_MAX**, as defined by the values returned by `sysconf()`, the maximum number of files that a single process can have open at one time.

_SC_SAVED_IDS

Represents the `_POSIX_SAVED_IDS` macro, which may be defined in `unistd.h` header file, indicating that this POSIX implementation has a saved set UID and a saved set GID. This symbol affects the behavior of such functions as `setuid()` and `setgid()`.

_SC_STREAM_MAX

Represents the `_STREAM_MAX` macro, which may be defined in the `unistd.h` header file, indicating the maximum number of streams that a process can have open at one time.

_SC_THREADS_MAX_NP

Represents the `THREAD_MAX` macro, as defined by the values returned by `sysconf()`, the maximum number of concurrent threads processed by `pthread_create()`, including running, queued, and exited undetached threads in the caller's process.

_SC_THREAD_TASKS_MAX_NP

Represents the `THREAD_TASKS_MAX` macro, as defined by the values returned by `sysconf()`, the maximum number of MVS tasks simultaneously in use for threads processed by `pthread_create()` in the caller's process.

_SC_TTY_GROUP

Retrieves the group number associated with the `TTYGROUP()` initialization parameter.

_SC_TZNAME_MAX

Represents the `_TZNAME_MAX` macro, which may be defined in the `unistd.h` header file, indicating the maximum length of the name of a time zone.

_SC_VERSION

Represents the `_POSIX_VERSION` macro, which will be defined in the `unistd.h` header file, indicating the version of the POSIX.1 standard that the system conforms to.

In addition to the symbols exposed by `_POSIX_SOURCE`, the following are visible when `_XOPEN_SOURCE` is defined:

_SC_XOPEN_CRYPT

Represents `_XOPEN_CRYPT`, the implementation supports the X/Open Encryption Option Group.

_SC_XOPEN_VERSION

Represents `_XOPEN_VERSION`, integer value indicating version of the X/Open Portability Guide to which the implementation conforms.

_SC_PASS_MAX

Represents `PASS_MAX`, as defined by the values returned by `sysconf()`, the maximum number of bytes allowed in a password, `PassTicket`, or password phrase.

Note:

It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

In addition to the symbols exposed by `_XOPEN_SOURCE`, the following are visible when `_XOPEN_SOURCE_EXTENDED` is defined to be 1:

_SC_PAGE_SIZE

Returns the current page size in bytes.

_SC_PAGESIZE

Returns the current page size in bytes.

In addition to the symbols exposed by `_POSIX_SOURCE`, the following are visible when `_POSIX_C_SOURCE` is defined to be 2:

_SC_2_C_BIND

Represents `_POSIX2_C_BIND`, the implementation supports the C-Language Binding option.

_SC_2_C_DEV

Represents `_POSIX2_C_DEV`, the implementation supports the C-Language Development Utilities option.

_SC_2_LOCALEDEF

Represents _POSIX2_LOCALEDEF, the implementation supports the creation of locales by the localedef utility.

_SC_2_UPE

Represents _POSIX2_UPE, the implementation supports the User Portability Utilities option. .

_SC_2_VERSION

Represents _POSIX2_VERSION, integer value indicating version of the Shell and Utilities to which the implementation conforms.

In addition to the symbols exposed by _POSIX_C_SOURCE defined to be 2, the following are visible when _POSIX_C_SOURCE is defined to be 200112L:

_SC_HOST_NAME_MAX

Represents HOST_NAME_MAX, Maximum length of a host name (not including the terminating null) as returned from the gethostname() function.

_SC_IPV6

Represents _POSIX_IPV6, the implementation supports the IPv6 option.

_SC_LOGIN_NAME_MAX

Represents LOGIN_NAME_MAX, Maximum length of a login name.

_SC_READER_WRITER_LOCKS

Represents _POSIX_READER_WRITER_LOCKS, the implementation supports the Read-Write Locks option. This is always set to a value greater than zero if the Threads option is supported.

_SC_REGEX

Represents _POSIX_REGEX, the implementation supports the Regular Expression Handling option.

_SC_SHELL

Represents _POSIX_SHELL, the implementation supports the POSIX shell.

_SC_SYMLOOP_MAX

Represents SYMLOOP_MAX, maximum number of symbolic links that can be reliably traversed in the resolution of a path name in the absence of a loop.

_SC_THREAD_ATTR_STACKSIZE

Represents _POSIX_THREAD_ATTR_STACKSIZE, the implementation supports the Thread Stack Size Attribute option.

_SC_THREAD_KEYS_MAX

Represents PTHREAD_KEYS_MAX, maximum number of data keys that can be created by a process.

_SC_THREAD_PROCESS_SHARED

Represents _POSIX_THREAD_PROCESS_SHARED, the implementation supports the Thread Process-Shared Synchronization option.

_SC_THREAD_SAFE_FUNCTIONS

Represents _POSIX_THREAD_SAFE_FUNCTIONS, the implementation supports the Thread-Safe Functions option.

_SC_THREAD_STACK_MIN

Represents PTHREAD_STACK_MIN, minimum size in bytes of thread stack storage.

_SC_THREAD_THREADS_MAX

Represents PTHREAD_THREADS_MAX, maximum number of threads that can be created per process.

_SC_THREADS

Represents _POSIX_THREADS, the implementation supports the Threads option.

_SC_TTY_NAME_MAX

Represents TTY_NAME_MAX, maximum length of terminal device name.

_SC_V6_ILP32_OFF32

Represents `_POSIX_V6_ILP32_OFF32`, the implementation provides a C-language compilation environment with 32-bit int, long, pointer, and `off_t` types.

_SC_V6_ILP32_OFFBIG

Represents `_POSIX_V6_ILP32_OFFBIG`, the implementation provides a C-language compilation environment with 32-bit int, long, and pointer types and an `off_t` type using at least 64 bits.

_SC_V6_LP64_OFF64

Represents `_POSIX_V6_LP64_OFF64`, the implementation provides a C-language compilation environment with 32-bit int and 64-bit long, pointer, and `off_t` types.

_SC_V6_LPBIG_OFFBIG

Represents `_POSIX_V6_LPBIG_OFFBIG`, the implementation provides a C-language compilation environment with an int type using at least 32 bits and long, pointer, and `off_t` types using at least 64 bits.

_SC_XOPEN_LEGACY

Represents `_XOPEN_LEGACY`, the implementation supports the Legacy Option Group.

The following symbols are available under `_XOPEN_SOURCE 500`:

_SC_GETPW_R_SIZE_MAX

Maximum size of `getpwuid_r()` and `getpwnam_r()` data buffers

_SC_GETGR_R_SIZE_MAX

Maximum size of `getgrgid_r()` and `getgrnam_r()` data buffers

Returned value

If successful, `sysconf()` returns the value associated with the specified option.

If the variable corresponding to *name* exists but is not supported by the system, `sysconf()` returns -1 but does not change the value of `errno`. If `sysconf()` fails in some other way, it returns -1.

If unsuccessful, `sysconf()` sets `errno` to one of the following values:

Error Code**Description****EINVAL**

The value specified for the *name* argument is incorrect.

Example**CELEBS61**

```
/* CELEBS61

   This example determines the value of ARG_MAX.

*/
#define _POSIX_SOURCE
#include <stdio.h>
#include <unistd.h>
#include <errno.h>

main() {
    long result;

    errno = 0;
    puts("examining ARG_MAX limit");
    if ((result = sysconf(_SC_ARG_MAX)) == -1)
        if (errno == 0)
            puts("ARG_MAX is not supported.");
        else perror("sysconf() error");
    else
        printf("ARG_MAX is %ld\n", result);
}
```

Output

```
examining ARG_MAX limit
ARG_MAX is 1048576
```

syslog() — Send a message to the control log

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <syslog.h>

void syslog(int priority, const char *message, ... /* argument */);
```

General description

The `syslog()` function sends a message to an implementation-specific logging facility, which loads it in an appropriate system log, writes it to the system console, forwards it to a list of users, or forwards it to the logging facility on another host over the network. The logged message includes a message header and a message body. The message header consists of a facility indicator, a severity indicator, a timestamp, a tag string, and optionally the process ID. The process ID is surrounded by square brackets. The code point values for the square brackets are taken from code page IBM-1047. The value for the left square bracket is 0xAD. The value for the right square bracket is 0xBD.

The message body is generated from the *message* and following arguments in the same manner as if these were arguments to the `printf()` function, except that occurrences of `%m` in the format string pointed to by the *message* argument are replaced by the error message string associated with the current value of `errno`. A trailing newline character is added if needed.

Note: If the total length of the format string and the parameters is greater than 4096 bytes, then the results are undefined.

Values of the *priority* argument are formed by ORing together a severity level values and an option facility value. If no facility value is specified, the current default facility value is used. Possible values of severity level include:

LOG_ALERT

A condition that should be corrected immediately, such as a corrupted system database.

LOG_CRIT

Critical conditions, such as hard device errors.

LOG_DEBUG

Messages that contain information normally of use only when debugging a program.

LOG_EMERG

A Panic condition. This is normally broadcast to all processes.

LOG_ERR

Errors.

LOG_INFO

Informational messages.

LOG_NOTICE

Conditions that are not error conditions, but that may require special handling.

LOG_WARNING

Warning messages.

The facility indicates the application or system component generating the message. Possible facility values include:

LOG_USER

Message generated by random processes. This is the default facility identifier if none is specified.

LOG_LOCAL0

Reserved for local use.

LOG_LOCAL1

Reserved for local use.

LOG_LOCAL2

Reserved for local use.

LOG_LOCAL3

Reserved for local use.

LOG_LOCAL4

Reserved for local use.

LOG_LOCAL5

Reserved for local use.

LOG_LOCAL6

Reserved for local use.

LOG_LOCAL7

Reserved for local use.

Returned value

syslog() returns no values.

system() — Execute a command

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 IEEE Std 1003.1, 2004 Edition | both | |

Format

```
#include <stdlib.h>

int system(const char *string);
```

General description

The `system()` function has two different behaviors. These behaviors are designated as ISO C/C++ `system()` and POSIX `system()`. The ISO C/C++ `system()` behavior is based on the ISO C standard definition of the function, whereas the POSIX `system()` behavior is based on the POSIX standard definition. The ISO C/C++ `system()` behavior is used when a) running POSIX(OFF) or b) when running POSIX(ON) and environment variable `__POSIX_SYSTEM` is set to NO. Otherwise the POSIX `system()` behavior is used.

Restriction:

- The `system()` function is not supported under CICS. If the *string* argument is NULL, `system()` returns 0 since there is no command processor under CICS, otherwise it returns -1.

ISO C/C++ `system()` function:

Note: In this topic, MVS specifically refers to MVS batch (excluding batch TSO/E), whereas TSO/E includes both batch TSO/E (IKJEFT01 as the program specified on the JCL EXEC statement) and interactive TSO/E (which is TSO/E at a terminal).

Using the ISO C/C++ `system()` function, you can call commands, EXECs, CLISTs, or executable modules under the MVS environment and TSO/E. You cannot use the ISO C/C++ `system()` function to invoke z/OS UNIX services shell programs.

The *string* argument can take one of the two formats:

command-line

A string with TSO/E command line syntax:

```
command_name parm1 parm2 ...
```

Example:

```
system("user_pgm1 1234 abcd xyz");
```

If the *string* argument is in the command-line format, the `system()` function passes the given string to the command processor, if available, for execution.

named-program

A string, of the following form, with no embedded blanks except in the PARM area.

```
"PGM=program_name[,PARM='...']"
```

Example:

```
system("PGM=user_pgm1, PARM='1234 abcd xyz'");
```

If the *string* argument is a named-program format, the `system()` function calls `program_name` with the parameters following “`PARM=`”, if any.

The two formats are supported under both MVS and TSO/E, but not all targets can be called from all environments. For example, TSO/E commands cannot be called in an MVS environment. As a result, the two formats are equivalent under the MVS environment, but are different under TSO/E. The details of each are provided below. For maximum portability when invoking executable modules under the different environments, use the named-program format.

If the specified executable module is a z/OS XL C or z/OS XL C++ module, full initialization and termination will be performed: including, but not limited to, automatic closing of files and releasing of fetched modules. In addition, if the ISO C/C++ `system()` call uses the named-program format under either MVS or TSO/E, or the command-line format under the MVS environment, information can be passed across the program boundary using memory files. Memory files are not removed until either the highest level (root) program in the call chain terminates or the `clrmemf()` function is used. Standard streams are also shared in this environment.

ISO C/C++ MVS considerations: Under the MVS environment, the ISO C/C++ `system()` function accepts either command-line or named-program format strings. However, the command-line string is restricted to specifying only executable modules (that is, TSO/E commands, EXECs, and CLISTs cannot be specified). Because of this restriction, both formats provide the same functionality.

In the case of either a command-line or named-program string, the ISO C/C++ `system()` function will search the usual MVS sources (STEPLIB/JOBLIB concatenation, Link Pack Area (LPA), Extended Link Pack Area (ELPA), and the link libraries) for the specified program name. The LINK SVC is used to give control to the program.

Under the MVS environment, using ATTACH instead of ISO C/C++ `system()` will prevent you from sharing memory files or standard streams between the programs.

ISO C/C++ TSO/E considerations: Under TSO/E, the ISO C/C++ `system()` function accepts either command-line or named-program format strings.

Command-line format strings are presented to the TSO/E command processor and can be used to execute user modules, TSO/E commands, EXECs or CLISTs. If there is any ambiguity as to what is to be run when a command-line format string is supplied, the hierarchy is:

1. TSO/E command or user module
2. CLIST or EXEC

Therefore, if a command-line format string is used and a CLIST or EXEC exists with the same name as a TSO/E command or user module, the TSO/E EXEC command must be used to specifically invoke the CLIST or EXEC.

If the command-line format string is used to call a user module, it effectively uses ATTACH to execute the program. As with MVS, when using ATTACH, memory files and standard streams are not shared between the programs. This is the reason that named-program format strings should be used for maximum portability. The named-program format provides the same memory file and standard stream sharing in both the MVS and TSO/E environments.

Notes:

1. If an executable module is placed in the STEPLIB or ISPLLIB (under ISPF), TSO/E will allow the module to be activated as a command. Recall from the discussion above, that, if a CLIST or EXEC has the same name, the module would be activated first, due to the hierarchy rules. Activating a module as a command involves a different input interface. If required, you can use the CALL command to activate a module that is not prepared to take the TSO/E command input format. z/OS XL C and z/OS XL C++ modules can be called as TSO/E commands.
2. A module that exists in the Link Pack Area (LPA) or Extended Link Pack Area (ELPA) and not in the STEPLIB concatenation (ISPLLIB on ISPF) will not be activated as a TSO/E command, and is treated as an executable module.

Named-program format strings are not presented to the TSO/E command processor and can only be used to execute user modules.

POSIX system() function: Using the POSIX system() function, you can call z/OS UNIX services shell programs. You cannot use the POSIX system() function to call commands, EXECs, CLISTs, or executable modules under the MVS environment and TSO/E.

The POSIX system() function passes *string* to the **sh** shell command for execution. The environment is established by the runtime library through a spawn() of the shell.

The POSIX system() function ignores the SIGINT and SIGQUIT signals, and blocks the SIGCHLD signal while it waits for the command specified by *string* argument to end.

Special considerations for POSIX C: The system() function has these additional considerations:

- A program running with POSIX(ON) can call another program that will also use POSIX(ON) only if the calling program uses the POSIX system() function to invoke the called program out of the shell. Using the ISO C/C++ system() function to call a program that will also use POSIX(ON) will result in message CEE3648S being issued, followed by ABENDU4093-AC.
- A program running with POSIX(ON) can receive signals other than SIGINT, SIGQUIT, or SIGCHLD while the POSIX system() function is waiting for the shell command to complete. If there is a signal catcher registered for the signal, it will be invoked immediately. If the signal catcher calls siglongjmp() or setcontext() to pass control back to the application, the SIGINT and SIGQUIT signals will remain ignored, and the SIGCHLD signal will remain blocked.
- If the calling program is the child of a forked process, it cannot use the ISO C/C++ system() function to run TSO/E commands since the TSO/E address space is not available.
- If the calling program was invoked using one of the exec or spawn functions, it cannot use the ISO C/C++ system() function to run TSO/E commands since the TSO/E address space is not available.
- The system() function is not thread-safe. It cannot be called simultaneously from more than one thread. A multithreaded application must ensure that no more than one system() call is ever outstanding from the various threads. Results are undefined if this restriction is violated..
- When using a signal handler and setting the default handler for SIGCHLD to be SIG_IGN, an errno value of ECHILD will be returned. This is due to the speed at which the process executes and finishes before system() can call waitpid() to wait for the child process to end. In this case, the ECHILD can be ignored because the process has already completed successfully and returned.

Note: If an application invokes a z/OS UNIX service shell command or utility that performs terminal I/O, the command may fail due to the z/OS UNIX services shell file descriptors not being initialized. z/OS UNIX files for terminal I/O must be defined. An example of how these can be defined in a C application are as follows:

```
stdin = fopen("/tmp/sys.stdin","r");
stdout = fopen("/tmp/sys.stdout","w");
stderr = fopen("/tmp/sys.stderr","w");
```

See z/OS XL C/C++ applications with z/OS UNIX System Services C functions in topic 1.9 for more information about using POSIX support.

Mixed environments across an ISO C/C++ system() call: The mixing of z/OS Language Environment, C/370 Library Version 1 or Version 2, and System Programming C (SPC) environments across a system() call is not supported. Whichever of these environments is active when the first system() call is made is the only one that is tolerated in the system() call chain. Results are undefined if this restriction is violated.

Returned value

If the *string* argument is a NULL pointer, the system() function returns nonzero if a command processor exists, or 0 if one does not exist.

ISO C/C++ MVS considerations: The returned value from ISO C/C++ system() will be that from the user module, if successfully called. If system() cannot call the specified module, the returned value is -1 and errno is set appropriately.

ISO C/C++ TSO/E considerations: The returned value from ISO C/C++ `system()` will be nonzero if the command processor cannot execute the command or user module. The macros `__abendcode` and `__rsncode` will contain the abend code and reason code from a failing TSO/E command, EXEC, or CLIST.

POSIX considerations: If the *string* argument is a NULL pointer, the POSIX `system()` function returns nonzero. If the *string* argument is not NULL, the POSIX `system()` function returns the termination status of the command language interpreter in the format specified by `waitpid()`. If a child process cannot be created, or if the termination status for the command language interpreter cannot be obtained, `system()` returns -1.

Note: When using a signal handler and setting the default handler for SIGCHLD to be SIG_IGN, an `errno` value of ECHILD will be returned. This is due to the speed at which the process executes and finishes before `system()` can call `waitpid()` to wait for the child process to end. In this case, the ECHILD can be ignored because the process has already completed successfully and returned.

If `system()` returns -1, `errno` may be set to one of the following:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

EAGAIN

There are insufficient resources to create another process, or the maximum number of processes you can run has been reached.

ECHILD

The new process finished before `system()` could call `waitpid()` to wait for the child process to end. This error can be ignored because the child process has already completed successfully and returned.

ENOMEM

The process requires more space than is available.

ENOSYS

The ISO C/C++ `system()` function was requested from an AMODE 64 application.

Example

```
/* This example illustrates how to use system() to execute a command which
   returns the time. The example works only under TSO.
   */
#include <stdlib.h>

int main(void)
{
    int rc;
    rc = system("time");
    exit(0);
}
```

```
/* This example may only be used in a POSIX program. */
#include <stdlib.h>

int main(void)
{
    int result;

    result = system("date | tee result.log");
}
```

t_accept() – Accept a connect request

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_accept(int fd, int resfd, struct t_call *call);
```

General description

t_accept() is issued by a transport user to accept a connect request. The parameter *fd* identifies the local transport endpoint where the connect indication arrived. *resfd* specifies the local transport endpoint where the connection is to be established, and *call* contains information required by the transport provider to complete the connection. The parameter *call* points to a *t_call* structure which contains the following members:

```
struct netbuf  addr;
struct netbuf  opt;
struct netbuf  udata;
int            sequence;
```

In *call*, *addr* is the protocol address of the calling transport user. *opt* indicates any options associated with the connection. *udata* points to any user data to be returned to the caller, and *sequence* is the value returned by t_listen() that uniquely associates the response with a previously received connect indication. The address of the caller, *addr* may be NULL (length zero). Where *addr* is not NULL, then it may optionally be checked by XTI.

A transport user may accept a connection on either the same, or on a different, local transport endpoint than the one on which the connect indication arrived. Before the connection can be accepted on the same endpoint (*resfd*==*fd*), the user must have responded to any previous connect indications received on that transport endpoint (using t_accept() or t_snddis()). Otherwise, t_accept() fails and sets *t_errno* to TINDOUT.

If a different transport endpoint is specified (*resfd*!=*fd*), then the user may or may not choose to bind the endpoint before the t_accept() is issued. If the endpoint is not bound before the t_accept() , then the transport provider will automatically bind it to the same protocol address *fd* is bound to. If the transport user chooses to bind the endpoint it must be bound to a protocol address with a *qlen* of zero and must be in the T_IDLE state before the t_accept() is issued.

The call to t_accept() will fail with *t_errno* set to TLOOK if there are indications (for example, connect or disconnect) waiting to be received on the endpoint *fd*.

Return of user data over a connection accept is not supported under TCP, so the *udata* field is always meaningless.

When the user does not indicate any option (*call->opt.len* == 0) it is assumed that the connection is to be accepted unconditionally. The transport provider may choose options other than the defaults to ensure that the connection is accepted successfully.

Due to implementation restrictions, behavior is undefined if a different process accepts a connection pending on an endpoint than obtained it (with t_listen).

Valid states: *fd*: T_INCON *resfd* (*fd*!=*resfd*): T_IDLE

Returned value

If successful, `t_accept()` returns 0.

If unsuccessful, `t_accept()` returns -1 and sets `t_errno` to one of the following values:

Error Code

Description

TACCES

The user does not have permission to accept a connection on the responding transport endpoint or to use the specified options.

TBADADDR

The specified protocol address was in an incorrect format or contained illegal information.

TBADDATA

The amount of user data specified was not within the bounds allowed by the transport provider.

TBADF

The file descriptor *fd* or *resfd* does not refer to a transport endpoint.

TBADOPT

The specified options were in an incorrect format or contained illegal information.

TBADSEQ

An invalid sequence number was specified.

TINDOUT

The function was called with *fd*==*resfd* but there are outstanding connection indications on the endpoint. Those other connection indications must be handled either by rejecting them using `t_snddis` (3) or accepting them on a different endpoint using `t_accept` (3).

TLOOK

An asynchronous event has occurred on the transport endpoint referenced by *fd* and requires immediate attention.

TNOTSUPPORT

This function is not supported by the underlying transport provider.

TOUTSTATE

The function was called in the wrong sequence on the transport endpoint referenced by *fd*, or the transport endpoint referred to by *resfd* is not in the appropriate state.

TPROTO

This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (*t_errno*).

TPROVMISMATCH

The file descriptors *fd* and *resfd* do not refer to the same transport provider.

TRESADDR

This transport provider requires both *fd* and *resfd* to be bound to the same address. This error results if they are not.

TRESQLEN

The endpoint referenced by *resfd* (where *resfd* != *fd*) was bound to a protocol address with a *qlen* that is greater than 0.

TSYSERR

A system error has occurred during execution of this function.

takesocket() — Acquire a socket from another program

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _OPEN_SYS SOCK_EXT
#include <sys/types.h>
#include <socket.h>

int takesocket(struct clientid *clientid, int sdesc);
```

General description

The takesocket() function acquires a socket from another program. Typically, the other program passes its client ID and socket descriptor, and/or process id (PID), to your program through your program's startup parameter list.

Parameter

Description

clientid

A pointer to the *clientid* of the application from which you are taking a socket.

sdesc

The descriptor of the socket to be taken.

If your program is using the PID to ensure integrity between givesocket() and takesocket(), before issuing the takesocket() call, your program should set the *c_pid.pid* field of the clientid structure to the PID of the giving program (that is, program that issued the givesocket() call). This identifies the process from which the socket is to be taken. If the *c_reserved.type* field of the clientid structure was set to SO_CLOSE on the givesocket() call, *c_close.SockToken* of clientid structure should be used as input to takesocket() instead of the normal socket descriptor. See [“givesocket\(\) — Make the specified socket available”](#) on page 805 for a description of the clientid structure.

Returned value

If successful, takesocket() returns the new socket descriptor.

If unsuccessful, takesocket() returns -1 and sets errno to one of the following values:

Error Code

Description

EACCES

The other application did not give the socket to your application.

EBADF

The *sdesc* parameter does not specify a valid socket descriptor owned by the other application, or the socket has already been taken.

EFAULT

Using the *clientid* parameter as specified would result in an attempt to access storage outside the caller's address space.

EINVAL

The *clientid* parameter does not specify a valid client identifier. Either the client process cannot be found, or the client exists, but has no outstanding givesockets.

EMFILE

The socket descriptor table is already full.

t_alloc() — Allocate a library structure

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

char *t_alloc(int fd, int struct_type, int fields);
```

General description

Dynamically allocates memory for the various transport function argument structures as specified below. `t_alloc()` allocates memory for the specified structure, and memory for buffers referenced by the structure.

The structure to allocate is specified by *struct_type* and must be one of the following:

| | |
|------------|-------------------|
| T_BIND | struct t_bind |
| T_CALL | struct t_call |
| T_OPTMGMT | struct t_optmgmt |
| T_DIS | struct t_discon |
| T_UNITDATA | struct t_unitdata |
| T_UDERROR | struct t_uderr |
| T_INFO | struct t_info |

where each of these structures may subsequently be used as an argument to one or more transport functions.

Each of the above structures, except `T_INFO`, contains at least one field of type `struct netbuf`. For each field of this type, the user may specify that the buffer for that field should be allocated as well. The length of the buffer allocated will be equal to or greater than the appropriate size as returned in the *info* argument of `t_open()` or `t_getinfo()`. The relevant fields of the *info* argument are described in the following list. The *fields* argument specifies which buffers to allocate, where the argument is the bitwise OR of any of the following:

T_ADDR

The *addr* field of the `t_bind`, `t_call`, `t_unitdata` or `t_uderr` structures.

T_OPT

The *opt* field of the `t_optmgmt`, `t_call`, `t_unitdata` or `t_uderr` structures.

T_UDATA

The *udata* field of the *t_call*, *t_discon* or *t_unitdata* structures.

T_ALL

All relevant fields of the given structure. Fields which are not supported by the transport provider specified by *fd* will not be allocated.

For each relevant field specified in *fields*, *t_alloc()* allocates memory for the buffer associated with the field, and initializes the *len* field to zero and the *buf* pointer and *maxlen* field accordingly. Irrelevant or unknown values passed in fields are ignored. Since the length of the buffer allocated will be based on the same size information that is returned to the user on a call to *t_open()* and *t_getinfo()*, *fd* must refer to the transport endpoint through which the newly allocated structure will be passed. In this way the appropriate size information can be accessed. If the size value associated with any specified field is -1 or -2 (see *t_open()* or *t_getinfo()*), *t_alloc()* will be unable to determine the size of the buffer to allocate and will fail, setting *t_errno* to *TSYSERR* and *errno* to *EINVAL*. For any field not specified in *fields*, *buf* will be set to the NULL pointer and *len* and *maxlen* will be set to zero.

Use of *t_alloc()* to allocate structures helps ensure the compatibility of user programs with future releases of the transport interface functions.

Valid states: All - except for *T_UNINIT*

Returned value

If successful, *t_alloc()* returns a pointer to the newly allocated structure.

If unsuccessful, *t_alloc()* returns a NULL pointer and sets *errno* to one of the following values:

Error Code**Description****TBADF**

The specified file descriptor does not refer to a transport endpoint.

TNOSTRUCTYPE

Unsupported *struct_type* requested. This can include a request for a structure type which is inconsistent with the transport provider type specified, that is, connection-oriented or connectionless.

TPROTO

This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (*t_errno*).

TSYSERR

A system error has occurred during execution of this function.

tan(), tanf(), tanl() – Calculate tangent

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#include <math.h>

double tan(double x);
float tan(float x);           /* C++ only */
long double tan(long double x); /* C++ only */
float tanf(float x);
long double tanl(long double x);
```

General description

Calculates the tangent of x , where x is expressed in radians. If x is large, a partial loss of significance in the result can occur.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

Returned value

Returns the calculated tangent of x .

If the correct value would cause an underflow, 0 is returned. If the result overflows, $\pm\text{HUGE_VAL}$ is returned. For both an underflow and an overflow, the value `ERANGE` is stored in `errno`.

Special behavior for XPG4.2: The following error is added:

Error Code

Description

EDOM

The argument exceeded an internal limit for the function (approximately 2^{50}).

Example

CELEBT01

```
/* CELEBT01
   This example computes x as the tangent of PI/4.
*/
#include <math.h>
#include <stdio.h>

int main(void)
{
    double pi, x;

    pi = 3.1415926;
    x = tan(pi/4.0);
```

```
printf("tan( %lf ) is %lf\n", pi/4, x);
}
```

Output

```
tan( 0.785398 ) is 1.000000
```

tand32(), tand64(), tand128() - Calculate tangent

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.10 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 tand32(_Decimal32 x);
_Decimal64 tand64(_Decimal64 x);
_Decimal128 tand128(_Decimal128 x);
_Decimal32 tan(_Decimal32 x); /* C++ only */
_Decimal64 tan(_Decimal64 x); /* C++ only */
_Decimal128 tan(_Decimal128 x); /* C++ only */
```

General description

Calculates the tangent of *x*, where *x* is expressed in radians. If *x* is large, a partial loss of significance in the result can occur.

These functions work in IEEE decimal floating-point format. See [“IEEE decimal floating-point” on page 97](#) for more information.

Note: To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

Returns the calculated tangent of *x*.

If the correct value would cause underflow, zero is returned. If the result overflows, $\pm\text{HUGE_VAL_D32}$, $\pm\text{HUGE_VAL_D64}$, or $\pm\text{HUGE_VAL_D128}$ is returned. For both underflow and overflow, the value `ERANGE` is stored in `errno`.

Example

CELEBT22

```
/* CELEBT22

   This example illustrates the tand64() function.

   This example computes x as the tangent of PI/4.

*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal64 pi, x;

    pi = 3.1415926DD;
    x = tand64(pi/4.0DD);

    printf("tand64( %Df ) is %Df\n", pi/4.0DD, x);
}
```

tanh(), tanhf(), tanhl() – Calculate hyperbolic tangent

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 ISO/ANSI C++ C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | |

Format

```
#include <math.h>

double tanh(double x);
float tanh(float x);           /* C++ only */
long double tanh(long double x); /* C++ only */
float tanhf(float x);
long double tanhl(long double x);
```

General description

Calculates the hyperbolic tangent of x , where x is expressed in radians. The result of the function cannot have a range error.

Note: These functions work in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See [“IEEE binary floating-point” on page 97](#) for more information about IEEE Binary Floating-Point.

Returned value

Returns the calculated value of the hyperbolic tangent of x .

If the result underflows, the function returns 0 and sets the `errno` to `ERANGE`.

Example

CELEBT02

```
/* CELEBT02

   This example computes x as the hyperbolic tangent of PI/4.

*/
#define _POSIX_SOURCE
#include <math.h>
#include <stdio.h>

int main(void)
{
    double pi, x;

    pi = 3.1415926;
    x = tanh(pi/4);

    printf("tanh( %lf ) = %lf\n", pi/4, x);
}
```

Output

```
tanh( 0.785398 ) = 0.655794
```

t_bind() — Bind an address to a transport endpoint

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_bind(int fd, struct t_bind *req, struct t_bind *ret);
```

General description

Associates a protocol address with the transport endpoint specified by *fd* and activates that transport endpoint. In connection mode, the transport provider may begin enqueueing incoming connect indications, or servicing a connection request on the transport endpoint. In connectionless mode, the transport user may send or receive data units through the transport endpoint.

The *req* and *ret* arguments point to a `t_bind` structure containing the following members:

```
struct netbuf    addr;
unsigned         qlen;
```

The *addr* field of the `t_bind` structure specifies a protocol address, and the *qlen* field is used to indicate the maximum number of outstanding connect indications.

The parameter *req* is used to request that an address, represented by the `netbuf` structure, be bound to the given transport endpoint. The parameter *len* specifies the number of bytes in the address, and *buf* points to the address buffer. The parameter *maxlen* has no meaning for the *req* argument. On return, *ret* contains the address that the transport provider actually bound to the transport endpoint. This is the same as the address specified by the user in *req*. In *ret*, the user specifies *maxlen*, which is the maximum size of the address buffer, and *buf* which points to the buffer where the address is to be placed. On return, *len* specifies the number of bytes in the bound address, and *buf* points to the bound address. If *maxlen* is not large enough to hold the returned address, an error results.

If the requested address is not available, `t_bind()` returns -1 with *t_errno* set as appropriate. If no address is specified in *req* (the *len* field of *addr* in *req* is zero or *req* is NULL), the transport provider will assign an appropriate address to be bound, and will return that address in the *addr* field of *ret*. If the transport provider could not allocate an address, `t_bind()` fails with *t_errno* set to `TNOADDR`.

The parameter *req* may be a NULL pointer if the user does not wish to specify an address to be bound. Here, the value of *qlen* is assumed to be zero, and the transport provider assigns an address to the transport endpoint. Similarly, *ret* may be a NULL pointer if the user does not care what address was bound by the provider and is not interested in the negotiated value of *qlen*. It is valid to set *req* and *ret* to the NULL pointer for the same call, in which case the provider chooses the address to bind to the transport endpoint and does not return that information to the user.

The *qlen* field specifies the number of outstanding connect indications that the transport provider should support for the given transport endpoint. An outstanding connect indication is one that has been passed to the transport user by the transport provider, but which has not been accepted or rejected. A value of *qlen* greater than 0 is only meaningful when issued by a passive transport user that expects other users to call it. The value of *qlen* will be negotiated by the transport provider and will always be negotiated to 1 (one) from any nonzero value. On return, the *qlen* field in *ret* will contain the negotiated value.

If *fd* refers to a connection-oriented service, then multiple endpoints may be bound to the same protocol address by way of connections accepted on an endpoint using `t_accept`. The TCP transport provider will not permit the user to explicitly bind multiple endpoints to the same address. It is also not possible to bind an endpoint to more than one protocol address. If a user attempts to explicitly bind multiple endpoints to a protocol address, the second and subsequent binds will fail with *t_errno* set to `TADDRBUSY`. When a user accepts a connection on the transport endpoint that is being used as the listening endpoint, the bound protocol address will be found to be busy for the duration of the connection, until a `t_unbind()` or `t_close()` call has been issued. No other transport endpoints may be bound for listening on that same protocol address while that initial listening endpoint is active (in the data transfer phase or in the `T_IDLE` state). This prevents more than one transport endpoint bound to the same protocol address from accepting connect indications.

Valid states: `T_UNBND`

Returned value

If successful, `t_bind()` returns 0.

If unsuccessful, `t_bind()` returns -1 and sets *errno* to one of the following values:

Error Code

Description

TACCES

The user does not have permission to use the specified address.

TADDRBUSY

The requested address is in use.

TBADADDR

The specified protocol address was in an incorrect format or contained illegal information.

TBADF

The specified file descriptor does not refer to a transport endpoint.

TBUFOVFLW

The number of bytes allowed for an incoming argument (*maxlen*) is greater than 0 but not sufficient to store the value of that argument. The provider's state will change to T_IDLE and the information to be returned in *ret* will be discarded.

TNOADDR

The transport provider could not allocate an address.

TOUTSTATE

The function was issued in the wrong sequence.

TPROTO

This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (*t_errno*).

TSYSERR

A system error has occurred during execution of this function.

tcdrain() — Wait until output has been transmitted

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <termios.h>

int tcdrain(int fildes);
```

General description

The tcdrain() function waits until all output sent to *fildes* has actually been sent to the terminal device. If tcdrain() is called from a background process group against the caller's controlling terminal, a SIGTTOU signal may be generated depending how the process is handling SIGTTOUs:

| Processing for SIGTTOU System Behavior | |
|--|---|
| Default or signal handler | The SIGTTOU signal is generated, and the function is not performed. tcdrain() returns -1 and sets errno to EINTR. |

Processing for SIGTTOU System Behavior

| | |
|--------------------|--|
| Ignored or blocked | The SIGTTOU signal is not sent, and the function continues normally. |
|--------------------|--|

Returned value

If successful, `tcdrain()` returns 0.

If unsuccessful, `tcdrain()` returns -1 and sets `errno` to one of the following values:

Error Code**Description****EBADF**

fildev is not a valid open file descriptor.

EINTR

A signal interrupted `tcdrain()`.

EIO

The process group of the process issuing the function is an orphaned, background process group, and the process issuing the function is not ignoring or blocking SIGTTOU.

ENOTTY

fildev is not associated with a terminal.

Example**CELEBT03**

```
/* CELEBT03 */

#define _POSIX_SOURCE
#include <termios.h>
#include <stdio.h>
#include <time.h>
#include <fcntl.h>
#include <unistd.h>
#include <sys/stat.h>
#include <string.h>

main() {
    char Manager[]="manager.tty";
    char Subsidiary[]="subsidiary.tty";
    char text[]="text to be written to tty";
    char data[80];
    int manager, subsidiary;
    time_t T;

    if (mknod(Manager, S_IFCHR|S_IRUSR|S_IWUSR, 0x00010000 + 10) !=0)
        perror("mknod() error for manager tty");
    else {
        if (mknod(Subsidiary, S_IFCHR|S_IRUSR|S_IWUSR, 0x00020000 + 10) !=0)
            perror("mknod() error for subsidiary tty");
        else {
            if ((manager = open(Manager, O_RDWR|O_NONBLOCK)) < 0)
                perror("open() error for manager tty");
            else {
                if ((subsidiary = open(Subsidiary, O_RDWR|O_NONBLOCK)) < 0)
                    perror("open() error for subsidiary tty");
                else {
                    if (fork() == 0) {
                        if (write(subsidiary, text, strlen(text)+1) == -1)
                            perror("write() error");
                        time(&T);
                        printf("child has written to tty, tcdrain() started at %s",
                               ctime(&T));
                        if (tcdrain(subsidiary) != 0)
                            perror("tcdrain() error");
                        time(&T);
                        printf("tcdrain() returned at %s", ctime(&T));
                        exit(0);
                    }
                    time(&T);
                }
            }
        }
    }
}
```

```
        printf("parent is starting nap at %s", ctime(&T));
        sleep(5);
        time(&T);
        printf("parent is done with nap at %s", ctime(&T));
        if (read(manager, data, sizeof(data)) == -1)
            perror("read() error");
        else printf("read '%s' from the tty\n", data);
        sleep(5);
        close(subsidiary);
    }
    close(manager);
}
unlink(Subsidiary);
}
unlink(Manager);
}
}
```

Output

```
parent is starting nap at Fri Jun 16 12:46:28 2006
child has written to tty, tcdrain() started at Fri Jun 16 12:46:28 2006
parent is done with nap at Fri Jun 16 12:46:34 2006
read 'text to be written to tty' from the tty
tcdrain() returned at Fri Jun 16 12:46:34 2006
```

tcflow() — Suspend or resume data flow on a terminal

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <termios.h>

int tcflow(int fildes, int action);
```

General description

Suspends or resumes transmission or reception of data on a terminal device.

int fildes

A file descriptor associated with a terminal device.

int action

Indicates the action you want to perform, represented by one of the following symbols defined in the `termios.h` include file:

Symbol**Meaning****TCOOFF**

Suspends output.

TCOON

Resumes suspended output.

TCIOFF

Sends a STOP character to the terminal, to stop the terminal from sending any further input.

TCION

Sends a START character to the terminal, to tell the terminal that it can resume sending input.

If `tcflow()` is called from a background process group against the caller's controlling terminal, a SIGTTOU signal may be generated depending how the process is handling SIGTTOUs:

| Processing for SIGTTOU System Behavior | |
|--|--|
| Default or signal handler | The SIGTTOU signal is generated, and the function is not performed. <code>tcflow()</code> returns -1 and sets <code>errno</code> to <code>EINTR</code> . |
| Ignored or blocked | The SIGTTOU signal is not sent, and the function continues normally. |

Returned value

If successful, `tcflow()` returns 0.

If unsuccessful, `tcflow()` returns -1 and sets `errno` to one of the following values:

Error Code**Description****EBADF**

fildev is not a valid open file descriptor.

EINTR

A signal interrupted `tcflow()`.

EINVAL

action had an incorrect value.

EIO

For either of the following reasons:

- TCIOFF or TCION was requested, but the other side of the pseudoterminal connection is closed.
- The process group of the process issuing the function is an orphaned, background process group, and the process issuing the function is not ignoring or blocking SIGTTOU.

ENOTTY

fildev is not associated with a terminal.

Example**CELEBT04**

```
/* CELEBT04
   This example suspends and then resumes transmission.
*/
#define _POSIX_SOURCE
#include <termios.h>
#include <stdio.h>
```

```

#include <fcntl.h>
#include <unistd.h>
#include <sys/stat.h>
#include <string.h>

main() {
    char Manager[]="/dev/ptyp0010";
    char Subsidiary[]="/dev/ttyp0010";
    char text[]="text to be written to tty";
    char data[80];
    int manager, subsidiary;

    if ((manager = open(Manager, O_RDWR|O_NONBLOCK)) < 0) {
        perror("open() error for manager tty");
        exit(1);
    }
    if ((subsidiary = open(Subsidiary, O_RDWR|O_NONBLOCK)) < 0) {
        perror("open() error for subsidiary tty");
        exit(1);
    }

    if (write(subsidiary, text, strlen(text)+1) == -1) {
        perror("write() error");
        exit(1);
    }
    puts("output is suspended to tty");
    if (read(manager, data, sizeof(data)) == -1)
        perror("read() error");
    else printf("read '%s' from the tty\n", data);
    if (tcflow(subsidiary, TCOON) != 0)
        perror("tcflow() error");
    exit(1);
}
puts("output is resumed to tty");
if (read(manager, data, sizeof(data)) == -1) {
    perror("read() error");
    exit(1);
}
printf("read '%s' from the tty\n", data);
close(subsidiary);
close(manager);
}

```

Output

```

output is suspended to tty
read() error: Resource temporarily unavailable
output is resumed to tty
read 'text to be written to tty' from the tty

```

tcflush() – Flush input or output on a terminal

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <termios.h>

int tcflush(int fildes, int where);
```

General description

Flushes input or output on a terminal.

int *fil*des;

Indicates a file descriptor associated with a terminal device.

int *where*;

Indicates whether the system is to flush input or output, represented by one of the following symbols defined in the `termios.h` header file.

Symbol

Meaning

TCIFLUSH

Flushes input data that has been received by the system but not read by an application.

TCOFLUSH

Flushes output data that has been written by an application but not sent to the terminal.

TCIOFLUSH

Flushes both input and output data.

If `tcflush()` is called from a background process group against the caller's controlling terminal, a SIGTTOU signal may be generated depending how the process is handling SIGTTOUs:

| Processing for SIGTTOU System Behavior | |
|--|---|
| Default or signal handler | The SIGTTOU signal is generated, and the function is not performed. <code>tcflush()</code> returns -1 and sets <code>errno</code> to <code>EINTR</code> . |
| Ignored or blocked | The SIGTTOU signal is not sent, and the function continues normally. |

Returned value

If successful, `tcflush()` returns 0.

If unsuccessful, `tcflush()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

*fil*des is not a valid open file descriptor.

EINTR

A signal interrupted `tcflush()`.

EINVAL

where has an incorrect value.

EIO

The process group of the process issuing the function is an orphaned, background process group, and the process issuing the function is not ignoring or blocking SIGTTOU.

ENOTTY

fildev is not associated with a terminal.

Example**CELEBT05**

```

/* CELEBT05

   This example flushes a string.

*/
#define _POSIX_SOURCE
#include <termios.h>
#include <stdio.h>
#include <fcntl.h>
#include <unistd.h>
#include <sys/stat.h>
#include <string.h>

main() {
    char Manager[]="manager.tty";
    char Subsidiary[]="subsidiary.tty";
    char text1[]="string that will be flushed from buffer";
    char text2[]="string that will not be flushed from buffer";
    char data[80];
    int manager, subsidiary;

    if (mknod(Manager, S_IFCHR|S_IRUSR|S_IWUSR, 0x00010000 + 10) != 0)
        perror("mknod() error for manager tty");
    else {
        if (mknod(Subsidiary, S_IFCHR|S_IRUSR|S_IWUSR, 0x00020000 + 10) != 0)
            perror("mknod() error for subsidiary tty");
        else {
            if ((manager = open(Manager, O_RDWR|O_NONBLOCK)) < 0)
                perror("open() error for manager tty");
            else {
                if ((subsidiary = open(Subsidiary, O_RDWR|O_NONBLOCK)) < 0)
                    perror("open() error for subsidiary tty");
                else {
                    if (write(subsidiary, text1, strlen(text1)+1) == -1)
                        perror("write() error");
                    else if (tcflush(subsidiary, TCOFLUSH) != 0)
                        perror("tcflush() error");
                    else {
                        puts("first string is written and tty flushed");
                        puts("now writing string that will not be flushed");
                        if (write(subsidiary, text2, strlen(text2)+1) == -1)
                            perror("write() error");
                        else if (read(manager, data, sizeof(data)) == -1)
                            perror("read() error");
                        else printf("read '%s' from the tty\n", data);
                    }
                }
                close(subsidiary);
            }
            close(manager);
        }
        unlink(Subsidiary);
    }
    unlink(Manager);
}

```

Output

```

first string is written and tty flushed
now writing string that will not be flushed
read 'string that will not be flushed from buffer' from the tty

```

tcgetattr() — Get the attributes for a terminal

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <termios.h>

int tcgetattr(int fildev, struct termios *termpptr);
```

General description

Gets a `termios` structure, which contains control information for a terminal associated with *fildev*. It stores that information in a memory location that *termpptr* points to. The contents of a `termios` structure are described in [“tcsetattr\(\) — Set the attributes for a terminal” on page 1835](#).

`tcgetattr()` can run in either a foreground or background process; however, if the process is in the background, a foreground process may subsequently change the attributes.

`tcgetattr()` only works in an environment where either a controlling terminal exists, or `stdin` and `stderr` refer to tty devices. Specifically, it does not work in a TSO environment.

Note: The `tcgetattr()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support ” on page 2123](#) for details.

Returned value

If successful, `tcgetattr()` returns 0.

If unsuccessful, `tcgetattr()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

fildev is not a valid open file descriptor.

ENOTTY

The file associated with *fildev* is not a terminal.

Example

CELEBT06

```

/* CELEBT06

   This example provides information about the attributes.

   */
#define _POSIX_SOURCE
#include <termios.h>
#include <stdio.h>
#include <unistd.h>

main() {
    struct termios term;

    if (tcgetattr(STDIN_FILENO, &term) != 0)
        perror("tcgetattr() error");
    else {
        if (term.c_iflag & BRKINT)
            puts("BRKINT is set");
        else
            puts("BRKINT is not set");
        if (term.c_cflag & PARODD)
            puts("Odd parity is used");
        else
            puts("Even parity is used");
        if (term.c_lflag & ECHO)
            puts("ECHO is set");
        else
            puts("ECHO is not set");
        printf("The end-of-file character is x'%02x'\n",
            term.c_cc[VEOF]);
    }
}

```

Output

```

ECHO is set
The End Of File character is x'37'

```

__tcgetcp() — Get terminal code page names

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _OPEN_SYS_PTY_EXTENSIONS
#include <termios.h>

int __tcgetcp(int fildev, size_t termcplen, struct __termcp *termcp_ptr);
```

General description

The `__tcgetcp()` function gets the terminal session code page information contained in the `termcp` structure and the Code Page Change Notification (CPCN) capability for the terminal file.

The following arguments are used:

`fildev`

The file descriptor of the terminal for which you want to get the code page names and CPCN capability.

`termcplen`

The length of the passed `termcp` structure.

`termcp_ptr`

A pointer to a `__termcp` structure.

`__tcgetcp()` stores the `termcp` information in a memory location pointed to by *termcp_ptr*. The return value contains the CPCN capability. The following CPCN capabilities are defined:

Symbol

Meaning

`_CPCN_NAMES`

Forward code page names only

Use the `__tcsetcp()` function to change the terminal session data conversion. The z/OS UNIX pseudotty device driver supports this CPCN capability.

`_CPCN_TABLES`

Forward code page names and tables

Use `__tcsettables()` to change the terminal session data conversion. The OCS remote-tty device driver supports this CPCN capability.

In the returned `termcp` structure, if the `_TCCP_FASTP` bit is set then the data conversion that is specified by the source and target code page names can be performed locally by the data conversion application. This is valid any time that a table-driven conversion can be performed. For example, the data conversion point (application) could use the z/OS UNIX `iconv()` service to build local data conversion tables and perform all data conversion using the local tables instead of using `iconv()` all in subsequent conversions. This provides for better-performing data conversion.

In the returned `termcp` structure, if the `_TCCP_BINARY` bit is set then no data conversion is being performed and the code page names contained in the `termcp` structure should be ignored.

`__tcgetcp()` can run in either a foreground or background process; however, if the process is in the background, a foreground process may subsequently change the terminal code pages.

Note: The `__tcgetcp()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support”](#) on page 2123 for details.

Returned value

If successful, `__tcgetcp()` returns the `termcp` structure in a memory location pointed to by *termcp_ptr*. The return value contains the CPCN capability.

If unsuccessful, `__tcgetcp()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

fildev is not a valid open file descriptor.

EINVAL

The value of *termcplen* was invalid.

ENODEV

One of the following error conditions exist:

- The terminal device driver does not support CPCN functions.
- CPCN functions have not been enabled.

For a z/OS UNIX pseudotty terminal device file, issue the `__tcsetcp()` function against the manager pty first to enable CPCN support.

ENOTTY

The file associated with *fildev* is not a terminal device.

Example

The following example retrieves the current code pages used in the data conversion and CPCN capability. Here, the `__tcgetcp()` function is issued against a session using a pty terminal device; ISO8859-1 and IBM-1047 code pages are being used.

```
#define _OPEN_SYS_PTY_EXTENSIONS
#include <unistd.h>
#include <stdio.h>
#include <fcntl.h>
#include <termios.h>

void main(void)
{
    struct __termcp mytermcp;
    int rv;
    int cterm_fd;

    if ((cterm_fd = open("/dev/tty", O_RDWR)) == -1)
        printf("No controlling terminal established.\n");
    else {
        if ((rv = __tcgetcp(cterm_fd, sizeof(mytermcp), &mytermcp)) == -1)
            perror("__tcgetcp() error");
        else {
            if (_CPCN_NAMES == rv)
                printf("Forward Code Page Names Only.\n");
            else
                printf("Forward Code Page Names and Tables.\n");
            if (_TCCP_BINARY == (mytermcp.__tccp_flags & _TCCP_BINARY))
                printf("Binary mode is in effect.\n");
            else {
                printf("ASCII code page name is %s.\n",
                    mytermcp.__tccp_fromname);
                printf("EBCDIC code page name is %s.\n",
                    mytermcp.__tccp_toname);
            }
        }
        close(cterm_fd);
    }
} /* main */
```

Output

```
Forward code page names only.
ASCII code page name is ISO8859-1.
EBCDIC code page name is IBM-1047.
```

tcgetpgrp() — Get the foreground process group ID

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

pid_t tcgetpgrp(int fildev);
```

General description

Gets the process group ID (PGID) of the foreground process group associated with the terminal referred to by *fildev*. `tcgetpgrp()` can run from a background process, but the information may subsequently be changed by a process in the foreground process group.

Returned value

If successful, `tcgetpgrp()` returns of the foreground process group's PGID.

If unsuccessful, `tcgetpgrp()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

fildev is not a valid open file descriptor.

ENOTTY

The calling process does not have a controlling terminal, or the file is not the controlling terminal.

Example

CELEBT07

```
/* CELEBT07
   This example gets the foreground PGID.
*/
#define _POSIX_SOURCE
#include <termios.h>
```

```
#include <unistd.h>
#include <sys/wait.h>      /*FIX: was #include <sys/wait.h> */
#include <stdio.h>

main() {
    pid_t pid;

    if ((pid = tcgetpgrp(STDOUT_FILENO)) < 0)
        perror("tcgetpgrp() error");
    else
        printf("the foreground process group id of stdout is %d\n",
               (int) pid);
}
```

Output

```
the foreground process group id of stdout is 4063240
```

tcgetsid() — Get process group ID for session leader for controlling terminal

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <termios.h>

pid_t tcgetsid(int fildev);
```

General description

The `tcgetsid()` obtains the process group ID of the session for which the terminal specified by *fildev* is the controlling terminal.

Returned value

If successful, `tcgetsid()` returns the process group ID associated with the terminal.

If unsuccessful, `tcgetsid()` returns `(pid_t)-1` and sets `errno` to one of the following values:

Error Code Description

EACCES

The *fildev* argument is not associated with a controlling terminal. If the environment variable `_EDC_SUSV3` is set to 1, `ENOTTY` will be returned instead of `EACCES`.

EBADF

The *fildev* argument is not a valid file descriptor.

ENOTTY

The calling process does not have a controlling terminal, or the file is not the controlling terminal.

Note: Starting with z/OS V1.9, environment variable `_EDC_SUSV3` can be used to control the behavior of `tcgetsid()` with respect to setting `errno` to `ENOTTY` instead of `EACCES`. By default, `tcgetsid()` will set `EACCES` when *fildev* is not associated with a controlling terminal. When `_EDC_SUSV3` is set to 1, `setenv()` will set `errno` to `ENOTTY` in place of `EACCES`.

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_close(int fd);
```

General description

Notifies the transport provider that the user is finished with the transport endpoint specified by *fd*, and frees any local library resources associated with the endpoint. `t_close()` also closes the file associated with the transport endpoint.

`t_close()` should be called from the `T_UNBND` state. However, `t_close()` does not check state information, so it may be called from any state to close a transport endpoint. If this occurs, the local library resources associated with the endpoint are freed automatically. In addition, `close()` is issued for that file descriptor. The `close()` will be abortive if there are no other descriptors in this, or in another process which references the transport endpoint, and in this case will break any transport connection that may be associated with that endpoint.

A `t_close()` issued on a connection endpoint may cause data previously sent, or data not yet received, to be lost. It is the responsibility of the transport user to ensure that data is received by the remote peer.

Valid states: All - except for `T_UNINIT`

Returned value

If successful, `t_close()` returns 0.

If unsuccessful, `t_close()` returns -1 and sets `errno` to one of the following values:

Error Code
Description

TBADF

The specified file descriptor does not refer to a transport endpoint.

TPROTO

This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (t_errno).

t_connect() — Establish a connection with another transport user

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_connect(int fd, struct t_call *call, struct t_call *rcvcall);
```

General description

Enables a transport user to request a connection to the specified destination transport user. This function can only be issued in the T_IDLE state. The parameter *fd* identifies the local transport endpoint where communication will be established, while *sndcall* and *rcvcall* point to a *t_call* structure which contains the following members:

```
struct netbuf  addr;
struct netbuf  opt;
struct netbuf  udata;
int            sequence;
```

The parameter *sndcall* specifies information needed by the transport provider to establish a connection, and *rcvcall* specifies information that is associated with the newly established connection.

In *sndcall*, *addr* specifies the protocol address of the destination transport user. *opt* presents any protocol-specific information that might be needed by the transport provider. *udata* points to optional user data that may be passed to the destination transport user during connection establishment. *sequence* has no meaning for this function.

On return, in *rcvcall*, *addr* contains the protocol address associated with the responding transport endpoint. *opt* represents any protocol-specific information associated with the connection. *udata* points to optional user data that may be returned by the destination transport user during connection establishment. *sequence* has no meaning for this function.

The *opt* argument permits users to define the options that may be passed to the transport provider. See the discussion of supported options in *t_optmgmt()*. The user may choose not to negotiate protocol options by setting the *len* field of *opt* to zero. In this case, the provider may use default options.

If used, *sndcall->opt.buf* must point to a buffer with the corresponding options. The *maxlen* and *buf* fields of the netbuf structure pointed by *rcvcall->addr* and *rcvcall->opt* must be set before the call.

Since passing of userdata over a connection request is not supported under TCP, the *udata* argument is always meaningless.

On return, the *addr*, *opt* and *udata* fields of *rcvcall* will be updated to reflect values associated with the connection. Thus, the *maxlen* field of each argument must be set before issuing this function to indicate the maximum size of the buffer for each. However, *rcvcall* may be a NULL pointer, in which case no information is given to the user on return from *t_connect()*.

By default, *t_connect()* executes in synchronous mode, and will wait for the destination user's response before returning control to the local user. A successful return (that is, return value of zero) indicates that the requested connection has been established. However, if *O_NONBLOCK* is set (using *t_open()* or *fcntl()*), *t_connect()* executes in asynchronous mode. In this case, the call will not wait for the remote user's response, but will return control immediately to the local user and return -1 with *t_errno* set to *TNODATA* to indicate that the connection has not yet been established. In this way, the function simply initiates the connection establishment procedure by sending a connect request to the destination transport user. The *t_rcvconnect()* function is used in conjunction with *t_connect()* to determine the status of the requested connection.

When a synchronous *t_connect()* call is interrupted by the arrival of a signal, the state of the corresponding transport endpoint is *T_OUTCON*, allowing a further call to either *t_rcvconnect()*, *t_rcvdis()* or *t_snddis()*.

Valid states: *T_IDLE*

Returned value

If successful, *t_connect()* returns 0.

If unsuccessful, *t_connect()* returns -1 and sets *errno* to one of the following values:

Error Code

Description

TACCES

The user does not have permission to use the specified address or options.

TADDRBUSY

This transport provider does not support multiple connections with the same local and remote addresses. This error indicates that a connection already exists.

TBADADDR

The specified protocol address was in an incorrect format or contained illegal information.

TBADDATA

The amount of user data specified was not within the bounds allowed by the transport provider.

TBADF

The specified file descriptor does not refer to a transport endpoint.

TBADOPT

The specified protocol options were in an incorrect format or contained illegal information.

TBUFOVFLW

The number of bytes allocated for an incoming argument (*maxlen*) is greater than 0 but not sufficient to store the value of that argument. If executed in synchronous mode, the provider's state, as seen by the user, changes to *T_DATAXFER*, and the information to be returned in *rcvcall* is discarded.

TLOOK

An asynchronous event has occurred on this transport endpoint and requires immediate attention.

TNODATA

O_NONBLOCK was set, so the function successfully initiated the connection establishment procedure, but did not wait for a response from the remote user.

TNOTSUPPORT

This function is not supported by the underlying transport provider.

TOUTSTATE

The function was issued in the wrong sequence.

TPROTO

This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (*t_errno*).

TSYSERR

A system error has occurred during execution of this function.

tcperror() — Print the error messages of a socket function

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _OPEN_SYS_SOCK_EXT
#include <sys/socket.h>
#include <stdio.h>
#include <errno.h>

void tcperror(const char *s);
```

General description

When a socket call produces an error, the call returns a negative value and the variable *errno* is set to an error value found in *ERRNO.H*. The *tcperror()* call prints a short error message describing the last error that occurred. If *s* is non-NULL, *tcperror()* prints the string *s* followed by a colon, followed by a space, followed by the error message, and terminated with a newline character. If *s* is NULL or points to a NULL string, only the error message and the newline character are output.

The *tcperror()* function is equivalent to the *perror()* function in UNIX.

Parameter

Description

s

A NULL or NULL-terminated character string.

Returned value

tcperror() returns no values.

Example

The following are examples of the tcperror() call.

Example 1:

```
if ((s=socket(AF_INET, SOCK_DGRAM, 0)) < 0) {
    tcperror("socket()");
    exit(2);
}
```

If the socket() call produces the error ENOMEM, socket() returns a negative value and sets errno to ENOMEM. When tcperror() is called, it prints the string:

```
socket(): not enough storage (ENOMEM)
```

Example 2:

```
if ((s=socket(AF_INET, SOCK_DGRAM, 0)) < 0)
    tcperror(NULL);
```

If the socket() call produces the error ENOMEM, socket() returns a negative value and sets errno to ENOMEM. When tcperror() is called, it prints the string:

```
Not enough storage (ENOMEM)
```

tcsendbreak() — Send a break condition to a terminal

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <termios.h>

int tcsendbreak(int fildes, int duration);
```

General description

Sends a break condition to a terminal (indicated by *fildev*) that is using asynchronous serial data transmission. `tcsendbreak()` sends a continuous stream of zero bits for the specified *duration*. `tcsendbreak()` is the usual method of sending a BREAK on a line.

If `tcsendbreak()` is issued against a pseudoterminal, this function has no effect.

If `tcsendbreak()` is called from a background process group against the caller's controlling terminal, a SIGTTOU signal may be generated depending how the process is handling SIGTTOUs:

| Processing for SIGTTOU System Behavior | |
|--|---|
| Default or signal handler | The SIGTTOU signal is generated, and the function is not performed. <code>tcsendbreak()</code> returns -1 and sets <code>errno</code> to <code>EINTR</code> . |
| Ignored or blocked | The SIGTTOU signal is not sent, and the function continues normally. |

Returned value

If successful, `tcsendbreak()` returns 0.

If unsuccessful, `tcsendbreak()` returns -1 and sets `errno` to one of the following values:

Error Code Description

EBADF
fildev is not a valid open file descriptor.

EINTR
A signal interrupted `tcsendbreak()`.

EIO
The process group of the process issuing the function is an orphaned, background process group, and the process issuing the function is not ignoring or blocking SIGTTOU.

ENOTTY
fildev is not associated with a terminal.

Example

CELEBT08

```
/* CELEBT08

   This example breaks terminal transmission.

*/
#define _POSIX_SOURCE
#include <stdio.h>
#include <termios.h>
#include <unistd.h>

main() {
    if (tcsendbreak(STDIN_FILENO, 100) != 0)
        perror("tcsendbreak() error");
    else
        puts("break sent");
}
```

tcsetattr() — Set the attributes for a terminal

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <termios.h>

int tcsetattr(int fd, int when, const struct termios *term_ptr);
```

General description

`tcsetattr()` only works in an environment where either a controlling terminal exists, or `stdin` and `stderr` refer to tty devices. Specifically, it does not work in a TSO environment.

Changes the attributes associated with a terminal. New attributes are specified with a `termios` control structure. Programs should always issue a `tcgetattr()` first, modify the desired fields, and then issue a `tcsetattr()`. `tcsetattr()` should never be issued using a `termios` structure that was not obtained using `tcgetattr()`. `tcsetattr()` should use only a `termios` structure that was obtained by `tcgetattr()`.

fd

Indicates an open file descriptor associated with a terminal.

when

Indicates a symbol, defined in the `termios.h` header file, specifying when to change the terminal attributes:

Symbol

Meaning

TCSANOW

The change should take place immediately.

TCSADRAIN

The change should take place after all output written to *fd* has been read by the manager pseudoterminal. Use this value when changing terminal attributes that affect output.

TCSAFLUSH

The change should take place after all output written to *fd* has been sent; in addition, all input that has been received but not read should be discarded (flushed) before the change is made.

**term_ptr*

A pointer to a `termios` control structure containing the desired terminal attributes.

A `termios` structure contains the following members:

tcflag_t c_iflag

Input modes. `tcflag_t` is defined in the `termios.h` header file. Each bit in `c_iflag` indicates an input attribute and is associated with a symbol defined in the `termios.h` include file. All symbols are bitwise distinct. Thus `c_iflag` is the bitwise inclusive-OR of several of these symbols. Possible symbols are:

Symbol**Meaning****BRKINT**

Indicates that an interrupt should be generated if the user types a BREAK.

ICRNL

Automatically converts input carriage returns to newline (line-feed) characters before they are passed to the application that reads the input.

IGNBRK

Ignores BREAK conditions. If this bit is set to 1, applications are not informed of any BREAK condition on the terminal; the setting of BRKINT has no effect.

If IGNBRK is 0 but BRKINT is 1, BREAK flushes all input and output queues. In addition, if the terminal is the controlling terminal of a foreground process group, the BREAK condition generates a single SIGINT signal for that foreground process group.

If both IGNBRK and BRKINT are 0, a BREAK condition is taken as the single input character NULL, if PARMRK is 0, and as the three input characters \377-NULL-NULL, if PARMRK is 1.

IGNCR

Ignores input carriage returns. If this bit is set to 1, the setting of ICRNL has no effect.

If IGNCR is 0 and ICRNL is 1, input carriage returns are converted to newline characters. For z/OS UNIX "NL" or '\n' is the EBCDIC character NL.

IGNPAR

Ignores input characters (other than BREAK) that have parity errors.

INLCR

Automatically converts input newline (line-feed) characters to carriage returns before they are passed to the application that reads the input.

INPCK

Enables input parity checking. If this bit is set to 0, it allows output parity generation without input parity errors. The enabling of input parity checking is independent of the enabling of parity checking in the control modes field. (See the description of "`tcflag_t c_cflag`," which follows.) While the control modes may dictate that the hardware recognizes the parity bit, but the terminal special file does not check whether this bit is set correctly.

ISTRIP

Strips valid input bytes to 7 bits. If this bit is set to 0, the complete byte is processed.

Note: Do not set this bit for pseudoterminals, since it will make the terminal unusable. If you strip the first bit off of EBCDIC characters, you destroy all printable EBCDIC characters.

IUCLC

Map uppercase to lowercase on the received character. In locales other than the POSIX locale, the mapping is unspecified. Thus, this function only applies to the characters in the POSIX-portable character set that have lowercase equivalents, namely the characters A-Z.

Note:

This symbol is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3.

If it is necessary to continue using this symbol in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

IXANY

Enable any character to restart output. If IXOFF and IXANY are set and a previous STOP character has been received, then receipt of any input character will cause the STOP condition to be removed. For pseudoterminals, data in the output queue is passed to the application during manager read() processing, and subsidiary pseudoterminal writes are allowed to proceed. The character which caused the output to restart is also processed normally as well (unless it is a STOP character).

IXOFF

Enables start/stop input control. If this bit is set to 1, the system attempts to prevent the number of bytes in the input queue from exceeding the MAX_INPUT value. It sends one or more STOP characters to the terminal device when the input queue is in danger of filling up. The character used as the STOP character is dictated by the c_cc member of the termios structure. It is intended to tell the terminal to stop sending input for a while. The system transmits one or more START characters when it appears that there is space in the input queues for more input. Again, the character used as the START character is dictated by the c_cc member. It is intended to tell the terminal that it can resume transmission of input.

Note: Do not use IXOFF while in DBCS mode. If you intersperse STOP and START characters inside DBCS data while using IXOFF, you could corrupt output data,

IXON

Enables start/stop output control. If the system receives a STOP character as input, it will suspend output on the associated terminal until a START character is received. An application reading input from the terminal does not see STOP or START characters; they are intercepted by the system, which does all the necessary processing.

If IXON is 0, any STOP or START characters read are passed on as input to an application reading from the terminal.

PARMRK

Marks characters with parity errors. If this bit is set to 1 and IGNPAR is 0, a byte with a framing or parity error is sent to the application as the characters \377 and NULL, followed by the data part of the byte that had the parity error. If ISTRIP is 0, a valid input character of \377 is sent as a pair of characters \377, \377 to avoid ambiguity.

If both PARMRK and IGNPAR are 0, a character with a framing or parity error is sent to the application as NULL.

tcflag_t c_oflag

Output modes. Each bit in c_oflag indicates an output attribute, and is associated with a symbol defined in the termios.h header file. Thus c_oflag is the bitwise inclusive-OR of a number of these symbols. Possible symbols are:

Symbol**Meaning****OPOST**

Modifies lines of text in an implementation-defined way to appear appropriately on the terminal device. If this bit is set to 0, characters that an application puts out are sent without change.

OLCUC

If OPOST and OLCUC are set, then map lowercase to uppercase on the output. In locales other than the POSIX locale, the mapping is unspecified. Thus, this function only applies to the characters in the POSIX-portable character set that have uppercase equivalents, namely the characters a-z.

Note:

This symbol is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3.

If it is necessary to continue using this symbol in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including

any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

ONLCR

If OPOST and ONLCR are set, the NL character is transmitted as the CR-NL character pair.

OCRNL

If OPOST and OCRNL are set, the CR character is transmitted as the NL character.

ONOCR

If OPOST and ONOCR are set, no CR character is transmitted if the current column is zero.

ONLRET

If OPOST and ONLRET are set, the NL character does the carriage return function; the column pointer is set to 0. If OPOST is set and ONLRET is not set, then the NL does the line-feed function; the column pointer is unchanged.

OFILL

Fill characters are used for delay instead of using a timed delay.

OFDEL

The fill character is DEL. If OFILL is not set, then the fill character is NUL.

NLDLY

Delay associated with newline character.

NLO

No delay.

NL1

0.10 seconds delay. If ONLRET is set, then carriage-return delays are used instead of newline delays. If OFILL is set, then two fill characters are transmitted.

CRDLY

Delay associated with carriage-return character.

CR0

No delay.

CR1

Delay dependent on column position, or if OFILL is set then two fill characters are transmitted.

CR2

0.10 seconds delay, or if OFILL is set then four fill characters are transmitted.

CR3

0.15 seconds delay.

TABDLY

Delay associated with tab character.

TAB0

No horizontal tab processing.

TAB1

Delay dependent on column position, or if OFILL is set then two fill characters are transmitted.

TAB2

0.10 seconds delay, or if OFILL is set then two fill characters are transmitted.

TAB3

Tabs are expanded into spaces.

BSDLY

Delay associated with backspace character.

BS0

No delay.

BS1

0.05 seconds delay, or if OFILL is set then one fill character is transmitted.

VTDLY

Delay associated with vertical-tab processing.

VTO

No delay.

VT1

2 seconds delay.

FFDLY

Delay associated with form-feed processing.

FFO

No delay.

FF1

2 seconds delay.

tcflag_t c_cflag

Control modes. Each bit in `c_cflag` indicates a control attribute and is associated with a symbol defined in the `termios.h` header file. Thus `c_cflag` is the bitwise inclusive-OR of several of these symbols. Possible symbols are:

Symbol**Meaning****CLOCAL**

Ignores modem status lines. A call to `open()` returns immediately without waiting for a modem connection to complete. If this bit is set to 0, modem status lines are monitored and `open()` waits for the modem connection.

CREAD

Enables reception. If this bit is set to 0, no input characters are received from the terminal.

Using z/OS UNIX pseudoterminal support, this bit is always enabled and set to 1.

CSIZE

Is a collection of bits indicating the number of bits per byte (not counting the parity bit, if any). These bits specify byte size for both transmission and reception. Possible settings of `CSIZE` are given with the following symbols:

```
CS5 - 5 bits per byte
CS6 - 6 bits per byte
CS7 - 7 bits per byte
CS8 - 8 bits per byte
```

Using z/OS UNIX pseudoterminal support, all values are accepted, but `CSIZE` is changed to `CS8`.

Using z/OS UNIX Outboard Communications Server (OCS) support, the specified value is used.

CSTOPB

Sends two stop bits when necessary. If `CSTOPB` is 0, only one stop bit is used.

Using z/OS UNIX pseudoterminal support, this bit is always 0. Using z/OS UNIX OCS support, the specified value is used.

HUPCL

Lowers the modem control lines for a port when the last process that has the port open closes the port (or the process ends). In other words, this tells the system to hang up when all relevant processes have finished using the port.

For pseudoterminals `HUPCL` controls what happens when the subsidiary pseudoterminals is closed. If `HUPCL` is set when the last file descriptor for the subsidiary pseudoterminal is closed, then the subsidiary pseudoterminal cannot be re-opened. The manager terminal has to be closed and re-opened before the pair can be used again.

PARENB

Enables parity generation and detection. A parity bit is added to each character on output, and expected from each character on input.

Under z/OS UNIX, if this bit is set to 1 in a request, it is ignored. It is always set to 0. Using z/OS UNIX OCS support, the specified value is used.

PARODD

Indicates odd parity (when parity is enabled). If PARODD is 0, even parity is used (when parity is enabled).

Under z/OS UNIX, if this bit is set to 1 in a request, it is ignored. It is always set to 0. Using z/OS UNIX OCS support, the specified value is used.

If the object for which the control modes are set is not an asynchronous serial connection, some bits may be ignored. For example, on a network connection, it may not be possible to set the baud rate.

tcflag_t c_lflag

Local modes. Each bit in `c_lflag` indicates a local attribute, and is associated with a symbol defined in the `termios.h` include file. Thus `c_lflag` is the bitwise inclusive-OR of a number of these symbols. Possible symbols are:

Symbol

Meaning

ECHO

Echoes input characters back to the terminal. If this bit is 0, input characters are not echoed.

ECHOE

Echoes the ERASE character as an error-correcting backspace. When the user inputs an ERASE character, the terminal erases the last character in the current line from the display (if possible). The character used as the ERASE character is dictated by the `c_cc` member of the `termios` structure. ECHOE has an effect only if the ICANON bit is 1.

ECHOK

Either causes the terminal to erase the line from the display, or echoes the KILL character followed by an `\n` character. ECHOK has an effect only if the ICANON bit is set to 1.

ECHONL

Echoes the newline (line-feed) character `'\n'` even if the ECHO bit is off. ECHONL has an effect only if the ICANON bit is set to 1.

ICANON

Enables canonical input processing, also called *line mode*. Input is not delivered to the application until an entire line has been input. The end of a line is indicated by a newline, End Of File (EOF), or EOL character (where the character used as the EOL character is directed by the `c_cc` member of the `termios` structure [described shortly]). Canonical input processing uses the ERASE character to erase a single input character, and the KILL character to erase an entire line. The `MAX_CANON` value specifies the maximum number of bytes in an input line in canonical mode.

If ICANON is 0, read requests take input directly from the input queue; the system does not wait for the user to enter a complete line. This is called *noncanonical mode*. ERASE and KILL characters are not handled by the system but passed directly to the application. See also the descriptions of MIN and TIME in the `c_cc` member.

IEXTEN

Enables extended implementation-defined functions. These are not defined, and IEXTEN is always set to 0.

If the ERASE, KILL or EOF character is preceded by a backslash character, the special character is placed in the input queue without doing the "special character" processing and the backslash is discarded.

ISIG

If ISIG is set to 1, signals are generated if special control characters are entered. SIGINT is generated if INTR is entered; SIGQUIT is generated if QUIT is entered; and SIGTSTP is generated if SUSP is entered and job control is supported. The special control characters are controlled by the `c_cc` member.

If ISIG is 0, the system does not generate signals when these special control characters are entered.

NOFLSH

If this bit is set to 1, the system does not flush the input and output queues if a signal is generated by one of the special characters described in ISIG above. If NOFLSH is set to 0, the queues are flushed if one of the special characters is found.

TOSTOP

If this bit is set to 1, a SIGTTOU signal is sent to the process group of a process that tries to write to a terminal when it is not in the terminal's foreground process group. However, if the process that tries to write to the terminal is blocking or ignoring SIGTTOU signals, the system does not raise the SIGTTOU signal.

If TOSTOP is 0, output from background processes is output to the current output stream, and no signal is raised.

XCASE

Do canonical lower and canonical upper presentation. In locales other than the POSIX locale, the effect is unspecified. XCASE set by itself makes all uppercase letters on input and output be preceded by a "\" character.

Some terminals can generate lowercase characters, but can display only uppercase characters. For these terminals, XCASE would be used by itself. Other terminals cannot generate lowercase characters either. For these terminals, XCASE would be used with IUCLC to generate lowercase characters when characters are typed without the backslash, and uppercase characters when the typed character is preceded by a backslash.

If a terminal can generate only uppercase characters, but can display either upper or lowercase, then XCASE would be used with OLCUC.

Note:

This symbol is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3.

If it is necessary to continue using this symbol in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

cc_t c_cc[NCCS]

Control characters. This is an array of characters that may have special meaning for terminal handling. You can access characters in this array using subscripts that are symbols defined in the `termios.h` header file. For example, the STOP character is given by `c_cc[VSTOP]`. Possible subscript symbols are:

Symbol

Meaning

VEOF

Gives the End Of File character EOF. It is recognized only in canonical (line) mode. When this is found in input, all bytes waiting to be read are immediately passed to the application without waiting for the end of the line. The EOF character itself is discarded. If EOF occurs at the beginning of a line, the `read` function that tries to read that line receives an End Of File (EOF) indication. Note that EOF results in End Of File only if it is at the beginning of a line; if it is preceded by one or more characters, it indicates only End Of Line (EOL).

VEOL

Gives the End Of Line character EOL. It is recognized only in canonical (line) mode. This is an alternate character for marking the end of a line (in addition to the newline `\n`).

VERASE

Gives the ERASE character. It is recognized only in canonical (line) mode. It deletes the last character in the current line. It cannot delete beyond the beginning of the line.

VINTR

Gives the interrupt character INTR. It is recognized only if ISIG is set to 1 in `c_lflag`. If the character is received, the system sends a SIGINT signal to all the processes in the foreground process group that has this device as its controlling terminal.

VKILL

Gives the KILL character. It is recognized only in canonical (line) mode. It deletes the entire contents of the current line.

VMIN

Gives the MIN value for noncanonical mode processing.

This is the minimum number of bytes that a call to `read` should return in noncanonical mode; it is not used in canonical mode.

If both MIN and TIME are greater than 0, `read` returns when MIN characters are available or when the timer associated with TIME runs out (whichever comes first). The timer starts running as soon as a single character has been entered; if there is already a character in the queue when `read` is called, the timer starts running immediately.

If MIN is greater than zero and TIME is zero, `read` waits for MIN characters to be entered, no matter how long that takes.

If MIN is zero and TIME is greater than zero, `read` returns when the timer runs out or when a single character is received (whichever comes first). `read` returns either one character (if one is received) or zero (if the timer runs out). The timer starts running as soon as `read` is called. (Contrast this with the case where MIN and TIME are both greater than zero, and the timer starts only when a character is received.)

If both MIN and TIME are zero, `read` returns immediately from every call. It returns the number of bytes that are immediately available, up to the maximum specified in the call to `read`.

VQUIT

Gives the quit character QUIT. It is recognized only if ISIG is set to 1 in `c_lflag`. If the character is received, the system sends a SIGQUIT signal to all the processes in the foreground process group that has this device as its controlling terminal.

VSUSP

Gives the suspend character SUSP. It is recognized only if ISIG is set to 1 in `c_lflag`. If the character is received, the system sends a SIGTSTP signal to all the processes in the foreground process group that has this device as its controlling terminal.

VTIME

Gives the TIME value, used in noncanonical mode in connection with MIN. It expresses a time in terms of tenths of a second.

VSTOP

Gives the STOP character. You can use this to suspend output temporarily when IXON is set to 1 in `c_iflag`. Users can enter the STOP character to prevent output from running off the top of a display screen.

VSTART

Gives the START character. You can use this to resume suspended output when IXON is set to 1 in `c_iflag`.

When `tcsetattr()` is called from a background session against a controlling terminal, SIGTTOU processing is as follows:

| Processing for SIGTTOU Expected Behavior | |
|--|---|
| Default or signal handler | The SIGTTOU signal is generated, and the function is not performed. <code>tcsetattr()</code> returns -1 and sets <code>errno</code> to <code>EINTR</code> . |
| Ignored or blocked | The SIGTTOU signal is not sent, and the function continues normally. |

Note: The `tcsetattr()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support”](#) on page 2123 for details.

Returned value

If successful, `tcsetattr()` returns 0.

If unsuccessful, `tcsetattr()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

fildev is not a valid open file descriptor.

EINTR

A signal interrupted `tcsetattr()`.

EINVAL

when is not a recognized value, or some entry in the supplied `termios` structure had an incorrect value.

EIO

The process group of the process issuing the function is an orphaned, background process group, and the process issuing the function is not ignoring or blocking SIGTTOU.

ENOTTY

fildev is not associated with a terminal.

Example

CELEBT09

```
/* CELEBT09
   The following attributes changes the terminal attributes.
*/
#define _POSIX_SOURCE
#include <termios.h>
#include <unistd.h>
#include <stdio.h>

main() {
    struct termios term1, term2;

    if (tcgetattr(STDIN_FILENO, &term1) != 0)
        perror("tcgetattr() error");
    else {
        printf("the original end-of-file character is x'%02x'\n",
               term1.c_cc[VEOF]);
        term1.c_cc[VEOF] = 'z';
        if (tcsetattr(STDIN_FILENO, TCSANOW, &term1) != 0)
            perror("tcsetattr() error");
        if (tcgetattr(STDIN_FILENO, &term1) != 0)
            perror("tcgetattr() error");
        else
            printf("the new end-of-file character is x'%02x'\n",
                   term1.c_cc[VEOF]);
    }
}
```

Output

```
the original End Of File character is x'37'
the new End Of File character is x'a9'
```

__tcsetcp() — Set terminal code page names

Standards

| Standards / Extensions | C or C++ | Dependencies |
|-------------------------------|-----------------|---------------------|
| z/OS UNIX | both | |

Format

```
#define _OPEN_SYS_PTY_EXTENSIONS
#include <termios.h>

int __tcsetcp(int fildev, size_t termcplen, const struct __termcp *termcpptr);
```

General description

The `__tcsetcp()` function sets (or changes) the terminal session code page information contained in the `termcp` structure.

The following arguments are used:

`fildev`

The file descriptor of the terminal for which you want to get the code page names and CPCN capability.

`termcplen`

The length of the passed `termcp` structure.

`termcpptr`

A pointer to a `__termcp` structure.

Use the `__tcsetcp()` function to send new code page information to the data conversion point in order to change the data conversion environment for the terminal session. This function is used with terminal devices that support the “forward code page names only” Code Page Change Notification (CPCN) capability. The z/OS UNIX pseudotty (pty) device driver supports this capability.

For terminal sessions that use the z/OS UNIX pty device driver, the data conversion point is the application that uses the manager pty device. An example data conversion point is the z/OS UNIX **rlogin** server. Here, **rlogin** uses CPCN functions to determine the ASCII source and/or EBCDIC target code pages to use for the conversion of the terminal data. During its processing of the `__tcsetcp()` function, the pty device driver applies the `__termcp` structure once the pty outbound data queue is drained. When

this occurs, the pty input data queue is also flushed and a TIOCPKT_CHCP packet exception event is generated if extended packet mode is enabled (PKTXTND is set in the termios structure) to notify the application using the manager pty that the code page information has been changed. The manager pty application can then use the `__tcgetcp()` function to retrieve the new code page information and establish a new data conversion environment.

The `__tcsetcp()` function is supported by both the manager and subsidiary pty device drivers, however, CPCN functions first must be enabled by the application that uses the manager pty; enabling CPCN functions is performed by the system during the initial `__tcsetcp()` invocation against the manager pty device. Once the `__tcsetcp()` function is performed against the manager pty then it may be subsequently issued against the subsidiary pty.

Note: The data conversion for a z/OS UNIX terminal session is performed on a session (terminal file) basis. If you change the data conversion characteristics for one file descriptor, the new data conversion will apply to all open file descriptors associated with this terminal file.

Attention: Use this service carefully. By changing the code pages for the data conversion you may cause unpredictable behavior in the terminal session if the actual data used for the session is not encoded to the specified source (ASCII) and target (EBCDIC) code pages.

A `__termcp` structure contains the following members:

__tccp_flags

Flags. The following symbols are defined as bitwise distinct values. Thus, `__tccp_flags` is the bitwise inclusive-OR of these symbols:

Symbol

Meaning

_TCCP_BINARY

Use `_TCCP_BINARY` to notify the data conversion point to stop data conversion. If this flag is set, the source and target code page names (`__tccp_fromname` and `__tccp_toname` respectively) are not changed from their current values.

Attention: Use this option carefully. Once the data conversion is disabled the z/OS UNIX Shell cannot be used until the data conversion is re-enabled, using valid code pages for the terminal session.

_TCCP_FASTP

Use `_TCCP_FASTP` to indicate to the data conversion point (for example, **rlogin**) that the data conversion specified by the source and target code page names can be performed locally to the application. This is valid any time that a table-driven conversion can be performed. For example, the data conversion point (application) could use the z/OS UNIX `iconv()` service to build the local data conversion tables and perform all data conversion using the local tables instead of using `iconv()` in subsequent conversions. This provides for better-performing data conversion.

__tccp_fromname

The source code page name; typically this is the ASCII code page name. `__tccp_fromname` is a NULL-terminated string with a maximum length of `_TCCP_CPNAME_MAX`, including the NULL (`\00`) character.

`__tccp_fromname` is case-sensitive.

__tccp_toname

The target code page name; typically this is the EBCDIC code page name. `__tccp_toname` is a NULL-terminated string with a maximum length of `_TCCP_CPNAME_MAX`, including the NULL (`\00`) character.

`__tccp_toname` is case-sensitive.

When `__tcsetcp()` is issued against the subsidiary pty from a process in a background process group, SIGTTOU processing is as follows:

| Processing for SIGTTOU Expected Behavior | |
|--|--|
| Default or signal handler | The SIGTTOU signal is generated. The function is not performed. __tcsetcp() returns -1 and sets errno to EINTR. |
| Ignored or blocked | The SIGTTOU signal is not sent. The function continues normally. |

Note: The __tcsetcp() function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support ” on page 2123](#) for details.

Returned value

If successful, __tcsetcp() returns 0.
If unsuccessful, __tcsetcp() returns -1 and sets errno to one of the following values:

| Error Code | Description |
|---------------|---|
| EBADF | <i>fildev</i> is not a valid open file descriptor. |
| EINTR | A signal interrupted the call. |
| EINVAL | The value of <i>termcplen</i> was invalid. |
| EIO | The process group of the process issuing the function is an orphaned, background process group, and the process issuing the function is not ignoring or blocking SIGTTOU. |
| ENODEV | One of the following error conditions exist: <ul style="list-style-type: none">• CPCN functions have not been enabled. The __tcsetcp() function must be issued against the manager pty before any CPCN function can be issued against the subsidiary pty.• The terminal device driver does not support the “forward code page names only” CPCN capability. |
| ENOTTY | The file associated with <i>fildev</i> is not a terminal device. |

Example

The following example retrieves the CPCN capability and code pages and then changes the ASCII code page to IBM-850.

```
#define _OPEN_SYS_PTY_EXTENSIONS
#include <unistd.h>
#include <stdio.h>
#include <fcntl.h>
#include <termios.h>

void main(void)
{
    struct __termcp mytermcp;
    int rv;
    int cterm_fd;

    if ((cterm_fd = open("/dev/tty",O_RDWR)) == -1)
        printf("No controlling terminal established.\n");
    else {
        if ((rv = __tcgetcp(STDIN_FILENO,sizeof(mytermcp),&mytermcp))== -1)
            perror("__tcgetcp() error");
        else {
            if (rv==_CPCN_NAMES) {
                if (_TCCP_BINARY == (mytermcp.__tccp_flags & _TCCP_BINARY))
```

```

        printf("Binary mode is in effect. No change made.\n");
    else {
        strcpy(mytermcp.__tccp_fromname,"IBM-850");
        if (__tcsetcp(STDOUT_FILENO,sizeof(mytermcp),&mytermcp)!=0)
            perror("__tcsetcp() error");
        else
            printf("ASCII code page changed to IBM-850.\n");
    } /*not binary mode */
} /* _CPCN_NAMES */
} /* __tcgetcp success */
close(cterm_fd);
} /* controlling terminal established */
} /* main */

```

Output

```
ASCII code page changed to IBM-850.
```

tcsetpgrp() – Set the foreground process group ID

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```

#define _POSIX_SOURCE
#include <unistd.h>

int tcsetpgrp(int fildes, pid_t newid);

```

General description

Sets the process group ID (PGID) of the foreground process group associated with the terminal referred to by *fildes*. This terminal must be the controlling terminal of the process calling `tcsetpgrp()` and must be currently associated with the session of the calling process. *newid* must match a PGID of a process in the same session as the calling process.

After the PGID associated with the terminal is set, reads by the process group formerly associated with the terminal fail or cause the process group to stop from a SIGTTIN signal. Writes may also cause the process to stop (from a SIGTTOU signal), or they may succeed, depending on how `tcsetattr()` sets TOSTOP and the signal options for SIGTTOU.

fildes can be any of the descriptors representing the controlling terminal (such as standard input, standard output, and standard error), and the function affects future access from any file descriptor in use for the terminal. Consider using redirection when specifying the file descriptor.

If `tcsetpgrp()` is called from a background process group against the caller's controlling terminal, a SIGTTOU signal may be generated depending how the process is handling SIGTTOUs:

Processing for SIGTTOU System Behavior

| | |
|---------------------------|---|
| Default or signal handler | The SIGTTOU signal is generated, and the function is not performed. tcsetpgrp() returns -1 and sets errno to EINTR. |
| Ignored or blocked | The SIGTTOU signal is not sent, and the function continues normally. |

Returned value

If successful, tcsetpgrp() returns 0.

If unsuccessful, tcsetpgrp() returns -1 and sets errno to one of the following values:

Error Code**Description****EBADF**

fildev is not a valid open file descriptor.

EINTR

A signal interrupted the tcsetpgrp() function.

EINVAL

The *newid* value is not supported by this implementation.

ENOTTY

The process calling tcsetpgrp() does not have a controlling terminal, or *fildev* is not associated with the controlling terminal, or the controlling terminal is no longer associated with the session of the calling process.

EPERM

The *newid* value is supported by the implementation but does not match the process group ID of any process in the same session as the process calling tcsetpgrp().

Example**CELEBT10**

```

/* CELEBT10

   This example changes the PGID.

   */
#define _POSIX_SOURCE
#include <termios.h>
#include <unistd.h>
#include <sys/wait.h>
#include <stdio.h>
#include <signal.h>

main() {
    pid_t pid;
    int status;

    if (fork() == 0)
        if ((pid = tcgetpgrp(STDOUT_FILENO)) < 0)
            perror("tcgetpgrp() error");
        else {
            printf("original foreground process group id of stdout was %d\n",
                (int) pid);
            if (setpgid(getpid(), 0) != 0)
                perror("setpgid() error");
            else {
                printf("now setting to %d\n", (int) getpid());
                if (tcsetpgrp(STDOUT_FILENO, getpid()) != 0)
                    perror("tcsetpgrp() error");
                else if ((pid = tcgetpgrp(STDOUT_FILENO)) < 0)
                    perror("tcgetpgrp() error");
                else
                    printf("new foreground process group id of stdout was %d\n",
                        (int) pid);
            }
        }
}

```

```
    else wait(&status);
}
```

Output

```
original foreground process group id of stdout was 2228230
now setting to 2949128
new foreground process group id of stdout was 2949128
```

__tcsettables() — Set terminal code page names and conversion tables

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _OPEN_SYS_PTY_EXTENSIONS
#include <termios.h>

int __tcsettables(int fildev, size_t termcplen,
                  const struct __termcp *termcp_ptr,
                  const char atoe[256],
                  const char etoe[256]);
```

General description

The `__tcsettables()` function changes the data conversion environment for terminal sessions that support the “forward code page names and tables” Code Page Change Notification (CPCN) capability. The OCS remote-tty (rty) device driver supports this capability.

The following arguments are used:

fildev

The file descriptor of the terminal for which you want to set the code page names and data conversion tables.

termcplen

The length of the passed `termcp` structure.

termcp_ptr

A pointer to a `__termcp` structure. A `__termcp` structure contains the following members:

__tccp_flags

Flags. The following symbols are defined as bitwise distinct values. Thus, `__tccp_flags` is the bitwise inclusive-OR of these symbols:

Symbol

Meaning

_TCCP_BINARY

Use `_TCCP_BINARY` to notify the data conversion point to stop data conversion. If this flag is set the source and target code page names (`__tccp_fromname` and `__tccp_toname` respectively) are not changed, and the data conversion tables *atoe* and *etoa* are not used.

Attention: Use this option carefully. Once the data conversion is disabled the z/OS shell cannot be used until the data conversion is re-enabled, using valid code pages for the terminal session.

_TCCP_FASTP

Use `_TCCP_FASTP` to indicate to the data conversion point that the data conversion specified by the source and target code page names can be performed locally by the application that performs the data conversion. This is valid any time that a table-driven conversion can be performed.

This value is not used by the OCS rty device driver and thus has no effect.

__tccp_fromname

The source code page name; typically this is the ASCII code page name. `__tccp_fromname` is a NULL-terminated string with a maximum length of `_TCCP_CPNAME_MAX`, including the NULL (`\0`) character.

`__tccp_fromname` is case-sensitive.

__tccp_toname

The target code page name; typically this is the EBCDIC code page name. `__tccp_toname` is a NULL-terminated string with a maximum length of `_TCCP_CPNAME_MAX`, including the NULL (`\0`) character.

`__tccp_toname` is case-sensitive.

const char *atoe*[256]

A 256-byte data conversion table for the source-to-target (ASCII-to-EBCDIC) data conversion. The byte offset into this table corresponds to the character code from the source (ASCII) code page. The data value at each offset is the “converted” target (EBCDIC) character code.

const char *etoe*[256]

A 256-byte data conversion table for the target-to-source (EBCDIC-to-ASCII) data conversion. The byte offset into this table corresponds to the character code from the target (EBCDIC) code page. The data value at each offset is the “converted” source (ASCII) character code.

Note: The data conversion for a z/OS UNIX terminal session is performed on a session (terminal file) basis. If you change the data conversion characteristics for one file descriptor, the new data conversion will apply to all open file descriptors associated with this terminal file.

For terminal sessions that use the OCS rty device driver, the ASCII/EBCDIC data conversion is performed outboard by OCS on the AIX server system. Use the `__tcsettables()` function to specify new code pages and conversion tables to be used in the data conversion.

During its processing of the `__tcsettables()` function, the OCS rty device driver applies the new code page names once the outbound data queue is drained. When this occurs, the rty input data queue is also flushed and the new conversion environment takes effect.

OCS processing of the *atoe* and *etoe* arguments is as follows:

- If the code page names specified in the `__termcp` structure are for supported double-byte data conversion then the *atoe* and *etoe* arguments are not used. The following double-byte translation is supported for OCS sessions:

- If `__fromname` specifies **ISO8859-1** and `__toname` specifies **IBM-1047** then OCS uses its own data conversion tables and `atoe` and `etoa` arguments are not used.
- Otherwise the conversion tables in `atoe` and `etoa` are used.

Attention: Use this service carefully. By changing the code pages for the data conversion you may cause unpredictable behavior in the terminal session if the actual data used for the session is not encoded to the specified source (ASCII) and target (EBCDIC) code pages.

When `__tcsettables()` is issued from a process in a background process group, SIGTTOU is processing in this way:

| Processing for SIGTTOU Expected Behavior | |
|--|--|
| Default or signal handler | The SIGTTOU signal is generated. The function is not performed. <code>__tcsettables()</code> returns -1 and sets <code>errno</code> to <code>EINTR</code> . |
| Ignored or blocked | The SIGTTOU signal is not sent. The function continues normally. |

Returned value

If successful, `__tcsettables()` returns 0.

If unsuccessful, `__tcsettables()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

fildev is not a valid open file descriptor.

EINTR

A signal interrupted the call.

EINVAL

One of the following error conditions exists:

- The value of *termcplen* was invalid.
- An invalid combination of multibyte code page names was specified in the `__termcp` structure.

One of the following applies:

- The source code page specified in `__tccp_fromname` specified a supported ASCII multibyte code page and the `__tccp_toname` did not specify a supported EBCDIC multibyte code page.
- The target code page specified in `__tccp_toname` specified a supported EBCDIC multibyte code page and the `__tccp_fromname` did not specify a supported ASCII multibyte code page.

EIO

The process group of the process issuing the function is an orphaned, background process group, and the process issuing the function is not ignoring or blocking SIGTTOU.

ENODEV

The terminal device driver does not support the “forward code page names and tables” CPCN capability.

ENOTTY

The file associated with *fildev* is not a terminal device.

Example

The following example retrieves the current code pages used in the data conversion and CPCN capability. The conversion tables using ASCII code page IBM-850 and the current EBCDIC code page are generated and exported to the data conversion point using `__tcsettables()`.

```
#define _OPEN_SYS_PTY_EXTENSIONS
#include <fcntl.h>
```

```

#include <unistd.h>
#include <stdio.h>
#include <termios.h>
#include <iconv.h>

main()
{
    struct __termcp mytermcp;          /* local __termcp          */
    unsigned char *intabptr;           /* pointer to input table  */
    unsigned char *outtabptr;          /* pointer to output table */
    unsigned char intab[256],
        atoe[256],
        etoa[256];                    /* conversion tables       */
    iconv_t cd;                        /* conversion descriptor   */
    size_t inleft;                     /* number of bytes left in input */
    size_t outleft;                    /* number of bytes left in output */
    int i;                             /* loop variable           */
    int rv;                             /* return value            */
    int cterm_fd;                      /* file descriptor for controlling
                                     terminal                  */

    if ((cterm_fd = open("/dev/tty", O_RDWR)) == -1)
    {
        printf("No controlling terminal established. ");
        printf("Code pages were not changed.\n");

tdelete() — Binary tree delete

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```

#define _XOPEN_SOURCE
#include <search.h>

void *tdelete(const void *__restrict key, void **__restrict rootp,
    int (*compar)(const void *, const void *));

```

General description

The `tdelete()` function deletes a node from a binary search tree. The arguments are the same as for the `tsearch()` function. The variable pointed to by `rootp` will be changed if the deleted node was the root of the tree. `tdelete()` returns a pointer to the parent of the deleted node, or a NULL pointer if the node is not found. If the deleted node was the root of the tree, the function returns a pointer to the deleted node, since it had no parent. It frees the storage for this node before returning, so the contents of storage at the returned address are unreliable in this case.

Comparisons are made with a user-supplied routine, the address of which is passed as the `compar` argument. This routine is called with two arguments, the pointers to the elements being compared. The

user-supplied routine must return an integer less than, equal to or greater than 0, according to whether the first argument is to be considered less than, equal to or greater than the second argument. The comparison functions need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared.

Threading Behavior: see “tsearch() — Binary tree search” on page 1903.

Special behavior for C++: Because C and C++ linkage conventions are incompatible, tdelete() cannot receive a C++ function pointer as the comparator argument. If you attempt to pass a C++ function pointer to tdelete(), the compiler will flag it as an error. You can pass a C or C++ function to tdelete() by declaring it as extern "C".

Returned value

If successful, tdelete() returns a pointer to the parent of the deleted node.

If the node is not found, tdelete() returns a NULL pointer.

If rootp is a NULL pointer on entry, tdelete() returns a NULL pointer.

No errors are defined.

telldir() — Current location of directory stream

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <dirent.h>

long telldir(DIR *dirp);
```

General description

The telldir() function obtains the current location associated with the directory stream specified by dirp.

If the most recent operation on the directory stream was a seekdir(), then the directory position returned from telldir() is the same as that supplied as a loc argument to seekdir().

Returned value

If successful, `telldir()` returns the current location of the specified directory stream.

If the *dirp* argument supplied is NULL or invalid, `telldir()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBADF

The *dirp* argument was invalid.

tempnam() — Generate a temporary file name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _XOPEN_SOURCE
#include <stdio.h>

char *tempnam(const char *dir, const char *pfx);
```

General description

The `tempnam()` function generates a path name that may be used for a temporary file. If the environment variable `TMPDIR` is set, then the directory it specifies will be used as the directory part of the generated path name if it is accessible. Otherwise, if the *dir* argument is non-NULL and accessible, it will be used in the generated path name. Otherwise, the value of `{P_tmpdir}` defined in the `<stdio.h>` header is used as the directory component of the name. If that is inaccessible, then `/tmp` is used.

The *pfx* argument can be used to specify an initial component of the file name part of the path name. It may be a NULL pointer or point to a string of up to five bytes to be used as the beginning of a file name.

The names generated are unique across processes and threads, and over time, so multiple threads should be able to each repeatedly call `tempnam()` and consistently obtain unique names.

This function is supported only in a POSIX program.

Returned value

If successful, `tempnam()` allocates space for the generated name, copies the name into it, and returns a pointer to the name.

If unsuccessful, `tempnam()` returns a NULL pointer and sets `errno` to one of the following values:

Error Code

Description

ENAMETOOLONG

The generated name exceeded the maximum allowable path name length.

ENOMEM

Insufficient storage is available.

terminate() — Terminate after failures in C++ error handling

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| ANSI/ISO C++ | C++ only | |

Format

```
#include <exception>

void terminate(void);
```

General description

The `terminate()` function is called when the C++ error handling mechanism fails. If `terminate()` is called directly by the program, the `terminate_handler` is the one most recently set by a call to `set_terminate()`. If `terminate()` is called for any of several other reasons during evaluation of a throw expression, the `terminate_handler` is the one in effect immediately after evaluating the throw expression. If `set_terminate()` has not yet been called, then `terminate()` calls `abort()`.

In a multithreaded environment, if a thread issues a throw, the stack is unwound until a matching catcher is found, up to and including the thread start routine. (The thread start routine is the function passed to `pthread_create()`.) If the exception is not caught, then the `terminate()` function is called, which in turn defaults to calling `abort()`, which in turn causes a `SIGABRT` signal to be generated to the thread issuing the throw. If the `SIGABRT` signal is not caught, the process is terminated. You can replace the default `terminate()` behavior for all threads in the process by using the `set_terminate()` function. One possible use of `set_terminate()` is to call a function which issues a `pthread_exit()`. If this is done, a throw of a condition by a thread that is uncaught results in thread termination but not process termination.

Returned value

terminate() returns no values.

Refer to [z/OS XL C/C++ Language Reference](#) for more information about C++ exception handling including the terminate() function.

Related information

t_error() — Produce error message

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_error(char *errmsg);
```

General description

Produces a language-dependent message on the standard error output which describes the last error encountered during a call to a transport function. The argument string *errmsg* is a user-supplied error message that gives context to the error.

The error message is written as follows: first (if *errmsg* is not a NULL pointer and the character pointed to by *errmsg* is not the NULL character) the string pointed to by *errmsg* followed by a colon and a space; then a standard error message string for the current error defined in *t_errno*. If *t_errno* has a value different from TSYSErr, the standard error message string is followed by a newline character. If, however, *t_errno* is equal to TSYSErr, the *t_errno* string is followed by the standard error message string for the current error defined in *errno* followed by a newline.

If the calling program is running in any one of the SAA, S370, C or POSIX locales, the error message string describing the value in *t_errno* is identical to the comments following the *t_errno* codes defined in *xti.h*. It is noteworthy that message numbers are not produced in this situation. The contents of the error message strings describing the value in *errno* are the same as those returned by the *strerror(3C)* function with an argument of *errno*.

The error number, *t_errno*, is only set when an error occurs and it is not cleared on successful calls.

Valid states: All - except for T_UNINIT

Returned value

No errors are defined for *t_error()*.

Example

If a `t_connect()` function fails on transport endpoint *fd2* because a bad address was given, the following call might follow the failure:

```
t_error("t_connect failed on fd2");
```

The diagnostic message to be printed would look like:

```
t_connect failed on fd2: incorrect addr format
```

where *incorrect addr format* identifies the specific error that occurred, and *t_connect failed on fd2* tells the user which function failed on which transport endpoint.

tfind() — Binary tree find node

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <search.h>

void *tfind(const void *key, void *const *rootp,
            int (*compar)(const void *, const void *));
```

General description

The `tfind()` function, like `tsearch()`, will search for a node in the tree, returning a pointer to it if found. However, if it is not found, the `tfind()` function will return a NULL pointer. The arguments for the `tfind()` function are the same as for the `tsearch()` function.

Comparisons are made with a user-supplied routine, the address of which is passed as the *compar* argument. This routine is called with two arguments, the pointers to the elements being compared. The user-supplied routine must return an integer less than, equal to or greater than 0, according to whether the first argument is to be considered less than, equal to or greater than the second argument. The comparison functions need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared.

Threading Behavior: see [“tsearch\(\) — Binary tree search” on page 1903](#).

Special behavior for C++: Because C and C++ linkage conventions are incompatible, `tfind()` cannot receive a C++ function pointer as the comparator argument. If you attempt to pass a C++ function pointer to `tfind()`, the compiler will flag it as an error. You can pass a C or C++ function to `tfind()` by declaring it as `extern "C"`.

Returned value

If the node is found, `tfind()` returns a pointer to it.

If unsuccessful, `tfind()` returns a NULL pointer.

If *rootp* is a NULL pointer on entry, *tfind()* returns a NULL pointer.

No errors are defined.

t_free() — Free a library structure

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_free(char *ptr, int struct_type);
```

General description

Frees memory previously allocated by *t_alloc()*. This function frees memory for the specified structure, and also frees memory for buffers referenced by the structure.

The argument *ptr* points to one of the seven structure types described for *t_alloc()* , and *struct_type* identifies the type of that structure which must be one of the following:

| | | |
|------------|--------|------------|
| T_BIND | struct | t_bind |
| T_CALL | struct | t_call |
| T_OPTMGMT | struct | t_optmgmt |
| T_DIS | struct | t_discon |
| T_UNITDATA | struct | t_unitdata |
| T_UDERROR | struct | t_uderr |
| T_INFO | struct | t_info |

where each of these structures is used as an argument to one or more transport functions.

t_free() checks the *addr*, *opt* and *udata* fields of the given structure (as appropriate) and frees the buffers pointed to by the *buf* field of the netbuf structure. If *buf* is a NULL pointer, *t_free()* does not attempt to free memory. After all buffers are freed, *t_free()* frees the memory associated with the structure pointed to by *ptr*.

Undefined results occur if *ptr* or any of the *buf* pointers points to a block of memory that was not previously allocated by *t_alloc()*.

Valid states: All - except for T_UNINIT

Returned value

If successful, *t_free()* returns 0.

If unsuccessful, `t_free()` returns -1 and sets `errno` to one of the following values:

Error Code**Description****TNOSTRUCTYPE**

Unsupported *struct_type* requested.

TPROTO

This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (`t_errno`).

TSYSERR

A system error has occurred during execution of this function.

- [“t_alloc\(\) — Allocate a library structure”](#) on page 1807

tgamma(), tgammaf(), tgamma1() — Calculate gamma function

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R5 |

Format

```
#define _ISOC99_SOURCE
#include <math.h>

double tgamma(double x);
float tgammaf(float x);
long double tgamma1(long double x);
```

C++ TR1 C99

```
#define _TR1_C99
#include <math.h>

float tgamma(float x);
long double tgamma1(long double x);
```

General description

The `tgamma` functions compute the gamma function of x . A domain error occurs if x is a negative integer or when x is zero and the result cannot be represented. A range error occurs if the magnitude of x is too large or too small.

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------------------|-----|------|
| <code>tgamma</code> | X | X |
| <code>tgammaf</code> | X | X |
| <code>tgamma1</code> | X | X |

Special behavior for IEEE: A pole error occurs if the input of tgammaf is 0 and sets errno to ERANGE. A domain error occurs if the input of tgammaf is a negative integer and sets errno to EDOM.

Returned value

The tgamma functions return $G(x)$.

tgammad32(), tgammad64(), tgammad128() - Calculate gamma function

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.10 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 tgammad32(_Decimal32 x);
_Decimal64 tgammad64(_Decimal64 x);
_Decimal128 tgammad128(_Decimal128 x);
_Decimal32 tgamma(_Decimal32 x);      /* C++ only */
_Decimal64 tgamma(_Decimal64 x);      /* C++ only */
_Decimal128 tgamma(_Decimal128 x);    /* C++ only */
```

General description

The tgamma() functions compute the gamma function of x .

These functions work in IEEE decimal floating-point format. See [“IEEE decimal floating-point” on page 97](#) for more information.

Note: To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

The tgamma functions return $G(x)$.

A domain error occurs if x is a negative integer or when x is zero and the result cannot be represented. A range error occurs if the magnitude of x is too large or too small.

Example

CELEBT24

```
/* CELEBT24
   This example illustrates the tgammad128() function.
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal128 x, y;
```

```

x = 5.6DL;
y = tgammad128(x);

printf("tgammad128(%DDf) = %DDf\n", x, y);
}

```

Related information

t_getinfo() — Get protocol-specific service information

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```

#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_getinfo(int fd, struct t_info *info);

```

General description

Returns the current characteristics of the underlying transport protocol and/or transport connection associated with file descriptor *fd*. The *info* pointer is used to return the same information returned by `t_open()`, although not necessarily precisely the same values. This function enables a transport user to access this information during any phase of communication. This argument points to a `t_info` structure which contains the following members:

```

long addr;      /* max size of the transport protocol address */
long options;   /* max number of bytes of protocol-specific options */
long tsdu;      /* max size of a transport service data unit (TSDU) */
long etsdu;     /* max size of an expedited transport service
                /* data unit (ETSDU)
long connect;   /* max amount of data allowed on connection
                /* establishment functions
long discon;    /* max amount of data allowed on t_snddis()
                /* and t_rcvdis() functions
long servtype;  /* sdis() functions
long servtype;  /* service type supported by the transport provider
long flags;     /* other info about the transport provider

```

The fields take on the following values:

addr

The size of a struct `sockaddr_in` is returned.

options

The value 304, which is the maximum number of bytes of options which can possibly be specified or requested, is returned.

tsdu

Zero is returned, indicating that the TCP transport provider does not support the concept of TSDUs.

etsdu

A value of -1 is returned, indicating that there is no limit on the size of an ETSDU.

connect

A value of -2 is returned, indicating that the TCP transport provider does not allow data to be sent with connection establishment functions.

discon

A value of -2 is returned, indicating that the transport provider does not allow data to be sent with the abortive release functions.

servtype

T_COTS is always returned, since this is the only service type supported.

flags

The T_SENDZERO bit is always set in this field, indicating that the TCP transport provider supports the sending of zero-length TSDUs.

If a transport user is concerned with protocol independence, the above sizes may be accessed to determine how large the buffers must be to hold each piece of information. Alternatively, the `t_alloc()` function may be used to allocate these buffers. An error results if a transport user exceeds the allowed data size on any function. The value of each field may change as a result of protocol option negotiation during connection establishment (the `t_optmgmt()` call has no effect on the values returned by `t_getinfo()`). These values will only change from the values presented to `t_open()` after the endpoint enters the T_DATAXFER state.

Valid states: All - except for T_UNINIT

Returned value

If successful, `t_getinfo()` returns 0.

If unsuccessful, `t_getinfo()` returns -1 and sets `errno` to one of the following values:

Error Code**Description****TBADF**

The specified file descriptor does not refer to a transport endpoint.

TPROTO

This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (`t_errno`).

TSYSERR

A system error has occurred during execution of this function.

t_getprotaddr() — Get the protocol addresses

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_getprotaddr(int fd, struct t_bind *boundaddr,
                  struct t_bind *peeraddr);
```

General description

Returns local and remote protocol addresses currently associated with the transport endpoint specified by *fd*. In *boundaddr* and *peeraddr* the user specifies *maxlen*, which is the maximum size of the address buffer, and *buf* which points to the buffer where the address is to be placed. On return, the *buf* field of *boundaddr* points to the address, if any, currently bound to *fd*, and the *len* field specifies the length of the address. If the transport endpoint is in the T_UNBND state, zero is returned in the *len* field of *boundaddr*. The *buf* field of *peeraddr* points to the address, if any, currently connected to *fd*, and the *len* field specifies the length of the address. If the transport endpoint is not in the T_DATAXFER state, zero is returned in the *len* field of *peeraddr*.

Valid states: All - except for T_UNINIT

Returned value

If successful, t_getprotaddr() returns 0.
If unsuccessful, t_getprotaddr() returns -1 and sets errno to one of the following values:

Error Code
Description

- TBADF**
The specified file descriptor does not refer to a transport endpoint.
- TBUFOVFLW**
The number of bytes allocated for an incoming argument (maxlen) is greater than 0 but not sufficient to store the value of that argument.
- TPROTO**
This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (t_errno).
- TSYSERR**
A system error has occurred during execution of this function.

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_getstate(int fd);
```

General description

Returns the current state of the provider associated with the transport endpoint specified by *fd*.
Valid states: All - except for T_UNINIT

Returned value

If successful, `t_getstate()` returns the state. The current state is one of the following:

T_DATAXFER

Data transfer.

T_IDLE

Idle.

T_INCON

Incoming connection pending.

T_OUTCON

Outgoing connection pending.

T_UNBND

Unbound.

If the provider is undergoing a state transition when `t_getstate()` is called, the function will fail.

If unsuccessful, `t_getstate()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

TBADF

The specified file descriptor does not refer to a transport endpoint.

TPROTO

This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (`t_errno`).

TSTATECHNG

The transport provider is undergoing a transient state change.

TSYSERR

A system error has occurred during execution of this function.

time(),time64() — Determine current UTC time

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```
#include <time.h>

time_t time(time_t *timeptr);
```

```
#define _LARGE_TIME_API
#include <time.h>
```

```
time64_t time64(time64_t *timer);
```

General description

Determines the current UTC time.

Returned value

The `time()` function returns the value of time in seconds since the Epoch.

Returns the current UTC time. The returned value is also stored in the location given by *timeptr*. If *timeptr* is NULL, the returned value is not stored. If the calendar time is not available, the value `(time_t)-1` is returned.

`time()` returns the current value of the time-of-day (TOD) clock value obtained with the STCK instruction, rounded off to the nearest second, and normalized to the POSIX Epoch, January 1, 1970. The TOD clock value does not account for leap seconds. If you need more accuracy, use the STCK instruction or the TIME macro which does account for leap seconds using whatever value the system operator has entered for number of leap seconds in the CVT field. For more information about the STCK instruction, refer to *z/Architecture Principles of Operation*.

A returned value of 0 indicates the epoch, which was at the Coordinated Universal Time (UTC) of 00:00:00 on January 1, 1970.

The function `time64()` will behave exactly like `time()` except it will support calendar times beyond 03:14:07 UTC on January 19, 2038.

Example

CELEBT11

```
/* CELEBT11

   This example gets the time and assigns it to ltime, then uses
   the &time. function to convert the number of seconds to the
   current date and time.
   Finally, it prints a message giving the current time.

*/
#include <time.h>
#include <stdio.h>

int main(void)
{
    time_t ltime;

    time(&ltime);
    printf("The time is %s\n", ctime(&ltime));
}
```

Output

```
The time is Fri Jun 16 11:01:41 2006
```

times() — Get process and child process times

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <sys/times.h>

clock_t times(struct tms *buffer);
```

General description

Gets processor times of interest to a process.

struct tms *buffer

Points to a memory location where `times()` can store a structure of information describing processor time used by the current process and other related processes.

`times()` returns information in a `tms` structure, which has the following elements:

clock_t tms_utime

Amount of processor time used by instructions in the calling process.

Under z/OS UNIX, this does not include processor time spent running in the kernel. It does include any processor time accumulated for the address space before it became a z/OS UNIX process.

clock_t tms_stime

Amount of processor time used by the system.

Under z/OS UNIX, this value represents kernel busy time running on behalf of the calling process. It does not include processor time performing other MVS system functions on behalf of the process.

clock_t tms_cutime

The sum of `tms_utime` and `tms_cutime` values for all waited-for child processes which have terminated.

clock_t tms_cstime

The sum of `tms_stime` and `tms_cstime` values for all terminated child processes of the calling process.

`clock_t` is an integral type determined in the `time.h` header file. It measures times in terms of *clock ticks*. The number of clock ticks in a second (for your installation) can be found in `sysconf(_SC_CLK_TCK)`.

Times for a terminated child can be determined once `wait()` or `waitpid()` have reported the child's termination.

Pthreads can not be separately clocked by the `times()` function because they do not run in a separate process like forked children do.

Returned value

If successful, `times()` returns a value giving the elapsed time since the process was last invoked (for example, at system startup). If this time value cannot be determined, `times()` returns `(clock_t)-1`.

If unsuccessful, `times()` sets `errno` to one of the following values:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

| | |
|---------------|--|
| ERANGE | An overflow having occurred computing time values. |
|---------------|--|

Example

CELEBT12

```

/* CELEBT12

   This example provides the amount of processor time
   used by instructions and the system for the parent and child
   processes.

*/
#define _POSIX_SOURCE
#include <sys/times.h>
#include <time.h>
#include <sys/types.h>
#include <sys/wait.h>
#include <stdio.h>
#include <unistd.h>

main() {
    int status;
    long i, j;
    struct tms t;
    clock_t dub;

    int tics_per_second;

    tics_per_second = sysconf(_SC_CLK_TCK);

    if (fork() == 0) {
        for (i=0, j=0; i<1000000; i++)
            j += i;
        exit(0);
    }

    if (wait(&status) == -1)
        perror("wait() error");
    else if (!WIFEXITED(status))
        puts("Child did not exit successfully");
    else if ((dub = times(&t)) == -1)
        perror("times() error");
    else {
        printf("process was dubbed %f seconds ago.\n\n",
            ((double) dub)/tics_per_second);
        printf("      utime      stime\n");
        printf("parent:      %f      %f\n",
            ((double) t.tms_utime)/tics_per_second,
            ((double) t.tms_stime)/tics_per_second);
        printf("child:      %f      %f\n",
            ((double) t.tms_cutime)/tics_per_second,
            ((double) t.tms_cstime)/tics_per_second);
    }
}

```

Output

```
process was dubbed 1.600000 seconds ago.

      utime      stime
parent: 0.000000  0.020000
child:  0.320000  0.000000
```

tinit() — Attach and initialize MTF subtasks

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | C only | |

Format

```
#include <mtf.h>

int tinit(const char *parallel_loadmod_name, int num_subtasks);
```

General description

Restriction: This function is not supported in AMODE 64.

Initializes the multitasking facility (MTF) environment under the [MVS environment](#).

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

tinit() is invoked from a main task to dynamically attach and initialize the number of subtasks specified by *num_subtasks*, where *num_subtasks* ranges from 1 to MAXTASK (which is defined in the header file mtf.h). After the subtasks have been attached and initialized by tinit(), each of the subtasks will be given a *task_id* and can then compute independent pieces of the program, in parallel with the main task, under the control of the tsched() and tsyncro() library functions.

The parallel load module (*parallel_loadmod_name*) must contain all parallel functions and reside in a partitioned data set named in the STEPLIB DD statement of the JCL that runs the program.

The tinit() function may be called by a main task only once before invoking tterm(). Invocations of tinit() after the first are one are terminated with a returned value indicating that MTF is already active.

After tterm() has been called to terminate and remove the MTF environment, or after an abend, tinit() can be called again to create a new MTF environment. The new initialization is independent of the old one and may provide a different number of tasks and/or a different parallel load module.

If `tinit()` is called from a parallel function, `tinit()` will be terminated with a returned value indicating that MTF calls cannot be issued from a parallel function.

If `tinit()` is called by a program running under IMS, CICS, or DB2, the request will not be processed and the returned value will indicate that MTF calls are not supported under these systems.

Returned value

If the subtasks have been attached successfully and the MTF environment created, `tinit()` returns `MTF_OK`.

If unsuccessful, `tinit()` sets `errno` to one of the following values:

Error Code

Description

EACTIVE

MTF has already been initialized and is active.

EAUTOALC

Automatic allocation of standard stream DD has failed.

EMODFIND

Parallel load module was not found.

EMODFMT

Parallel load module has an invalid format.

EMODREAD

Parallel load module was not successfully read.

ENAME2LNG

Parallel load module name is longer than 8 characters.

ENOMEM

There was insufficient storage for MTF-internal areas.

ESUBCALL

The MTF call was issued from a subtask.

ETASKABND

One or more subtasks have terminated abnormally.

ETASKFAIL

The attempt to attach task(s) failed.

ETASKNUM

Number of tasks specified is invalid (<1 or >MAXTASK).

EWRONGOS

MTF is not supported under IMS, CICS or DB2*.

Note: These values are macros and can be found in the `mtf.h` header file.

t_listen() — Listen for a connect indication

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_listen(int fd, struct t_call *call);
```

General description

Listens for a connect request from a calling transport user. The argument *fd* identifies the local transport endpoint where connect indications arrive, and on return, *call* contains information describing the connect indication. The parameter *call* points to a *t_call* structure which contains the following members:

```
struct netbuf  addr;
struct netbuf  opt;
struct netbuf  udata;
int            sequence;
```

In *call*, *addr* returns the protocol address of the calling transport user. This address is in a format usable in future calls to *t_connect()*. However, *t_connect()* may fail for other reasons; For example *TADDRBUSY*. *opt* returns options associated with the connect request. *udata* is meaningless because transmission of user data is not supported across a connect request. *sequence* is a number that uniquely identifies the returned connect indication. The value of sequence enables the user to listen for multiple connect indications before responding to any of them.

Since this function returns values for the *addr*, *opt* and *udata* fields of *call*, the *maxlen* field of each must be set before issuing the *t_listen()* to indicate the maximum size of the buffer for each.

By default, *t_listen()* executes in synchronous mode and waits for a connect indication to arrive before returning to the user. However, if *O_NONBLOCK* is set using *t_open()* or *fcntl()*, *t_listen()* executes asynchronously, reducing to a poll for existing connect indications. If none are available, it returns -1 and sets *t_errno* to *TNODATA*.

Valid states: *T_IDLE*, *T_INCON*

Returned value

If successful, *t_listen()* returns 0. The TCP transport provider does not differentiate between a connect indication and the connection itself. A successful return of *t_listen()* indicates an existing connection.

If unsuccessful, *t_listen()* returns -1 and sets *errno* to one of the following values:

Error Code

Description

TBADF

The specified file descriptor does not refer to a transport endpoint.

TBADQLEN

The argument *qlen* of the endpoint referenced by *fd* is zero.

TBUFOVFLW

The number of bytes allocated for an incoming argument (*maxlen*) is greater than 0 but not sufficient to store the value of that argument. The provider's state, as seen by the user, changes to *T_INCON*, and the connect indication information to be returned in *call* is discarded. The value of sequence returned can be used to do a *t_snddis()*.

TLOOK

An asynchronous event has occurred on this transport endpoint and requires immediate attention.

TNODATA

O_NONBLOCK was set, but no connect indications had been queued.

TNOTSUPPORT

This function is not supported by the underlying transport provider.

TOUTSTATE

The function was issued in the wrong sequence on the transport endpoint referenced by *fd*.

TPROTO

This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (*t_errno*).

TQFULL

The maximum number of outstanding indications has been reached for the endpoint referenced by *fd*.

TSYSERR

A system error has occurred during execution of this function.

t_look() — Look at the current event on a transport endpoint

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_look(int fd);
```

General description

Returns the current event on the transport endpoint specified by *fd*. This function enables a transport provider to notify a transport user of an asynchronous event when the user is calling functions in synchronous mode. Certain events require immediate notification of the user and are indicated by a specific error, TLOOK, on the current or next function to be executed. This function also enables a transport user to poll a transport endpoint periodically for asynchronous events.

Additional functionality for handling events is provided through select and poll.

Valid states: All - except for T_UNINIT

The following list describes the asynchronous events which cause an XTI call to return with a TLOOK error:

t_accept()

T_DISCONNECT, T_LISTEN

t_connect()

T_DISCONNECT, T_LISTEN

This occurs only when a t_connect is done on an endpoint which has been bound with a *qlen* > 0 and for which a connect indication is pending.

t_listen()

T_DISCONNECT

This event indicates a disconnect on an outstanding connect indication.

t_rcv()

T_DISCONNECT

This occurs only when all pending data has been read.

t_rcvconnect()

T_DISCONNECT

t_rcvudata()

T_UDERR

t_snd()

T_DISCONNECT

t_sndudata()

T_UDERR

t_unbind()

T_LISTEN, T_DATA

T_DATA may only occur for the connectionless mode.

t_snddis()

T_DISCONNECT

Once a TLOOK error has been received on a transport endpoint using an XTI function, subsequent calls to that and other XTI functions, to which the same TLOOK error applies, will continue to return TLOOK until the event is consumed. An event causing the TLOOK error can be determined by calling t_look() and then can be consumed by calling the corresponding consuming XTI function as defined in [Table 70 on page 1873](#).

Table 70. Events and t_look()

| Event | Cleared on t_look()? | Consuming XTI functions |
|--------------|----------------------|--|
| T_LISTEN | No | t_listen() |
| T_CONNECT | No | t_{rcv}connect() In the case of the t_connect() function the T_CONNECT event is both generated and consumed by the execution of the function and is therefore not visible to the application. |
| T_DATA | No | t_rcv() |
| T_EXDATA | No | t_rcv() |
| T_DISCONNECT | No | t_rcvdis() |
| T_GODATA | Yes | t_snd() |
| T_GOEXDATA | Yes | t_snd() |

Returned value

If successful, `t_look()` returns a value that indicates which of the allowable events has occurred, or returns 0 if no event exists. One of the following events is returned:

T_CONNECT

Connect confirmation received.

T_DATA

Normal data received.

T_DISCONNECT

Disconnect received.

T_EXDATA

Expedited data received.

T_GODATA

Flow control restrictions on normal data flow that led to a TFLOW error have been lifted. Normal data may be sent again.

T_GOEXDATA

Flow control restrictions on expedited data flow that led to a TFLOW error have been lifted. Expedited data may be sent again.

T_LISTEN

Connection indication received.

If unsuccessful, `t_look()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

TBADF

The specified file descriptor does not refer to a transport endpoint.

TPROTO

This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (`t_errno`).

TSYSERR

A system error has occurred during execution of this function.

tmpfile() — Create temporary file

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdio.h>

FILE *tmpfile(void);
```

General description

Creates a temporary binary file. It opens the temporary file in wb+ mode. The file is automatically removed when it is closed or when the program is terminated.

Note: When the tmpfile() function is issued from multiple tasks within one address space, the temporary file names may not be unique. The execution of the tmpfile() function concurrently within one address space will result in errors. For example, an open will fail because the file is already open.

Returned value

If successful, tmpfile() returns a pointer to the stream associated with the file created.

If tmpfile() cannot open the file, it returns a NULL pointer. On normal termination (exit()), these temporary files are removed. On abnormal termination, an effort is made to remove these files.

Returned value for POSIX C

When the calling application is a z/OS UNIX program, the temporary file is created in the hierarchical file system. The file is created in the directory referred to by the TMPDIR environment variable, or '/tmp' if TMPDIR is not defined.

Special behavior for XPG4: The following are the possible values of errno:

Error Code

Description

EINTR

A signal was caught during tmpfile().

EMFILE

OPEN_MAX file descriptors are currently open in the calling process.

{FOPEN_MAX} streams are currently open in the calling process.

ENFILE

The maximum allowable number of files is currently open in the system.

ENOMEM

Insufficient storage space is available.

ENOSPC

The directory or file system which would contain the new file cannot be expanded.

Example

CELEBT13

```
/* CELEBT13

   This example creates a temporary file and if successful,
   writes tmpstring to it.
   At program termination, the file is removed.

*/
#include <stdio.h>

int main(void) {
    FILE *stream;
    char tmpstring[ ] = "This string will be written";

    {
        if((stream = tmpfile( )) == NULL)
```

```

        printf("Cannot make a temporary file\n");
    else
        fprintf(stream, "%s", tmpstring);
}

```

Related information

- [“stdio.h — Standard input and output” on page 63](#)
- [“fopen\(\) — Open a file” on page 571](#)

tmpnam() — Produce temporary file name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```

#include <stdio.h>

char *tmpnam(char *string);

```

General description

Produces a valid file name that is not the same as the name of any existing file. It stores this name in *string*. If *string* is a NULL pointer, tmpnam() leaves the result in an internal static buffer. Any subsequent calls may modify this object. If *string* is not a NULL pointer, it must point to an array of at least L_tmpnam bytes. The value of L_tmpnam is defined in the stdio.h header file.

Returned value

If *string* is a NULL pointer, tmpnam() returns the pointer to the internal static object in which the generated unique name is placed. Otherwise, if *string* is not a NULL pointer, it returns the value of *string*. The tmpnam() function produces a different name each time it is called within a module up to at least TMP_MAX names. Files created using names returned by tmpnam() are not automatically discarded at the end of the program.

Returned value for POSIX C

The tmpnam() function behaves differently when a program is running with POSIX(ON).

When the __POSIX_TMPNAM environment variable is unset or is not set to NO, the file name returned is a unique file name in the UNIX file system. The directory component of the file name will be the value of the TMPDIR environment variable, or '/tmp' if TMPDIR is not defined.

When the __POSIX_TMPNAM environment variable is set to NO, the file name returned is as if the calling application were running POSIX(OFF).

Example

CELEBT14

```
/* CELEBT14

   This example calls &tmpnam. to produce a valid file name.

*/
#include <stdio.h>

int main(void)
{
    char *name1;
    if ((name1 = tmpnam(NULL)) != NULL)
        printf("%s can be used as a file name.\n", name1);
    else printf("Cannot create a unique file name\n");
}
```

- [“stdio.h — Standard input and output” on page 63](#)
- [“fopen\(\) — Open a file” on page 571](#)

toascii() — Translate integer to a 7-bit ASCII character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

_XOPEN_SOURCE

```
#define _XOPEN_SOURCE
#include <ctype.h>

int toascii(int c);
```

_ALL_SOURCE

```
#define _ALL_SOURCE
#include <ctype.h>

int toascii(int c);
```

General description

Special behavior for `_XOPEN_SOURCE`: The `toascii()` function converts its argument to a 7-bit US-ASCII character code.

The `toascii()` function is not intended to be used to convert EBCDIC characters to ASCII, attempts to use it in this manner will not function as expected.

Special behavior for `_ALL_SOURCE`: The `toascii()` function assumes `c` modulo 256 is a single-byte EBCDIC encoding for a Latin 1 character, `<input-character>`, in the current locale. Then, `toascii()` determines to what character, `<output-character>`, `toascii()` would map `<input-character>` in an ASCII locale (for example, on an `*IX` system) and returns the EBCDIC encoding for `<output-character>` in the current locale.

For example, if the program invoking `toascii()` was compiled with `_ALL_SOURCE` defined and if the value `c` input to `toascii()` modulo 256 is the EBCDIC encoding for `<international-currency-symbol>` in the current locale, `toascii()` returns the EBCDIC encoding for `<dollar>` in the current locale because `toascii()` maps `<international-currency-symbol>` to `<dollar>` on ASCII platforms.

Returned value

EBCDIC and ASCII encodings and `<input-character>` to `<output-character>` mapping performed by `toascii()` in an IBM-1047 locale are as follows:

```

/*****
/*
/* IBM-1047 toascii table (sorted by ebcdic)
/*
/* For ISO-8859 character encoding toascii(ch) returns ch for
/* values of ch less than 128 and ch-128 for values between
/* 128 and 255, inclusive. Table below shows corresponding
/* toascii(ch) equivalence for IBM-1047 character encoding
/* of the Latin character set.
/*
/*
/* Character          IBM 1047          ISO 8859-1
/* (Symbolic Name)   (Hexadecimal)   (Hexadecimal)

```

Special behavior for `_XOPEN_SOURCE`: The `toascii()` function returns the value `(c & 0x7f)`.

Special behavior for `_ALL_SOURCE`: If the current locale is not a single-byte locale (that is, `mb_cur_max > 1`), `toascii()` sets `errno` to **ENOSYS** and returns `-1`. Otherwise, `toascii()` assumes `c` modulo 256 is the encoding of a Latin 1 character, `<input_character>`, in the current locale and returns the EBCDIC encoding of the same or another Latin 1 character, `<output-character>`, in the current locale; where `<output-character>` corresponds to the character to which `toascii()` would map `<input-character>` on an ASCII platform.

__toCcsid() – Convert codeset name to coded character set ID

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R2 |

Format

```
#include <_Ccsid.h>

__ccsid_t __toCcsid(char *codesetName);
```

General description

The __toCcsid() function returns the coded character set ID corresponding to the provided *codesetName* argument.

Returned value

If successful, __toCcsid() returns the corresponding CCSID for *codesetName*, if one exists. The returned __ccsid_t type is defined in <_Ccsid.h> as an unsigned short.

If unsuccessful, __toCcsid() returns 0 and sets errno to one of the following values:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

| | |
|--------|--|
| EINVAL | The length of the <i>codesetName</i> argument is greater than _CSNAME_LEN_MAX as defined in header <_Ccsid.h>. |
|--------|--|

Related information

- [“_Ccsid.h – CCSID to codeset name conversion” on page 17](#)
- [“__CcsidType\(\) – Return coded character set ID type” on page 247](#)

__toCSName() – Convert coded character set ID to codeset name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R2 |

Format

```
#include <_Ccsid.h>

int __toCSName(__ccsid_t Ccsid, char *codesetName);
```

General description

The __toCSName() function returns the codeset name, corresponding to coded character codeset ID, *Ccsid*, in *codesetName*.

Returned value

If successful, __toCSName() returns 0 and stores the codeset name in *codesetName*, when a corresponding codeset name exists for *Ccsid*.

If unsuccessful, __toCSName() returns -1.

If `__toCSName()` returns -1 for a reason other than no corresponding codeset name exists, it sets `errno` to one of the following values:

Error Code
Description

EINVAL

The corresponding *codesetName* length is greater than `_CSNAME_LEN_MAX` as defined in header `<_Ccsid.h>`.

tolower(), toupper() — Convert character case

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <ctype.h>

int tolower(int c); /* Convert c to lowercase if appropriate */
int toupper(int c); /* Convert c to uppercase if appropriate */
```

General description

Converts *c* to a lowercase letter, if possible. Conversely, the `toupper()` function converts *c* to an uppercase letter, if possible.

The DBCS is not supported. The use of characters from the DBCS results in unspecified behavior.

Returned value

If successful, `tolower()` and `toupper()` return the corresponding character, as defined in the `LC_CTYPE` category of the current locale, if such a character exists.

If unsuccessful, `tolower()` and `toupper()` return the unchanged value *c*.

Example

CELEBT15

```
/* CELEBT15

   This example demonstrates the result of using
   &toupper. and &tolower. on a lower-case a.

*/
#include <stdio.h>
```

```
#include <ctype.h>

int main(void)
{
    int ch;

    ch = 0x81;
    printf("toupper=%#04x\n", toupper(ch));
    printf("tolower=%#04x\n", tolower(ch));
}
```

Related information

_tolower() — Translate uppercase characters to lowercase

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <ctype.h>

int _tolower(int c);
```

General description

The `_tolower()` macro is equivalent to `tolower(c)` except that the argument `c` must be an uppercase letter.

Returned value

`_tolower()` returns the lowercase letter corresponding to the argument passed.

Related information

- [“ctype.h — Character classification” on page 17](#)
- [“tolower\(\), toupper\(\) — Convert character case” on page 1883](#)

t_open() — Establish a transport endpoint

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_open(char *name, int oflag, struct t_info *info);
```

General description

t_open() must be called as the first step in the initialization of a transport endpoint. This function establishes a transport endpoint by supplying a transport provider identifier that indicates a particular transport provider (that is, transport protocol) and returning a file descriptor that identifies that endpoint.

Note: There must be at least one available file descriptor less than 65536.

The argument *name* points to a transport provider identifier. The only supported transport provider is "/dev/tcp", indicating a TCP transport provider. No device by that name actually exists in the file system. It is purely used to follow historical convention. The argument *oflag* identifies any open flags (as in open()). It is constructed from O_RDWR optionally bitwise inclusive-OR'ed with O_NONBLOCK. These flags are defined by the header <fcntl.h>. The file descriptor returned by t_open() will be used by all subsequent functions to identify the particular local transport endpoint.

This function also returns various default characteristics of the underlying transport protocol by setting fields in the *info* structure. This argument points to a t_info structure which contains the following members:

```
long addr;          /* max size of the transport protocol address */
long options;       /* max number of bytes of options */
long tsdu;          /* max size of a transport service data unit (TSDU) */
long etsdu;         /* max size of an expedited transport service data unit (ETSDU) */
long connect;       /* max amount of data allowed on connection establishment functions */
long discon;        /* max amount of data allowed on t_snddis() and t_rcvdis() functions */
long servtype;      /* service type supported by the transport provider */
long flags;         /* other info about the transport provider */
```

The fields take on the following values:

addr

The size of a struct sockaddr_in is returned.

options

The value 304, which is the maximum number of bytes of options which can possibly be specified or requested, is returned.

tsdu

Zero is returned, indicating that the TCP transport provider does not support the concept of TSUs.

etsdu

A value of -1 is returned, indicating that there is no limit on the size of an ETSDU.

connect

A value of -2 is returned, indicating that the TCP transport provider does not allow data to be sent with connection establishment functions.

discon

A value of -2 is returned, indicating that the transport provider does not allow data to be sent with the abortive release functions.

servtype

T_COTS is always returned, since this is the only service type supported.

flags

The T_SENDZERO bit is always set in this field, indicating that the TCP transport provider supports the sending of zero-length TSDUs.

If info is set to a NULL pointer by the transport user, no protocol information is returned by t_open().

Valid states: T_UNINIT

Returned value

If successful, t_open() returns a valid file descriptor.

If unsuccessful, t_open() returns -1 and sets errno to one of the following values:

Error Code**Description****TBADFLAG**

An invalid flag is specified.

TBADNAME

Invalid transport provider name.

TPROTO

This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (*t_errno*).

TSYSERR

A system error has occurred during execution of this function.

t_optmgmt() — Manage options for a transport endpoint

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_optmgmt(int fd, struct t_optmgmt *req, struct t_optmgmt *ret);
```

General description

Enables a transport user to retrieve, verify or negotiate protocol options with the transport provider. The argument *fd* identifies a transport endpoint. The *req* and *ret* arguments point to a t_optmgmt structure containing the following members:

```
struct netbuf    opt;
long            flags;
```

The *opt* field identifies protocol options and the *flags* field is used to specify the action to take with those options.

The options are represented by a *netbuf* structure in a manner similar to the address in *t_bind()*. The *netbuf* structure contains the following members:

| | | |
|--------------|--------|-----------------------------|
| unsigned int | maxlen | maximum buffer value length |
| unsigned int | len | actual buffer value length |
| char * | buf | pointer to buffer |

The argument *req* is used to request a specific action of the provider and to send options to the provider. The argument *len* specifies the number of bytes in the options, *buf* points to the options buffer, and *maxlen* has no meaning for the *req* argument. The transport provider may return options and flag values to the user through *ret*. For *ret*, *maxlen* specifies the maximum size of the options buffer, and *buf* points to the buffer where the options are to be placed. On return, *len* specifies the number of bytes of options returned. The value in *maxlen* has no meaning for the *req* argument, but must be set in the *ret* argument to specify the maximum number of bytes the options buffer can hold.

Each option in the options buffer is of the form struct *t_opthdr* possibly followed by an option value. The *t_opthdr* structure contains the following members:

AMODE(31):

| | | |
|---------------|--------|-----------------------------|
| unsigned long | len | sizeof(t_opthdr)+optval len |
| unsigned long | level | protocol affected |
| unsigned long | name | option value |
| unsigned long | status | status value |

AMODE(64):

| | | |
|--------------|--------|-----------------------------|
| unsigned int | len | sizeof(t_opthdr)+optval len |
| unsigned int | level | protocol affected |
| unsigned int | name | option value |
| unsigned int | status | status value |

The *level* field of struct *t_opthdr* identifies the XTI level or a protocol of the transport provider. The *name* field identifies the option within the level, and *len* contains its total length. The total length is the length of the option header *t_opthdr* plus the length of the option value. If *t_optmgmt()* is called with the action *T_NEGOTIATE* set, the *status* field of the returned options contains information about the success or failure of a negotiation.

Each option in the input or output option buffer must start at a long-word boundary. The macro *OPT_NEXTHDR(pbuf, buflen, poption)* can be used for that purpose. The parameter *pbuf* denotes a pointer to an option buffer *opt.buf*, and *buflen* is its length. The parameter *poption* points to the current option in the option buffer. *OPT_NEXTHDR* returns a pointer to the position of the next option, or returns a NULL pointer if the option buffer is exhausted. The macro is helpful for writing and reading. See “[xti.h — _XOPEN_SOURCE_EXTENDED feature test macro](#)” on page 81 for the exact definition.

If the transport user specifies several options on input, all options must address the same level.

If any option in the options buffer does not indicate the same level as the first option, or the level specified is unsupported, then the *t_optmgmt()* request will fail with *TBADOPT*. If the error is detected, some options have possibly been successfully negotiated. The transport user can check the current status by calling *t_optmgmt()* with the *T_CURRENT* flag set.

Before using this function, you should read Chapter 6 , “Use of Options in XTI”, in *X/Open CAE Specification, Networking Services, Issue 4*

The *flags* field of *req* must specify one of the following actions:

T_NEGOTIATE

This action enables the transport user to negotiate option values.

The user specifies the options of interest and their values in the buffer specified by *req->opt.buf* and *req->opt.len*. The negotiated option values are returned in the buffer pointed to by *ret->opt.buf*. The *status* field of each returned option is set to indicate the result of the negotiation. The value is *T_SUCCESS* if the proposed value was negotiated, *T_PARTSUCCESS* if a degraded value was negotiated, *T_FAILURE* if the negotiation failed (according to the negotiation rules), *T_NOTSUPPORT* if the transport provider does not support this option or illegally requests negotiation of a privileged

option, and T_READONLY if modification of a read-only option was requested. If the status is T_SUCCESS, T_FAILURE, T_NOTSUPPORT or T_READONLY, the returned option value is the same as the one requested on input.

The overall result of the negotiation is returned in *ret->flags*.

This field contains the worst single result, whereby the rating is done according to the order T_NOTSUPPORT, T_READONLY, T_FAILURE, T_PARTSUCCESS, T_SUCCESS. The value T_NOTSUPPORT is the worst result and T_SUCCESS is the best.

For each level, the option T_ALLOPT (see below) can be requested on input. No value is given with this option; only the *t_opthdr* part is specified. This input requests to negotiate all supported options of this level to their default values. The result is returned option by option in *ret->opt.buf*. (Note that depending on the state of the transport endpoint, not all requests to negotiate the default value may be successful.)

T_CHECK

This action enables the user to verify whether the options specified in *req* are supported by the transport provider.

If an option is specified with no option value (it consists only of a *t_opthdr* structure), the option is returned with its status field set to T_SUCCESS if it is supported, T_NOTSUPPORT if it is not or needs additional user privileges, and T_READONLY if it is read-only (in the current XTI state). No option value is returned.

If an option is specified with an option value, the *status* field of the returned option has the same value, as if the user had tried to negotiate this value with T_NEGOTIATE. If the status is T_SUCCESS, T_FAILURE, T_NOTSUPPORT or T_READONLY, the returned option value is the same as the one requested on input.

The overall result of the option checks is returned in *ret->flags*. This field contains the worst single result of the option checks, whereby the rating is the same as for T_NEGOTIATE.

Note that no negotiation takes place. All currently effective option values remain unchanged.

T_DEFAULT

This action enables the transport user to retrieve the default option values. The user specifies the options of interest in *req->opt.buf*. The option values are irrelevant and will be ignored. It is sufficient to specify the *t_opthdr* part of an option only. The default values are then returned in *ret->opt.buf*.

The status field returned is T_NOTSUPPORT if the protocol level does not support this option or the transport user illegally requested a privileged option, T_READONLY if the option is read-only, and set to T_SUCCESS in all other cases. The overall result of the request is returned in *ret->flags*. This field contains the worst single result, whereby the rating is the same as for T_NEGOTIATE.

For each level, the option T_ALLOPT (see below) can be requested on input. All supported options of this level with their default values are then returned. In this case, *ret->opt.maxlen* must be given at least the value *info->options* (see *t_getinfo()*, *t_open()*) before the call.

T_CURRENT

This action enables the transport user to retrieve the currently effective option values. The user specifies the options of interest in *req->opt.buf*. The option values are irrelevant and will be ignored. It is sufficient to specify the *t_opthdr* part of an option only. The currently effective values are then returned in *ret->opt.buf*.

The status field returned is T_NOTSUPPORT if the protocol level does not support this option, or the transport user illegally requested a privileged option, T_READONLY if the option is read-only, and set to T_SUCCESS in all other cases. The overall result of the request is returned in *ret->flags*. This field contains the worst single result, whereby the rating is the same as for T_NEGOTIATE.

For each level, the option T_ALLOPT (see below) can be requested on input. All supported options of this level with their currently effective values are then returned.

The option T_ALLOPT can only be used with *t_optmgmt()* and the actions T_NEGOTIATE, T_DEFAULT and T_CURRENT. It can be used with any supported level and addresses all supported options of this level.

The option has no value; it consists of a *t_opthdr* only. Since in a *t_optmgmt()* call only options of one level may be addressed, this option should not be requested together with other options. The function returns as soon as this option has been processed.

Options are independently processed in the order they appear in the input option buffer. If an option is multiply input, it depends on the implementation whether it is multiply output or whether it is returned only once.

The function *t_optmgmt()* may block under various circumstances and depending on the implementation. The function will block, for instance, if the protocol addressed by the call resides on a separate controller. It may also block due to flow control constraints. For example, if data sent previously across this transport endpoint has not yet been fully processed. If the function is interrupted by a signal, the option negotiations that have been done so far may remain valid. The behavior of the function is not changed if *O_NONBLOCK* is set.

Valid states: All - except for *T_UNINIT*

XTI-level options: XTI-level options are not specific for a particular transport provider. An XTI implementation supports none, all or any subset of the options defined below. An implementation may restrict the use of any of these options by offering them only in the privileged or read-only mode, or if *fd* relates to specific transport providers.

The subsequent options are not association-related. They may be negotiated in all XTI states except *T_UNINIT*. See Chapter 6, “Use of Options in XTI”, in *X/Open CAE Specification, Networking Services, Issue 4* for more information.

The protocol level is *XTI_GENERIC*. For this level, the following options are defined:

XTI_DEBUG

This option enables debugging. The valid values of this option are:

- None (option header only) - indicating that debug is to be turned off.
- -1 - indicating that debug output is to go to *stderr*.
- A file descriptor - indicating the destination file for debug output.

The debug output contains varying information depending on the XTI services invoked. It is meant to be used by customer support personnel.

XTI_LINGER

This option is used to linger the execution of a *t_close()* or *close()* if send data is still queued in the send buffer. The option value specifies the linger period. If a *close()* or *t_close()* is issued and the send buffer is not empty, the system attempts to send the pending data within the linger period before closing the endpoint. Data still pending after the linger period has elapsed is discarded.

Depending on the implementation, *t_close()* or *close()* either block for at maximum the linger period, or immediately return, whereupon the system holds the connection in existence for at most the linger period.

The *option* value consists of a structure *t_linger* declared as:

```
struct t_linger {
    long l_onoff; /* switch option on/off */
    long l_linger; /* linger period in seconds */
}
```

Legal values for the field *l_onoff* are:

T_NO

switch option off

T_YES

activate option

The value *l_onoff* is an absolute requirement.

The field *l_linger* determines the linger period in seconds. The transport user can request the default value by setting the field to *T_UNSPEC*. The default timeout value depends on the underlying transport

provider (it is often T_INFINITE). Legal values for this field are T_UNSPEC, T_INFINITE and all nonnegative numbers.

The *l_linger* value is not an absolute requirement. The implementation may place upper and lower limits to this value. Requests that fall short of the lower limit are negotiated to the lower limit.

Note that this option does not linger the execution of `t_snddis()`.

XTI_RCVBUF

This option is used to adjust the internal buffer size allocated for the receive buffer. The buffer size may be increased for high-volume connections, or decreased to limit the possible backlog of incoming data.

This request is not an absolute requirement. The implementation may place upper and lower limits on the option value. Requests that fall short of the lower limit are negotiated to the lower limit.

Legal values are all positive numbers.

XTI_SNDBUF

This option is used to adjust the internal buffer size allocated for the send buffer.

This request is not an absolute requirement. The implementation may place upper and lower limits on the option value. Requests that fall short of the lower limit are negotiated to the lower limit.

Legal values are all positive numbers.

TCP-level options: The protocol level is INET_TCP. The following TCP-level options are supported. They are not association-related.

TCP_KEEPALIVE

If this option is set, a keep-alive timer is activated to monitor idle connections that might no longer exist. If a connection has been idle since the last keep-alive timeout, a keep-alive packet is sent to check if the connection is still alive or broken.

The option value consists of a structure *t_kpalive* declared as:

```
struct t_kpalive {
    long    kp_onoff;        /* switch option on/off */
    long    kp_timeout;      /* keep-alive timeout in minutes */
}
```

Legal values for the field *kp_onoff* are:

T_NO

switch keep-alive timer off

T_YES

activate keep-alive timer

The field *kp_timeout* determines the frequency of keep-alive packets being sent, in minutes. The transport user can request the default value by setting the field to T_UNSPEC. The default is 120 minutes. Legal values for this field are T_UNSPEC and all positive numbers.

The timeout value is not an absolute requirement. However, no limits are currently specified by the TCP transport provider.

IP-level options: The protocol level is INET_IP. The following IP-level options are supported. They are not association-related.

IP_REUSEADDR

Generally, users are not allowed to bind more than one transport endpoint to addresses with identical port numbers. If IP_REUSEADDR is set to T_YES this restriction is relaxed in the sense that it is now permissible to bind a transport endpoint to an address with a port number and an under-specified internet address and further endpoints to addresses with the same port number and (mutually exclusive) fully specified internet addresses.

Returned value

If successful, `t_optmgmt()` returns 0.

If unsuccessful, `t_optmgmt()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

TACCES

The user does not have permission to negotiate the specified options.

TBADF

The specified file descriptor does not refer to a transport endpoint.

TBADFLAG

An invalid flag was specified.

TBADOPT

The specified options were in an incorrect format or contained illegal information.

TBUFOVFLW

The number of bytes allowed for an incoming argument (*maxlen*) is greater than 0 but not sufficient to store the value of that argument. The information to be returned in *ret* will be discarded.

TNOTSUPPORT

This action is not supported by the transport provider.

TOUTSTATE

The function was issued in the wrong sequence.

TPROTO

This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (*t_errno*).

TSYSERR

A system error has occurred during execution of this function.

_toupper() — Translate lowercase characters to uppercase

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <ctype.h>

int _toupper(int c);
```

General description

The `_toupper()` macro is equivalent to `toupper(c)` except that the argument `c` must be a lowercase letter.

Returned value

`_toupper()` returns the uppercase letter corresponding to the argument passed.

Related information

- [“ctype.h — Character classification” on page 17](#)
- [“isalnum\(\) to isxdigit\(\) — Test integer value” on page 895](#)
- [“tolower\(\), toupper\(\) — Convert character case” on page 1883](#)

tolower(), toupper() — Convert wide character case

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#include <wctype.h>

wint_t tolower(wint_t wc);
wint_t toupper(wint_t wc);
```

General description

Converts `wc` to the corresponding lowercase letter. The `toupper()` function converts `wc` to the corresponding uppercase letter.

Returned value

If `wc` is a wide character for which `iswupper()` (or `iswlower()`) is true and there is a corresponding wide character for which `iswlower()` (or `iswupper()`) is true, `tolower()` (or `toupper()`) returns the corresponding wide character; otherwise, `wc` is returned unchanged.

Related information

- [“wctype.h — Wide character properties” on page 81](#)

- [“tolower\(\), toupper\(\) — Convert character case” on page 1883](#)

towctrans() – Transliterate wide character transliteration

The information for this function is included in “wctrans(), towctrans() – Transliterate wide character ” on page 2041.

t_rcv() – Receive data or expedited data sent over a connection

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_rcv(int fd, char *buf, unsigned int nbytes, int *flags);
```

General description

Receives either normal or expedited data. The argument *fd* identifies the local transport endpoint through which data will arrive. *buf* points to a receive buffer where user data is placed. *nbytes* specifies the size of the receive buffer. The argument *flags* may be set on return from *t_rcv()* and specifies optional flags as described below.

By default, *t_rcv()* operates in synchronous mode and will wait for data to arrive if none is currently available. However, if *O_NONBLOCK* is set (using *t_open()* or *fcntl()*), *t_rcv()* will execute in asynchronous mode and will fail if no data is available. (See *TNODATA* below.)

On return from the call, if *T_MORE* is set in *flags*, this indicates that there is more data, and the current expedited transport service data unit (ETSDU) must be received in multiple *t_rcv()* calls. In the asynchronous mode, the *T_MORE* flag may be set on return from the *t_rcv()* call even when the number of bytes received is less than the size of the receive buffer specified. Each *t_rcv()* with the *T_MORE* flag set indicates that another *t_rcv()* must follow to get more data for the current ETSDU. The end of the ETSDU is identified by the return of a *t_rcv()* call with the *T_MORE* flag not set. The *T_MORE* flag is not meaningful for normal data when using the TCP transport provider and should be ignored. If *nbytes* is greater than zero on the call to *t_rcv()* , *t_rcv()* will return 0 only if the end of a TSDU is being returned to the user.

On return, the data returned is expedited data if *T_EXPEDITED* is set in *flags*. If the number of bytes of expedited data exceeds *nbytes*, *t_rcv()* will set *T_EXPEDITED* and *T_MORE* on return from the initial call. Subsequent calls to retrieve the remaining ETSDU will have *T_EXPEDITED* set on return. The end of the ETSDU is identified by the return of a *t_rcv()* call with the *T_MORE* flag not set.

In synchronous mode, the only way for the user to be notified of the arrival of normal or expedited data is to issue this function or check for the *T_DATA* or *T_EXDATA* events using the *t_look()* function. Additionally, the process can arrange to be notified by the select/poll interface.

Valid states: *T_DATAXFER*

Returned value

If successful, *t_rcv()* returns the number of bytes received.

If unsuccessful, *t_rcv()* returns -1 and sets *errno* to one of the following values:

Error Code

Description

TBADF

The specified file descriptor does not refer to a transport endpoint.

TLOOK

An asynchronous event has occurred on this transport endpoint and requires immediate attention.

TNODATA

O_NONBLOCK was set, but no data is currently available from the transport provider.

TNOTSUPPORT

This function is not supported by the underlying transport provider.

TOUTSTATE

The function was issued in the wrong sequence on the transport endpoint referenced by *fd*.

TPROTO

This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (*t_errno*).

TSYSERR

A system error has occurred during execution of this function.

t_rcvconnect() — Receive the confirmation from a connect request

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_rcvconnect(int fd, struct t_call *call);
```

General description

Enables a calling transport user to determine the status of a previously sent connect request. *t_rcvconnect()* is used in conjunction with *t_connect()* to establish a connection in asynchronous mode. The connection will be established on successful completion of this function.

The argument *fd* identifies the local transport endpoint where communication will be established, and *call* contains information associated with the newly established connection. The argument *call* points to a *t_call* structure which contains the following members:

```
struct netbuf  addr;
struct netbuf  opt;
struct netbuf  udata;
int            sequence;
```

In *call*, *addr* returns the protocol address associated with the responding transport endpoint. *opt* presents any options associated with the connection. *udata* is meaningless since the TCP transport provider does not support transmission of user data during connection establishment. *sequence* has no meaning for this function.

The *maxlen* field of each argument must be set before issuing this function to indicate the maximum size of the buffer for each. However, *call* may be a NULL pointer, in which case no information is given to the user on return from `t_rcvconnect()`. By default, `t_rcvconnect()` executes in synchronous mode and waits for the connection to be established before returning. On return, the *addr* field contains the address of the remote endpoint, and *opt* reflects the result of negotiation of the options the user specified on input.

If `O_NONBLOCK` is set (using `t_open()` or `fcntl()`), `t_rcvconnect()` executes in asynchronous mode, and reduces to a poll for existing connect confirmations. If none are available, `t_rcvconnect()` fails and returns immediately without waiting for the connection to be established. (See `TNODATA` below.) In this case, `t_rcvconnect()` must be called again to complete the connection establishment phase and retrieve the information returned in *call*.

Valid states: `T_OUTCON`

Returned value

If successful, `t_rcvconnect()` returns 0.

If unsuccessful, `t_rcvconnect()` returns -1 and sets `errno` to one of the following values:

Error Code Description

TBADF

The specified file descriptor does not refer to a transport endpoint.

TBUFOVFLW

The number of bytes allocated for an incoming argument (*maxlen*) is greater than 0 but not sufficient to store the value of that argument, and the connect information to be returned in *call* will be discarded. The provider's state, as seen by the user, will be changed to `T_DATAXFER`.

TLOOK

An asynchronous event has occurred on this transport connection and requires immediate attention.

TNODATA

`O_NONBLOCK` was set, but a connect confirmation has not yet arrived.

TNOTSUPPORT

This function is not supported by the underlying transport provider.

TOUTSTATE

The function was issued in the wrong sequence on the transport endpoint referenced by *fd*.

TPROTO

This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (*t_errno*).

TSYSERR

A system error has occurred during execution of this function.

t_rcvdis() — Retrieve information from disconnect

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_rcvdis(int fd, struct t_discon *discon);
```

General description

Used to identify the cause of a disconnect. The argument *fd* identifies the local transport endpoint where the connection existed, and *discon* points to a *t_discon* structure containing the following members:

```
struct netbuf    udata;
int              reason;
int              sequence;
```

The field *reason* specifies the reason for the disconnect through a protocol-dependent reason code, *udata* is always empty since the TCP transport provider does not support sending of user data with a disconnect, and *sequence* may identify an outstanding connect indication with which the disconnect is associated. The field *sequence* is only meaningful when *t_rcvdis()* is issued by a passive transport user who has executed one or more *t_listen()* functions and is processing the resulting connect indications. If a disconnect indication occurs, *sequence* can be used to identify which of the outstanding connect indications is associated with the disconnect.

If a user does not care if there is incoming data and does not need to know the value of *reason* or *sequence*, *discon* may be a NULL pointer. However, if a user has retrieved more than one outstanding connect indication (using *t_listen()*) and *discon* is a NULL pointer, the user will be unable to identify with which connect indication the disconnect is associated.

Valid states: T_DATAXFER,T_OUTCON,T_INCON(ocnt > 0)

Returned value

If successful, *t_rcvdis()* returns 0.

If unsuccessful, *t_rcvdis()* returns -1 and sets *errno* to one of the following values:

Error Code

Description

TBADF

The specified file descriptor does not refer to a transport endpoint.

TBUFOVFLW

The number of bytes allocated for incoming data (*maxlen*) is greater than 0 but not sufficient to store the data. If *fd* is a passive endpoint with *ocnt* > 1, it remains in state T_INCON; otherwise, the endpoint state is set to T_IDLE.

TNODIS

No disconnect indication currently exists on the specified transport endpoint.

TNOTSUPPORT

This function is not supported by the underlying transport provider.

TOUTSTATE

The function was issued in the wrong sequence on the transport endpoint referenced by *fd*.

TPROTO

This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (*t_errno*).

TSYSERR

A system error has occurred during execution of this function.

t_rcvrel() — Acknowledge receipt of an orderly release indication

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_rcvrel(int fd);
```

General description

Since orderly release is not supported, this function always fails.

Returned value

t_rcvrel() always returns -1 and sets *t_errno* to TNOTSUPPORT.

Related information

- [“xti.h — _XOPEN_SOURCE_EXTENDED feature test macro” on page 81](#)
- [“t_getinfo\(\) — Get protocol-specific service information” on page 1862](#)

trunc(), truncf(), trunc() — Truncate an integer value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R5 |

Format

```
#define _ISOC99_SOURCE
#include <math.h>

double trunc(double x);
float truncf(float x);
long double Trunc1(long double x);
```

C++ TR1 C99

```
#define _TR1_C99
#include <math.h>

float trunc(float x);
long double trunc(long double x);
```

General description

The trunc functions round x to the integer value, in floating-point format, nearest to but no larger in magnitude than x .

Note: The following table shows the viable formats for these functions. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

| Function | Hex | IEEE |
|----------|-----|------|
| trunc | X | X |
| truncf | X | X |
| trunc1 | X | X |

Returned value

The trunc functions return the truncated integer value of x .

Related information

- [“math.h — Floating-point math functions”](#) on page 40

truncd32(), truncd64(), truncd128() – Truncate an integer value

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <math.h>

_Decimal32 truncd32(_Decimal32 x);
_Decimal64 truncd64(_Decimal64 x);
_Decimal128 truncd128(_Decimal128 x);
_Decimal32 trunc(_Decimal32 x); /* C++ only */
_Decimal64 trunc(_Decimal64 x); /* C++ only */
_Decimal128 trunc(_Decimal128 x); /* C++ only */
```

General description

The trunc functions round *x* to the integer value, in decimal floating-point format, nearest to but no larger in magnitude than *x*.

Notes:

1. To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.
2. These functions work in IEEE decimal floating-point format. See "IEEE Decimal Floating-Point" for more information.

Returned value

The trunc functions return the truncated integer value of *x*.

Example

```
/* CELEBT21
   This example illustrates the truncd128() function.
*/

#define __STDC_WANT_DEC_FP__
#include <math.h>
#include <stdio.h>

int main(void)
{
    _Decimal128 x = 123456789.40DL, y;

    y = truncd128(x);

    printf("The result of truncd128(%DDf) is %DDf\n", x, y);
}
```

Related information

- [“math.h — Floating-point math functions” on page 40](#)
- [“trunc\(\), truncf\(\), trunci\(\) — Truncate an integer value” on page 1899](#)

truncate() — Truncate a file to a specified length

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int truncate(const char *path, off_t length);
```

General description

Truncates the file indicated by the *path* to the indicated *length*. The calling process must have write permission for the file. If the file size exceeds *length*, any extra data is discarded. If the file size is smaller than *length*, bytes between the old and new lengths are read as zeros. A change to the size of the file has no impact on the file offset.

If truncate() would cause the file size to exceed the soft file size limit for the process, truncate() will fail and a SIGXFSZ signal will be generated for the process.

If successful, truncate() marks the st_ctime and st_mtime fields of the file.

If unsuccessful, the file is unchanged.

Large file support for z/OS UNIX files: Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the [long long data type support](#) enabled and define the `_LARGE_FILES` feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the `_LARGE_FILES` feature test macro as well.

Returned value

If successful, truncate() returns 0.

If unsuccessful, truncate() returns -1 and sets errno to one of the following values:

Error Code

Description

EFBIG

The length argument was greater than the maximum file size.

EINTR

A signal was caught during execution

EINVAL

path does not refer to a regular file, or the length specified is incorrect.

EIO

An I/O error occurred while reading from or writing to a file system.

EISDIR

The file specified is a directory. The system cannot perform the requested function on a directory.

EROFS

The file resides on a read-only file system.

Related information

- [“ftruncate\(\) — Truncate a file” on page 663](#)
- [“open\(\) — Open a file” on page 1157](#)

tsched() — Schedule MTF subtask

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | C only | |

Format

```
#include <mtf.h>

int tsched(int task_id, const char *func_name, ...);
```

General description

Restriction: This function is not supported in AMODE 64.

The `tsched()` built-in library function is used to schedule parallel functions under the [MVS environment](#).

The `tsched()` library function schedules a parallel function (*func_name*) to be executed in a subtask that has been attached and initialized by `tinit()`. The first argument *task_id* can be used to specify the task where the parallel function is to be executed. The *task_id* can be set to `MTF_ANY` to indicate that the parallel function can be run in any task or, *task_id* can be set to a specific task number between 1 and the number of subtasks specified on `tinit()`.

The `tsched()` function allocates approximately 2K of space as a work area. This work area is not freed. However, a call to the `tsyncro()` function will make work areas previously allocated by `tsched()` available for reuse by `tsched()`. Because `tsched()` does not free the work area storage, it is possible the `tsched()` will cause an application Short on Storage condition to occur if enough calls are made to the `tsched()` function.

You can call `tsched()` from your main C task as often as necessary to schedule parallel functions for execution. If all of the subtasks are busy running previously scheduled functions, each call in excess of the number of subtasks will cause *func_name* to be run after previously scheduled functions in the first qualifying subtask that becomes available.

All scheduled functions must be computationally independent. A function cannot use variables that are modified by another scheduled function or the scheduling function. To determine if all other scheduled functions have completed, use the `tsyncro()` library function (see [“tsyncro\(\) — Wait for MTF subtask termination” on page 1911](#)).

The name of the parallel function, *func_name*, must not be longer than 8 characters. If it is, the name will be truncated to the first 8 characters with no warning.

Usually `tsched()` returns to the calling main task program before the scheduled parallel function has completed execution. Therefore, you must call `tsyncro()` to ensure that your parallel functions have completed execution.

If `tinit()` has not been successfully called before `tsched()`, `tsched()` indicates that MTF is inactive.

If `tinit()` is called by a program running under IMS, CICS, or DB2, the request will not be processed and the returned value will indicate that MTF calls are not supported under these systems.

Note: This function is *not* supported under the z/OS UNIX with the POSIX(ON) runtime option.

Returned value

If successful, scheduling the parallel function for execution in a subtask, `tsched()` returns `MTF_OK`.

If unsuccessful, `tsched()` returns one of the following values:

Error Code

Description

EBADLNKG

`tsched()` has been invoked using an invalid linkage. The header file `mtf.h` may have been missing from the source at compile.

EENTRY

The parallel function was not found in the parallel module.

EINACTIVE

MTF is inactive.

ENOMEM

There was insufficient storage for MTF-internal areas.

ETASKABND

One or more subtasks have terminated abnormally.

ETASKID

The `task_id` specified is not valid.

Note: These values are macros. They can be found in the `mtf.h` header file.

Related information

tsearch() — Binary tree search

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <search.h>

void *tsearch(const void *key, void **rootp,
              int (*compar)(const void *, const void *));
```

General description

The `tsearch()` function is used to build and access a binary search tree. The `key` argument is a pointer to an element to be accessed or stored. If there is a node in the tree whose element is equal to the value pointed to by `key`, a pointer to this found node is returned. Otherwise, the value pointed to by `key` is inserted (that is, a new node is created and the value of `key` is copied to this node), and a pointer to this node returned. Only pointers are copied, so the calling routine must store the data. The `rootp` argument points to a variable that points to the root node of the tree. A NULL pointer value for the variable pointed

to by *rootp* denotes an empty tree; in this case, the variable will be set to point to the node which will be at the root of the new tree.

Comparisons are made with a user-supplied routine, the address of which is passed as the *compar* argument. This routine is called with two arguments, the pointers to the elements being compared. The user-supplied routine must return an integer less than, equal to or greater than 0, according to whether the first argument is to be considered less than, equal to or greater than the second argument. The comparison functions need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared.

Threading Behavior: Since the tree is anchored by the user's *rootp* pointer, the tree storage is visible to the user and could be shared among threads. The user would be responsible for serializing access to a shared tree. There are no variables related to these functions which are internal to the library and/or give rise to multithreading considerations.

Special behavior for C++: Because C and C++ linkage conventions are incompatible, `tsearch()` cannot receive a C++ function pointer as the comparator argument. If you attempt to pass a C++ function pointer to `tsearch()`, the compiler will flag it as an error. You can pass a C or C++ function to `tsearch()` by declaring it as `extern "C"`.

Returned value

If the node is found, `tsearch()` returns a pointer to it, otherwise it returns a pointer to the inserted item.

If there is not enough space available to create a new node, or if *rootp* is a NULL pointer on entry, `tsearch()` returns a NULL pointer.

No errors are defined.

t_snd() — Send data or expedited data over a connection

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_snd(int fd, char *buf, unsigned int nbytes, int flags);
```

General description

Sends either normal or expedited data. The argument *fd* identifies the local transport endpoint over which data should be sent, *buf* points to the user data, *nbytes* specifies the number of bytes of user data to be sent, and *flags* specifies any optional flags described below:

T_EXPEDITED

If set in *flags*, the data will be sent as expedited data and will be subject to the interpretations of the transport provider.

T_MORE

Since the TCP transport provider does not support the concept of a TSDU, the T_MORE flag is not meaningful and will be ignored if set.

By default, `t_snd()` operates in synchronous mode and may wait if flow control restrictions prevent the data from being accepted by the local transport provider at the time the call is made. However, if `O_NONBLOCK` is set (using `t_open()` or `fcntl()`), `t_snd()` will execute in asynchronous mode, and will fail immediately if there are flow control restrictions. The process can arrange to be informed when the flow control restrictions are cleared using either `t_look()` or `select/poll`.

If successful, `t_snd()` returns the number of bytes accepted by the transport provider. Normally this will equal the number of bytes specified in *nbytes*. However, if `O_NONBLOCK` is set, it is possible that only part of the data will actually be accepted by the transport provider. In this case, `t_snd()` will return a value that is less than the value of *nbytes*.

The size of each TSDU or ETSDU must not exceed the limits of the transport provider as specified by the current values in the TSDU or ETSDU fields in the *info* argument returned by `t_getinfo()`. The error `TL00K` may be returned to inform the process that an event (for example, a disconnect) has occurred.

Valid states: T_DATAXFER

Returned value

If successful, `t_snd()` returns the number of bytes accepted by the transport provider.

Note that in asynchronous mode, if the number of bytes accepted by the transport provider is less than the number of bytes requested, this may indicate that the transport provider is blocked due to flow control.

If unsuccessful, `t_snd()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

TBADDATA

Illegal amount of data:

- A single send was attempted specifying a TSDU (ETSDU) or fragment TSDU (ETSDU) greater than that specified by the current values of the TSDU or ETSDU fields in the *info* argument.
- Multiple sends were attempted resulting in a TSDU (ETSDU) larger than that specified by the current value of the TSDU or ETSDU fields in the *info* argument

TBADF

The specified file descriptor does not refer to a transport endpoint.

TBADFLAG

An invalid flag was specified.

TFLOW

`O_NONBLOCK` was set, but the flow control mechanism prevented the transport provider from accepting any data at this time.

TLOOK

An asynchronous event has occurred on this transport endpoint.

TNOTSUPPORT

This function is not supported by the underlying transport provider.

TOUTSTATE

The function was issued in the wrong sequence on the transport endpoint referenced by *fd*.

TPROTO

This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (*t_errno*).

TSYSERR

A system error has occurred during execution of this function.

It is important to remember that the transport provider treats all users of a transport endpoint as a single user. Therefore if several processes issue concurrent *t_snd()* calls then the different data may be intermixed. Multiple sends which exceed the maximum TSDU or ETSDU size may not be discovered by XTI. In this case an implementation-dependent error will result (generated by the transport provider) perhaps on a subsequent XTI call. This error may take the form of a connection abort, a *TSYSERR*, a *TBADDATA* or a *TPROTO* error. If multiple sends which exceed the maximum TSDU or ETSDU size are detected by XTI, *t_snd()* fails with *TBADDATA*.

t_snddis() — Send user-initiated disconnect request

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_snddis(int fd, struct t_call *call);
```

General description

Initiates an abortive release on an already established connection, or rejects a connect request. The argument *fd* identifies the local transport endpoint of the connection, and *call* specifies information associated with the abortive release. The argument *call* points to a *t_call* structure which contains the following members:

```
struct netbuf  addr;
struct netbuf  opt;
struct netbuf  udata;
int            sequence;
```

The values in *call* have different semantics, depending on the context of the call to *t_snddis()*. When rejecting a connect request, *call* must be non-NULL and contain a valid value of *sequence* to uniquely identify the rejected connect indication to the transport provider. The *sequence* field is only meaningful if the transport connection is in the *T_INCON* state. The *addr* and *opt* fields of *call* are ignored. In all other cases, *call* should be a NULL pointer, since its only use would be to specify user data to be passed on the disconnect request, which is not supported by the TCP transport provider.

t_snddis() is an abortive disconnect. Therefore a t_snddis() issued on a connection endpoint may cause data previously sent using t_snd(), or data not yet received, to be lost (even if an error is returned).

Because of implementation restrictions, a t_snddis() called on one descriptor referring to an endpoint will not affect descriptors in other processes referring to the same endpoint. If descriptors in multiple processes refer to the same endpoint, the endpoint will not actually be disconnected by a t_snddis in one process. Multiple processes cooperating on an endpoint are responsible for providing their own explicit synchronization to support coordinated disconnects.

Valid states: T_DATAXFER, T_OUTCON, T_INCON(ocnt > 0)

Returned value

If successful, t_snddis() returns 0.

If unsuccessful, t_snddis() returns -1 and sets errno to one of the following values:

Error Code

Description

TBADDATA

The amount of user data specified was not within the bounds allowed by the transport provider.

TBADF

The specified file descriptor does not refer to a transport endpoint.

TBADSEQ

An invalid sequence number was specified, or a NULL *call* pointer was specified, when rejecting a connect request.

TLOOK

An asynchronous event, which requires attention, has occurred.

TNOTSUPPORT

This function is not supported by the underlying transport provider.

TOUTSTATE

The function was issued in the wrong sequence on the transport endpoint referenced by *fd*.

TPROTO

This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (t_errno).

TSYSERR

A system error has occurred during execution of this function.

t_sndrel() — Initiate an orderly release

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_sndrel(int fd);
```

General description

Since orderly release is not supported, `t_sndrel()` always fails.

Returned value

`t_sndrel()` always returns -1 and sets `t_errno` to TNOTSUPPORT.

Related information

- [“xti.h — _XOPEN_SOURCE_EXTENDED feature test macro” on page 81](#)
- [“t_getinfo\(\) — Get protocol-specific service information” on page 1862](#)
- [“t_open\(\) — Establish a transport endpoint” on page 1884](#)

t_sndudata() — Send a data unit

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_sndudata(int fd, struct t_unitdata *unitdata);
```

General description

T_CLTS service is not supported in this implementation, so this function always fails.

Returned value

`t_sndudata()` always returns -1 and sets `t_errno` to TNOTSUPPORT.

Related information

- [“xti.h — _XOPEN_SOURCE_EXTENDED feature test macro” on page 81](#)
- [“t_open\(\) — Establish a transport endpoint” on page 1884](#)

t_strerror() — Produce an error message string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

char *t_strerror(int errnum);
```

General description

Maps the error number in *errnum* that corresponds to an XTI error to a language-dependent error message string and returns a pointer to the string. The string pointed to should not be modified by the program, but may be overwritten by a subsequent call to the `t_strerror` function. The string is not terminated by a newline character. If the calling program is operating in any one of the C, POSIX, SAA or S370 locales, then the error message string describing the value in *t_errno* is identical to the comments following the *t_errno* codes defined in `<xti.h>`. Note that no message number is prefixed to the message text in this situation. If an error code is unknown, and the language is English, `t_strerror()` returns the string:

```
"<error>: error unknown"
```

where `<error>` is the error number supplied as input. In other languages, an equivalent text is provided.

Valid states: All - except for T_UNINIT

Returned value

`t_strerror()` returns a pointer to the generated message string.

Related information

- [“xti.h — _XOPEN_SOURCE_EXTENDED feature test macro”](#) on page 81
- [“t_error\(\) — Produce error message”](#) on page 1857

t_sync() — Synchronize transport library

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_sync(int fd);
```

General description

Synchronizes the data structures managed by the transport library with information from the underlying transport provider, for the transport endpoint specified by *fd*. In doing so, it can convert an uninitialized file descriptor (obtained using `open()`, `dup()`, or as a result of a `fork()` and `exec()`) to an initialized transport endpoint, assuming that the file descriptor referenced a transport endpoint, by updating and allocating the necessary library data structures. This function also allows two cooperating processes to synchronize their interaction with a transport provider.

For example, if a process forks a new process and issues an `exec()` , the new process must issue a `t_sync()` to build the private library data structure associated with a transport endpoint and to synchronize the data structure with the relevant provider information.

It is important to remember that the transport provider treats all users of a transport endpoint as a single user. If multiple processes are using the same endpoint, they should coordinate their activities so as not to violate the state of the transport endpoint. The function `t_sync()` returns the current state of the transport endpoint to the user, thereby enabling the user to verify the state before taking further action. This coordination is only valid among cooperating processes. It is possible that a process or an incoming event could change the endpoint's state after a `t_sync()` is issued.

If the transport endpoint is undergoing a state transition when `t_sync()` is called, the function will fail.

Valid states: All - except for `T_UNINIT`

Returned value

If successful, `t_sync()` returns the state of the transport endpoint. The state returned is one of the following:

T_DATAXFER

Data transfer.

T_IDLE

Idle.

T_INCON

Incoming connection pending.

T_OUTCON

Outgoing connection pending.

T_UNBND

Unbound.

If unsuccessful, `t_sync()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

TBADF

The specified file descriptor does not refer to a transport endpoint. This error may be returned when the `fd` has been previously closed or an erroneous number may have been passed to the call.

TPROTO

This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (`t_errno`).

TSTATECHNG

The transport endpoint is undergoing a state change.

TSYSERR

A system error has occurred during execution of this function.

tsyncro() — Wait for MTF subtask termination

Standards

| Standards / Extensions | C or C++ | Dependencies |
|-------------------------|----------|--------------|
| Language Environment | C only | |

Format

```
#include <mtf.h>

int tsyncro(int MTF_ANY|MTF_ALL|nn);
```

General description

Waits for termination of parallel functions under the [MVS environment](#).

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

The tsyncro() library function causes the main task to wait for the first subtask, a particular subtask, or all subtasks to finish executing all of the parallel functions that have been scheduled for them. You can monitor the completion of any, all, or a specific subtask by specifying:

MTF_ANY

To wait for the completion of any subtask.

MTF_ALL

To wait for the completion of all subtasks.

nn

To wait for the completion of the subtask having a *task_id* of *nn*. See “[tinit\(\) — Attach and initialize MTF subtasks](#)” on page 1869 for a description of *task_id*.

You can invoke tsyncro() from your main task program as often as necessary.

If tinit() is called by a program running under IMS, CICS, or DB2, the request will not be processed and the returned value will indicate that MTF calls are not supported under these systems.

Note: This function is *not* supported under the z/OS UNIX with the POSIX(ON) runtime option.

Returned value

If successful, tsyncro() will always return a value suitable for use as a target task on a subsequent tsched(). In particular, the return codes on success depend on the nature of the tsyncro() call, and the state of the subtasks at the time of the tsyncro() call as follows:

| Task_id passed to tsyncro() | Return code (if successful) |
|---|--|
| MTF_ANY (and at least one subtask not previously returned from a tsyncro()) | <i>nn</i> = <i>task_id</i> of first subtask to become free |
| MTF_ANY (and all subtasks have previously been returned from a tsyncro()) | MTF_ANY |

| Task_id passed to tsyncro() | Return code (if successful) |
|-----------------------------|-----------------------------|
| MTF_ALL | MTF_ANY |
| <i>nn = task_id</i> | <i>nn</i> |

If tinit() has not been successfully called before the tsyncro() call, tsyncro() indicates that MTF is inactive and returns one of the following values:

Error Code

Description

EINACTIVE

MTF is inactive.

ETASKABND

One or more subtasks have terminated abnormally.

ETASKID

The *task_id* argument specified is out of range.

Note: These values are macros. They can be found in the mtf.h header file.

Related information

- [“mtf.h — Multitasking facility functions” on page 45](#)
- [“tinit\(\) — Attach and initialize MTF subtasks” on page 1869](#)
- [“tsched\(\) — Schedule MTF subtask” on page 1902](#)
- [“tterm\(\) — Terminate MTF subtasks” on page 1912](#)

tterm() — Terminate MTF subtasks

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | C only | |

Format

```
#include <mtf.h>

int tterm(void);
```

General description

Restriction: This function is not supported in AMODE 64.

Terminates the MTF environment under the MVS environment. The function is invoked by a main task to await the completion of all parallel functions that were scheduled by tsched() and to detach all subtasks and remove the MTF environment created by tinit(), see [“tinit\(\) — Attach and initialize MTF subtasks” on page 1869](#).

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

If tinit() has not been successfully called before a tterm() call, tterm() indicates that MTF is already inactive.

If a `tterm()` call is not issued before main program termination, a system abend with completion code A03 will occur. The program's termination will terminate the main task while subtasks are still active even if all scheduled parallel functions have completed execution.

If `tinit()` is called by a program running under IMS, CICS, or DB2, the request will not be processed and the returned value will indicate that MTF calls are not supported under these systems.

Note: This function is *not* supported under the z/OS UNIX with the POSIX(ON) runtime option.

Returned value

If successful, detaching the subtasks and removing the MTF environment, `tterm()` returns `MTF_OK`.

If unsuccessful, `tsched()` returns one of the following values:

Error Code

Description

EINACTIVE

MTF is inactive.

ETASKABND

One or more subtasks have terminated abnormally.

Note: These values are macros. They can be found in the `mtf.h` header file ([“mtf.h — Multitasking facility functions”](#) on page 45).

Related information

- [“mtf.h — Multitasking facility functions”](#) on page 45

ttyname() — Get the name of a terminal

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

char *ttyname(int fildes);
```

General description

Returns a string containing the path name of the terminal associated with the given file descriptor, *fil*des. Subsequent calls to `ttyname()` may overwrite this string, because the pointer returned may point to static data.

Returned value

If successful, `ttyname()` returns a string containing a path name.

If unsuccessful because *fildev* is not a terminal, or the path name cannot be determined, `ttyname()` returns a NULL pointer.

Special behavior for XPG4: The `ttyname()` function sets `errno` to one of the following values:

Error Code
Description

EBADF
The *fildev* argument is not a valid open file descriptor.

ENOTTY
The *fildev* argument is not associated with a terminal.

Example

CELEBT16

```
/* CELEBT16

   This example provides the pathname of the terminal
   associated with stdin.

*/
#define _POSIX_SOURCE
#include <unistd.h>
#include <stdio.h>

main() {
    char *ret, tty[40];

    if ((ret = ttyname(STDIN_FILENO)) == NULL)
        perror("ttyname() error");
    else {
        strcpy(tty, ret);
        printf("The ttyname associated with my stdin is %s\n", tty);
    }
}
```

Output

The ttyname associated with my stdin is /dev/tty0000

Related information

- [“unistd.h — Implementation-specific functions” on page 77](#)
- [“ctermid\(\) — Generate path name for controlling terminal” on page 358](#)
- [“isatty\(\) — Test if descriptor represents a terminal” on page 903](#)
- [“ttynamer_r\(\) — Find path name of a terminal” on page 1914](#)

ttynamer_r() — Find path name of a terminal

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| Single UNIX Specification, Version 2 Single UNIX Specification, Version 3 | both | OS/390 V2R8 |

Format

```
#define _XOPEN_SOURCE 500
#include <unistd.h>

int ttypslot(int fdes, char *name, size_t namesize);
```

General description

The `ttypslot()` function stores the NULL-terminated path name of the terminal associated with the file descriptor, *fdes*, in the character array referenced by *name*. The array is *namesize* characters long and should have space for the name and the terminating NULL character. The maximum length of the terminal name is **TTY_NAME_MAX**.

Returned value

If successful, `ttypslot()` returns 0.

If unsuccessful, `ttypslot()` sets `errno` to one of the following values:

EBADF

The *fdes* argument is not a valid file descriptor.

ENOTTY

The *fdes* argument does not refer to a tty.

ERANGE

The value of *namesize* is smaller than the length of the string to be returned including the terminating NULL character.

Related information

- [“unistd.h — Implementation-specific functions” on page 77](#)
- [“isatty\(\) — Test if descriptor represents a terminal” on page 903](#)
- [“ctermid\(\) — Generate path name for controlling terminal” on page 358](#)

ttypslot() — Find the slot in the utmpx file of the current user

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

int ttypslot(void);
```

General description

The `ttypslot()` function returns the index of the current user's entry in the `utmpx` database. The current user's entry is an entry for which the `ut_line` member matches the name of a terminal device associated with any of the process's file descriptors 0, 1 or 2. The `ttypslot()` function is used to obtain the terminal device. The `"/dev/"` part returned by `ttypslot()` is not used when searching the `utmpx` database member `ut_line`.

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

If successful, `ttyslot()` returns the index of the current user's entry in the `utmpx` database.

If unsuccessful, `ttyslot()` returns -1 if an error was encountered while searching the database or if none of the file descriptors 0, 1, or 2 is associated with a terminal device.

No errors are defined.

Related information

- [“stdlib.h — Standard library functions” on page 65](#)
- [“endutxent\(\) — Close the utmpx database” on page 425](#)
- [“ttyname\(\) — Get the name of a terminal” on page 1913](#)

t_unbind() — Disable a transport endpoint

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <xti.h>

int t_unbind(int fd);
```

General description

Disables the transport endpoint specified by *fd* which was previously bound by `t_bind()`. On completion of this call, no further data or events destined for this transport endpoint will be accepted by the transport provider. An endpoint which is disabled by using `t_unbind()` can be enabled by a subsequent call to `t_bind()`.

Due to implementation-imposed restrictions, `t_unbind` does not affect descriptors in processes other than the caller which were derived from *fd* by normal descriptor inheritance. Processes cooperating on an endpoint in this way must explicitly provide their own synchronization for endpoint takedown.

Valid states: `T_IDLE`

Returned value

If successful, `t_unbind()` returns 0.

If unsuccessful, `t_unbind()` returns -1 and sets `errno` to one of the following values:

Error Code**Description**

TBADF

The specified file descriptor does not refer to a transport endpoint.

TLOOK

An asynchronous event has occurred on this transport endpoint.

TOUTSTATE

The function was issued in the wrong sequence.

TPROTO

This error indicates that a communication problem has been detected between XTI and the transport provider for which there is no other suitable XTI (`t_errno`).

TSYSERR

A system error has occurred during execution of this function.

Related information

- [“xti.h — _XOPEN_SOURCE_EXTENDED feature test macro” on page 81](#)
- [“t_bind\(\) — Bind an address to a transport endpoint” on page 1814](#)

twalk() — Binary tree walk

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <search.h>

void *twalk(const void *root, void (*action)(const void *, VISIT, int));
```

General description

The `twalk()` function traverses a binary search tree. The *root* argument is a pointer to the root node of the tree to be traversed. (Any node in a tree may be used as the root for a walk below that node.) The argument *action* is the name of a routine to be invoked at each node. This routine is, in turn, called with three arguments. The first argument is the address of the node being visited. The structure pointed to by this argument is unspecified and must not be modified by the application, but is guaranteed that a pointer-to-node can be converted to pointer-to-pointer-to-element to access the element stored in the node. The second argument is a value from an enumeration data type:

```
typedef enum {preorder, postorder, endorder, leaf } VISIT;
```

(defined in the `<search.h>` header), depending on whether this is the first, second or third time that the node is visited (during a depth-first, left-to-right traversal of the tree), or whether the node is a leaf. The third argument is the level of the node in the tree, with the root being level zero.

Threading Behavior: see [“tsearch\(\) — Binary tree search” on page 1903](#).

Special behavior for C++: Because C and C++ linkage conventions are incompatible, `twalk()` cannot receive a C++ function pointer as the argument. If you attempt to pass a C++ function pointer to `twalk()`, the compiler will flag it as an error. You can pass a C or C++ function to `twalk()` by declaring it as extern "C".

Returned value

twalk() returns no values.

No errors are defined.

tzset() — Set the time zone

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1 XPG4 XPG4.2 z/OS UNIX Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <time.h>

void tzset(void);
```

General description

The tzset() function uses the value of the environment variable TZ to set time conversion information used by ctime(), localtime(), mktime(), and strftime(). If TZ is absent from the environment, or it is incorrect, time-conversion information is obtained from the LC_TOD locale category.

tzset() also sets the external variable *tzname*:

```
extern char *tzname[2] = {"std", "dst"};
```

Here, *std* and *dst* are Standard and Daylight Savings time zone names, specified by TZ or the LC_TOD local category, respectively.

tzset() is called by ctime(), localtime(), mktime(), setlocale(), and strftime(). It can also be called explicitly by an application program.

The format of TZ values recognized by tzset() is as follows:

```
stdoffset[dst[offset][,rule]]
```

std and dst

Indicate no fewer than three, but not more than TZNAME_MAX, bytes that are the designation for the standard (*std*) and daylight savings (*dst*) time zones. If more than TZNAME_MAX bytes are specified for *std* or *dst*, tzset() truncates to TZNAME_MAX bytes. Only *std* is required; if *dst* is missing, daylight savings time does not apply in this locale. Uppercase and lowercase letters are explicitly allowed. Any character except a leading colon (:) or digits, the comma (,), the minus (-), the plus (+), and the NULL character are permitted to appear in these fields. The meaning of these letters and characters is unspecified.

offset

Indicates the value that must be added to the local time to arrive at Coordinated Universal Time (UTC). *offset* has the form: hh[:mm[:ss]] The minutes (mm) and seconds (ss) are optional. The hour (hh) is required and may be a single digit. *offset* following *std* is required. If no *offset* follows *dst*, daylight savings time is assumed to be 1 hour ahead of standard time. One or more digits may be used; the value is always interpreted as a decimal number. The hour must be between 0 and 24; minutes and seconds, if present, between 0 and 59. The difference between standard time *offset* and daylight savings time *offset* must be greater than or equal to 0, but the difference may not be greater than 24 hours. Use of values outside of these ranges causes tzset() to use the LC_TOD category rather than the TZ environment variable for time conversion information. An *offset* preceded by a minus (-) indicates a time zone east of the Prime Meridian. A plus (+) preceding *offset* is optional and indicates the time zone west of the Prime Meridian.

rule

Indicates when to change to and back from daylight savings time. The rule has the form: date[/time],date[/time]

The first date describes when the change from standard to daylight savings time occurs and the second date describes when the change back happens. Each time field describes when, in current local time, the change to the other time is made.

The format of date must be one of the following:

Jn

The Julian day *n* ($1 \leq n \leq 365$). Leap days are not counted. That is, in all years—including leap years—February 28 is day 59 and March 1 is day 60. It is impossible to explicitly refer to the occasional February 29.

n

The zero-based Julian day ($0 \leq n \leq 365$). Leap days are counted, and it is possible to refer to February 29.

Mm.n.d

The *d*th day ($0 \leq d \leq 6$) of week *n* of month *m* of the year ($1 \leq n \leq 5$, and $1 \leq m \leq 12$, where week 5 means “the last *d* day in month *m*,” which may occur in either the fourth or the fifth week). Week 1 is the first week in which the *d*th day occurs. Day zero is Sunday.

The time has the same format as offset except that no leading sign, minus (-) or plus (+), is allowed. The default, if time is not given, is 02:00:00.

If *dst* is specified and *rule* is not specified by TZ or in LC_TOD category, the default for the daylight savings time start date is M4.1.0 and for the daylight savings time end date is M10.5.0.

Special behavior for XPG4: The tzset() function sets the external variable `timezone` to the difference, in seconds, between Coordinated Universal Time (UTC) and local standard time. tzset() sets the external variable `daylight` to 0 if summer time conversions should never be applied for the time zone in use; otherwise to nonzero.

Since the external variables `timezone` and `daylight` are global to the process, they cannot be reliably used in a multithreaded application or an application running from a DLL. The runtime library provides two special functions, `__tzzone()` and `__dlght()`, which return the address of thread-specific versions of these external variables.

Special behavior for POSIX C: The tzset() function only parses the TZ environment variable if it is called from the initial processing thread (IPT) by a threaded application.

Note: This function is sensitive to time zone information which is provided by:

- The TZ environmental variable when POSIX(ON) and TZ is correctly defined, or by the _TZ environmental variable when POSIX(OFF) and _TZ is correctly defined.
- The LC_TOD category of the current locale if POSIX(OFF) or TZ is not defined.
- When neither TZ nor _TZ is defined, the current locale is interrogated for time zone information. If neither TZ nor _TZ is defined and LC_TOD time zone information is not present in the current locale, a default value is applied to local time. POSIX programs simply default to Coordinated Universal Time (UTC), while non-POSIX programs establish an offset from UTC based on the setting of the system clock. For more information about customizing a time zone to work with local time, see “Customizing a time zone” in *z/OS XL C/C++ Programming Guide*.

The time zone external variables tzname, timezone, and daylight declarations remain feature test protected in time.h.

Returned value

tzset() returns no values.

There are no documented errno values.

Example

CELEBT17

```
/* CELEBT17

   This example set time conversion information for
   Eastern Standard and Eastern Daylight Savings Time in the
   United States.

*/
#define _POSIX_SOURCE
#include <env.h>
#include <time.h>

int main(void)
{
    setenv("TZ", "EST5EDT", 1);
    tzset();
}
```

ualarm() — Set the interval timer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| XPG4.2 Single Unix Standard, Version 3 | both | POSIX(ON) |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

useconds_t ualarm(useconds_t uscs, useconds_t intrval)
```

General description

The `ualarm()` function causes the SIGALRM signal to be generated for the calling process after the number of real-time microseconds specified by the *uscs* argument has elapsed. When the *intrval* argument is nonzero, repeated timeout notification occurs with a period in microseconds specified by the *intrval* argument. If the notification signal, SIGALRM, is not caught or ignored, the calling process is terminated.

The `ualarm()` function is a simplified interface to `setitimer()` and uses the ITIMER_REAL interval timer.

Note: The `ualarm()` and `usleep()` functions have been moved to obsolescence in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The `setitimer()`, `timer_create()`, `timer_delete()`, `timer_getoverrun()`, `timer_gettime()`, or `timer_settime()` functions are preferred for portability.

Returned value

`ualarm()` returns the number of microseconds remaining from the previous `ualarm()`, `alarm()`, or `setitimer(ITIMER_REAL)` call.

If no timeouts are pending, `ualarm()` returns 0.

No `errno`s are defined for the `ualarm()` function.

__ucreate() — Create a heap using user-provided storage

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <uheap.h>

__uheapid_t __ucreate(void *block,
                      size_t size,
                      __uheap_cellpool_attrib_table_t *cellpool_attrib_table,
                      void *rsvd1,
                      void *rsvd2,
                      void *rsvd3,
                      void *rsvd4);
```

General description

The `__ucreate()` function creates a heap out of storage that is provided by the caller. The heap is divided up into cell pools based on the information provided in the `cellpool_attrib_table`. Up to 12 cell pools can be created within the heap. Note that this is a fixed-size heap; when storage within a given cell pool is exhausted, no additional storage will be allocated. `__ucreate()` returns a `uheapid` that is used to identify the heap on subsequent user-created heap function calls, such as `__umalloc()`, `__ufree()`, and `__uheapreport()` calls.

Parameter Description

block

A pointer to the storage which is to be used for the heap.

size

The size of the block of storage. Note that Language Environment reserves approximately 328 bytes of this storage for use in allocating heap management control blocks. Additional storage is reserved if storage report usage statistics are being collected for the heap. The amount of this storage is related to the largest cell size and the granularity of the statistics, and is calculated as: storage amount = $((\text{largestcellsize} + \text{granularity} - 1) / \text{granularity}) * 4$.

cellpool_attrib_table

A pointer to a structure describing the attributes of the cell pools to be created by `__ucreate()`.

The first field of the structure, `number_of_pools`, indicates the number of cell pools to be created. Up to 12 cell pools can be created in the heap.

The second field of the structure, `granularity`, indicates the granularity to which storage usage statistics is to be collected. This value must be zero, or a power of 2 greater than or equal to 8. If the value is zero, then statistics are not collected.

Following these words are pairs of words describing the attributes of each cell pool in the heap:

The first field in the pair, `size`, is the size of the cell in the cell pool. The cell size must be a multiple of 8 and greater than or equal to 8, up to a maximum of 64K (65536). Note that Language Environment adds an additional 8 bytes to the size of the cell for use in managing the cells. The second field in the pair, `count`, is the number of cells of this size to be allocated. Note the minimum is four.

rsvd1-rsvd4

Reserved for future use.

Returned value

If successful, `__ucreate()` returns a `uheapid`.

If unsuccessful, `__ucreate()` returns -1 and sets `errno` to `EINVAL`.

Related information

- [“__umalloc\(\) — Allocate storage from a user-created heap” on page 1928](#)

[__ufree\(\) — Return storage to a user-created heap](#)

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <uheap.h>

void __ufree(__uheapid_t heapid, void *ptr);
```

General description

The `__ufree()` function returns storage to the heap identified by the `heapid`. If the returned storage does not belong to the given heap, the result is unpredictable.

Parameter

Description

heapid

The identifier of the user-created heap to which the storage is to be returned.

ptr

A pointer to the storage to be returned to the heap.

Returned value

`__ufree()` returns no values.

Related information

- [“uheap.h — Heap storage” on page 77](#)
- [“__ucreate\(\) — Create a heap using user-provided storage” on page 1922](#)

__uheapreport() – Produce a storage report for a user-created heap

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <uheap.h>

void __uheapreport(__uheapid_t heapid);
```

General description

The `__uheapreport()` function generates a report of the storage used within the user-created heap identified by *heapid*. The report is directed to the ddname specified in the MSGFILE runtime option except for AMODE 64 applications, in which case the report is directed to the stderr stream. The report format is similar to the heap pools portion of the storage report generated for the RPTSTG runtime option.

Statistics for the user-created heap will only be collected if the granularity field of the `cellpool_attrb_table` passed to `__ucreate()` is nonzero and a valid value.

Parameter

Description

heapid

The identifier of the user-created heap for which a report is to be produced.

Returned value

`__uheapreport()` returns no values.

Related information

- [“uheap.h – Heap storage” on page 77](#)
- [“__ucreate\(\) – Create a heap using user-provided storage” on page 1922](#)

ulimit() – Get or set process file size limits

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <ulimit.h>
```

```
long int ulimit(int cmd, ...);
```

General description

The `ulimit()` function provides control over the process file size limits. The *cmd* argument controls whether the file size limits are obtained or set. The *cmd* argument can be one of the following, defined in `<ulimit.h>`:

UL_GETFSIZE

Return the soft (current) file size limit of the process. The limit returned is in units of 512-byte blocks. The return value is the integer portion of the soft file size limit divided by 512. Refer to the `setrlimit()` function, `RLIMIT_FSIZE` resource description for more detail.

UL_SETFSIZE

Set the hard (maximum) and soft (current) file size limits for output operations of the process. The value of the second argument is used, and is treated as a long int. Refer to the `setrlimit()` function, `RLIMIT_FSIZE` resource description for more detail and restrictions on lowering and raising file size limits. The hard and soft file size limits are set to the specified value multiplied by 512. The new file size limit (in 512 byte increments) is returned.

Returned value

If successful, `ulimit()` returns the value of the requested limit.

If unsuccessful, `ulimit()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

The *cmd* argument is not valid.

EPERM

To increase the file size limit, superuser authority is required.

Related information

- [“ulimit.h — ulimit commands” on page 77](#)

ulltoa() — Convert unsigned long long into a string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R5 |

Format

```
#define _OPEN_SYS_ITOA_EXT
#include <stdlib.h>

char * ulltoa(uint64_t ll, char * buffer, int radix);
```

Compile Requirement

Use of this function requires the long long data type. See [z/OS XL C/C++ Language Reference](#) for information on how to make long long available.

General description

The `ulltoa()` function converts the `uint64_t ll` into a character string. The string is placed in the buffer passed, which must be large enough to hold the output. The radix values can be OCTAL, DECIMAL, or HEX. When the radix is DECIMAL, `ulltoa()` produces the same result as the following statement:

```
(void) sprintf(buffer, "%llu", ll);
```

with `buffer` the returned character string. When the radix is OCTAL, `ulltoa()` formats `uint64_t ll` into an octal constant. When the radix is HEX, `ulltoa()` formats `uint64_t ll` into a hexadecimal constant. The hexadecimal value will include lower case `abcdef`, as necessary.

Returned value

String pointer (same as `buffer`) will be returned. When passed an invalid radix argument, function will return NULL and set `errno` to `EINVAL`.

Portability considerations

This is a non-standard function. Even though the prototype given is commonly used by compilers on other platforms, there is no guarantee that this function will behave the same on all platforms, in all cases. You can use this function to help port applications from other platforms, but you should avoid using it when writing new applications, in order to ensure maximum portability.

Example

CELEBU12

```
/* CELEBU12

   This example reads uint64_t and formats it to a decimal,
   octal, hexadecimal constants converted to a character string.

*/

#define _OPEN_SYS_ITOA_EXT
#include <stdio.h>
#include <stdlib.h>

int main ()
{
    uint64_t i;
    char buffer [sizeof(uint64_t)*8+1];
    printf ("Enter a number: ");
    if (scanf ("%llu",&i) == 1) {
        ulltoa (i,buffer,DECIMAL);
        printf ("decimal: %s\n",buffer);
        ulltoa (i,buffer,HEX);
        printf ("hexadecimal: %s\n",buffer);
        ulltoa (i,buffer,OCTAL);
        printf ("octal: %s\n",buffer);
    }
    return 0;
}
```

Output

If the input is 1234, then the output should be:

```
decimal: 1234
hexadecimal: 4d2
octal: 2322
```

ultoa() — Convert unsigned long into a string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R5 |

Format

```
#define _OPEN_SYS_ITOA_EXT
#include <stdlib.h>

char * ultoa(unsigned long l, char * buffer, int radix);
```

General description

The `ultoa()` function converts the unsigned long `l` into a character string. The string is placed in the buffer passed, which must be large enough to hold the output. The radix values can be OCTAL, DECIMAL, or HEX. When the radix is DECIMAL, `ultoa()` produces the same result as the following statement:

```
(void) sprintf(buffer, "%lu", l);
```

with `buffer` the returned character string. When the radix is OCTAL, `ultoa()` formats unsigned long `l` into an octal constant. When the radix is HEX, `ultoa()` formats unsigned long `l` into a hexadecimal constant. The hexadecimal value will include lower case `abcdef`, as necessary.

Returned value

String pointer (same as `buffer`) will be returned. When passed an invalid radix argument, function will return NULL and set `errno` to `EINVAL`.

Portability considerations

This is a non-standard function. Even though the prototype given is commonly used by compilers on other platforms, there is no guarantee that this function will behave the same on all platforms, in all cases. You can use this function to help port applications from other platforms, but you should avoid using it when writing new applications, in order to ensure maximum portability.

Example

CELEBU11

```
/* CELEBU11

   This example reads an unsigned long and formats it to a decimal,
   octal, hexadecimal constants converted to a character string.

*/

#define _OPEN_SYS_ITOA_EXT
#include <stdio.h>
#include <stdlib.h>

int main ()
{
```

```
unsigned long i;
char buffer [sizeof(unsigned long)*8+1];
printf ("Enter a number: ");
if (scanf ("%lu",&i) == 1) {
    ultoa (i,buffer,DECIMAL);
    printf ("decimal: %s\n",buffer);
    ultoa (i,buffer,HEX);
    printf ("hexadecimal: %s\n",buffer);
    ultoa (i,buffer,OCTAL);
    printf ("octal: %s\n",buffer);
}
return 0;
}
```

Output

If the input is 1234, then the output should be:

```
decimal: 1234
hexadecimal: 4d2
octal: 2322
```

__umalloc() – Allocate storage from a user-created heap

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <uheap.h>

void *__umalloc(__uheapid_t heapid, size_t size);
```

General description

The __umalloc() function allocates storage from the heap identified by the heapid. __umalloc() will search for an available cell within the cell pool that contains cells at least as large and closest in size to the requested size.

Parameter

Description

heapid

The identifier of the user-created heap from which the storage is to be allocated.

size

The amount of storage to be allocated.

Returned value

If successful, `__umalloc()` returns a pointer to the reserved cell.

If a cell of the required size is not available, if size was larger than the largest available cell size, or if size was specified as 0, `__umalloc()` returns `NULL`.

If there is not enough storage or if the requested size was too large, `__umalloc()` returns `NULL` and sets `errno` to one of the following values:

Error Code

Description

E2BIG

Requested amount of storage is larger than the largest available cell size

ENOMEM

Insufficient memory is available

Related information

- [“uheap.h — Heap storage” on page 77](#)
- [“__ucreate\(\) — Create a heap using user-provided storage” on page 1922](#)
- [“__ufree\(\) — Return storage to a user-created heap” on page 1923](#)
- [“__uheapreport\(\) — Produce a storage report for a user-created heap” on page 1924](#)

umask() — Set and retrieve file creation mask

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <sys/stat.h>

mode_t umask(mode_t newmask);
```

General description

Changes the file creation mask of the process. *newmask* specifies new file-permission bits for the file creation mask of the process.

This mask restricts the setting of (or turns off) file-permission bits specified in the *mode* argument that is used with all `open()`, `creat()`, `mkdir()`, and `mkfifo()` functions issued by the current process. File-permission bits set to 1 in the file creation mask are set to 0 in the file-permission bits of files that are created by the process.

For example, if a call to `open()` specifies a *mode* argument with file-permission bits, the file creation mask of the process affects the *mode* argument; bits that are 1 in the mask are set to 0 in the *mode* argument, and therefore in the mode of the created file.

Only the file-permission bits of the new mask are used. The meaning of other bits is implementation-defined. For more information on these symbols, refer to [“chmod\(\) — Change the mode of a file or directory”](#) on page 274.

The `_EDC_UMASK_DFLT` environment variable controls how the C runtime library sets the default umask.

- When `_EDC_UMASK_DFLT` is not set:
 - If the system parameter `UMASK` is set to a valid value, the default umask value is the same as that value.
 - If the system parameter `UMASK` is not set, the C runtime library sets the default umask value to 022.
- When `_EDC_UMASK_DFLT` is set to one of the following values:

NO (case insensitive)

The C runtime library does not change the umask. The default umask value depends on the value of the system parameter `UMASK`.

A valid octal value

The library uses this octal value as the default umask value no matter how the system parameter `UMASK` is set.

Any other value

When the system parameter `UMASK` is set to a valid value, the C runtime library does not change default umask. When the system parameter `UMASK` is not set, the C runtime library set the default umask value to 022.

Returned value

`umask()` is always successful and returns the previous value of the file creation mask.

There are no documented `errno` values.

Example

CELEBU01

```
/* CELEBU01

   This example will work only from C/MVS, not C++/MVS.

*/
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
    int fd;
    mode_t oldmask;

    printf("Your old umask is %i\n",oldmask=umask(S_IRWXG));
    if ((fd = creat("umask.file", S_IRWXU|S_IRWXG)) < 0)
        perror("creat() error");
    else {
        system("ls -l umask.file");
        close(fd);
        unlink("umask.file");
    }
    umask(oldmask);
}
```

Output

```
-IWX----- 1 WELLIE  SYS1          0 Apr 19 14:50 umask.file
```

```

General description

`umount()` supports different input parameters and functions when it is defined under different feature test macros.

When only `_OPEN_SYS` is defined:

Removes a file system from the file hierarchy, or changes the mount mode of a mounted file system between read-only and read/write. The *filesystem* argument is a NULL-terminated string that contains the file system name. This is the same name that is specified when the file system is mounted.

To unmount a file system, the caller must be an authorized program, or must be running for a user with appropriate privileges.

The *mtm* argument can be one of the following:

MTM_UMOUNT

A normal unmount request. If the files in the named file system are not in use, the unmount is done. Otherwise, the request is rejected.

MTM_DRAIN

An unmount drain request. The requester is willing to wait for all uses of this file system to be ended normally before the file system is unmounted.

MTM_IMMED

An immediate unmount request. The file system is unmounted immediately, forcing any users of files in the specified file system to fail. All data changes that were made up to the time of the request are saved. If there is a problem saving the data, the unmount request fails.

MTM_FORCE

A forced unmount request. The file system is unmounted immediately, forcing any users of any files in the specified file system to fail. All data changes that were made up to the time of the request are saved. If there is a problem saving the data, the request continues, and the data may be lost. To prevent lost data, issue an immediate `umount()` request before issuing a forced `umount()` request.

MTM_RESET

A reset unmount request. This allows a previous unmount drain request to be stopped.

MTM_REMOUNT

A remount request. This changes the mount mode of a file system from read-only to read/write or from read/write to read-only. If neither `MTM_RDONLY` nor `MTM_RDWR` is specified, the mode is set to the opposite of its current state. If a mode is specified, it must be the opposite of the current state.

MTM_SAMEMODE

A remount request to unmount and mount back without changing the mount mode. If either `MTM_RDONLY` or `MTM_RDWR` is also specified, it must be the current state. This can be used to attempt to regain use of a file system that has had I/O errors.

When both `_OPEN_SYS` and `_XPLATFORM_SOURCE` are defined:

`umount()` removes the attachment of the topmost file system that is mounted on *target*.

To unmount a file system, the caller must be an authorized program, or must be running for a user with appropriate privileges.

Returned value

If successful, `umount()` returns 0.

If unsuccessful, `umount()` returns -1 and sets `errno` to one of the following values:

When only `_OPEN_SYS` is defined:

Error Code

Description

EBUSY

The file system is busy, for one of these reasons:

- A `umount()` (`MTM_UMOUNT`) is requested, and the file system has open files or other file systems that are mounted under it.
- A file system is mounted on the requested file system.
- A `RESET` is requested, and the previous `umount()` request is either immediate or forced, instead of a drain request.
- There is a `umount()` request in progress for the specified file system.
- A `umount()` drain request is being reset.

EINTR

`umount()` is interrupted by a signal.

EINVAL

A parameter is incorrectly specified. Verify the spelling of the file system name and the setting of *mtm*.

EIO

An I/O error occurs.

EPERM

Superuser authority is required to issue an unmount.

When both `_OPEN_SYS` and `_XPLATFORM_SOURCE` are defined:

Error Code

Description

EBUSY

target is busy for one of the following reasons:

- A `umount()` (`MTM_UMOUNT`) is requested, and the file system has open files or other file systems that are mounted under it.
- A file system is mounted on the requested file system.
- There is an unmount request in progress for the specified file system.

EINTR

`umount()` is interrupted by a signal.

EINVAL

target is not a mount point.

EIO

An I/O error occurs.

ENAMETOOLONG

A path name is longer than `PATH_MAX`, or some component of path name is longer than `NAME_MAX` characters.

ENOENT

A target is empty or has a nonexistent component.

ENOTDIR

A component of the path prefix is not a directory.

EPERM

Superuser authority is required to issue an unmount.

Example**CELEBU02**

```
/* CELEBU02

   This example removes a file, using umount().

*/
#define _OPEN_SYS 1
#include <sys/stat.h>
#include <stdio.h>
#include <unistd.h>

main() {
    char HFS[]="POSIX.NEW.HFS";
    char filesystem[9]="HFS ";
    setvbuf(stdout, NULL, _IOLBF, 0);
    puts("before umount()");
    system("df -Pk");
    if (umount(HFS, MTM_UMOUNT) != 0)
        perror("umount() error");
    else {
        puts("After umount()");
        system("df -Pk");
    }
}
```

Output

```
before umount()
Filesystem 1024-blocks      Used Available Capacity Mounted on
POSIX.NEW.HFS      200          20         180      10%    /new_fs
POSIX.ROOT.FS     9600        8180        1420      85%    /

After umount()
Filesystem 1024-blocks      Used Available Capacity Mounted on
POSIX.ROOT.FS     9600        8180        1420      85%    /
```

umount2() — Unmount file system

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <sys/mount.h>

int umount2(const char *target, int flags);
```

General description

`umount2()` removes the attachment of the topmost file system that is mounted on *target*.

To unmount a file system, the caller must be an authorized program, or must run for a user with appropriate privileges.

The *flags* specifies the flag that controls the behavior of the operation. The valid value of *flags* is:

MNT_DETACH

Perform a lazy unmount:

1. Make the mount unavailable for new accesses.
2. Disconnect the file system and all file systems that are mounted under it from each other and from the mount table.
3. Unmount when the mount ceases to be busy.

An unmount drain request. The requester waits for all uses of this file system to be ended normally before the file system is unmounted.

Returned value

If successful, `umount2()` returns 0.

If unsuccessful, `umount2()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EBUSY

target cannot be unmounted because it is busy for one of the following reasons:

- A `umount2()` is requested, and the attached file system has open files or other file systems that are mounted under it.
- A file system is mounted on the requested file system.
- There is an unmount request in progress for the specified file system.

EINTR

`umount2()` is interrupted by a signal.

EINVAL

target is not a mount point.

`umount2()` is called with an invalid flag value in *flags*.

EIO

An I/O error occurs.

ENAMETOOLONG

A target is longer than PATH_MAX, or some component of path name is longer than NAME_MAX characters.

ENOTDIR

A component of the path prefix is not a directory.

ENOENT

A target is empty or has a nonexistent component.

EPERM

Superuser authority is required to issue an unmount.

Related information

- [“sys/mount.h — File system mount and unmount” on page 69](#)

uname() — Display current operating system name

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <sys/utsname.h>

int uname(struct utsname *name);
```

General description

The `uname()` function retrieves information identifying the operating system you are running on. The argument *name* points to a memory area where a structure describing the operating system the process is running on can be stored.

The information about the operating system is returned in a `utsname` structure, which has the following elements:

char *sysname;

The name of the implementation of the operating system.

char *nodename;

The node name of this particular machine. The node name is set by the `SYSNAME` sysparm (specified at IPL), and usually differentiates machines running at a single location.

char *release;

The current release level of the implementation.

char *version;

The current version level of the release.

char *machine;

The name of the hardware type the system is running on.

Each of the utsname structure elements is a normal C string, terminated with a NULL character.

As of OS/390 Release 2, the `uname()` function will return "OS/390" as the *sysname* value, even if the true name of the operating system is different. This is for compatibility purposes. The version value will increase at every new version of the operating system. The release value will increase at every new release of the operating system.

Table 71 on page 1936 lists the operating system names and corresponding values returned by the `uname()` function. To retrieve the true operating system name, version, and release, use the `__osname()` function.

Table 71. Operating system information returned by the `uname()` function

| Operating system | Sysname | Release | Version |
|------------------|---------|---------|---------|
| z/OS 3.2 | OS/390 | 30.00 | 05 |
| z/OS 3.1 | OS/390 | 29.00 | 04 |
| z/OS 2.5 | OS/390 | 28.00 | 04 |

Returned value

If successful, the `uname()` function returns a non-negative value.

If unsuccessful, the `uname()` function returns -1. An `errno` might be set to indicate the reason for the failure, but no `errno` values are specified by the POSIX.1 standard.

Example

CELEBU03

```
/* CELEBU03

   This example gets information about the system you are running on.

*/
#define _POSIX_SOURCE
#include <sys/utsname.h>
#include <stdio.h>

main() {
    struct utsname uts;

    if (uname(&uts) < 0)
        perror("uname() error");
    else {
        printf("Sysname: %s\n", uts.sysname);
        printf("Nodename: %s\n", uts.nodename);
        printf("Release: %s\n", uts.release);
        printf("Version: %s\n", uts.version);
        printf("Machine: %s\n", uts.machine);
    }
}
```

Output

```
Sysname:  OS/390
Nodename: SY1
Release:  30.00
Version:  05
Machine:  8561
```

uncaught_exception() — Determine if an exception is being processed

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| ANSI/ISO C++ | C++ only | z/OS V1R2 |

Format

```
#include <exception>

bool uncaught_exception(void);
```

General description

The `uncaught_exception()` function returns true only if a thrown exception is currently being processed. When `uncaught_exception()` is true, throwing an exception can result in a call of `terminate()`.

Returned value

`uncaught_exception()` returns true after completing evaluation of a throw expression and before completing initialization of the exception declaration in the matching handler or calling `unexpected()` as a result of the throw expression.

Otherwise, `uncaught_exception()` returns false.

Example

```
#include <exception>
#include <iostream>

using namespace std;

class X
{
public:
    ~X ();
};

X::~X()
{
    if (uncaught_exception ())
        printf (" X::~X called during stack unwind\n");
    else
        printf (" X::~X called normally\n");
}

int main()
{
    X x1;
    try
    {
        X x2;
        throw 1;
    }
    catch (...) { /*...*/ }
    return 0;
}

// under a Standard-conforming implementation, this program yields
```

```
// X::~X called during stack unwind
// X::~X called normally
```

UnDoExportWorkUnit() — WLM undo export service

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | OS/390 V2R9 |

Format

```
#include <sys/__wlm.h>

int UnDoExportWorkUnit(wlmxtok_t *exporttoken, unsigned long *conntoken);
```

AMODE 64:

```
#include <sys/__wlm.h>

int UnDoExportWorkUnit(wlmxtok_t *exporttoken, unsigned int *conntoken);
```

General description

Undoes an earlier request to export an enclave using the ExportWorkUnit() function. The caller is expected to invoke UnDoExportWorkUnit() after all importing systems have invoked the UnDoImportWorkUnit() function.

The UnDoExportWorkUnit() function uses the following parameters:

***exporttoken**

Points to a work unit export token that was returned from a call to ExportWorkUnit().

***conntoken**

Specifies the connect token that represents the connection to WLM.

Returned value

If successful, UnDoExportWorkUnit() returns 0.

If unsuccessful, UnDoExportWorkUnit() returns -1 and sets errno to one of the following values:

Error Code

Description

EFAULT

An argument of this function contained an address that was not accessible to the caller.

EINVAL

An argument of this function contained a value that is not correct.

EMVSSAF2ERR

An error occurred in the security product.

EMVSWLMERROR

A WLM service failed. Use `__errno2()` to obtain the WLM service reason code for the failure.

EPERM

The calling thread's address space is not permitted to the BPX.WLMSEVER Facility class. The caller's address space must be permitted to the BPX.WLMSEVER Facility class, if the BPX.WLMSEVER class is defined. If BPX.WLMSEVER is not defined, the calling process is not defined as a superuser (UID=0).

UnDoImportWorkUnit() — WLM undo import service

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | OS/390 V2R9 |

Format

```
#include <sys/__wlm.h>

int UnDoImportWorkUnit(wlmxtok_t *exporttoken, unsigned long *conntoken);
```

AMODE 64:

```
#include <sys/__wlm.h>

int UnDoImportWorkUnit(wlmxtok_t *exporttoken, unsigned int *conntoken);
```

General description

Undoes an earlier request to import an enclave using the `ImportWorkUnit()` function.

The `UnDoImportWorkUnit()` function uses the following parameters:

***exporttoken**

Points to a work unit export token that was returned from a call to `ExportWorkUnit()`.

***conntoken**

Specifies the connect token that represents the connection to WLM.

Returned value

If successful, `UnDoImportWorkUnit()` returns 0.

If unsuccessful, `UnDoImportWorkUnit()` returns -1 and sets `errno` to one of the following values:

Error Code**Description****EFAULT**

An argument of this function contained an address that was not accessible to the caller.

EINVAL

An argument of this function contained a value that is not correct.

EMVSSAF2ERR

An error occurred in the security product.

EMVSWLMERROR

A WLM service failed. Use `__errno2()` to obtain the WLM service reason code for the failure.

EPERM

The calling thread's address space is not permitted to the BPX.WLMSERVER Facility class. The caller's address space must be permitted to the BPX.WLMSERVER Facility class, if the BPX.WLMSERVER class is defined. If BPX.WLMSERVER is not defined, the calling process is not defined as a superuser (UID=0).

unexpected() — Handle exception not listed in exception specification

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| ANSI/ISO C++ | C++ only | |

Format

```
#include <exception>

void unexpected(void);
```

General description

The `unexpected()` function is part of the z/OS XL C++ error handling mechanism. If `unexpected()` is called directly by the program, the `unexpected_handler` is the one most recently set by a call to `set_unexpected()`. If `unexpected()` is called when control leaves a function by a thrown exception of a type not permitted by an exception specification for the function, as in:

```
void f() throw()      // function may throw no exceptions
{throw "bad"; }      // throw calls unexpected()
```

the `unexpected_handler` is the one in effect immediately after evaluating the throw expression.

An `unexpected_handler` may not return to its caller. It may terminate execution by:

- Throwing an object of a type listed in the exception specification (or an object of any type if the `unexpected_handler` is called directly by the program).
- Throwing an object of type `bad_exception`.
- Calling `terminate()`, `abort()`, or `exit(int)`.

If `set_unexpected()` has not yet been called, then `unexpected()` calls `terminate()`.

In a multithreaded environment, if a thread throws an exception that is not listed in its exception specification, then `unexpected()` is called. The default for `unexpected()` is to call `terminate()`, which defaults to calling `abort()`, which then causes a SIGABRT signal to be generated to the thread issuing the throw. If the SIGABRT signal is not caught, the process is terminated. You can replace the default `unexpected()` behavior for all threads in the process by using the `set_unexpected()` function. One possible use of `set_unexpected()` is to call a function which issues a `pthread_exit()`. If this is done, a throw of a condition by a thread that is not in the exception specification results in thread termination, but not process termination.

Returned value

`unexpected()` returns no values.

Refer to *z/OS XL C/C++ Language Reference* for more information about z/OS XL C++ exception handling, including the `unexpected()` function.

Related information

- [“exception — Exception handling” on page 87](#)
- [“set_unexpected\(\) — Register a function for unexpected\(\)” on page 1587](#)

ungetc() — Push character onto input stream

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C POSIX.1 XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```
#include <stdio.h>

int ungetc(int c, FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int ungetc_unlocked(int c, FILE *stream);
```

General description

Pushes the character specified by the value of `c` converted to the unsigned char back onto the given input *stream*. The pushed-back characters are returned by any subsequent read on the same stream in the reverse order of their pushing. That is, the last character pushed will be returned first.

Up to 4 characters can be pushed back to a given input stream. You can call `ungetc()` up to 4 times consecutively; this will result in 4 characters being pushed back in total.

The *stream* must be open for reading. A subsequent read operation on the *stream* starts with `c`. You cannot push EOF back on the stream using `ungetc()`. A successful call to the `ungetc()` function clears the EOF indicator for the stream.

Characters pushed back by `ungetc()`, and subsequently not read in, will be erased if a `fseek()`, `fsetpos()`, `rewind()`, or `fflush()` function is called before the character is read from the *stream*. After all the pushed-back characters are read in, the file position indicator is the same as it was before the characters were pushed back.

Each character of pushback backs up the file position by one byte. This affects the value returned by `ftell()` or `fgetpos()`, the result of an `fseek()` using `SEEK_CUR`, or the result of an `fflush()`. For example, consider a file that contains: a b c d e f g h

After you have just read 'a', the current file position is at the start of 'b'. The following operations will all result in the file position being at the start of 'a', ready to read 'a' again.

```
/* 1 */      ungetc('a', fp);
              fflush(fp); /* flushes ungetc char and keeps position */

/* 2 */      ungetc('a', fp);
              pos = ftell(fp); /* points to first character */
              fseek(fp, pos, SEEK_SET);

/* 3 */      ungetc('a', fp);
              fseek(fp, 0, SEEK_CUR) /* starts at new file pos'n */

/* 4 */      ungetc('a', fp);
              fgetpos(fp, &fpos); /* gets position of first char */
              fsetpos(fp, &fpos);
```

You can use the environment variable `_EDC_COMPAT` to cause a z/OS XL C/C++ application to ignore `ungetc()` characters for `fflush()`, `fgetpos()`, and `fseek()` using `SEEK_CUR`. For more details, see [z/OS XL C/C++ Programming Guide](#).

The `ungetc()` function is not supported for files opened with `type=record` or `type=blocked`.

`ungetc()` has the same restriction as any read operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

`ungetc_unlocked()` is functionally equivalent to `ungetc()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

If successful, `ungetc()` returns the integer argument `c` converted to an unsigned `char`.

If `c` cannot be pushed back, `ungetc()` returns EOF.

`ungetc()` is treated as a read operation. A flush or reposition is required after a call to `ungetc()` and before the next write operation.

Example

CELEBU04

```
/* CELEBU04

In this example, the while statement reads decimal digits
from an input data stream by using arithmetic statements to
compose the numeric values of the numbers as it reads them.
When a nondigit character appears before the EOF, &ungetc.
replaces it in the input stream so that later input functions
can process it.

*/
#include <stdio.h>
#include <ctype.h>

int main(void)
{
```

```

FILE *stream;
int ch;
unsigned int result = 0;

stream = fopen("myfile.dat","r+");
while ((ch = getc(stream)) != EOF && isdigit(ch))
{
    result = result * 10 + ch - '0';
}
printf("result is %i\n",result);
if (ch != EOF)
{
    ungetc(ch,stream);          /* Put the nondigit character back */
    ch=getc(stream);
    printf("value put back was %c\n",ch);
}
}

```

ungetwc() — Push a wide character onto a stream

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```

#include <wchar.h>

wint_t ungetwc(wint_t wc, FILE *stream);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

wint_t ungetwc_unlocked(wint_t wc, FILE *stream);

```

General description

Pushes the wide character specified by *wc* back onto the input stream pointed to by *stream*. The pushed-back wide characters will be returned by subsequent reads on that stream in the reverse order of their pushing. A successful intervening call (with the stream pointed to by *stream*) to a file positioning function (*fseek()*, *fsetpos()*, or *rewind()*) discards any pushed-back wide characters for the stream. The external storage corresponding to the stream is unchanged. There is always at least one wide character of push-back.

If the value of *wc* equals that of the macro *WEOF*, the operation fails and the input stream is unchanged.

A successful call to the *ungetwc()* function clears the EOF indicator for the stream. The value of the file position indicator for the stream after reading or discarding all pushed-back wide characters is the same as it was before the wide characters were pushed back.

For a text stream, the file position indicator is backed up by one wide character. This affects `ftell()`, `fflush()`, `fseek()` using `SEEK_CUR`, and `fgetpos()`. The environment variable, `_EDC_COMPAT` can be used to cause a pushed-back wide char to be ignored by `fflush()`, `fseek()` with `SEEK_CUR`, and `fgetpos()`. For details, see [z/OS XL C/C++ Programming Guide](#).

For a binary stream, the position indicator is unspecified until all characters are read or discarded, unless the last character is pushed back, in which case the file position indicator is backed up by one wide character. This affects `ftell()` and `fseek()` with `SEEK_CUR`, `fgetpos()`, and `fflush()`. The environment variable `_EDC_COMPAT` can be used to cause the pushed-back wide character to be ignored by `fflush()`, `fgetpos()`, and `fseek()`.

`ungetwc()` is not supported for files opened with `type=record` or `type=blocked`.

`ungetwc()` has the same restriction as any read operation for a read immediately following a write, or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

`ungetwc_unlocked()` is functionally equivalent to `ungetwc()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

If successful, `ungetwc()` returns the wide character pushed back after conversion.

If unsuccessful, `ungetwc()` returns `WEOF`.

Notes:

1. For z/OS XL C/C++ applications, only 1 wide character can be pushed back.
2. The position on the stream after a successful `ungetwc()` is one wide character before the current position. See [z/OS XL C/C++ Programming Guide](#) for details on backing up a wide char.

Example

```
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    FILE    *stream;
    wint_t   wc;
    unsigned int result = 0;
    :
    while ((wc = fgetwc(stream)) != WEOF && iswdigit(wc))
        result = result * 10 + wc - L'0';

    if (wc != WEOF)
        ungetwc(wc, stream);
    /* Put the nondigit wide character back */
}
```

unlink() — Remove a directory entry

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

int unlink(const char *pathname);
```

General description

Removes a directory entry. This unlink() deletes the link named by *pathname* and decrements the link count for the file itself.

pathname can refer to a pathname, a link, or a symbolic link. If the *pathname* refers to a symbolic link, unlink() removes the symbolic link but not any file or directory named by the contents of the symbolic link.

If the link count becomes 0 and no process currently has the file open, the file itself is deleted. The space occupied by the file is freed for new use, and the current contents of the file are lost. If one or more processes have the file open when the last link is removed, unlink() removes the link, but the file itself is not removed until the last process closes the file.

unlink() cannot be used to remove a directory; use rmdir() instead.

If unlink() succeeds, the change and modification times for the parent directory are updated. If the file's link count is not 0, the change time for the file is also updated. If unlink() fails, the link is not removed.

Returned value

If successful, unlink() returns 0.

If unsuccessful, unlink() returns -1 and sets errno to one of the following values:

Error Code

Description

EACCES

The process did not have search permission for some component of *pathname*, or did not have write permission for the directory containing the link to be removed.

EBUSY

pathname cannot be unlinked because it is currently being used by the system or some other process.

ELOOP

A loop exists in symbolic links. This error is issued if more than POSIX_SYMLINK_MAX symbolic links are detected in the resolution of *pathname*.

ENAMETOOLONG

pathname is longer than **PATH_MAX** characters, or some component of *pathname* is longer than **NAME_MAX** characters while _POSIX_NO_TRUNC is in effect. For symbolic links, the length of the pathname string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values can be determined using pathconf().

ENOENT

pathname does not exist, or it is an empty string.

ENOTDIR

Some component of the *pathname* prefix is not a directory.

EPERM

pathname is a directory, and `unlink()` cannot be used on directories.

EROFS

The link to be removed is on a read-only file system.

Example

CELEBU06

```
/* CELEBU06

   This example removes a directory entry, using unlink().

*/
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdio.h>

main() {
    int fd;
    char fn[]="unlink.file";

    if ((fd = creat(fn, S_IWUSR)) < 0)
        perror("creat() error");
    else {
        close(fd);
        if (unlink(fn) != 0)
            perror("unlink() error");
    }
}
```

unlinkat() — Remove a directory or directory entry

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1-2008 Single UNIX Specification, Version 4 | both | |

Format

```
#define _POSIX_C_SOURCE 200809L
#include <fcntl.h>          /* Definition of AT_* constants */
#include <unistd.h>

int unlinkat(int dirfd, const char *pathname, int flags);
```

General description

`unlinkat()` operates in the same way as either `unlink()` or `rmdir()`, depending on whether or not *flags* includes the `AT_REMOVEDIR` flag except for the following differences.

- If *pathname* is relative, it is interpreted relative to the directory that is referred to by the file descriptor *dirfd* (rather than relative to the current working directory of the calling process, as is done by `unlink()` and `rmdir()` for a relative path name).
- If *pathname* is relative and *dirfd* is the special value `AT_FDCWD`, *pathname* is interpreted relative to the current working directory of the calling process (like `unlink()` and `rmdir()`).
- If *pathname* is absolute, *dirfd* is ignored.

flags is a bit mask that can either be specified as 0, or by ORing together flag values that control the operation of `unlinkat()`. The valid flag value is:

AT_REMOVEDIR

By default, `unlinkat()` performs the equivalent of `unlink()` on *pathname*. If the `AT_REMOVEDIR` flag is specified, performs the equivalent of `rmdir()` on *pathname*.

Returned value

If successful, `unlinkat()` returns 0.

If unsuccessful, `unlinkat()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

The process does not have search permission for some component of *pathname*, or does not have write permission for the directory that contains the link to be removed.

EBADF

The file descriptor that is specified for *dirfd* is incorrect.

EBUSY

pathname cannot be unlinked because it is used by the system or some other process.

EINVAL

One of the input parameters is not valid.

EISDIR

pathname refers to a directory.

ELOOP

A loop exists in symbolic links. This error is issued if more than `POSIX_SYMLINK_MAX` symbolic links are detected in the resolution of *pathname*.

ENAMETOOLONG

pathname is longer than 1023 characters, or a component of *pathname* is longer than 255 characters.

ENOENT

A component of *pathname* does not name an existing file or *pathname* is an empty string.

ENOTDIR

Some component of the *pathname* prefix is not a directory.

EROFS

The file resides on a read-only file system.

unlockpt() — Unlock a pseudoterminal manager and subsidiary pair

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

int unlockpt(int fildev);
```

General description

The `unlockpt()` function unlocks the subsidiary pseudoterminal device associated with the manager to which *fildev* refers.

Portable applications must call `unlockpt()` before opening the subsidiary side of a pseudoterminal device.

Returned value

If successful, `unlockpt()` returns 0.

If unsuccessful, `unlockpt()` returns -1 and sets `errno` to one of the following values:

Error Code**Description****EACCESS**

Either a `grantpt()` has not yet been issued, or an `unlockpt()` has already been issued. An `unlockpt()` must be issued after a `grantpt()`, and can only be issued once.

EBADF

The *fildev* argument is not a file descriptor open for writing.

EINVAL

The *fildev* argument is not associated with a manager pseudoterminal device.

Related information

- [“stdlib.h — Standard library functions” on page 65](#)
- [“grantpt\(\) — Grant access to the subsidiary pseudoterminal device” on page 814](#)

unsetenv() — Delete an environment variable

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--------------------------------------|----------|--------------|
| Single UNIX Specification, version 3 | both | z/OS V1R7 |

Format

```
#define _UNIX03_SOURCE
#include <stdlib.h>

int unsetenv(const char *name);
```

General description

unsetenv() deletes an environment variable from the environment of the calling process. The *name* argument points to a string, which is the name of the variable to be removed. If the string pointed to by *name* contains an '=' character, unsetenv() will fail. If the named variable does not exist in the current environment, the environment will not be changed and unsetenv() will succeed.

Returned value

If successful, unsetenv() returns 0. If unsuccessful, unsetenv() returns -1 and sets errno to indicate the error.

- EINVAL – The name argument is a null pointer, points to an empty string, or points to a string containing an '=' character.

Related information

- "Using Environment Variables" in the [z/OS XL C/C++ Programming Guide](#).

unshare() — Isolate a process from one or more of its namespaces

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XPLATFORM_SOURCE
#include <sched.h>

int unshare(int flags);
```

General description

unshare() disassociates the current process from a mount, network, IPC, and/or UTS namespace into a newly created namespace or disassociate subsequent children from the PID namespace.

The flags argument is a bit mask that specifies which namespaces are to be disassociated by the process and a new namespace created. This argument is specified by zero or more of the following supported constants:

| Table 72. Supported constants for the flag argument | |
|---|--|
| Flag | Description |
| CLONE_NEWIPC | Unshare the process from the IPC namespace and move into a new IPC namespace. |
| CLONE_NEWNS | Unshare the process from the mount namespace and move into a new mount namespace. |
| CLONE_NEWPID | Unshare the PID namespace so the children of the process have a new PID namespace. |
| CLONE_NEWUTS | Unshare the process from the UTS namespace and move into a new UTS namespace. |

If flags is specified as zero, unshare() is a no-op; no changes are made to the calling process's execution context and unshare() indicates success on return.

Restriction: The CLONE_NEWNET or CLONE_NEWUTS flags cannot be specified in a multi-process address space. This results in an errno EINVAL.

Returned value

If successful, unshare() returns 0.

If unsuccessful, unshare() returns -1 and sets errno to one of the following values:

Error Code

Description

EINVAL

An invalid bit was specified in flags. Flags that are supported by unshare() are CLONE_NEWNS, CLONE_NEWPID, CLONE_NEWIPC, CLONE_NEWNET, and CLONE_NEWUTS. Any other flag results in the operation failing with an EINVAL error.

ENOMEM

The process requires more space than is available.

ENOSPC

A system limit is reached.

EPERM

The calling process does not have the required privileges for this operation.

Related information

- [“sched.h — Manipulate and examine process execution scheduling” on page 57](#)
- [“clone\(\) — Create a child process” on page 289](#)

usleep() — Suspend execution for an interval

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

int usleep(useconds_t useconds);
```

General description

The `usleep()` function suspends thread execution for the number of microseconds specified by the *useconds* argument. Because of other activity, or because of the time spent processing the call, the actual suspension time may be longer than the amount of time specified.

The *useconds* argument must be less than 1,000,000. If the value of *useconds* is 0, then the call has no effect.

The `usleep()` function will not interfere with a previous setting of the real-time interval timer. If the thread has set this timer before calling `usleep()`, and if the time specified by *useconds* equals or exceeds the interval timer's prior setting, then the thread will be awakened when the previously set timer interval expires.

Note: The `ualarm()` and `usleep()` functions have been moved to obsolescence in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The `setitimer()`, `timer_create()`, `timer_delete()`, `timer_getoverrun()`, `timer_gettime()`, or `timer_settime()` functions are preferred for portability.

Returned value

If successful, `usleep()` returns 0.

If unsuccessful, `usleep()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

The *useconds* argument was greater than or equal to 1,000,000.

Related information

utime(), utime64() – Set file access and modification times

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

utime:

```
#define _POSIX_SOURCE
#include <utime.h>

int utime(const char *pathname, const struct utimbuf *newtimes);
```

utime64:

```
#define _POSIX_SOURCE
#define _LARGE_TIME_API
#include <utime.h>

int utime64(const char *pathname, const struct utimbuf64 *newtimes);
```

Compile requirement: Use of the utime64() function requires the long long data type. For more information on how to make the long long data type available, see [z/OS XL C/C++ Language Reference](#).

General description

Function utime() sets the access and modification times of *pathname* to the values in the utimbuf structure. If *newtimes* is a NULL pointer, the access and modification times are set to the current time. Normally, the effective user ID (UID) of the calling process must match the owner UID of the file, or the calling process must have appropriate privileges. However, if *newtimes* is a NULL pointer, the effective UID of the calling process must match the owner UID of the file, or the calling process must have write permission to the file or appropriate privileges.

The contents of a utimbuf structure are:

time_t actime

The new access time (The time_t type gives the number of seconds since the epoch.)

time_t modtime

The new modification time

The utime64() function behaves exactly like utime() except utime64() uses struct utimbuf64 instead of struct utimbuf to support times beyond 03:14:07 UTC on January 19, 2038.

The contents of a utimbuf64 structure are as follows:

time64_t actime

The new access time (The time64_t type gives the number of seconds since the epoch.)

time64_t modtime

The new modification time

Returned value

If successful, utime() returns 0 and updates the access and modification times of the file to those specified.

If unsuccessful, `utime()` returns -1, does not update file times, and sets `errno` to one of the following values:

Error Code Description

EACCES

The process does not have search permission on some component of the *pathname* prefix; or all of the following are true:

- *newtimes* is NULL.
- The effective user ID of the process does not match the file's owner.
- The process does not have write permission on the file.
- The process does not have appropriate privileges.

ELOOP

A loop exists in symbolic links. This error is issued if more than POSIX_SYMLOOP symbolic links (defined in the `limits.h` header file) are detected in the resolution of *pathname*.

ENAMETOOLONG

pathname is longer than **PATH_MAX** characters, or some component of *pathname* is longer than **NAME_MAX** characters while `_POSIX_NO_TRUNC` is in effect. For symbolic links, the length of the *pathname* string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values can be determined using `pathconf()`.

ENOENT

There is no file named *pathname*, or the *pathname* argument is an empty string.

ENOTDIR

Some component of the *pathname* prefix is not a directory.

EPERM

newtimes is not NULL, the effective user ID of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges.

EROFS

pathname is on a read-only file system.

Example

CELEBU07

```
/* CELEBU07 */
#define _POSIX_SOURCE
#include <fcntl.h>
#include <stdio.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <time.h>
#include <unistd.h>
#include <utime.h>

main() {
    int fd;
    char fn[]="utime.file";
    struct utimbuf ubuf;

    if ((fd = creat(fn, S_IWUSR)) < 0)
        perror("creat() error");
    else {
        close(fd);
        puts("before utime()");
        system("ls -l utime.file");
        ubuf.modtime = 0;
        time(&ubuf.actime);
        if (utime(fn, &ubuf) != 0)
            perror("utime() error");
        else {
            puts("after utime()");
            system("ls -l utime.file");
        }
    }
}
```

```
        unlink(fn);
    }
}
```

Output

```
before utime()
--w----- 1 WELLIE  SYS1      0 Apr 19 15:23 utime.file
after utime()
--w----- 1 WELLIE  SYS1      0 Dec 31  1969 utime.file
```

utimensat() — Change file timestamps with nanosecond precision

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1-2008 Single UNIX Specification, Version 4 | both | |

Format

```
#define _POSIX_C_SOURCE 200809L
#include <fcntl.h>
#include <sys/stat.h>

/* Definition of AT_* constants */

int utimensat(int dirfd, const char *pathname, const struct timespec times[2], int flags);
```

General description

utimensat() updates the timestamps of a file with nanosecond precision while utime() and utimes() permit only second and microsecond precision, respectively, when setting file timestamps. The new file timestamps are specified in the array *times*: *times*[0] specifies the new “last access time” (atime); *times*[1] specifies the new “last modification time” (mtime). Each of the elements of *times* specifies a time as the number of seconds and nanoseconds since the Epoch, 1970-01-01 00:00:00 + 0000 (UTC). This information is conveyed in a structure of the following form:

```
struct timespec {
    time_t tv_sec;      /* seconds */
    long tv_nsec;      /* nanoseconds */
};
```

- If the *tv_nsec* field of one of the *timespec* structures has the special value *UTIME_NOW*, the corresponding file timestamp is set to the current time.
- If the *tv_nsec* field of one of the *timespec* structures has the special value *UTIME_OMIT*, the corresponding file timestamp is left unchanged.
- In both of these cases, the value of the corresponding *tv_sec* field is ignored.

If *times* is NULL, both timestamps are set to the current time.

If *pathname* is relative, by default it is interpreted relative to the directory referred to by the open file descriptor *dirfd* (rather than relative to the current working directory of the calling process, as is done by *utimes()* for a relative *pathname*).

If *pathname* is absolute, *dirfd* is ignored.

The *flags* field is a bit mask that may be 0, or include the following constant, which is defined in `<fcntl.h>`:

AT_SYMLINK_NOFOLLOW

If *pathname* specifies a symbolic link, update the timestamps of the link, rather than the file to which it refers.

Returned value

If successful, `utimensat()` returns 0.

If unsuccessful, `utimensat()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

The process does not have appropriate permissions. Possible reasons include:

- The process attempts to set access time or modification time to current time (*times* is NULL), but the effective UID of the process does not match the file's owner.
- The process does not have write permission on the file.
- The process does not have appropriate privileges.

EBADF

pathname is relative but *dirfd* is not `AT_FDCWD` or a valid file descriptor, or *dirfd* is not a valid file descriptor.

EBUSY

The file is open by a remote NFS client with a share reservation that conflicts with the requested operation.

EINVAL

- Invalid value in *flags*.
- *pathname* is NULL, *dirfd* is not `AT_FDCWD`, and *flags* contains `AT_SYMLINK_NOFOLLOW`.
- Invalid value in one of the *tv_nsec* fields (value outside range 0 to 999,999,999, and not `UTIME_NOW` or `UTIME_OMIT`); or an invalid value in one of the *tv_sec* fields.

ELOOP

A loop exists in symbolic links. This error is issued if more than `POSIX_SYMLINK_MAX` symbolic links are detected in the resolution of *pathname*.

EMVSERR

An MVS environmental error is detected.

ENAMETOOLONG

pathname is longer than `PATH_MAX` characters, or some component of *pathname* is longer than `NAME_MAX` characters while `_POSIX_NO_TRUNC` is in effect. For symbolic links, the length of the *pathname* string that is substituted for a symbolic link exceeds `PATH_MAX`.

ENOENT

There is no file that is named *pathname*, or the *pathname* argument is an empty string.

ENOTDIR

Some component of the *pathname* prefix is not a directory.

EPERM

times is not NULL. The effective user ID of the calling process does not match the owner of the file. The calling process does not have appropriate privileges.

EROFS

pathname is on a read-only file system.

utimes(), utimes64() — Set file access and modification times

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

utimes:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/time.h>

int utimes(const char *path, const struct timeval times[2]);
```

utimes64:

```
#define _XOPEN_SOURCE_EXTENDED 1
#define _LARGE_TIME_API
#include <sys/time.h>

int utimes64(const char *path, const struct timeval64 times64[2]);
```

Compile requirement: Use of the utimes64() function requires the long long data type. For more information on how to make the long long data type available, see [z/OS XL C/C++ Language Reference](#).

General description

The utimes() function sets the access and modification times of the file pointed to by the path argument to the value of the times argument.

The times argument is an array of two timeval structures. The first array member represents the date and time of the last access, and the second member represents the date and time of the last modification. The times in the timeval structure are measured in seconds and microseconds since the Epoch, but the actual time stored with the file are rounded to the nearest second. The timeval members are:

tv_sec

Seconds since January 1, 1970 (UTC)

tv_usec

Microseconds

If the times argument is a NULL pointer, the access and modification times of the file are set to the current time. The same process privilege requirements of the utime() function are required by utimes(). The last file status change, field st_ctime in a stat(), is updated with the current time.

Note: The utimes() function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The utime() function is preferred for portability.

The `utimes64()` function behaves exactly like `utimes()` except `utimes64()` supports calendar times beyond 03:14:07 UTC on January 19, 2038. The `times64` argument is an array of two `timeval64` structures:

tv_sec64

Seconds since January 1, 1970 (UTC)

tv_usec64

microseconds

Returned value

If successful, `utimes()` returns 0.

If unsuccessful, `utimes()` returns -1 and sets `errno` to one of the following values:

Error Code**Description****EACCES**

The process does not have search permission on some component of the *path* prefix; or all of the following are true:

- *times* is NULL
- The effective user ID of the process does not match the file's owner
- The process does not have write permission on the file
- The process does not have appropriate privileges

ELOOP

A loop exists in symbolic links. This error is issued if more than **POSIX_SYMLLOOP** symbolic links (defined in the `limits.h` header file) are detected in the resolution of *path*.

ENAMETOOLONG

path is longer than **PATH_MAX** characters or some component of *path* is longer than **NAME_MAX** characters while **_POSIX_NO_TRUNC** is in effect. For symbolic links, the length of the *pathname* string substituted for a symbolic link exceeds **PATH_MAX**. The **PATH_MAX** and **NAME_MAX** values can be determined using *pathconf()*.

ENOTDIR

Some component of the *path* prefix is not a directory.

ENOTENT

There is no file named *path*, or the *path* argument is an empty string.

EPERM

times is not NULL, the effective user ID of the calling process does not match the owner of the file, and the calling process does not have appropriate privileges.

EROFS

path is on a read-only file system.

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <utmpx.h>

int __utmpxname(char *file);
```

General description

The `__utmpxname()` function changes the name of the utmpx database file for the current thread from default `/etc/utmpx` to the name specified by *file*. The `__utmpxname()` function does not open the file. It closes the old utmpx database file, if it is currently opened for the current thread, and saves the new utmpx database file name. If the file does not exist no indication is given.

Because the `__utmpxname()` function processes thread-specific data the `__utmpxname()` function can be used safely from a multithreaded application. If multiple threads in the same process open the database, then each thread opens the database with a different file descriptor. The thread's database file descriptor is closed when the calling thread terminates or the `endutxent()` function is called by the calling thread.

Programs must not reference the data passed back by `getutxline()/getutxline64()`, `getutxent()/getutxent64()`, `getutxid()/getutxid64()`, or `pututxline()/pututxline64()` after `__utmpxname()` has been called (the storage has been freed.) The `endutxent()` function resets the name of the utmpx database back to the default value. If you must do additional utmpx operations on a nonstandard utmpx database after calling `endutxent()`, then call `__utmpxname()` again, to reestablish the nonstandard name.

Returned value

If successful, `__utmpxname()` returns 0.

If unsuccessful, `__utmpxname()` returns -1.

utoa() — Convert unsigned int into a string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R5 |

Format

```
#define _OPEN_SYS_ITOA_EXT
#include <stdlib.h>

char * utoa(unsigned int n, char * buffer, int radix);
```

General description

The `utoa()` function converts the unsigned integer `n` into a character string. The string is placed in the buffer passed, which must be large enough to hold the output. The radix values can be OCTAL, DECIMAL, or HEX. When the radix is DECIMAL, `utoa()` produces the same result as the following statement:

```
(void) sprintf(buffer, "%u", n);
```

with `buffer` the returned character string. When the radix is OCTAL, `utoa()` formats unsigned integer `n` into an octal constant. When the radix is HEX, `utoa()` formats unsigned integer `n` into a hexadecimal constant. The hexadecimal value will include lower case `abcdef`, as necessary.

Returned value

String pointer (same as `buffer`) will be returned. When passed an invalid radix argument, function will return NULL and set `errno` to `EINVAL`.

Portability considerations

This is a non-standard function. Even though the prototype given is commonly used by compilers on other platforms, there is no guarantee that this function will behave the same on all platforms, in all cases. You can use this function to help port applications from other platforms, but you should avoid using it when writing new applications, in order to ensure maximum portability.

Example

CELEBU10

```
/* CELEBU10

   This example reads an unsigned int and formats it to decimal,
   octal, hexadecimal constants converted to a character string.
*/

#define _OPEN_SYS_ITOA_EXT
#include <stdio.h>
#include <stdlib.h>

int main ()
{
    unsigned int i;
    char buffer [sizeof(unsigned int)*8+1];
    printf ("Enter a number: ");
    if (scanf ("%u",&i) == 1) {
        utoa (i,buffer,DECIMAL);
        printf ("decimal: %s\n",buffer);
        utoa (i,buffer,HEX);
        printf ("hexadecimal: %s\n",buffer);
        utoa (i,buffer,OCTAL);
        printf ("octal: %s\n",buffer);
    }
    return 0;
}
```

Output

If the input is 1234, then the output should be:

```
decimal: 1234
hexadecimal: 4d2
octal: 2322
```

va_arg(), va_copy(), va_end(), va_start() – Access function arguments

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdarg.h>

var_type va_arg(va_list arg_ptr, var_type);
void va_end(va_list arg_ptr);
void va_start(va_list arg_ptr, variable_name);
```

C99:

```
#define _ISOC99_SOURCE
#include <stdarg.h>

var_type va_arg(va_list arg_ptr, var_type);
void va_end(va_list arg_ptr);
void va_start(va_list arg_ptr, variable_name);
void va_copy(va_list dest, va_list src);
```

General description

The va_arg(), va_end(), and va_start() macros access the arguments to a function when it takes a fixed number of required arguments and a variable number of optional arguments. You declare required arguments as ordinary parameters to the function and access the arguments through the parameter names.

The va_start() macro initializes the arg_ptr pointer for subsequent calls to va_arg() and va_end().

The argument variable_name is the identifier of the rightmost named parameter in the parameter list (preceding , ...). Use the va_start() macro before the va_arg() macro. Corresponding va_start() and va_end() macro calls must be in the same function. If variable_name is declared as a register, with a function or an array type, or with a type that is not compatible with the type that results after application of the default argument promotions, then the behavior is undefined.

The `va_arg()` macro retrieves a value of the given *var_type* from the location given by *arg_ptr* and increases *arg_ptr* to point to the next argument in the list. The `va_arg()` macro can retrieve arguments from the list any number of times within the function.

The macros also provide fixed-point decimal support under z/OS XL C. The `sizeof(xx)` operator is used to determine the size and type casting that is used to generate the values. Therefore, a call, such as, `x = va_arg(ap, _Decimal(5,2));` is valid. The size of a fixed-point decimal number, however, cannot be made a variable. Therefore, a call, such as, `z = va_arg(ap, _Decimal(x,y))` where `x = 5` and `y = 2` is invalid.

The `va_end()` macro is needed by some systems to indicate the end of parameter scanning.

`va_start()` and `va_arg()` do not work with parameter lists of functions whose linkages were changed with the `#pragma linkage` directive.

`stdarg.h` and `varargs.h` are mutually exclusive. Whichever `#include` comes first, determines the form of macro that is visible.

The type definition for the `va_list` type is normally `"char *va_list[2]"`. Some applications (especially ported applications) require that the `va_list` type be defined as `"char *va_list"`. This alternate `va_list` type is available if the user defines the feature test macro `_VARARG_EXT_` before the inclusion of any system header file. If the `_VARARG_EXT_` feature test macro is defined, `va_list` will be typed as `char *va_list`, and the functions `vprintf()`, `vfprintf()`, `vsprintf()`, and `vswprintf()` will use this alternate `va_list` type.

The `va_copy()` function creates a copy (*dest*) of a variable of type `va_list` (*src*). The copy appear as if it has gone through a `va_start()` and the exact set of sequences of `va_arg()` as that of *src*.

After `va_copy()` initializes *dest*, the `va_copy()` macro shall not be invoked to reinitialize *dest* without an intervening invocation of the `va_end()` macro for the same *dest*.

Returned value

The `va_arg()` macro returns the current argument.

The `va_end()`, `va_copy()`, and `va_start()` macros return no values.

Example

CELEBV01

```
/* CELEBV01

   This example passes a variable number of arguments to a function,
   stores each argument in an array, and prints each argument.

*/
#include <stdio.h>
#include <stdarg.h>

void vout(int max, ...);

int main(void)
{
    vout(3, "Sat", "Sun", "Mon");
    printf("\n");
    vout(5, "Mon", "Tues", "Wed", "Thurs", "Fri");
}

void vout(int max, ...)
{
    va_list arg_ptr;
    int args = 0;
    char *days[7];

    va_start(arg_ptr, max);
    while(args < max)
    {
        days[args] = va_arg(arg_ptr, char *);
        printf("Day: %s \n", days[args++]);
    }
    va_end(arg_ptr);
}
```

```
}

```

Output

```
Day:  Sat
Day:  Sun
Day:  Mon

Day:  Mon
Day:  Tues
Day:  Wed
Day:  Thurs
Day:  Fri

```

```
/* This example uses a variable number of arguments for
   fixed-point decimal data types.
   The example works in z/OS XL C only.
*/
#include <stdio.h>
#include <stdarg.h>
#include <decimal.h>

void vprint(int, ...);

int main(void) {
    int i = 168;
    decimal(10,2) pd01 = 12345678.12d;
    decimal(20,5) pd02 = -987.65d;
    decimal(31,20) pd03 = 12345678901.12345678900987654321d;
    int j = 135;

    vprint(0, i, pd01, pd02, pd03, j);

    return(0);
}

void vprint(int whichcase, ...) {
    va_list arg_ptr;
    int m, n;
    decimal(10,2) va01;
    decimal(20,5) va02;
    decimal(31,20) va03;

    va_start(arg_ptr, whichcase);

    switch (whichcase) {
        case 0:
            m = va_arg(arg_ptr, int);
            va01 = va_arg(arg_ptr, decimal(10,2));
            va02 = va_arg(arg_ptr, decimal(20,5));
            va03 = va_arg(arg_ptr, decimal(31,20));
            n = va_arg(arg_ptr, int);
            printf("m      = %d\n", m);
            printf("va01 = %D(10,2)\n", va01);
            printf("va02 = %D(20,5)\n", va02);
            printf("va03 = %D(31,20)\n", va03);
            printf("n      = %d\n", n);
            break;
        default:
            printf("Illegal case number : %d\n", whichcase);
    }

    va_end(arg_ptr);
}

```

Output:

```
m      = 168
va01 = 12345678.12
va02 = -987.65000
va03 = 12345678901.12345678900987654321
n      = 135

```

CELEBV02

valloc() — Page-aligned memory allocator

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <stdlib.h>

void *valloc(size_t size);
```

General description

Restriction: This function is not supported in AMODE 64.

The `valloc()` function has the same effect as `malloc()`, except that the allocated memory will be aligned to a multiple of the value returned by `sysconf(_SC_PAGESIZE)`.

Note: When `free()` is used to release storage obtained by `valloc()`, the storage is not made available for reuse. The storage will not be freed until the enclave goes away.

Special behavior for C++: The C++ keywords `new` and `delete` are not interoperable with `valloc()`, `aligned_alloc()`, `calloc()`, `free()`, `malloc()`, or `realloc()`.

Note:

This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. The `malloc()` or `mmap()` functions are preferred for portability.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

If successful, `valloc()` returns a pointer to the reserved storage. The storage space to which the returned value points is guaranteed to be aligned on a page boundary.

If unsuccessful, `valloc()` returns `NULL` if there is not enough storage available, or if `size` is 0. If `valloc()` returns `NULL` because there is not enough storage, it sets `errno` to one of the following values:

Error Code

Description

ENOMEM

Insufficient memory is available

Related information

vfork() — Create a new process

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/types.h>
#include <unistd.h>

pid_t vfork(void);
```

Note: Although POSIX.1 does not require that the `<sys/types.h>` include file be included, XPG4 has it as an optional header. Therefore it is recommended that you include it for portability.

General description

The `vfork()` function creates a new process. The `vfork()` function has the same effect as `fork()`, except that the behavior is undefined, if the process created by `vfork()` attempts to call any other C/370 function before calling either `exec()` or `_exit()`. The new process (the *child process*) is an exact duplicate of the process that calls `vfork()` (the *parent process*), except for the following:

- The child process has a unique process ID (PID), which does not match any active process group ID.
- The child has a different parent process ID, that is, the process ID of the process that called `vfork()`.
- The child has its own copy of the parent's file descriptors. Each file descriptor in the child refers to the same open file description as the corresponding file descriptor in the parent.
- The child has its own copy of the parent's open directory streams. Each child's open directory stream may share directory stream positioning with the corresponding parent's directory stream.
- The following elements in the `tms` structure are set to 0 in the child:

```
tms_utime
tms_stime
tms_cutime
tms_cstime
```

For more information about these elements, see [“times\(\) — Get process and child process times” on page 1867](#).

- The child does not inherit any file locks previously set by the parent.
- The child process has no alarms set (similar to the results of a call to `alarm()` with an argument value of 0).
- The child has no pending signals.
- The child process may have its own copy of the parent's message catalog descriptors.
- All `semadj` values are cleared.
- Interval timers are reset in the child process.

In all other respects, the child is identical to the parent. Because the child is a duplicate, it contains the same call to `vfork()` that was in the parent. Execution begins with this `vfork()` call, which returns a value of 0; the child then proceeds with normal execution.

The `vfork()` function is not supported from a multithread environment.

For more information on `vfork()` from a z/OS perspective, refer to [z/OS UNIX System Services Programming: Assembler Callable Services Reference](#).

You can use z/OS memory files from a z/OS UNIX program. However, use of the `vfork()` function from the program removes access from a hiperspace memory file for the child process. Use of an `exec` function from the program clears a memory file when the process address space is cleared.

Special behavior for C: For POSIX resources, `vfork()` behaves as just described. But in general, MVS resources that existed in the parent do *not* exist in the child. This is true for open streams in MVS data sets and assembler-accessed z/OS facilities, such as STIMERS. In addition, z/OS allocations (through JCL, SVC99, or ALLOCATE) are not passed to the child process.

Note: The `vfork()` function has been moved to obsolescence in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The `fork()` function is preferred for portability.

Returned value

If successful, `vfork()` returns 0 to the child process and the process ID of the newly created child to the parent process.

If unsuccessful, `vfork()` fails to create a child process and returns -1 to the parent. `vfork()` sets `errno` to one of the following values:

Error Code Description

EAGAIN

There are insufficient resources to create another process, or else the process has already reached the maximum number of processes you can run.

ELEMSGERR

Language Environment message file not available.

ELEMULTITHREAD

`vfork()` was invoked from a multi-threaded environment.

ELENOFORK

Application contains a language that does not support `fork()`.

ENOMEM

The process requires more space than is available.

vfprintf() — Format and print data to stream

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```
#include <stdarg.h>
#include <stdio.h>

int vfprintf(FILE * __restrict__ stream,
             const char * __restrict__ format, va_list arg_ptr);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int vfprintf_unlocked(FILE * __restrict__ stream,
                    const char * __restrict__ format, va_list arg_ptr);
```

General description

The `vfprintf()` function is similar to `fprintf()`, except that *arg_ptr* points to a list of arguments whose number can vary from call to call in the program. These arguments should be initialized by `va_start()` for each call. In contrast, `fprintf()` can have a list of arguments, but the number of arguments in that list is fixed when you compile the program. For a specification of the *format* string, see [“fprintf\(\), printf\(\), sprintf\(\) — Format and write data”](#) on page 593.

`vfprintf()` is not supported for files opened with `type=record` or `type=blocked`.

`vfprintf()` has the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

`vfprintf_unlocked()` is functionally equivalent to `vfprintf()` with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the `flockfile()` or `ftrylockfile()` function.

Returned value

If successful, `vfprintf()` returns the number of characters written to *stream*.

If unsuccessful, `vfprintf()` returns a negative value.

Note: In contrast to some UNIX-based implementations of the C language, the z/OS XL C/C++ implementation of the `vfprintf()` family increments the pointer to the variable arguments list. To control whether the pointer to the argument is incremented, call the `va_end` macro after each call to `vsprintf()`.

Example

CELEBV03

```
/* CELEBV03

   This example prints out a variable number of strings to the
   file myfile.dat, using &vfprt..

*/
#include <stdarg.h>
#include <stdio.h>

void vout(FILE *stream, char *fmt, ...);
char fmt1 [] = "%s %s %s\n";

int main(void)
{
    FILE *stream;
    stream = fopen("myfile.dat", "w");

    vout(stream, fmt1, "Sat", "Sun", "Mon");
}

void vout(FILE *stream, char *fmt, ...)
{
    va_list arg_ptr;

    va_start(arg_ptr, fmt);
    vfprintf(stream, fmt, arg_ptr);
    va_end(arg_ptr);
}
```

Output:

Sat Sun Mon

vfscanf(), vscanf(), vsscanf() — Format input of a STDARG argument list

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| C99 Single UNIX Specification, Version 3 Language Environment C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _ISOC99_SOURCE
#include <stdarg.h>
#include <stdio.h>
```

```
int vfscanf(FILE *__restrict__ stream,
            const char *__restrict__ format, va_list arg);

int vscanf(const char *__restrict__ format, va_list arg);

int vsscanf(const char *__restrict__ s,
            const char *__restrict__ format, va_list arg);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int vfscanf_unlocked(FILE *__restrict__ stream,
                    const char *__restrict__ format, va_list arg);

int vscanf_unlocked(const char *__restrict__ format, va_list arg);
```

General description

The vfscanf(), vscanf(), and vsscanf() functions are equivalent to the fscanf(), scanf(), and sscanf() functions, respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined in stdarg.h.

The argument list should be initialized using the va_start macro before each call. These functions do not invoke the va_end macro, but instead invoke the va_arg macro causing the value of arg after the return to be unspecified.

vfscanf() and vscanf() are not supported for files opened with a record type. They also have the same restrictions as a write immediately following a read or a read immediately following a write. This is because, between a write and a subsequent read, there must be an intervening flush or reposition and between a read and a subsequent write, there must also be an intervening flush or reposition unless EOF has been reached.

Note: In contrast to some UNIX-based implementations of the C language, the z/OS XL C/C++ implementation of the vscanf() family increments the pointer to the variable arguments list. To control whether the pointer is incremented, call the va_end macro after each function call.

vfscanf_unlocked() and vscanf_unlocked() are functionally equivalent to vfscanf() and vscanf() with the exception that they are not thread-safe. These functions may safely be used in a multithreaded application if and only they are called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Returned value

Refer to fscanf().

vwfprintf(), vswprintf(), vwprintf() – Format and write wide characters of a STDARG argument list

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

Non-XP4:

```
#include <stdarg.h>
#include <wchar.h>

int vfwprintf(FILE * __restrict__ stream,
              const wchar_t * __restrict__ format, va_list arg);
int vswprintf(wchar_t * __restrict__ wcs, size_t n,
              const wchar_t * __restrict__ format, va_list arg);
int vwprintf(const wchar_t * __restrict__ format, va_list arg);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

int vfwprintf_unlocked(FILE * __restrict__ stream,
                      const wchar_t * __restrict__ format, va_list arg);
int vwprintf_unlocked(const wchar_t * __restrict__ format, va_list arg);
```

XP4:

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <stdarg.h>
#include <wchar.h>

int vfwprintf(FILE * __restrict__ stream,
              const wchar_t * __restrict__ format, va_list arg);
int vswprintf(wchar_t * __restrict__ wcs, size_t n,
              const wchar_t * __restrict__ format, va_list arg);
int vwprintf(const wchar_t * __restrict__ format, va_list arg);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <wchar.h>

int vfwprintf_unlocked(FILE * __restrict__ stream,
                      const wchar_t * __restrict__ format, va_list arg);
int vwprintf_unlocked(const wchar_t * __restrict__ format, va_list arg);
```

General description

vfwprintf(), vswprintf(), and vwprintf() functions are equivalent to fprintf(), sprintf(), and printf() functions, respectively, except for the following:

- Instead of being called with a variable number of arguments, they are called with an argument list as defined in stdarg.h.
- For vswprintf(), the argument *wcs* specifies an array of type `wchar_t`, rather than an array of type `char`, into which the generated output is to be written.
- The argument *format* specifies an array of type `wchar_t`, rather than an array of type `char`, which describes how subsequent arguments are converted for output.
- `%c` without an `l` prefix means an integer argument is to be converted to `wchar_t`, as if by calling `mbtowl()`, and then written.
- `%c` with `l` prefix means a `wint_t` is converted to `wchar_t` and then written.
- `%s` without an `l` prefix means a character array containing a multibyte character sequence is to be converted to an array of `wchar_t` and written. The conversion will take place as if `mbtowl()` were called repeatedly.
- `%s` with `l` prefix means an array of `wchar_t` will be written. The array is written up to but not including the terminating NULL character, unless the precision specifies a shorter output.

For vswprintf(), a NULL wide character is written at the end of the wide characters written; the NULL wide character is not counted as part of the returned sum. If copying takes place between objects that overlap, the behavior is undefined.

Note: The vfwprintf() and vwprintf() functions have a dependency on the level of the Enhanced ASCII Extensions. See “Enhanced ASCII support ” on page 2123 for details.

vfwprintf_unlocked() and vwprintf_unlocked() are functionally equivalent to vfwprintf() and vwprintf() with the exception that they are not thread-safe. These functions may safely be used in a multithreaded application if and only if they are called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or ftrylockfile() function.

Special behavior for XPG4: If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then you must also define the _MSE_PROTOS feature test macro to make the declaration of the vfwprintf(), vswprintf(), or vwprintf() function in the wchar header available when you compile your program. Please see [Table 2 on page 4](#) for a list of XPG4 and other feature test macros.

Returned value

If successful, vfwprintf(), vswprintf(), and vwprintf() return the number of wide characters written, not counting the terminating NULL wide character.

If unsuccessful, a negative value is returned.

If *n* or more wide characters were requested to be written, vswprintf() returns a negative value and sets errno to indicate the error.

Note: In contrast to some UNIX-based implementations of the C language, the IBM z/OS C++ implementation of the vprintf() family increments the pointer to the variable arguments list. To control whether the pointer to the argument is incremented, call the va_end macro after each call to vfwprintf(), vswprintf(), or vwprintf().

Example

CELEBV06

```
/* CELEBV06 */
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <stdio.h>
#include <stdarg.h>
#include <wchar.h>

void vout(wchar_t *, size_t, wchar_t *, ...);

wchar_t *format3 = L"%S %d %S";
wchar_t *format5 = L"%S %d %S %d %S";

int main(void)
{
    wchar_t wcstr[100];

    vout(wcstr, 100, format3, L"ONE", 2L, L"THREE");
    printf("%S\n", wcstr);
    vout(wcstr, 100, format5, L"ONE", 2L, L"THREE", 4L, L"FIVE");
    printf("%S\n", wcstr);
}

void vout(wchar_t *wcs, size_t n, wchar_t *fmt, ...)
{
    va_list arg_ptr;

    va_start(arg_ptr, fmt);
    if(vswprintf(wcs, n, fmt, arg_ptr) < 0)
        perror("vswprintf() error");
    va_end(arg_ptr);
}
```

vprintf() — Format and print data to stdout

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C XPG4.2 C99 Single UNIX Specification, Version 3 Language Environment | both | |

Format

```
#include <stdarg.h>
#include <stdio.h>

int vprintf(const char * __restrict__format, va_list arg_ptr);

#define _OPEN_SYS_UNLOCKED_EXT 1
#include <stdio.h>

int vprintf_unlocked(const char * __restrict__format, va_list arg_ptr);
```

General description

The vprintf() function is similar to printf(), except that *arg_ptr* points to a list of arguments whose number can vary from call to call in the program. These arguments should be initialized by va_start() for each call. In contrast, printf() can have a list of arguments, but the number of arguments in that list is fixed when you compile the program. For a specification of the *format* string, see [“fprintf\(\), printf\(\), sprintf\(\) — Format and write data”](#) on page 593.

vprintf() is not supported for files opened with type=record or type=blocked.

vprintf() has the same restriction as any write operation for a read immediately following a write or a write immediately following a read. Between a write and a subsequent read, there must be an intervening flush or reposition. Between a read and a subsequent write, there must also be an intervening flush or reposition unless an EOF has been reached.

vprintf_unlocked() is functionally equivalent to vprintf() with the exception that it is not thread-safe. This function can safely be used in a multithreaded application if and only if it is called while the invoking thread owns the (FILE*) object, as is the case after a successful call to either the flockfile() or frylockfile() function.

Returned value

If successful, vprintf() returns the number of characters written to *stdout*.

If unsuccessful, vprintf() returns a negative value.

Note: In contrast to some UNIX-based implementations of the C language, the z/OS XL C/C++ implementation of the `vprintf()` family increments the pointer to the variable arguments list. To control whether the pointer to the argument is incremented, call the `va_end` macro after each call to `vprintf()`.

Example

CELEBV04

```
/* CELEBV04

   This example prints out a variable number of strings to stdout,
   using &vprintf..

*/
#include <stdarg.h>
#include <stdio.h>

void vout(char *fmt, ...);
char fmt1 [] = "%s %s %s %s %s \n";

int main(void)
{
    FILE *stream;
    stream = fopen("myfile.dat", "w");

    vout(fmt1, "Mon", "Tues", "Wed", "Thurs", "Fri");
}

void vout(char *fmt, ...)
{
    va_list arg_ptr;

    va_start(arg_ptr, fmt);
    vprintf(fmt, arg_ptr);
    va_end(arg_ptr);
}
```

Output

```
Mon  Tues  Wed   Thurs  Fri
```

vsprintf() – Format and print data to fixed length buffer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R6 |

Format

```
#define _ISOC99_SOURCE
#include <stdio.h>
#include <stdarg.h>

int vsprintf(char *__restrict__ s, size_t n,
             const char *__restrict__ format, va_list arg);
```

General description

Equivalent to sprintf(), except that instead of being called with a variable number of arguments, it is called with an argument list as defined by <stdarg.h>.

Returned value

Returns the number of characters that would have been written had *n* been sufficiently large, not counting the terminating null character, or a negative value if an encoding error occurred. Thus, the null-terminated output has been completely written if and only if the returned value is nonnegative and less than *n*.

vsprintf() – Format and print data to buffer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdarg.h>
#include <stdio.h>

int vsprintf(char * __restrict__ target-string,
             const char * __restrict__ format, va_list arg_ptr);
```

General description

The vsprintf() function is similar to sprintf(), except that *arg_ptr* points to a list of arguments whose number can vary from call to call in the program. In contrast, sprintf() can have a list of arguments, but the number of arguments in that list is fixed when you compile the program. For a specification of the *format* string, see [“fprintf\(\), printf\(\), sprintf\(\) – Format and write data” on page 593](#).

Returned value

If successful, vsprintf() returns the number of characters written *target-string*.
If unsuccessful, vsprintf() returns a negative value.

Note: In contrast to some UNIX-based implementations of the C language, the z/OS XL C/C++ implementation of the vprintf() family increments the pointer to the variable arguments list. To control whether the pointer to the argument is incremented, call the va_end macro after each call to vsprintf().

Example

CELEBV05

```
/* CELEBV05

   This example assigns a variable number of strings to string
   and prints the resultant string, using &vsprintf..

*/
#include <stdarg.h>
#include <stdio.h>

void vout(char *string, char *fmt, ...);
char fmt1 [] = "%s %s %s\n";

int main(void)
{
    char string[100];

    vout(string, fmt1, "Sat", "Sun", "Mon");
    printf("The string is: %s\n", string);
}
void vout(char *string, char *fmt, ...)
{
    va_list arg_ptr;

    va_start(arg_ptr, fmt);
    vsprintf(string, fmt, arg_ptr);
    va_end(arg_ptr);
}
```

Output

```
The string is:  Sat  Sun  Mon
```

vswprintf() — Format and write wide characters of a stdarg argument list

The information for this function is included in [“vfwprintf\(\), vswprintf\(\), vwprintf\(\) — Format and write wide characters of a STDARG argument list” on page 1970](#).

vwprintf() — Format and write wide characters of a stdarg argument list

The information for this function is included in [“vfwprintf\(\), vswprintf\(\), vwprintf\(\) — Format and write wide characters of a STDARG argument list” on page 1970](#).

wait() — Wait for a child process to end

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <sys/wait.h>

pid_t wait(int *status_ptr);
```

General description

Suspends the calling process until any one of its child processes ends. More precisely, `wait()` suspends the calling process until the system obtains status information on the ended child. If the system already has status information on a completed child process when `wait()` is called, `wait()` returns immediately. `wait()` is also ended if the calling process receives a signal whose action is either to execute a signal handler or to end the process.

The argument `status_ptr` points to a location where `wait()` can store a status value. This status value is zero if the child process explicitly returns 0 status. If it is not zero, it can be analyzed with the status analysis macros, described in “Status Analysis Macros,” below.

The `status_ptr` pointer may also be NULL, in which case `wait()` ignores the child's return status.

The following function calls are equivalent:

```
wait(status_ptr);
waitpid(-1, status_ptr, 0);
wait3(status_ptr, 0, NULL);
```

For more information, see “[waitpid\(\) — Wait for a specific child process to end](#)” on page 1981.

Special behavior for XPG4.2: If the calling process has `SA_NOCLDWAIT` set or has `SIGCHLD` set to `SIG_IGN`, and the process has no unwaited for children that were transformed into zombie processes, it will block until all of the children terminate, and `wait()` will fail and set `errno` to `ECHILD`.

Status analysis macros: If the `status_ptr` argument is not NULL, `wait()` places the child's return status in `*status_ptr`. You can analyze this return status with the following macros, defined in the `sys/wait.h` header file:

WIFEXITED(*status_ptr)

This macro evaluates to a nonzero (true) value if the child process ended normally, that is, if it returned from `main()` or called one of the `exit()` or `_exit()` functions.

WEXITSTATUS(*status_ptr)

When `WIFEXITED()` is nonzero, `WEXITSTATUS()` evaluates to the low-order 8 bits of the child's return status passed on the `exit()` or `_exit()` function.

WIFSIGNALED(*status_ptr)

This macro evaluates to a nonzero (true) value if the child process ended because of a signal that was not caught.

WIFSTOPPED(*status_ptr)

This macro evaluates to a nonzero (true) value if the child process is currently stopped. This should only be used after a `waitpid()` with the `WUNTRACED` option.

WSTOPSIG(*status_ptr)

When `WIFSTOPPED()` is nonzero, `WSTOPSIG()` evaluates to the number of the signal that stopped the child.

WTERMSIG(*status_ptr)

When `WIFSIGNALED()` is nonzero, `WTERMSIG()` evaluates to the number of the signal that ended the child process.

Returned value

If successful, `wait()` returns a value that is the process ID (PID) of the child whose status information has been obtained.

If unsuccessful, `wait()` returns -1 and sets `errno` to one of the following values:

Error Code**Description****ECHILD**

The caller has no appropriate child processes, that is, it has no child processes whose status has not been obtained by previous calls to `wait()`, `waitid()`, `waitpid()`, or `wait3()`. `ECHILD` is also returned when the `SA_NOCLDWAIT` flag is set.

EINTR

`wait()` was interrupted by a signal. The value of `*status_ptr` is undefined.

Example**CELEBW01**

```
/* CELEBW01

   This example suspends the calling process until any child processes ends.

*/
#define _POSIX_SOURCE
#include <sys/types.h>
#include <sys/wait.h>
#include <unistd.h>
#include <stdio.h>
#include <time.h>

main() {
    pid_t pid;
    time_t t;
    int status;

    if ((pid = fork()) < 0)
        perror("fork() error");
    else if (pid == 0) {
        time(&t);
        printf("child (pid %d) started at %s", (int) getpid(), ctime(&t));
        sleep(5);
        time(&t);
        printf("child exiting at %s", ctime(&t));
        exit(42);
    }
    else {
        printf("parent has forked child with pid of %d\n", (int) pid);
        time(&t);
        printf("parent is starting wait at %s", ctime(&t));
        if ((pid = wait(&status)) == -1)
            perror("wait() error");
        else {
            time(&t);
            printf("parent is done waiting at %s", ctime(&t));
            printf("the pid of the process that ended was %d\n", (int) pid);
            if (WIFEXITED(status))
                printf("child exited with status of %d\n", WEXITSTATUS(status));
```

```

        else if (WIFSIGNALED(status))
            printf("child was terminated by signal %d\n",
                WTERMSIG(status));
        else if (WIFSTOPPED(status))
            printf("child was stopped by signal %d\n", WSTOPSIG(status));
        else puts("reason unknown for child termination");
    }
}
}

```

Output:

```

parent has forked child with pid of 65546
parent is starting wait at Fri Jun 16 10:53:03 2006
child (pid 65546) started at Fri Jun 16 10:53:04 2006
child exiting at Fri Jun 16 10:53:09 2006
parent is done waiting at Fri Jun 16 10:53:10 2006
the pid of the process that ended was 65546
child exited with status of 42

```

General description

The `waitid()` function suspends the calling process until one of its children changes state. It records the current state of a child in the structure pointed to by *infop*. If a child process changed state before the call, `waitid()` returns immediately.

The *idtype* and *id* arguments are used to specify which children `waitid()` will wait for.

If *idtype* is `P_PID` `waitid()` will wait for the child with a process ID equal to `(pid_t)id`.

If *idtype* is `P_GID` `waitid()` will wait for any child with a process group ID equal to `(pid_t)id`.

If *idtype* is `P_ALL` `waitid()` will wait for any children and *id* is ignored.

The *options* argument is used to specify which state changes to wait for. It is formed by OR-ing together one or more of the following flags:

WCONTINUED

Status will be returned for any child that has stopped and has been continued.

WEXITED

Wait for processes that have exited.

WNOHANG

Return immediately if there are no children to wait for.

WNOWAIT

Keep the process whose status is returned in *infop* in a waitable state. This will not affect the state of the process; the process may be waited for again after this call completes.

WSTOPPED

Status will be returned for any child that has stopped upon receipt of a signal.

The *infop* argument must point to a `siginfo_t` structure. If `waitid()` returns because a child process was found that specified the conditions indicated by the arguments *idtype* and *options* then the structure pointed to by *infop* will be filled in by the system with the status of the process. The `si_signo` member will always be equal to `SIGCHLD`.

Returned value

If `waitid()` returns due to the change of state of one of its children, it returns 0.

If unsuccessful, `waitid()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

ECHILD

The calling process has no existing unwaited-for child processes.

EINTR

The `waitid()` function was interrupted due to the receipt of a signal by the calling process.

EINVAL

An invalid value was specified for *options*, or *idtype* and *id* specify an invalid set of processes.

waitpid() — Wait for a specific child process to end

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <sys/wait.h>

pid_t waitpid(pid_t pid, int *status_ptr, int options);
```

General description

Suspends the calling process until a child process ends or is stopped. More precisely, waitpid() suspends the calling process until the system gets status information on the child. If the system already has status information on an appropriate child when waitpid() is called, waitpid() returns immediately. waitpid() is also ended if the calling process receives a signal whose action is either to execute a signal handler or to end the process.

pid_t pid

Specifies the child processes the caller wants to wait for:

- If *pid* is greater than 0, waitpid() waits for termination of the specific child whose process ID is equal to *pid*.
- If *pid* is equal to zero, waitpid() waits for termination of any child whose process group ID is equal to that of the caller.
- If *pid* is -1, waitpid() waits for any child process to end.
- If *pid* is less than -1, waitpid() waits for the termination of any child whose process group ID is equal to the absolute value of *pid*.

int *status_ptr

Points to a location where waitpid() can store a status value. This status value is zero if the child process explicitly returns zero status. Otherwise, it is a value that can be analyzed with the status analysis macros described in “Status Analysis Macros”, below.

The *status_ptr* pointer may also be NULL, in which case waitpid() ignores the child's return status.

int options

Specifies additional information for waitpid(). The *options* value is constructed from the bitwise inclusive-OR of zero or more of the following flags defined in the sys/wait.h header file:

WCONTINUED

Special behavior for XPG4.2: Reports the status of any continued child processes as well as terminated ones. The WIFCONTINUED macro lets a process distinguish between a continued process and a terminated one.

WNOHANG

Demands status information immediately. If status information is immediately available on an appropriate child process, waitpid() returns this information. Otherwise, waitpid() returns immediately with an error code indicating that the information was not available. In other words, WNOHANG checks child processes without causing the caller to be suspended.

WUNTRACED

Reports on stopped child processes as well as terminated ones. The WIFSTOPPED macro lets a process distinguish between a stopped process and a terminated one.

Special behavior for XPG4.2: If the calling process has SA_NOCLDWAIT set or has SIGCHLD set to SIG_IGN, and the process has no unwaited for children that were transformed into zombie processes, it will block until all of the children terminate, and waitpid() will fail and set errno to ECHILD.

Status analysis macros: If the *status_ptr* argument is not NULL, waitpid() places the child's return status in **status_ptr*. You can analyze this return status with the following macros, defined in the sys/wait.h header file:

WEXITSTATUS(*status_ptr)

When WIFEXITED() is nonzero, WEXITSTATUS() evaluates to the low-order 8 bits of the status argument that the child passed to the exit() or _exit() function, or the value the child process returned from main().

WIFCONTINUED(*status_ptr)

Special behavior for XPG4.2: This macro evaluates to a nonzero (true) value if the child process has continued from a job control stop. This should only be used after a waitpid() with the WCONTINUED option.

WIFEXITED(*status_ptr)

This macro evaluates to a nonzero (true) value if the child process ended normally (that is, if it returned from main(), or else called the exit() or _exit() function).

WIFSIGNALED(*status_ptr)

This macro evaluates to a nonzero (true) value if the child process ended because of a signal that was not caught.

WIFSTOPPED(*status_ptr)

This macro evaluates to a nonzero (true) value if the child process is currently stopped. This should only be used after a waitpid() with the WUNTRACED option.

WSTOPSIG(*status_ptr)

When WIFSTOPPED() is nonzero, WSTOPSIG() evaluates to the number of the signal that stopped the child.

WTERMSIG(*status_ptr)

When WIFSIGNALED() is nonzero, WTERMSIG() evaluates to the number of the signal that ended the child process.

Returned value

If successful, waitpid() returns a value of the process (usually a child) whose status information has been obtained.

If WNOHANG was given, and if there is at least one process (usually a child) whose status information is not available, waitpid() returns 0.

If unsuccessful, waitpid() returns -1 and sets errno to one of the following values:

| Error Code | Description |
|---------------|--|
| ECHILD | The process specified by <i>pid</i> does not exist or is not a child of the calling process, or the process group specified by <i>pid</i> does not exist or does not have any member process that is a child of the calling process. |
| EINTR | waitpid() was interrupted by a signal. The value of <i>*status_ptr</i> is undefined. |
| EINVAL | The value of <i>options</i> is incorrect. |

Example**CELEBW02**

```
/* CELEBW02

The following function suspends the calling process using &waitpid.
until a child process ends.

*/
#define _POSIX_SOURCE
#include <sys/types.h>
#include <sys/wait.h>
#include <unistd.h>
#include <stdio.h>
```

```
#include <time.h>

main() {
    pid_t pid;
    time_t t;
    int status;

    if ((pid = fork()) < 0)
        perror("fork() error");
    else if (pid == 0) {
        sleep(5);
        exit(1);
    }
    else do {
        if ((pid = waitpid(pid, &status, WNOHANG)) == -1)
            perror("wait() error");
        else if (pid == 0) {
            time(&t);
            printf("child is still running at %s", ctime(&t));
            sleep(1);
        }
        else {
            if (WIFEXITED(status))
                printf("child exited with status of %d\n", WEXITSTATUS(status));
            else puts("child did not exit successfully");
        }
    } while (pid == 0);
}
```

Output:

```
child is still running at Fri Jun 16 11:05:43 2006
child is still running at Fri Jun 16 11:05:44 2006
child is still running at Fri Jun 16 11:05:45 2006
child is still running at Fri Jun 16 11:05:46 2006
child is still running at Fri Jun 16 11:05:47 2006
child is still running at Fri Jun 16 11:05:48 2006
child is still running at Fri Jun 16 11:05:49 2006
child exited with status of 1
```

wait3(), wait4() — Wait for child process to change state

Standards

wait3():

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| XPG4.2 | both | |

wait4():

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

wait3():

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/wait.h>

pid_t wait3(int *stat_loc, int options, struct rusage *resource_usage);
```

wait4():

```
#define _XOPEN_SOURCE_EXTENDED 1
#define _XPLATFOM_SOURCE
#include <sys/wait.h>

pid_t wait4(pid_t pid, int *wstatus, int options, struct rusage *resource_usage);
```

General description

`wait3()` and `wait4()` functions allow the calling process to obtain status information for the specified child processes.

The following `wait3()` call:

```
wait3(stat_loc, options, resource_usage)
```

is equivalent to the call:

```
waitpid((pid_t)-1, stat_loc, options);
```

The following `wait4()` call:

```
wait4(pid, wstatus, options, resource_usage);
```

is equivalent to the call:

```
waitpid(pid, wstatus, options);
```

except that on successful completion, if the *resource_usage* argument to `wait3()` or `wait4()` is not a NULL pointer, the `rusage` structure that the third argument points to is filled in for the child process that is identified by the return value.

In other words, `wait3()` waits for any child whereas `wait4()` can be used to select a specific child or any child on which to wait. With a *pid* argument of -1, `wait4()` is equivalent to `wait3()`.

Note: This function is kept for historical reasons. It was part of the Legacy Feature in Single UNIX Specification, Version 2, but has been withdrawn and is not supported as part of Single UNIX Specification, Version 3. The `waitpid()` function is preferred for portability.

If it is necessary to continue using this function in an application written for Single UNIX Specification, Version 3, define the feature test macro `_UNIX03_WITHDRAWN` before including any standard system headers. The macro exposes all interfaces and symbols removed in Single UNIX Specification, Version 3.

Returned value

If successful, `wait3()` and `wait4()` return a value of the process (usually a child) whose status information has been obtained.

If unsuccessful, `wait3()` and `wait4()` might fail and set `errno` to one of the following values:

Error Code Description

ECHILD

The process that is specified by *pid* does not exist or is not a child of the calling process, or the process group specified by *pid* does not exist or does not have any member process that is a child of the calling process.

EINTR

`wait3()` or `wait4()` is interrupted by a signal.

EINVAL

The value of *options* is incorrect.

ECHILD

The calling process has no existing unwaited-for child processes, or if the set of processes specified by the argument *pid* can never be in the states that is specified by the argument *options*.

ESRCH

`wait4()` only: *pid* is equal to `INT_MIN`.

wcpcpy() — Copy wide-character string, returning pointer to its end

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1-2008 Single UNIX Specification, Version 4 | Both | z/OS 3.2 |

Format

```
#define _POSIX_C_SOURCE 200809L
#include <wchar.h>

wchar_t *wcpcpy(wchar_t *__restrict__ string1, const wchar_t *__restrict__
string2);
```

General description

The `wcpcpy()` function copies *string2*, including the terminating NULL wide-character (`L'\0'`), to the location that is specified by *string1*.

There must be room for at least `wcslen(string2)+1` wide-characters in the string that is pointed to by *string1*.

You cannot use a string literal for a *string1* value, although *string2* may be a string literal.

string2 and *string1* must not overlap. Otherwise, the behavior is undefined.

Returned value

`wcpncpy()` returns a pointer to the end of *string1*.

Note: No return values are reserved to indicate an error. To check for error situations, set `errno` to 0, call this function, then check `errno`.

Example

```
/*
 * This example copies the contents of wsource to wdest,
 * returning a pointer to the end of wdest.
 */

#define _POSIX_C_SOURCE 200809L
#include <stdio.h>
#include <wchar.h>

#define SIZE    40

int main(void)
{
    wchar_t wsource[ SIZE ] = L"test string";
    wchar_t wdest[ SIZE ];
    wchar_t * result;

    result = wcpncpy( wdest, wsource );

    /* use wcslen() to calculate length of wsource */
    printf( "result: \"%ls\\n", result - wcslen(wsource): \"%ls\\n\\n",
           result, result - wcslen(wsource) );
}
```

Output

```
result: "", result - wcslen(wsource): "test string"
```

wcpncpy() — Copy fixed-size wide-character string, returning pointer to its end

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1-2008 Single UNIX Specification, Version 4 | Both | z/OS 3.2 |

Format

```
#define _POSIX_C_SOURCE 200809L
#include
<wchar.h>

wchar_t *wcpncpy(wchar_t *__restrict__ string1, const wchar_t *__restrict__ string2, size_t
n);
```

General description

The `wcpncpy()` function copies at most *n* wide-characters before and including the terminating NULL wide-character (L'\0') from the string that is pointed to by *string2* to the location that is specified by *string1*.

If the string that is pointed to by *string2* is smaller than *n* wide-characters, the remaining wide-characters in the string that is pointed to by *string1* are filled with terminating NULL wide-characters (L'\0').

You cannot use a string literal for a *string1* value, although *string2* may be a string literal.

string2 and *string1* must not overlap. Otherwise, the behavior is undefined.

Returned value

`wcpncpy()` returns a pointer to the terminating NULL wide-character (L'\0') in *string1* if *string1* is null-terminated. Otherwise, `wcpncpy()` returns `&string1[n]`.

Note: No return values are reserved to indicate an error. To check for error situations, set `errno` to 0, call this function, then check `errno`.

Example

```
/*
   This example copies at most max_len wide-characters from
   wsource to wdest, returning a pointer to the end of wdest.
*/

#define _POSIX_C_SOURCE 200809L
#include <stdio.h>
#include <wchar.h>

#define SIZE    40

int main(void)
{
    wchar_t wsource[ SIZE ] = L"test string";
    wchar_t wdest[ SIZE ];
    size_t max_len = 9;
    wchar_t * result;

    result = wcpncpy( wdest, wsource, max_len );

    /* use wcsnlen() to calculate length of source string */
    printf( "result: \"%ls\\", "
            "result - wcsnlen(wsource, max_len): \"%ls\\\"\\n",
            result, result - wcsnlen(wsource, max_len) );
}
```

Output

```
result: "", result - wcsnlen(wsource, max_len): "test stri"
```

wcrtomb() – Convert a wide character to a multibyte character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C Amendment C99 Single UNIX Specification, Version 3 | both | |

Format

Non-XP4:

```
#include <wchar.h>

size_t wrtomb(char * __restrict__, wchar_t wchar, mbstate_t * __restrict__pss);
```

XP4:

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

size_t wrtomb(char *s, wchar_t wchar, mbstate_t *pss);
```

General description

If *s* is a NULL pointer, the `wrtomb()` function determines the number of bytes necessary to enter the initial shift state (zero if encodings are not state-dependent or if the initial conversion state is described). The resulting state described is the initial conversion state.

If *s* is not a NULL pointer, the `wrtomb()` function determines the number of bytes needed to represent the multibyte character that corresponds to the wide character given by *wchar* (including any shift sequences), and stores the resulting bytes in the array whose first element is pointed to by *s*. At most, `MB_CUR_MAX` bytes are stored. If *wchar* is a NULL wide character, the resulting state described is the initial conversion state.

`wrtomb()` is a “restartable” version of `wctomb()`. That is, shift state information is passed as one of the arguments and is updated on return. With `wrtomb()`, you can switch from one multibyte string to another, provided that you have kept the shift-state information for each multibyte string.

The behavior of this wide-character function is affected by the `LC_CTYPE` category of the current locale. If you change the category, undefined results can occur.

Special behavior for XP4: If you define any feature test macro specifying XP4 behavior before the statement in your program source file to include the `wchar` header, then you must also define the `_MSE_PROTOS` feature test macro to make the declaration of the `wrtomb()` function in the `wchar` header available when you compile your program. Please see [Table 2 on page 4](#) for a list of XP4 and other feature test macros.

Returned value

If *s* is a NULL pointer, `wrtomb()` returns the number of bytes needed to enter the initial shift state. The value returned will not be greater than that of `MB_CUR_MAX`.

If *s* is not a NULL pointer, `wrtomb()` returns the number of bytes stored in the array object (including any shift sequences) when *wchar* is a valid wide character. Otherwise, when *wchar* is not a valid wide character, an encoding error occurs, the value of the macro `EILSEQ` is stored in `errno` and `-1` is returned, but the conversion state remains unchanged.

Example

```
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    char    *string;
    wchar_t wc;
    size_t  length;
    length = wrtomb(string, wc, NULL);
}
```

wcscat() — Append to wide-character string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <wchar.h>

wchar_t *wcscat(wchar_t * __restrict__string1, const wchar_t * __restrict__string2);
```

General description

Appends a copy of the string pointed to by *string2* to the end of the string pointed to by *string1*.

The `wcscat()` function operates on NULL-terminated wide-character strings. The string arguments to this function must contain a wide NULL character marking the end of the string. Bounds checking is not performed.

The behavior of this wide-character function is affected by the `LC_CTYPE` category of the current locale. If you change the category, undefined results can occur.

Returned value

`wcscat()` returns the value of *string1*.

Example

CELEBW04

```
/* CELEBW04

   This example creates the wide character string "computer
   program" using &wcscat..

*/
#include <stdio.h>
#include <wchar.h>

#define SIZE 40

int main(void)
```

```

{
    wchar_t buffer1[SIZE] = L"computer";
    wchar_t * string      = L" program";
    wchar_t * ptr;

    ptr = wcscat( buffer1, string );
    printf( "buffer1 = %ls\n", buffer1 );
}

```

Output:

```
buffer1 = computer program
```

wcschr() — Search for wide-character substring

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C Amendment SAA XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```

#include <wchar.h>

wchar_t *wcschr(const wchar_t *string1, wchar_t character);

```

General description

Searches *string* for the occurrence of *character*. The *character* may be a wide NULL character (`\0`). The wide NULL character at the end of *string* is included in the search. The `wcschr()` function operates on NULL-terminated wide-character strings. The argument to this function must contain a wide NULL character marking the end of the string.

The behavior of this wide-character function is affected by the `LC_CTYPE` category of the current locale. If you change the category, undefined results can occur.

Returned value

If successful, wcschr() returns a pointer to the first occurrence of *character* in *string*.
If the character is not found, wcschr() returns a NULL pointer.

Example

CELEBW05

```
/* CELEBW05

   This example finds the first occurrence of the character p in
   the wide character string "computer program" using &wcschr..

*/
#include <stdio.h>
#include <wchar.h>

#define SIZE 40

int main(void)
{
    wchar_t buffer1[SIZE] = L"computer program";
    wchar_t * ptr;
    wint_t ch = L'p';

    ptr = wcschr( buffer1, ch );
    printf( "The first occurrence of %lc in '%ls' is '%ls'\n",
           ch, buffer1, ptr );
}
```

Output:

The first occurrence of p in 'computer program' is 'puter program'

wcscmp() – Compare wide-character strings

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <wchar.h>

int wcscmp(const wchar_t *string1, const wchar_t *string2);
```

General description

Compares two wide-character strings. The `wcscmp()` function operates on NULL-terminated wide-character strings. The string arguments to this function must contain a wide NULL character marking the end of the string.

The behavior of this wide-character function is affected by the `LC_CTYPE` category of the current locale. If you change the category, undefined results can occur.

Returned value

`wcscmp()` returns a value indicating the relationship between the two strings, as follows:

Value

Meaning

< 0

string pointed to by *string1* less than string pointed to by *string2*

= 0

string pointed to by *string1* identical to string pointed to by *string2*

> 0

string pointed to by *string1* greater than string pointed to by *string2*

Example

CELEBW06

```
/* CELEBW06

   This example compares the wide character string string1 to
   string2 using &wcscmp..

*/
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    int result;
    wchar_t string1[] = L"abcdef";
    wchar_t string2[] = L"abcdefg";

    result = wcscmp( string1, string2 );

    if ( result == 0 )
        printf( "\\%ls\\n" is identical to \\%ls\\n", string1, string2);
    else if ( result < 0 )
        printf( "\\%ls\\n" is less than \\%ls\\n", string1, string2 );
    else
        printf( "\\%ls\\n" is greater than \\%ls\\n", string1, string2);
}
```

Output:

```
"abcdef" is less than "abcdefg"
```

wscoll() — Language collation string comparison

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <wchar.h>

int wscoll(const wchar_t *wcs1, const wchar_t *wcs2);
```

General description

Compares the wide-character string pointed to by `wcs1` to the wide-character string pointed to by `wcs2`, both interpreted as appropriate to the `LC_COLLATE` category of the current locale.

Returned value

`wscoll()` returns an integer greater than, equal to, or less than zero, according to whether the wide string pointed to by `wcs1` is greater than, equal to, or less than the wide-character string pointed to by `wcs2`, when both wide-character strings are interpreted as appropriate to the `LC_COLLATE` category of the current locale.

`wscoll()` differs from `wscmp()`. `wscoll()` function performs a comparison between two wide character strings based on language collation rules as controlled by the `LC_COLLATE` category. On the other hand, `wscmp()` performs a wide-character code to wide-character code comparison.

`wscoll()` indicates error conditions by setting `errno`; however, there is no returned value to indicate an error. To check for errors, `errno` should be set to zero, and then checked upon return from `wscoll()`. If `errno` is nonzero, an error has occurred.

The `EILSEQ` error can be set to indicate that the `wcs1` or `wcs2` arguments contain characters outside the domain of the collating sequence.

Note: The ISO/C Multibyte Support Extensions do not indicate that the `wscoll()` function may return with an error.

Example

CELEBW07

```

/* CELEBW07 */
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    int result;
    wchar_t *wcs1 = L"first_wide_string";
    wchar_t *wcs2 = L"second_wide_string";

    result = wcscoll(wcs1, wcs2);

    if ( result == 0)
        printf("\'%ls\' is identical to \'%ls\'\\n", wcs1, wcs2);
    else if ( result < 0)
        printf("\'%ls\' is less than \'%ls\'\\n", wcs1, wcs2);
    else
        printf("\'%ls\' is greater than \'%ls\'\\n", wcs1, wcs2);
}

```

Output:

```
"first_wide_string" is less than "second_wide_string"
```

Related information

wcscopy() — Copy wide-character string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```

#include <wchar.h>

wchar_t *wcscopy(wchar_t * __restrict__string1, const wchar_t * __restrict__string2);

```

General description

Copies the contents of *string2* (including the ending wide NULL character) into *string1*. The *wcscopy()* function operates on NULL-terminated wide-character strings. The string arguments to this function must contain a wide NULL character marking the end of the string. Bounds checking is not performed.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Returned value

wcscpy() returns the value of *string1*.

Example

CELEBW08

```
/* CELEBW08

   This example copies the contents of source to destination using
   wcscpy().

*/
#include <stdio.h>
#include <wchar.h>

#define SIZE      40

int main(void)
{
    wchar_t source[ SIZE ] = L"This is the source string";
    wchar_t destination[ SIZE ] = L"And this is the destination string";
    wchar_t * return_string;

    printf( "destination is originally = \"%ls\\n", destination );
    return_string = wcscpy( destination, source );
    printf( "After wcscpy, destination becomes \"%ls\\n", destination );
}
```

Output:

destination is originally = "And this is the destination string"
After wcscpy, destination becomes "This is the source string"

wcscspn() — Find offset of first wide-character match

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <wchar.h>

size_t wcscspn(const wchar_t *string1, const wchar_t *string2);
```

General description

Determines the number of wide characters in the initial segment of the string pointed to by *string1* that do not appear in the string pointed to by *string2*. The `wcscspn()` function operates on NULL-terminated wide-character strings. The string arguments to these functions must contain a NULL wide character marking the end of the string.

The behavior of this wide-character function is affected by the `LC_CTYPE` category of the current locale. If you change the category, undefined results can occur.

Returned value

`wcscspn()` returns the number of wide characters in the segment.

Example

CELEBW09

```
/* CELEBW09

   This example uses &wcscspn. to find the first occurrence of
   any of the characters a, x, l, or e in string.

*/
#include <stdio.h>
#include <wchar.h>

#define SIZE    40

int main(void)
{
    wchar_t string[ SIZE ] = L"This is the source string";
    wchar_t * substring = L"axle";

    printf( "The first %i characters in the string \"%ls\" are not in the "
           "string \"%ls\" \n", wcscspn( string, substring),
           string, substring );
}
```

Output:

```
The first 10 characters in the string "This is the source string" are not
in the string "axle"
```

wcsftime() – Format date and time

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

Non-XPG4:

```
#include <wchar.h>

size_t wcsftime(wchar_t * __restrict__ wcs, size_t maxsize,
                const wchar_t * __restrict__ format,
                const struct tm * __restrict__ time_ptr)
```

XPG4:

```
#define _XOPEN_SOURCE
#include <wchar.h>

size_t wcsftime(wchar_t * __restrict__ wcs, size_t maxsize,
                const char * __restrict__ format,
                const struct tm * __restrict__ time_ptr)
```

XPG4 and MSE:

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

size_t wcsftime(wchar_t * __restrict__ wcs, size_t maxsize,
                const wchar_t * __restrict__ format,
                const struct tm * __restrict__ time_ptr)
```

General description

Format date and time into a wide character string. The wcsftime() function is equivalent to the strftime() function, except that:

- The argument *wcs* specifies an array of a wide string into which the generated output is to be placed.
- The argument *maxsize* indicates a number of wide characters.
- The argument **format* specifies an array of wide characters comprising the format string.
- The returned value indicates a number of wide characters.

Special behavior for XPG4: If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the wchar header, then the compiler assumes that your program is using the XPG4 variety of the wcsftime() function unless you also define the _MSE_PROTOS feature test macro. Please see [Table 2 on page 4](#) for a list of XPG4 and other feature test macros.

The prototype for the XPG4 variety of the wcsftime() function is:

```
size_t wcsftime(wchar_t *wcs, size_t maxsize, const char *format,
                const struct tm *time_ptr)
```

The difference between this variety and the MSE variety of the `wcsftime()` function is that the third argument *format* specifies an array of characters rather than an array of wide characters comprising the format string.

Returned value

If the total number of resulting wide characters including the terminating NULL wide character is not more than *maxsize*, `wcsftime()` returns the number of wide characters placed into the array pointed to by *wcs* not including the terminating NULL wide character.

If unsuccessful, `wcsftime()` returns 0 and the contents of the array are indeterminate.

Example

CELEBW10

```
/* CELEBW10 */
#include <stdio.h>
#include <time.h>
#include <wchar.h>

int main(void)
{
    struct tm *timeptr;
    wchar_t dest[100];
    time_t temp;
    size_t rc;

    temp = time(NULL);
    timeptr = localtime(&temp);
    rc = wcsftime(dest, sizeof(dest)-1, L" Today is %A,"
                  L" %b %d.\n Time: %I:%M %p", timeptr);
    printf("%d characters placed in string to make:\n\n%S", rc, dest);
}
```

Output:

42 characters placed in string to make:

Today is Friday, Jun 16.
Time: 01:48 pm

wcsid() — Character set ID for wide character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|-------------------------|----------|--------------|
| Language Environment | both | |

Format

```
#include <stdlib.h>

int wcsid(const wchar_t c)
```

External entry point: @@WCSID, __wcsid

General description

Determines the character set identifier for the specified wide character.

To avoid infringing on the user's name space, this nonstandard function has two names. One name is prefixed with two underscore characters, and one name is not. The name without the prefix underscore characters is exposed only when using the [runtime library extensions](#).

Returned value

If successful, wcsid() returns the character set identifier for the wide character.

If the wide character is not valid, wcsid() returns -1.

Example

CELEBW11

```
/* CELEBW11
   This example checks character set id for wide character.
*/
#include <locale.h>
#include <stdio.h>
#include <stdlib.h>

main() {
    wchar_t wc = L'A';
    int rc;

    rc = wcsid(wc);
    printf("wide character '%lc' is in character set id %i\n", wc, rc);
}
```

wcslen() – Calculate length of wide-character string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <wchar.h> /* or #include <wctype.h> */
size_t wcslen(const wchar_t *string);
```

General description

Computes the number of wide characters in the string pointed to by *string*.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Returned value

wcslen() returns the number of wide characters that precede the terminating wide NULL character.

Example

CELEBW12

```
/* CELEBW12

   This example computes the length of a wide-character string,
   using &wcslen.

   */
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    wchar_t * string = L"abcdef";

    printf( "Length of \"%ls\" is %i\n", string, wcslen( string ) );
}
```

Output:

```
Length of "abcdef" is 6
```

wcsncat() — Append to wide-character string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <wchar.h>

wchar_t *wcsncat(wchar_t * __restrict__ string1,
                 const wchar_t * __restrict__ string2, size_t count);
```

General description

Appends up to *count* wide characters from *string2* to the end of *string1* and appends a NULL wide character to the result. The `wcsncat()` function operates on NULL-terminated wide-character strings. The string arguments to this function must contain a NULL wide character marking the end of the string.

The behavior of this wide-character function is affected by the `LC_CTYPE` category of the current locale. If you change the category, undefined results can occur.

Returned value

`wcsncat()` returns *string1*.

Example

CELEBW13

```
/* CELEBW13

   This example demonstrates the difference between &wscat. and
   &wcsncat..
   &wscat. appends the entire second string to the first
   whereas &wcsncat. appends only the specified number of
   characters in the second string to the first.

*/
#include <stdio.h>
#include <wchar.h>
#include <string.h>

#define SIZE 40

int main(void)
{
    wchar_t buffer1[SIZE] = L"computer";
    wchar_t * ptr;

    /* Call wscat with buffer1 and " program" */

    ptr = wscat( buffer1, L" program" );
    printf( "wscat : buffer1 = \"%ls\\n\"", buffer1 );

    /* Reset buffer1 to contain just the string "computer" again */

    memset( buffer1, L'\0', sizeof( buffer1 ));
    ptr = wcsncpy( buffer1, L"computer" );

    /* Call wcsncat with buffer1 and " program" */
    ptr = wcsncat( buffer1, L" program", 3 );
    printf( "wcsncat: buffer1 = \"%ls\\n\"", buffer1 );
}
```

Output:

```
wscat : buffer1 = "computer program"
wcsncat: buffer1 = "computer pr"
```

wcsncmp() — Compare wide-character strings

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <wchar.h>

int wcsncmp(const wchar_t *string1, const wchar_t *string2, size_t count);
```

General description

Compares up to *count* wide characters in *string1* to *string2*. The `wcsncmp()` function operates on NULL-terminated wide-character strings. The string arguments to this function must contain a NULL wide character marking the end of the string.

The behavior of this wide-character function is affected by the `LC_CTYPE` category of the current locale. If you change the category, undefined results can occur.

Returned value

`wcsncmp()` returns a value indicating the relationship between the two strings, as follows:

Value

Meaning

< 0

string pointed to by *string1* less than the string pointed to by *string2*

= 0

string pointed to by *string1* identical to string pointed to by *string2*

> 0

string pointed to by *string1* greater than string pointed to by *string2*

Example

CELEBW14

```
/* CELEBW14

   This example demonstrates the difference between &wcsncmp.
   and &wcsncmp..

*/
#include <stdio.h>
#include <wchar.h>

#define SIZE 10

int main(void)
{
    int result;
    int index = 3;
    wchar_t buffer1[SIZE] = L"abcdefg";
    wchar_t buffer2[SIZE] = L"abcfg";
    void print_result( int, wchar_t *, wchar_t * );
```

```
result = wcsncmp( buffer1, buffer2, index);
printf( "\nComparison of only the first %i characters\n", index );
printf( "    wcsncmp: " );
print_result( result, buffer1, buffer2 );
}

void print_result( int res, wchar_t * p_buffer1, wchar_t * p_buffer2 )
{
    if ( res == 0 )
        printf( "\"%ls\" is identical to \"%ls\"\n", p_buffer1, p_buffer2);
    else if ( res < 0 )
        printf( "\"%ls\" is less than \"%ls\"\n", p_buffer1, p_buffer2 );
    else
        printf( "\"%ls\" is greater than \"%ls\"\n", p_buffer1, p_buffer2 );
}
```

Output:

```
Comparison of each character
wcsncmp: "abcdefg" is less than "abcfg"

Comparison of only the first 3 characters
wcsncmp: "abcdefg" is identical to "abcfg"
```

wcsncpy() — Copy wide-character string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <wchar.h>

wchar_t *wcsncpy(wchar_t * __restrict_string1,
                 const wchar_t * __restrict_string2, size_t count);
```

General description

Copies up to *count* wide characters from *string2* to *string1*. If *string2* is shorter than *count* characters, *string1* is padded out to *count* characters with NULL wide characters. The `wcsncpy()` function operates on

NULL-terminated wide-character strings. The string arguments to this function must contain a NULL wide character marking the end of the string.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Returned value

wcsncpy() returns *string1*.

Example

CELEBW15

```
/* CELEBW15

   This example demonstrates the difference between &wcscpy. and &wcsncpy..

*/
#include <stdio.h>
#include <wchar.h>

#define SIZE    40

int main(void)
{
    wchar_t source[ SIZE ] = L"123456789";
    wchar_t source1[ SIZE ] = L"123456789";
    wchar_t destination[ SIZE ] = L"abcdefg";
    wchar_t destination1[ SIZE ] = L"abcdefg";
    wchar_t * return_string;
    int index = 5;

    /* This is how wcscpy works */
    printf( "destination is originally = '%ls'\n", destination );
    return_string = wcscpy( destination, source );
    printf( "After wcscpy, destination becomes '%ls'\n\n", destination );

    /* This is how wcsncpy works */
    printf( "destination1 is originally = '%ls'\n", destination1 );
    return_string = wcsncpy( destination1, source1, index );
    printf( "After wcsncpy, destination1 becomes '%ls'\n", destination1 );
}
```

Output:

```
destination is originally = 'abcdefg'
After wcscpy, destination becomes '123456789'

destination1 is originally = 'abcdefg'
After wcsncpy, destination1 becomes '12345fg'
```

wcsnlen() — Determine fixed-size wide-character string length

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| POSIX.1-2008 Single UNIX Specification, Version 4 | both | z/OS 3.2 |

Format

```
#define _POSIX_C_SOURCE 200809L
#include <wchar.h>

size_t wcsnlen(const wchar_t *string, size_t n);
```

General description

The `wcsnlen()` function computes the smaller of the number of wide-characters in the string that is pointed to by *string*, not including the terminating NULL wide-character (L'\0'), or the value of the argument *n*. At most *n* wide-characters are compared.

Returned value

`wcsnlen()` returns the length of *string*, if that value is less than *n*, or *n* if there is no terminating NULL wide-character (L'\0) within the first *n* wide-characters of the string that is pointed to by *string*.

Example

```
/*
   This example determines the length of a
   wide-character string, up to SIZE bytes.
*/

#include _POSIX_C_SOURCE 200809L
#include <stdio.h>
#include <wchar.h>

#define SIZE    40

int main(void)
{
    wchar_t string[ SIZE ] = L"abcdefghijklmnopqrstuvwxyz";
    size_t result;

    result = wcsnlen( string, SIZE );

    printf( "Wide-character string \"%ls\" has a length of %d\n",
           string, result );
}
```

Output

```
Wide-character string "abcdefghijklmnopqrstuvwxyz" has a length of 26
```

wcpbrk() — Locate first wide characters in string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <wchar.h>

wchar_t *wcpbrk(const wchar_t *string1, const wchar_t *string2);
```

General description

Locates the first occurrence in the string pointed to by *string1* of any character from the string pointed to by *string2*.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Returned value

If successful, wcpbrk() returns a pointer to the character.

If no wchar_t from *string2* occurs in *string1*, wcpbrk() returns NULL.

Example

CELEBW16

```
/* CELEBW16

   This example returns a pointer to the first occurrence in the
   array string of either a or b, using &wcpbrk..

*/
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    wchar_t * result;
    wchar_t * string = L"The Blue Danube";
    wchar_t *chars = L"ab";

    result = wcpbrk( string, chars);
    printf("The first occurrence of any of the characters \"%ls\" in "
          "\"%ls\" is \"%ls\"\n", chars, string, result);
}
```

Output:

```
The first occurrence of any of the characters "ab" in "The Blue Danube" is "anube"
```

wcsrchr() — Locate last wide character in string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <wchar.h>

wchar_t *wcsrchr(const wchar_t *string, wchar_t character);
```

General description

Locates the last occurrence of *character* in the string pointed to by *string*. The terminating NULL wide character is considered to be part of the string.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Returned value

If successful, wcsrchr() returns a pointer to the character.

If *character* does not occur in the string, wcsrchr() returns NULL.

Example

CELEBW17

```
/* CELEBW17

   This example compares the use of wcschr() and wcsrchr().
   It searches the string for the first and last occurrence of p in the
   wide character string.

*/
#include <stdio.h>
#include <wchar.h>

#define SIZE 40

int main(void)
{
```

```

wchar_t buf[SIZE] = L"computer program";
wchar_t * ptr;
int ch = 'p';

/* This illustrates wcschr */
ptr = wcschr( buf, ch );
printf( "The first occurrence of %c in '%ls' is '%ls'\n", ch, buf, ptr );

/* This illustrates wcsrchr */
ptr = wcsrchr( buf, ch );
printf( "The last occurrence of %c in '%ls' is '%ls'\n", ch, buf, ptr );
}

```

Output:

```

The first occurrence of p in 'computer program' is 'puter program'
The last occurrence of p in 'computer program' is 'program'

```

wcsrtombs() — Convert wide-character string to multibyte string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment C99 Single UNIX Specification, Version 3 | both | |

Format**Non-XP4:**

```

#include <wchar.h>

size_t wcsrtombs(char * __restrict __dst,
                  const wchar_t ** __restrict __src, size_t len,
                  mbstate_t * __restrict __ps);

```

XP4:

```

#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

size_t wcsrtombs(char *dst,
                  const wchar_t **src, size_t len, mbstate_t *ps);

```

General description

Converts a sequence of wide characters from the array indirectly pointed to by *src* into a sequence of corresponding multibyte characters that begin in the shift state described by *ps*, which, if *dst* is not a NULL pointer, are then stored into the array pointed to by *dst*. Conversion continues up to and including the terminating NULL wide character; the terminating NULL wide character (byte) shall be stored.

Conversion shall stop earlier in two cases:

- When a code is reached that does not correspond to a valid multibyte character.
- If *dst* is not a NULL pointer, conversion stops when the next multibyte element would exceed the limit of *len* total bytes to be stored into the array pointed to by *dst*.

Each conversion takes places as if by a call to the `wcrtomb()` function.

If *dst* is not NULL a pointer, the object pointed to by *src* shall be assigned either a NULL pointer (if conversion stopped due to reaching a terminating NULL wide character) or the address of the code just past the last wide character converted. If conversion stopped due to reaching a terminating NULL wide character, the resulting state described shall be the initial conversion state.

`wcsrtombs()` is a “restartable” version of `wcstombs()`. That is, shift state information is passed as on of the arguments, and gets updated on exit. With `wcsrtombs()`, you may switch from one multibyte string to another, provided that you have kept the shift state information.

The behavior of this wide-character function is affected by the `LC_CTYPE` category of the current locale. If you change the category, undefined results can occur.

Special behavior for XPG4: If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the `wchar` header, then you must also define the `_MSE_PROTOS` feature test macro to make the declaration of the `wcsrtombs()` function in the `wchar` header available when you compile your program. Please see [Table 2 on page 4](#) for a list of XPG4 and other feature test macros.

Returned value

If successful, `wcsrtombs()` returns the number of bytes in the resulting multibyte character sequence, which is the same as the number of array elements modified when *dst* is not a NULL pointer.

If the string contains an invalid wide character, an encoding error occurs. `wcsrtombs()` returns `(size_t)-1` and stores the value of the macro `EILSEQ` in `errno`, but the conversion state shall be unchanged.

Example

CELEBW18

```
/* CELEBW18 */
#include <stdio.h>
#include <string.h>
#include <wchar.h>

#define SIZE 20

int main(void)
{
    char    dest[SIZE];
    wchar_t *wcs = L"string";
    const wchar_t *ptr;
    size_t   count = SIZE;
    size_t   length;

    ptr = (wchar_t *) wcs;
    length = wcsrtombs(dest, &ptr, count, NULL);
    printf("%d characters were converted.\n", length);
    printf("The converted string is \"%s\"\n\n", dest);

    /* Reset the destination buffer */
    memset(dest, '\\0', sizeof(dest));

    /* Now convert only 3 characters */
```

```

ptr = (wchar_t *) wcs;
length = wcsrtombs(dest, &ptr, 3, NULL);
printf("%d characters were converted.\n", length);
printf("The converted string is \"%s\"\n\n", dest);
}

```

Output:

```

6 characters were converted.
The converted string is "string"

3 characters were converted.
The converted string is "str"

```

wcssp() — Search for wide characters in a string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```

#include <wchar.h>

size_t wcssp(const wchar_t *string1, const wchar_t *string2);

```

General description

Computes the number of wide characters in the initial segment of the string pointed to by *string1*, which consists entirely of wide characters from the string pointed to by *string2*.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Returned value

wcssp() returns the number of wide characters in the segment.

Example

CELEBW19

```
/* CELEBW19

This example finds the first occurrence in the array string
of a character that is neither an a, b, nor c. Because the
string in this example is cabbage, &wcssp. returns 5, the
index of the segment of cabbage before a character that is
not an a, b, or c.

*/
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    wchar_t * string = L"cabbage";
    wchar_t * source = L"abc";
    int index;

    index = wcssp( string, L"abc" );
    printf( "The first %d characters of \"%ls\" are found in \"%ls\"\\n",
            index, string, source );
}
```

Output:

The first 5 characters of "cabbage" are found in "abc"

wcsstr() — Locate a wide character sequence

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C Amendment C99 Single UNIX Specification, Version 3 | both | |

Format

Non-XP4:

```
#include <wchar.h>

wchar_t *wcsstr(const wchar_t *__restrict__ wcs1,
                const wchar_t *__restrict__ wcs2);
```

XPG4:

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

wchar_t *wcsstr(const wchar_t *__restrict__ wcs1,
                const wchar_t *__restrict__ wcs2);
```

General description

Locates the first occurrence in the wide-character string pointed to by *wcs1* of the sequence of wide characters (excluding the terminating NULL character) in the wide-character string pointed to by *wcs2*.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Special behavior for XPG4: If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the *wchar* header, then you must also define the *_MSE_PROTOS* feature test macro to make the declaration of the *wcsstr()* function in the *wchar* header available when you compile your program. Please see [Table 2 on page 4](#) for a list of XPG4 and other feature test macros.

Returned value

If successful, *wcsstr()* returns a pointer to the located wide string. If *wcs2* points to a wide-character string with zero length, *wcsstr()* returns *wcs1*.

If the wide-character string is not found, *wcsstr()* returns NULL.

Example**CELEBW20**

```
/* CELEBW20 */
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    wchar_t *wcs1 = L"needle in a haystack";
    wchar_t *wcs2 = L"hay";
    wchar_t *result;

    result = wcsstr(wcs1, wcs2);

    /* result = a pointer to "hatstack" */

    printf("result: '%S'\n", result);
}
```

wcstod() — Convert wide-character string to a double floating-point

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <wchar.h>

double wcstod(const wchar_t * __restrict__ nptr, wchar_t ** __restrict__ endptr);
```

General description

The `wcstod()` function converts a `wchar_t *` type floating-point number input string to a double value.

See the “*fscanf* Family of Formatted Input Functions” on `fscanf()`, `scanf()`, `sscanf()` — Read and format data for a description of special infinity and NaN sequences recognized by z/OS formatted input functions, including `wcstod()` in IEEE Binary Floating-Point mode.

Converts the initial portion of the wide-character string pointed to by *nptr* to double representation. First it decomposes the input string into three parts:

1. An initial, possibly empty, sequence of white space characters (as specified by the `iswspace()` function)
2. A subject sequence interpreted as a floating-point constant or representing infinity or a NaN.
3. A final string of one or more unrecognized characters, including the terminating NULL character of the input string.

Then it attempts to convert the subject sequence to a floating-point number, and returns the result.

The expected form of the subject sequence is an optional plus or minus sign, then one of the following:

- A non-empty sequence of decimal digits optionally containing a radix character, then an optional exponent part. Where radix character is the character that separates the integer part of a number from the fractional part.
- A 0x or 0X, then a non-empty sequence of hexadecimal digits optionally containing a radix character, then an optional binary exponent part. Where radix character is the character that separates the integer part of a number from the fractional part.
- One of INF or INFINITY, ignoring case.
- One of NANQ or NANQ(n-char-sequence), ignoring case.
- One of NANS or NANS(n-char-sequence), ignoring case.
- One of NAN or NAN(n-char-sequence), ignoring case.

The subject sequence is defined as the longest initial subsequence of the input wide-character string, starting with the first non-white space wide character, that is of the expected form. The subject sequence contains no wide characters if the input wide-character string is empty or consists entirely of white space wide characters, or if the first non-white space wide character is other than a sign, a digit, or a decimal-point wide character.

If the subject sequence has the expected form, the sequence of wide characters starting with the first digit or the decimal-point wide character (whichever occurs first) is interpreted as a floating constant according to the rules of ISO/IEC 9899: subclause 6.1.3.1, except the decimal-point wide character is used in place of a period, and if neither an exponent part nor a decimal-point wide character appears, a decimal-point is assumed to follow the last digit in the wide-character string. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A pointer to the final wide-character string is stored in the object pointed to by *endptr*, provided that *endptr* is not a NULL pointer.

In a locale other than the C locale, additional implementation-defined subject sequence forms may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *nptr* is stored in the object pointed to by *endptr*, provided that *endptr* is not a NULL pointer.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Returned value

If successful, `wcstod()` returns the converted value, if any.

If no conversion could be performed, `wcstod()` returns 0.

The double value is hexadecimal floating-point or IEEE Binary Floating-Point format depending on the floating-point mode of the thread invoking `wcstod()`. The `wcstod()` function uses `__isBFP()` to determine the floating-point format (hexadecimal floating-point or IEEE Binary Floating-Point) of the invoking thread.

If the correct value is outside the range of representable values, `wcstod()` returns $\pm\text{HUGE_VAL}$ —according to the sign of the value—and the value of the macro `ERANGE` is stored in `errno`.

Example

CELEBW21

```
/* CELEBW21 */
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    wchar_t *wcs;
    wchar_t *stopwcs;
    double d;

    wcs = L"3.1415926This stopped it";
    d = wcstod(wcs, &stopwcs);
    printf("wcs = '%ls'\n", wcs);
    printf("    wcstod = %f\n", d);
    printf("    Stopped scan at '%ls'\n", stopwcs);
}
```

wcstod32(), wcstod64(), wcstod128() – Convert wide-character string to decimal floating point

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C/C++ DFP | both | z/OS V1.8 |

Format

```
#define __STDC_WANT_DEC_FP__
#include <wchar.h>

_Decimal32 wcstod32(const wchar_t * __restrict__ nptr,
                    wchar_t ** __restrict__ endptr);

_Decimal64 wcstod64(const wchar_t * __restrict__ nptr,
                    wchar_t ** __restrict__ endptr);

_Decimal128 wcstod128(const wchar_t * __restrict__ nptr,
                      wchar_t ** __restrict__ endptr);
```

General description

The `wcstod32()`, `wcstod64()`, and `wcstod128()` functions convert the initial portion of the wide-character string pointed to by *nptr* to `_Decimal32`, `_Decimal64`, and `_Decimal128` representation, respectively.

First, they decompose the input wide-character string into three parts:

1. An initial, possibly empty, sequence of white-space wide characters (as specified by the `iswspace()` function).
2. A subject sequence resembling a floating-point constant or representing an infinity or NaN.
3. A final wide-character string of one or more unrecognized wide characters, including the terminating null wide character of the input wide-character string.

Then, they attempt to convert the subject sequence to a floating-point number, and return the result.

The expected form of the subject sequence is an optional plus or minus sign, then one of the following:

- a nonempty sequence of decimal digits optionally containing a decimal-point wide character, then an optional exponent part
- INF or INFINITY, ignoring case
- NAN, NAN(n-char-sequence), NANQ, NANQ(n-char-sequence), NANS, or NANS(n-char-sequence), ignoring case in the NAN, NANQ, or NANS part, where n-char-sequence is one or more decimal numeric digits

Note: If the input string is not one of these forms (for example "INFINITE"), the output results are undefined.

The subject sequence is defined as the longest initial subsequence of the input wide-character string, starting with the first non-white-space wide character, that is of the expected form. The subject sequence contains no wide characters if the input wide character string is not of the expected form.

If the subject sequence has the expected form for a floating-point number, the sequence of wide characters starting with the first digit or the decimal-point wide character (whichever occurs first) is interpreted as a floating constant. If neither an exponent nor a decimal-point character appears in a decimal floating point number, an exponent with value zero is assumed to follow the last digit in the string. If the subject sequence begins with a minus sign, the sequence is interpreted as negated. A wide character sequence INF or INFINITY is interpreted as an infinity. A wide character sequence NAN,

NAN(), or NAN(n-char-sequence) is interpreted as a quiet NaN. A wide character sequence of NANS, NANS(), or NANS(n-char-sequence), is interpreted as a signalling NaN.

A pointer to the final wide-character string is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

The converted value keeps the same precision as the input if possible, and the value may be denormalized. Otherwise, rounding may occur. Rounding happens after any negation.

In other than the "C" locale, additional locale-specific subject sequence forms are accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *nptr* is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

| Argument | Description |
|---------------|--|
| <i>nptr</i> | Input pointer to start of the wide-character string to be converted |
| <i>endptr</i> | NULL, or a pointer to a output pointer field that is filled in with the address of the first wide character in the input wide-character string that is not used in the conversion. |

Note: To use IEEE decimal floating-point, the hardware must have the Decimal Floating-Point Facility installed.

Returned value

The functions return the converted value, if any. If no conversion could be performed, the value +0.E0DF, +0.E0DD, or +0.E0DL is returned. If the correct value is outside the range of representable values, plus or minus HUGE_VAL_D32, HUGE_VAL_D64, or HUGE_VAL_D128 is returned (according to the return type and sign of the value), and *errno* is set to ERANGE. If the result underflows, the functions return a value whose magnitude is no greater than the smallest normalized positive number in the return type. No signal is raised at the point of returning a signaling NaN.

| errno | Description |
|--------|--|
| ERANGE | The input wide-character string represents a value too large to fit in the output Decimal Floating Point type. |

Example

See [“wcstod\(\) — Convert wide-character string to a double floating-point” on page 2014](#) for an example.

Related information

- [“wchar.h — ISO/C Multibyte Support extensions” on page 79](#)
- [“wcstod\(\) — Convert wide-character string to a double floating-point” on page 2014](#)

wcstof() – Convert a wide-character string to float

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _ISOC99_SOURCE
#include <wchar.h>

float wcstof(const wchar_t *__restrict__ nptr, wchar_t **__restrict__ endptr);
```

General description

wcstof() converts a wchar_t * floating-point number input string to a float value. The parameter *nptr* points to a sequence of wide-characters that can be interpreted as a numerical float value.

It decomposes the input wide-character string into three parts:

1. An initial, possibly empty, sequence of white-space character codes (as specified by `iswspace()`).
2. A subject sequence resembling a floating-point constant, infinity, or NaN.
3. A final wide-character string of one or more unrecognized wide-characters codes, including the terminating NULL wide-character of the input wide-character string.

The function then attempts to convert the subject string into the floating-point number, and returns the result.

The expected form of the subject sequence is an optional plus or minus sign, then one of the following:

- A non-empty sequence of decimal digits optionally containing a radix character, then an optional exponent. A radix character is the character that separates the integer part of a number from the fractional part.
- A 0x or 0X, a non-empty sequence of hexadecimal digits optionally containing a radix character, then a base 2 decimal exponent part with a p or P as prefix, a plus or minus sign, then a sequence of at least one decimal digit. (Example [-]0xh.hhhhp+/-d). A radix character is the character that separates the integer part of a number from the fractional part.
- One INF or INFINITY, ignoring case.
- One NANQ or NANQ(n-char-sequence), ignoring case.
- One NANS or NANS(n-char-sequence), ignoring case.
- One NAN or NAN(n-char-sequence), ignoring case.

See the "scanf() Family of Formatted Input Functions" for a description of special infinity and NaN sequences recognized by z/OS formatted input functions in IEEE Binary Floating-Point mode. A pointer to the final wide-character string is stored in the object pointed to by *endptr*, provided that *endptr* is not a NULL pointer.

Returned value

If successful, wcstof() returns the converted value, if any. If no conversion could be performed, it returns 0.

The float value is a hexadecimal floating-point or IEEE Binary Floating-Point format depending on the floating-point mode of the thread invoking `wcstof()`. This function uses `__isBFP()` to determine the floating-point mode of the invoking thread.

If the correct value is outside the range of representable values, then `+/-HUGE_VALF`, according to the sign of the value, is returned and the value of the `ERANGE` macro is stored in `errno`. If the correct value would cause an underflow, 0 is returned and the value of the `ERANGE` macro is stored in `errno`.

wcstoimax() — Convert a wide-character string to a intmax_t

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _ISOC99_SOURCE
#include <inttypes.h>

intmax_t wcstoimax(const wchar_t * __restrict__ nptr,
                  wchar_t ** __restrict__ endptr, int base);
```

Compile requirement: Function `wcstoimax()` requires `long long` to be available.

General description

The `wcstoimax()` function converts the wide-character string `nptr` to an `intmax_t` integer type. Valid input values for `base` are 0 and in the range 2-36. The `wcstoimax()` function is equivalent to `wcstol()` and `wcstoll()`. The only difference being that the return value is of type `intmax_t`. See `wcstoll()` for more information.

Returned value

If successful, `wcstoimax()` returns the converted value, if any.

If unsuccessful, `wcstoimax()` returns 0 if no conversion could be performed. If the correct value is outside the range of representable values, `wcstoimax()` returns `INTMAX_MAX` or `INTMAX_MIN`, according to the sign of the value. If the value of `base` is not supported, `wcstoimax()` returns 0.

If unsuccessful `wcstoimax()` sets `errno` to one of the following values:

Error Code
Description

EINVAL
The value of *base* is not supported.

ERANGE
The conversion caused an overflow.

Example

```
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>

int main(void)
{
    wchar_t *nptr;
    wchar_t *endptr;
    intmax_t j;
    int base = 10;
    nptr = L"10110134932";
    printf("nptr = `%ls`\n", nptr);
    j = wcstoimax(nptr, &endptr, base);
    printf("wcstoimax = %jd\n", j);
    printf("Stopped scan at `%ls`\n\n", endptr);
}
```

Output

```
nptr = `10110134932`
wcstoimax = 10110134932
Stopped scan at ``
```

wcstok() – Break a wide-character string into tokens

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

Non-XP4:

```
#include <wchar.h>

wchar_t *wcstok(wchar_t * __restrict __wcs1,
                const wchar_t * __restrict __wcs2, wchar_t ** __restrict __ptr);
```

XP4:

```
#define _XOPEN_SOURCE
#include <wchar.h>

wchar_t *wcstok(wchar_t *wcs1, const wchar_t *wcs2);
```

XP4 and MSE:

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

wchar_t *wcstok(wchar_t *wcs1,
                const wchar_t *wcs2, wchar_t **ptr);
```

General description

A sequence of calls to the `wcstok()` function breaks the wide string pointed to by `wcs1` into a sequence of tokens, each of which is delimited by a wide character from the wide string pointed to by `wcs2`. The third argument points to a caller-provided wide-character pointer into which the `wcstok()` function stores information necessary for it to continue scanning the same string.

The first call in the sequence, `wcs1` shall point to a wide-character string, while in subsequent calls for the same wide string, `wcs1` shall be a NULL pointer. If `wcs1` is a NULL pointer, the value pointed to by `ptr` shall match that set by the previous call for the same wide-character string; otherwise its value is ignored. The separator wide-character string pointed to by `wcs2` may be different from call to call.

The first call in the sequence, searches the wide-character string pointed to by `wcs1` for the first wide character that is not contained in the current separator wide-character string pointed to by `wcs2`. If no such wide character is found, then there are no tokens in the wide-character string pointed to by `wcs1` and `wcstok()` returns a NULL pointer. If such a wide character is found, it is the start of the first token.

`wcstok()` then searches from there for a wide character that is contained in the current separator wide string. If no such wide character is found, the current token extends to the end of the wide-character string pointed to by `wcs1`, and subsequent searches for a token will return a NULL pointer. If such a wide character is found, it is overwritten by a NULL character, which terminates the current token.

In all cases, the `wcstok()` function stores sufficient information in the pointer `ptr` so that subsequent calls, with a NULL pointer as the value of the first argument and the unmodified pointer value as the third, will start searching just past the end of the previously returned token (if any).

The behavior of this wide-character function is affected by the `LC_CTYPE` category of the current locale. If you change the category, undefined results can occur.

Special behavior for XP4: If you define any feature test macro specifying XP4 behavior before the statement in your program source file to include the `wchar` header, then the compiler assumes that your program is using the XP4 variety of the `wcstok()` function, unless you also define the `_MSE_PROTOS` feature test macro. Please see [Table 2 on page 4](#) for a list of XP4 and other feature test macros.

The prototype for the XP4 variety of the `wcstok()` function is:

```
wchar_t *wcstok(wchar_t *wcs1, const wchar_t *wcs2);
```

This variety of the `wcstok()` function is missing a third parameter to specify the address of restart information in your program storage. Instead, C/370 provides comparable restart information in runtime

library storage. Please note that this library storage is provided on a per thread basis making the XPG4 wcstok() function thread-specific for a threaded application.

Returned value

If successful, wcstok() returns a pointer to the first wide character of a token.
If there is no token, wcstok() returns a NULL pointer.

Example

CELEBW22

```
/* CELEBW22 */
#include <wchar.h>
int main(void)
{
    static wchar_t str1[] = L"?a??b,,,#c";
    static wchar_t str2[] = L"\t \t";
    wchar_t *t, *ptr1, *ptr2;

    t = wcstok(str1, L"?", &ptr1);    /* t points to the token L"a" */
    t = wcstok(NULL, L",", &ptr1);    /* t points to the token L"??b" */
    t = wcstok(str2, L" \t", &ptr2);  /* t is a null pointer */
    t = wcstok(NULL, L"#", &ptr1);    /* t points to the token L"c" */
    t = wcstok(NULL, L"?", &ptr1);    /* t is a null pointer */
}
```

wcstol() — Convert a wide-character string to a long integer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <wchar.h>

long int wcstol(const wchar_t * __restrict_nptr,
                wchar_t ** __restrict_endptr, int base);
```

General description

Converts the initial portion of the wide-character string pointed to by nptr to long int representation. First it decomposes the input wide-character string into three parts:

1. An initial, possibly empty, sequence of white space wide characters (as specified by the `iswspace()` function).
2. A subject sequence resembling an integer determined by the value of `base`.
3. A final wide-character string of one or more unrecognized wide characters, including the terminating NULL character of the input wide-character string.

Then it attempts to convert the subject sequence to an integer, and returns the result.

If the value of `base` is zero, the expected form of the subject sequence is that of an integer constant as described in ISO/IEC 9899: subclause 6.1.3.2, optionally preceded by a plus or minus sign, but not including an integer suffix. If the value of `base` is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits from the portable character set representing an integer with the radix specified by `base`, optionally preceded by a plus or minus sign, but not including an integer suffix. The letters from `a` (or `A`) through `z` (or `Z`) are ascribed the values 10 to 35; only letters whose ascribed values are less than that of `base` are permitted. If the value of `base` is 16, the characters `0x` or `0X` may optionally precede the sequence of letters and digits, following the sign if present.

The subject sequence is defined as the longest initial subsequence of the input wide-character string, starting with the first non-white space wide character, that is of the expected form. The subject sequence contains no wide characters if the input wide-character string is empty or consists entirely of white space, or if the first non-white space wide character is other than a sign or a permissible letter or digit.

If the subject sequence has the expected form and the value of `base` is zero, the sequence of wide characters starting with the first digit is interpreted as an integer constant according to the rules of ISO/IEC 9899: subclause 6.1.3.2. If the subject sequence has the expected form and the value of `base` is between 2 and 36, it is used as the base for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A pointer to the final wide-character string is stored in the object pointed to by `endptr`, provided that `endptr` is not a NULL pointer.

In a locale other than the C or POSIX locale, additional implementation-defined subject sequence forms may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of `nptr` is stored in the object pointed to by `endptr`, provided that `endptr` is not a NULL pointer.

The behavior of this wide-character function is affected by the `LC_CTYPE` category of the current locale. If you change the category, undefined results can occur.

Since 0, `{LONG_MIN}` and `{LONG_MAX}` are returned on error and are also valid returns on success, an application wishing to check for error situations should set `errno` to 0, then call `wcstol()`, then check `errno`.

Returned value

If successful, `wcstol()` returns the converted value, if any.

If unsuccessful, `wcstol()` returns 0 if no conversion could be performed. If the correct value is outside the range of representable values, `wcstol()` returns `LONG_MAX` or `LONG_MIN`, according to the sign of the value. If the value of `base` is not supported, `wcstol()` returns 0.

If unsuccessful `wcstol()` sets `errno` to one of the following values:

Error Code

Description

EINVAL

The value of `base` is not supported.

ERANGE

The conversion caused an overflow.

Example

CELEBW23

```
/* CELEBW23 */
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    wchar_t *wcs;
    wchar_t *stopwcs;
    long    l;
    int     base;

    wcs = L"10110134932";
    printf("wcs = `%ls`\n", wcs);
    for (base=2; base<=8; base*=2) {
        l = wcstol(wcs, &stopwcs, base);
        printf("    wcstol = %ld\n", l);
        printf("    Stopped scan at `%ls`\n\n", stopwcs);
    }
}
```

wcstold() — Convert a wide-character string to long double

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _ISOC99_SOURCE
#include <wchar.h>

long double wcstold(const wchar_t *__restrict__ nptr,
                    wchar_t **__restrict__ endptr);
```

General description

wcstold() converts a wchar_t * floating-point number input string to a long double value. The parameter nptr points to a sequence of wide-characters that can be interpreted as a numerical long double value. It decomposes the input wide-character string into three parts:

1. An initial, possibly empty, sequence of white-space wide-character codes (as specified by iswspace()).
2. A subject sequence resembling a floating-point constant, infinity, or NaN.
3. A final wide-character string of one or more unrecognized wide-characters codes, including the terminating NULL wide-character of the input wide-character string.

The function then attempts to convert the subject string into the floating-point number, and returns the result.

The expected form of the subject sequence is an optional plus or minus sign, then one of the following:

- A non-empty sequence of decimal digits optionally containing a radix character, then an optional exponent. A radix character is the character that separates the integer part of a number from the fractional.
- A 0x or 0X, a non-empty sequence of hexadecimal digits optionally containing a radix character, then a base 2 decimal exponent part with a p or P as prefix, a plus or minus sign, then a sequence of at least one decimal digit. (Example [-]0xh.hhhhp+/-d). A radix character is the character that separates the integer part of a number from the fractional part.
- One INF or INFINITY, ignoring case.
- One NANQ or NANQ(n-char-sequence), ignoring case.
- One NANS or NANS(n-char-sequence), ignoring case.
- One NAN or NAN(n-char-sequence), ignoring case.

See the "scanf() Family of Formatted Input Functions" for a description of special infinity and NaN sequences recognized by z/OS formatted input functions in IEEE Binary Floating-Point mode. The pointer to the final wide-character string is stored in the object pointed to by *endptr*, provided that *endptr* is not a NULL pointer.

Returned value

If successful, `wcstold()` returns the converted value, if any. If no conversion could be performed, it returns 0.

The long double value is a hexadecimal floating-point or IEEE Binary Floating-Point format depending on the floating-point mode of the invoking thread. This function uses `__isBFP()` to determine the floating-point mode of the invoking thread.

If the correct value is outside the range of representable values, then `+/-HUGE_VALL`, according to the sign of the value, is returned and the value of the `ERANGE` macro is stored in `errno`.

wcstoll() — Convert a wide-character string to a long long integer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| z/OS UNIX System Services C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | OS/390 V2R10 |

Format

```
#include <wchar.h>

long long wcstoll(const wchar_t * __restrict_nptr,
                  wchar_t ** __restrict_endptr, int base);
```

Compile requirement: Use of this function requires the long long data type. See [z/OS XL C/C++ Language Reference](#) for information on how to make long long available.

General description

Converts the initial portion of the wide-character string pointed to by *nptr* to long long representation. First it decomposes the input wide-character string into three parts:

1. An initial, possibly empty, sequence of white space wide characters (as specified by the `iswspace()` function).
2. A subject sequence resembling an integer determined by the value of *base*.
3. A final wide-character string of one or more unrecognized wide characters, including the terminating NULL character of the input wide-character string.

Then it attempts to convert the subject sequence to a long long integer, and returns the result.

If the value of *base* is zero, the expected form of the subject sequence is that of an integer constant as described in ISO/IEC 9899: subclause 6.1.3.2, optionally preceded by a plus or minus sign, but not including an integer suffix. If the value of *base* is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits from the portable character set representing an integer with the radix specified by *base*, optionally preceded by a plus or minus sign, but not including an integer suffix. The letters from a (or A) through z (or Z) are ascribed the values 10 to 35; only letters whose ascribed values are less than that of *base* are permitted. If the value of *base* is 16, the characters 0x or 0X may optionally precede the sequence of letters and digits, following the sign if present.

The subject sequence is defined as the longest initial subsequence of the input wide-character string, starting with the first non-white space wide character, that is of the expected form. The subject sequence contains no wide characters if the input wide-character string is empty or consists entirely of white space, or if the first non-white space wide character is other than a sign or a permissible letter or digit.

If the subject sequence has the expected form and the value of *base* is zero, the sequence of wide characters starting with the first digit is interpreted as an integer constant according to the rules of ISO/IEC 9899: subclause 6.1.3.2. If the subject sequence has the expected form and the value of *base* is between 2 and 36, it is used as the *base* for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A pointer to the final wide-character string is stored in the object pointed to by *endptr*, provided that *endptr* is not a NULL pointer.

In a locale other than the C or POSIX locale, additional implementation-defined subject sequence forms may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *nptr* is stored in the object pointed to by *endptr*, provided that *endptr* is not a NULL pointer. The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Since 0, {LLONG_MIN} and {LLONG_MAX} are returned on error and are also valid returns on success, an application wishing to check for error situations should set `errno` to 0, then call `wcstoll()`, then check `errno`.

Note: The `wcstoll()` function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support”](#) on page 2123 for details.

Returned value

If successful, `wcstoll()` returns the converted value, if any.

If unsuccessful, `wcstoll()` returns 0 if no conversion could be performed. If the correct value is outside the range of representable values, `wcstoll()` returns `LLONG_MAX` (`LONGLONG_MAX`) or `LLONG_MIN` (`LONGLONG_MIN`), according to the sign of the value. If the value of `base` is not supported, `wcstoll()` returns 0.

If unsuccessful `wcstoll()` sets `errno` to one of the following values:

Error Code

Description

EINVAL

The value of *base* is not supported.

ERANGE

The conversion caused an overflow.

Example

```
/* Long Long example */
#define _LONG_LONG 1
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    wchar_t *wcs;
    wchar_t *stopwcs;
    long long l;
    int base;

    wcs = L"10110134932";
    printf("wcs = `%ls`\n", wcs);
    for (base=2; base<=8; base*=2) {
        l = wcstoll(wcs, &stopwcs, base);
        printf("    wcstoll = %lld\n", l);
        printf("    Stopped scan at `%ls`\n\n", stopwcs);
    }
}
```

wcstombs() – Convert wide-character string to multibyte character string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdlib.h>

size_t wcstombs(char * __restrict__dest,
                const wchar_t * __restrict__string, size_t count);
```

General description

Converts the wide-character string pointed to by *string* into the multibyte array pointed to by *dest*. The converted string begins in the initial shift state. The conversion stops after *count* bytes in *dest* are filled up or a NULL wide character is encountered.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

If unsuccessful, `mbstowcs()` returns `(size_t) -1` and sets `errno` to one of the following values:

Error Code

Description

EINVAL

The input argument is a NULL rather than a pointer to a wide character.

EILSEQ

`wcstombs()` encountered a sequence that is not a valid wide character code.

The `mbstowcs()` interface checks for an invalid input arg. If the third arg, which should be a pointer to a string of `wchar_t` elements, is NULL, the interface will set `errno` to `EINVAL` as well as returning `-1`. This clearly differentiates from the situation in which the third arg is a pointer to null, in which case should return 1 and the multibyte target string will contain a null byte.

Returned value

Returns the length in bytes of the multibyte character string, not including a terminating NULL wide character. The value `(size_t) -1` is returned if an invalid multibyte character is encountered or if **string* is a NULL pointer.

If *count* is the returned value, the array is not NULL-terminated.

If **dest* is a NULL pointer, the number of characters required to convert the wide-character string is returned.

If the area pointed to by **dest* is too small (as indicated by the value of *count*) to contain the wide character codes represented as multibyte characters, the number of bytes containing complete multibyte characters is returned.

Note: `wcstombs()` does not generate redundant shift characters between the DBCS characters. When the `wctomb()` function is called for each character, redundant shift characters are generated.

Example

CELEBW24

```
/* CELEBW24

   In this example, a wide-character string is converted to a
   char string twice. The first call converts the entire string, while
   the second call only converts three characters. The results are
   printed each time.

*/
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define SIZE 20

int main(void)
{
    char dest[SIZE];
    wchar_t * dptr = L"string";
    size_t count = SIZE;
    size_t length;

    length = wcstombs( dest, dptr, count );
    printf( "%d characters were converted.\n", length );
    printf( "The converted string is \"%s\"\n\n", dest );

    /* Reset the destination buffer */
    memset( dest, '\\0', sizeof(dest));

    /* Now convert only 3 characters */
    length = wcstombs( dest, dptr, 3 );
    printf( "%d characters were converted.\n", length );
    printf( "The converted string is \"%s\"\n", dest );
}
```

Output:

```
6 characters were converted.
The converted string is "string"

3 characters were converted.
The converted string is "str"
```

wcstoul() — Convert a wide-character string to an unsigned long integer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <wchar.h>

unsigned long int wcstoul(const wchar_t * __restrict __nptr,
                        wchar_t ** __restrict __endptr, int base);
```

General description

Converts the initial portion of the wide-character string pointed to by *nptr* to unsigned long integer representation. First it decomposes the input wide-character string into three parts:

1. An initial, possibly empty, sequence of white space wide characters (as specified by the `iswspace()` function).
2. A subject sequence resembling an unsigned integer represented in some radix determined by the value of `base`.
3. A final wide-character string of one or more unrecognized wide characters, including the terminating NULL character of the input wide-character string.

Then it attempts to convert the subject sequence to an unsigned integer, and returns the result.

If the value of `base` is zero, the expected form of the subject sequence is that of an integer constant as described in ISO/IEC 9899: subclause 6.1.3.2, optionally preceded by a plus or minus sign, but not including an integer suffix. If the value of `base` is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits from the portable character set representing an integer with the radix specified by `base`, optionally preceded by a plus or minus sign, but not including an integer suffix. The letters from a (or A) through z (or Z) are ascribed the values 10 to 35; only letters whose ascribed values are less than that of `base` are permitted. If the value of `base` is 16, the characters 0x or 0X may optionally precede the sequence of letters and digits, following the sign if present.

The *subject sequence* is defined as the longest initial sub-sequence of the input wide-character string, starting with the first non-white space wide character, that is of the expected form. The subject sequence contains no wide characters if the input wide-character string is empty or consists entirely of white space, or if the first non-white space wide character is other than a sign or a permissible letter or digit.

If the subject sequence has the expected form and the value of `base` is zero, the sequence of wide characters starting with the first digit is interpreted as an integer constant according to the rules of ISO/IEC 9899: subclause 6.1.3.2. If the subject sequence has the expected form and the value of `base` is between 2 and 36, it is used as the base for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A pointer to the final string is stored in the object pointed to by *endptr*, provided that *endptr* is not a NULL pointer.

In a locale other than the C or POSIX locale, additional implementation-defined subject sequence forms may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *nptr* is stored in the object pointed to by *endptr*, provided that *endptr* is not a NULL pointer.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Since 0 and {ULONG_MAX} are returned on error and 0 is also a valid return on success, an application wishing to check for error situations should set *errno* to 0, then call *wcstoul()*, then check *errno*.

Returned value

If successful, *wcstoul()* returns the converted value, if any.

If unsuccessful, *wcstoul()* returns 0 if no conversion could be performed. If the correct value is outside the range of representable values, *wcstoul()* returns ULONG_MAX. If the value of *base* is not supported, *wcstoul()* returns 0.

If unsuccessful *wcstoul()* sets *errno* to one of the following values:

Error Code

Description

EINVAL

The value of *base* is not supported.

ERANGE

The conversion caused an overflow.

Example

CELEBW25

```
/* CELEBW25 */
#include <stdio.h>
#include <wchar.h>

#define BASE 2

int main(void)
{
    wchar_t *wcs = L"1000e13 camels";
    wchar_t **endptr;
    unsigned long int answer;

    answer = wcstoul(wcs, endptr, BASE);
    printf("The input wide string used: '%ls'\n", wcs);
    printf("The unsigned long int produced: %lu\n", answer);
    printf("The substring of the input wide string that was not");
    printf(" converted to unsigned long: '%ls'\n", *endptr);
}
```

wcstoull() — Convert a wide-character string to an unsigned long long integer

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| z/OS UNIX C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | OS/390 V2R10 |

Format

```
#include <wchar.h>

unsigned long long wcstoull(const wchar_t * __restrict__ nptr,
                           wchar_t ** __restrict__ endptr, int base);
```

Compile requirement: Use of this function requires the long long data type. See [z/OS XL C/C++ Language Reference](#) for information on how to make long long available.

General description

Converts the initial portion of the wide-character string pointed to by *nptr* to unsigned long long integer representation. First it decomposes the input wide-character string into three parts:

1. An initial, possibly empty, sequence of white space wide characters (as specified by the `iswspace()` function).
2. A subject sequence resembling an unsigned integer represented in some radix determined by the value of *base*.
3. A final wide-character string of one or more unrecognized wide characters, including the terminating NULL character of the input wide-character string.

Then it attempts to convert the subject sequence to an unsigned long long integer, and returns the result.

If the value of *base* is zero, the expected form of the subject sequence is that of an integer constant as described in ISO/IEC 9899: subclause 6.1.3.2, optionally preceded by a plus or minus sign, but not including an integer suffix. If the value of *base* is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits from the portable character set representing an integer with the radix specified by *base*, optionally preceded by a plus or minus sign, but not including an integer suffix. The letters from a (or A) through z (or Z) are ascribed the values 10 to 35; only letters whose ascribed values are less than that of *base* are permitted. If the value of *base* is 16, the characters 0x or 0X may optionally precede the sequence of letters and digits, following the sign if present.

The subject sequence is defined as the longest initial sub-sequence of the input wide-character string, starting with the first non-white space wide character, that is of the expected form. The subject sequence contains no wide characters if the input wide-character string is empty or consists entirely of white space, or if the first non-white space wide character is other than a sign or a permissible letter or digit.

If the subject sequence has the expected form and the value of *base* is zero, the sequence of wide characters starting with the first digit is interpreted as an integer constant according to the rules of ISO/IEC 9899: subclause 6.1.3.2. If the subject sequence has the expected form and the value of *base* is between 2 and 36, it is used as the *base* for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A pointer to the final string is stored in the object pointed to by *endptr*, provided that *endptr* is not a NULL pointer. In a locale other than the C or POSIX locale, additional implementation-defined subject sequence forms may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *nptr* is stored in the object pointed to by *endptr*, provided that *endptr* is not a NULL pointer.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Since 0 and {ULLONG_MAX} are returned on error and 0 is also a valid return on success, an application wishing to check for error situations should set errno to 0, then call wcstoull(), then check errno.

Note: The wcstoull() function has a dependency on the level of the Enhanced ASCII Extensions. See [“Enhanced ASCII support”](#) on page 2123 for details.

Returned value

If successful, wcstoull() returns the converted value, if any.

If unsuccessful, wcstoull() returns 0 if no conversion could be performed. If the correct value is outside the range of representable values, wcstoull() returns ULLONG_MAX (ULONG_LONG_MAX). If the value of base is not supported, wcstoull() returns 0.

If unsuccessful wcstoull() sets errno to one of the following values:

Error Code

Description

EINVAL

The value of *base* is not supported.

ERANGE

The conversion caused an overflow.

Example

```
/* LongLong conversion */
#define _LONG_LONG 1
#include <stdio.h>
#include <wchar.h>

#define BASE 2

int main(void)
{
    wchar_t *wcs = L"1000e13 camels";
    wchar_t **endptr;
    unsigned long long answer;

    answer = wcstoull(wcs, endptr, BASE);
    printf("The input wide string used: '%ls'\n", wcs);
    printf("The unsigned long long produced: %llu\n", answer);
    printf("The substring of the input wide string that was not");
    printf(" converted to unsigned long long: '%ls'\n", *endptr);
}
```

wcstoumax() – Convert a wide-character string to a intmax_t

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| C99 Single UNIX Specification, Version 3 C++ TR1 C99 | both | z/OS V1R7 |

Format

```
#define _ISOC99_SOURCE
#include <inttypes.h>

uintmax_t wcstoumax(const wchar_t * __restrict__ nptr,
                    wchar_t ** __restrict__ endptr, int base);
```

Compile requirement: Function wcstoumax() requires long long to be available.

General description

The wcstoumax() function converts the wide-character string nptr to an uintmax_t integer type. Valid input values for base are 0 and in the range 2-36. The wcstoumax() function is equivalent to wcstoul() and wcstoull(). The only difference being that the return value is of type uintmax_t. See wcstoull() for more information.

Returned value

If successful, wcstoumax() returns the converted value, if any.

If unsuccessful, wcstoumax() returns 0 if no conversion could be performed. If the correct value is outside the range of representable values, wcstoumax() returns UINTMAX_MAX. If the value of base is not supported, wcstoumax() returns 0.

If unsuccessful wcstoumax() sets errno to one of the following values:

Error Code

Description

EINVAL

The value of *base* is not supported.

ERANGE

The conversion caused an overflow.

Example

```
#define _ISOC99_SOURCE
#include <inttypes.h>
#include <stdio.h>

int main(void)
{
    wchar_t *nptr;
    wchar_t *endptr;
    uintmax_t j;
    int base = 10;
    nptr = L"10110134932";
    printf("nptr = '%ls'\n", nptr);
    j = wcstoumax(nptr, &endptr, base);
    printf("wcstoumax = %ju\n", j);
    printf("Stopped scan at '%ls'\n\n", endptr);
}
```

Output

```
nptr = `10110134932`
wcstoumax = 10110134932
Stopped scan at ``
```

wcswcs() — Locate wide-character substring in wide-character string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <wchar.h>

wchar_t *wcswcs(const wchar_t *string1, const wchar_t *string2);
```

General description

Locates the first occurrence in the string pointed to by *string1* of the sequence of wide characters (excluding the terminating wide NULL character) in the string pointed to by *string2*.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Note: The `wcswcs()` function has been moved to the Legacy Option group in Single UNIX Specification, Version 3 and may be withdrawn in a future version. The `wcsstr()` function is preferred for portability.

Returned value

If successful, `wcswcs()` returns a pointer to the located string.

If *string2* points to a string with zero length, `wcswcs()` returns *string1*.

If the string is not found, `wcswcs()` returns NULL.

Example

CELEBW26

```
/* CELEBW26

   This example finds the first occurrence of the wide character string pr
   in buffer1, using wcs wcs().

*/
#include <stdio.h>
#include <wchar.h>

#define SIZE 40

int main(void)
{
    wchar_t buffer1[SIZE] = L"computer program";
    wchar_t *ptr;
    wchar_t *wch = L"pr";

    ptr = wcs wcs( buffer1, wch );
    printf( "The first occurrence of %ls in '%ls' is '%ls'\n",
           wch, buffer1, ptr );
}
```

Output:

The first occurrence of pr in 'computer program' is 'program'

wcswidth() — Determine the display width of a wide-character string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#include <wchar.h>

int wcswidth(const wchar_t *wcs, size_t n);
```

General description

Determines the number of printing positions that a graphic representation of n wide characters (or fewer than n wide characters, if a NULL wide character is encountered before n wide characters have been exhausted), in the wide-character string pointed to by *wcs*, occupies on a display device. The number of printing positions is independent of its location on the device.

Returned value

If successful, `wcswidth()` returns the number of printing positions occupied by the wide-character string pointed to by *wcs*.

If *wcs* points to a NULL wide character, `wcswidth()` returns 0.

If any wide character in the wide-character string pointed to by *wcs* is not a printing wide character, `wcswidth()` returns -1.

The behavior of `wcswidth()` is affected by the LC_CTYPE category.

Note: Under z/OS XL C/C++ applications, the width returned will be 1 for each single-byte character and 2 for each double-byte character.

Example

CELEBW27

```
/* CELEBW27 */
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    wchar_t *wcs = L"ABC";

    printf("wcs has a width of: %d\n", wcswidth(wcs,3));
}
```

Output:

```
wcs has a width of: 3
```

Related information

- [“wchar.h — ISO/C Multibyte Support extensions” on page 79](#)

wcsxfrm() — Transform a wide-character string

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <wchar.h>
```

```
size_t wcsxfrm(wchar_t * __restrict __wcs1,
               const wchar_t * __restrict __wcs2, size_t n);
```

General description

Transforms the wide-character string pointed to by *wcs2* to values which represent character collating weights and places the resulting wide-character string into the array pointed to by *wcs1*. The transformation is such that if the `wcscmp()` function is applied to two transformed wide-character strings, it returns a value greater than, equal to, or less than zero, corresponding to the result of the `wcscoll()` function applied to the same two original wide-character strings. No more than *n* elements are placed into the resulting array pointed to by *wcs1*, including the terminating NULL wide-character code. If *n* is zero, *wcs1* is permitted to be a NULL pointer. If copying takes place between objects that overlap, the behavior is undefined.

Since no return value is reserved to indicate an error, an application wishing to check for error situations should set `errno` to 0, then call `wcsxfrm()`, then check `errno`.

Returned value

Returns the length of the transformed wide-character string (not including the terminating NULL wide character code). If the value returned is *n* or more, the contents of the array pointed to by *wcs1* are indeterminate.

If *wcs1* is a NULL pointer, `wcsxfrm()` returns the number of elements required to contain the transformed wide string.

The transformed value of invalid wide-character codes shall be either less than or greater than the transformed values of valid wide-character codes depending on the option chosen for the particular locale definition. In this case `wcsxfrm()` returns `(size_t)-1`.

`wcsxfrm()` is controlled by the `LC_COLLATE` category.

The `EILSEQ` error may be set, indicating that the wide character string pointed to by *wcs2* contains wide character codes outside the domain of the collating sequence.

Note: The ISO/C Multibyte Support Extensions do not indicate that the `wcsxfrm()` function may return with an error.

Example

CELEBW28

```
/* CELEBW28 */
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    wchar_t *wcs;
    wchar_t  buffer[80];
    int      length;

    printf("Type in a string of characters.\n");
    wcs = fgetws(buffer, 80, stdin);
    length = wcsxfrm(NULL, wcs, 0);
    printf("You would need a %d element array to hold the wide string", length);
    printf("\n\n%ls\n\ntransformed according", wcs);
    printf(" to this program's locale.\n");
}
```

Related information

- [“wchar.h — ISO/C Multibyte Support extensions” on page 79](#)

wctob() — Convert wide character to byte

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment C99 Single UNIX Specification, Version 3 | both | |

Format

Non-XPG4:

```
#include <wchar.h>

int wctob(wint_t c);
```

XPG4:

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

int wctob(wint_t c);
```

General description

Determines whether *c* corresponds to a member of the extended character set whose multibyte character corresponds to a single byte when in initial shift state.

The behavior of this wide-character function is affected by the LC_CTYPE category of the current locale. If you change the category, undefined results can occur.

Special behavior for XPG4: If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the `wchar` header, then you must also define the `_MSE_PROTOS` feature test macro to make the declaration of the `wctob()` function in the `wchar` header available when you compile your program. Please see [Table 2 on page 4](#) for a list of XPG4 and other feature test macros.

Returned value

If successful, `wctob()` returns the single-byte representation.

If *c* does not correspond to a multibyte character with length one, `wctob()` returns EOF.

Example

CELEBW29

```
/* CELEBW29 */
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    wint_t wc = L'A';

    if (wctob(wc) == wc)
        printf("wc is a valid single byte character\n");
    else
        printf("wc is not a valid single byte character\n");
}
```

Output:

```
wc is a valid single-byte character
```

Related information

- [“wchar.h — ISO/C Multibyte Support extensions” on page 79](#)

wctomb() — Convert wide character to multibyte character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <stdlib.h>

int wctomb(char *string, wchar_t character);
```

General description

Converts the `wchar_t` value of *character* into a multibyte array pointed to by *string*. If the value of *character* is 0, the function is left in the initial shift state. At most, `wctomb()` stores **MB_CUR_MAX** characters in *string*.

The behavior of this wide-character function is affected by the `LC_CTYPE` category of the current locale. If you change the category, undefined results can occur.

Returned value

If successful, `wctomb()` returns the length in bytes of the multibyte character.

If *character* is not a valid multibyte character, `wctomb()` returns -1.

If *string* is a NULL pointer, `wctomb()` returns nonzero if shift-dependent encoding is used, or 0 otherwise.

Example**CELEBW30**

```
/* CELEBW30

   This example converts the wide character c to a character using wctomb().

*/
#include <stdio.h>
#include <stdlib.h>

#define SIZE 40

int main(void)
{
    static char  buffer[ SIZE ];
    wchar_t wch = L'c';
    int length;
```

```

length = wctomb( buffer, wch );
printf( "The number of bytes that comprise the multibyte "
        "character is %i\n", length );
printf( "And the converted string is \"%s\"\n", buffer );
}

```

Output:

```

The number of bytes that comprise the multibyte character is 1
And the converted string is "c"

```

wctrans(), towctrans() — Transliterate wide character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment C99 Single UNIX Specification, Version 3 | both | |

Format

```

#include <wchar.h>

wctrans_t  wctrans(const char * charclass);
wint_t     towctrans(wint_t wc, wctrans_t desc);

```

General description

These two functions work together to provide transliteration of wide characters. For valid results, the setting of the LC_CTYPE category of the current locale must remain the same across the two calls. Character mapping rules are defined in the LC_CTYPE category.

The wctrans() function takes the character mapping name pointed to by *charclass* and returns a value of type wctrans_t for use as the second argument to the towctrans() function.

The towctrans() function applies the indicated mapping to wide-character code *wc* from the codeset identified in the current locale. The towctrans() function applies the mapping returned by wctrans() and passed as *desc*.

The following character mapping names are reserved by the standard and are defined in all locales: *tolower* and *toupper*.

Notes:

1. towctrans(wc, wctrans("tolower")) is equivalent to towlower(wc)
2. towctrans(wc, wctrans("toupper")) is equivalent to towupper(wc)

Returned value

If successful, `wctrans()` returns the non-zero value of type `wctrans_t` for use in calls to `towctrans()`.

If unsuccessful, `wctrans()` returns 0 and sets `errno` to `EINVAL` if the mapping name pointed to by *charclass* is not valid for the current locale.

If successful, the `towctrans()` function returns the mapped value of *wc* using the mapping described by *desc*.

If unsuccessful, `towctrans()` returns *wc* unchanged. If the value of *desc* is invalid, `towctrans()` returns 0.

Related information

- [“wctype.h – Wide character properties” on page 81](#)
- [“tolower\(\), toupper\(\) – Convert character case” on page 1883](#)

wctype() – Obtain handle for character property classification

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment XPG4 XPG4.2 C99 Single UNIX Specification, Version 3 | both | |

Format

```
#include <wchar.h>

wctype_t wctype(const char *property);
```

SUSV3:

```
#define _POSIX_C_SOURCE 200112L
#include <wctype.h>
wctype_t wctype(const char *property);
```

General description

The `wctype()` function is defined for valid property names as defined in the current locale. The *property* is a string identifying a generic character class for which code-page-specific type information is required. The function returns a value of type `wctype_t`, which can be used as the second argument to a call of `iswctype()`. The `wctype()` function determines values of `wctype_t` according to rules of the coded character set defined by character type information in the program's locale (category `LC_CTYPE`). Values returned by `wctype()` are valid until a call to `setlocale()` that modifies the category `LC_CTYPE`.

The behavior of this wide-character function is affected by the `LC_CTYPE` category of the current locale. If you change the category, undefined results can occur.

Returned value

If successful, `wctype()` returns a value of type `wctype_t` that can be used in calls to `iswctype()`.

If the given property name is not valid for the current locale (category `LC_CTYPE`), `wctype()` returns 0.

Related information

- [“wchar.h — ISO/C Multibyte Support extensions” on page 79](#)
- [“wctype.h — Wide character properties” on page 81](#)

wcwidth() — Determine the display width of a wide character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

Non-XPG4:

```
#include <wchar.h>

int wcwidth(const wint_t wc);
```

XPG4:

```
#define _XOPEN_SOURCE
#include <wchar.h>

int wcwidth(const wchar_t wc);
```

General description

Determines the number of printing positions that a graphic representation of *wc* occupies on a display device. Each of the printing wide characters occupies its own number of printing positions on a display device. The number is independent of its location on the device.

Special behavior for XPG4: If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the `wchar` header, then the compiler assumes that your program is using the XPG4 variety of the `wcwidth()` function. Please see [Table 2 on page 4](#) for a list of XPG4 and other feature test macros.

The prototype for the XPG4 variety of the `wcwidth()` function is:

```
int wcwidth(const wchar_t wc);
```

The difference between this variety and the C/370, non-XPG4 variety of the `wcwidth()` function is that its parameter, *wc*, is a `wchar_t` rather than a `wint_t` type.

Returned value

If successful, `wcwidth()` returns the number of printing positions occupied by *wc*.

If *wc* is a NULL or non-spacing wide character, `wcwidth()` returns 0.

If *wc* is not a printing wide character, `wcwidth()` returns -1.

The behavior of `wcwidth()` is affected by the `LC_CTYPE` category.

Notes:

1. Under z/OS XL C/C++ applications, the width returned will be zero for a NULL or non-spacing character, 1 for a single-byte character, and 2 for a double-byte character.

2. A non-spacing character is a character belonging to the charclass named `_zlc` (zero length character class) in the `LC_CTYPE` category.

Example

CELEBW31

```
/* CELEBW31 */
#include <stdio.h>
#include <wchar.h>

int main(void)
{
    wint_t wc = L'A';

    printf("wc has a width of: %d\n", wcwidth(wc));
}
```

Output:

```
wc has a width of: 1
```

Related information

- [“wchar.h — ISO/C Multibyte Support extensions” on page 79](#)

w_getmntent() – Get information on mounted file systems

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#define _OPEN_SYS
#include <sys/mntent.h>

int w_getmntent(char *buffer, int size);
```

General description

Gets information about all currently mounted file systems.

buffer

A pointer to storage that is to be filled with the retrieved information. The storage consists of a header and an entry table that correspond to one of the available mapping formats. The mappings available are defined in the `<sys/mntent.h>` header file. Each entry in the entry table contains information for a single mounted file system.

size

The length of the buffer. If *size* is zero, the total number of mount entries is returned. You can use this information to obtain a buffer large enough to hold all the information about all the entries. Use the new buffer on the subsequent call.

Three mapping formats available. Their corresponding headers are as follows:

| | Header | Eye Catcher | Entry |
|--------------|------------------------|--------------------|------------------------------|
| struct mnte3 | MNTE3H (struct mnte3h) | MNTE3H_ID ("MNT3") | W_MNTENT3 (struct w_mntent3) |
| struct mnte2 | MNTE2H (struct mnte2h) | MNTE2H_ID ("MNT2") | W_MNTENT2 (struct w_mntent2) |
| struct mnte | W_MNTH (struct w_mnth) | "MNTE" | W_MNTENT (struct w_mntent) |

The buffer should be set to zero before setting of fields or the `w_getmntent()` call. The default mapping format is struct mnte when the eyecatcher field is unset.

Using structure w_mntent3: Before calling `w_getmntent()` with the `w_mntent3` structure mapping, set the following fields in MNTE3H:

1. mnt3H_cbid eyecatcher to MNTE3H_ID
2. mnt3H_cblen to the size of struct mnte3
3. mnt3H_bodylen to the size of struct w_mntent3
4. [Optional] mh3_devno to the device number

In the header, the field `mnt3H_cblen` returns the number of bytes of data that is put in the buffer. The field `mh3_cursor` contains positioning information that `w_getmntent()` uses to store the information. If multiple calls are made, use the same buffer because the positioning information in `mh3_cursor` indicates where the function should continue with its list. The positioning information should not be changed between calls. Information about a specific file system can be obtained if the device number of that file system is known. In this case, the device number can be filled into the field `mh3_devno`, and the `w_getmntent` call returns a single entry with information about that file system. Or a device number value of `x40000000` can be used to indicate that the returned path name should be up to 64 bytes of the mount point path name at the time of the mount.

After a successful call to `w_getmntent()`, the following `w_mntent3` structure fields will be available for reference:

mnt3_fstype

The file system type.

mnt3_mode

The mount mode of the file system. A flag field that specifies the mount mode and more mount options: `mntentfsaunmount`.

mntentfsaunmount

If it is 1 after the file system is mounted, the file system will be unmounted when a system leaves the sysplex. If it is 0, then the setting of `mntentfsnoautomove` is used. See `mntentfsnoautomove` below.

mntentfsclient

If it is 0, then the file system is a sysplex client. If it is 1, then the file system is not a sysplex client.

mntentfsnoautomove

If it is 0 after the file system is mounted, it can be moved automatically. If it is 1 after the file system is mounted, it will not be moved automatically.

mntentfsmodenosec

If it is 1, then the file system will not enforce security checks. If it is 0, then the file system will enforce security checks.

mntentfsmodeexport

If it is 0, then the file system has not been exported by DFS. If it is 1, then the file system has been exported by DFS.

mntentfsmoderonly

If it is 0, then the file system is mounted as read/write. If it is 1, then the file system is mounted as read-only.

mntentfsmodenosuid

If it is 1, then the SETUID and SETGID mode flags will be ignored for programs that reside in this file system. If it is 0 then the SETUID and SETGID mode flags will be enforced for programs that reside in this file system.

mnt3_dev

Device number which stat() will return for all files in this file system.

mnt3_parentdev

st_dev of parent file system.

mnt3_rootino

The ino of the mount point.

mnt3_status

The status of the file system

mnt3_ddname

The ddname specified on mount.

mnt3_fstname

The name of the file system type that is specified by the FILESYS statement. The name for the file system that performed the mount.

mnt3_fsname

The name of the file system that was mounted.

mnt3_pathlen

The length of mount point path.

mnt3_mountpoint

The name of the directory where the file system is mounted.

mnt3_jobname

If this file system is quiesced, this is the job that made the request.

mnt3_PID

If this file system is quiesced, this is the PID that made the request.

mnt3_parmoffset

Offset of mount parameter parm_point, starting from the address of the mnt3_fstype member of the w_mnte3 struct.

mnt3_parmlen

The length of the mount parameter parm_point.

mnt3_sysname

The name of the target system.

mnt3_qsystem

The name of the quiesce system.

mnt3_fromsys

The name of the system from which the file system has moved.

mnt3_flags

The field containing the request flags.

mnt3_status2

The file system status extensions.

mnt3_readct

The number of reads done.

mnt3_writect

The number of writes done.

mnt3_diribc

The number of directory I/O blocks.

mnt3_readibc

The number of read I/O blocks.

mnt3_writeibc

The number of write I/O blocks.

mnt3_bytesreadhw

Total number of bytes read from high word.

mnt3_bytesreadlw

Total number of bytes read from low word.

mnt3_byteswrittenhw

Total number of bytes written to high word.

mnt3_byteswrittenlw

Total number of bytes written to low word.

mnt3_filetag

Mount tag.

mnt3_syslistoffset

Offset of system list.

mnt3_syslistlength

Length of system list.

mnt3_aggnamelength

Length of the aggregate name in mnt2_aggname. The length does not include the null terminating character, and is only valid if mnt3_aggnameoffset has a nonzero value.

mnt3_aggnameoffset

The offset of mnt2_aggname from w_mntent3. If the value is zero, then no aggregate name is returned.

mnt3_mntsec

The mount time in seconds when the file system was mounted.

mnt3_fstoken

This field is a virtual file system pointer for the file system.

mnt3_pfsnormalstatusoffset

This field provides the offset of the physical file system normal status string location.

mnt3_pfsnormalstatuslength

This field provides the length of the physical file system normal status string.

mnt3_pfsexcpstatuslength

This field provides the length of the exception status string of the physical file system.

mnt3_pfsexcptstatusoffset

This field provides the offset of the exception status string of the physical file system.

mnt3_fsusrmntUID

The effective UID (EUID) of the user that mounted the file system.

mnt3_unmntver

If this field is 1, the file system is automatically unmounted when no longer being used as a version file system. If this field is 0, the file system is not automatically unmounted when no longer being used as a version file system.

parm_point

This field contains the mount point parameters to be used when mounting a file system. It is a separate field in the mnte3 structure but contiguously allocated following the w_mnte3 body, its address is the sum of the address of w_mnte3 and mnt3_parmoffset.

If all entries do not fit in the buffer that is supplied, multiple calls are required. If an entry together with its mount parameter will not fit in the buffer, the entry is returned without the mount parameter. In this case, *mnt3_parmlen* contains the length of the mount parameter, and *mnt3_parmoffset* is zero.

To assure that at least one entry, including the mount parameter, is returned, it is advisable to allocate space for at least two entries.

When the final entry has been placed in the buffer, `w_getmntent()` returns no entries.

Using structure `w_mntent2`: Before calling `w_getmntent()` with the `w_mntent2` structure mapping, set the following fields in `MNTE2H`:

1. `mh2_hdr.mnth2_cbid` eyecatcher to `MNTE2H_ID`
2. `mh2_hdr.mnt2h_cblen` to the size of struct `mnte2`
3. `mh_bodylen` to the size of struct `w_mntent2`
4. [Optional] `mh2_devno` to the device number

In the header, the field `mnt2h_cblen` returns the number of bytes of data that is put in the buffer. The field `mh2_cursor` contains positioning information that `w_getmntent()` uses to store the information. If multiple calls are made, use the same buffer because the positioning information in `mh2_cursor` indicates where the function should continue with its list. The positioning information should not be changed between calls. Information about a specific file system can be obtained if the device number of that file system is known. In this case, the device number can be filled into the field `mh2_devno`, and the `w_getmntent` call returns a single entry with information about that file system. Or a device number value of `x40000000` can be used to indicate that the returned path name should be up to 64 bytes of the mount point path name at the time of the mount.

After a successful call to `w_getmntent()`, the following `w_mntent2` structure fields will be available for reference:

`mnt2_fstype`

The file system type.

`mnt2_mode`

The mount mode of the file system. A flag field that specifies the mount mode and additional mount options:

`mntentfsaunmount`

If it is 1 after the file system is mounted, the file system will be unmounted when a system leaves the sysplex. If it is 0, then the setting of `mntentfsnoautomove` is used. See `mntentfsnoautomove` below.

`mntentfsclient`

If it is 0, then the file system is a sysplex client. If it is 1, then the file system is not a sysplex client.

`mntentfsnoautomove`

If it is 0 after the file system is mounted, it can be moved automatically. If it is 1 after the file system is mounted, it will not be moved automatically.

`mntentfsmodenosec`

If it is 1, then the file system will not enforce security checks. If it is 0, then the file system will enforce security checks.

`mntentfsmodeexport`

If it is 0, then the file system has not been exported by DFS. If it is 1, then the file system has been exported by DFS.

`mntentfsmoderonly`

If it is 0, then the file system is mounted as read/write. If it is 1, then the file system is mounted as read-only.

`mntentfsmodenosuid`

If it is 1, then the `SETUID` and `SETGID` mode flags will be ignored for programs that reside in this file system. If it is 0 then the `SETUID` and `SETGID` mode flags will be enforced for programs that reside in this file system.

mnt2_dev

Device # which stat() returns for all files in this file system.

mnt2_parentdev

st_dev of parent file system.

mnt2_rootino

The ino of the mount point.

mnt2_status

status of the file system.

mnt2_ddname

The ddname that is specified on mount.

mnt2_fstype

The name of the file system type that is specified by the FILESYS statement. The name for the file system that performed the mount.

mnt2_fsname

The name of the file system that was mounted.

mnt2_pathlen

The length of mount point path.

mnt2_mountpoint

The name of the directory where the file system is mounted.

mnt2_jobname

If this file system is quiesced, this is the job that made the request.

mnt2_PID

If this file system is quiesced, this is the PID that made the request.

mnt2_parmoffset

Offset of mount parameter parm_point, starting from the address of the mnt2_fstype member of the w_mnt2 struct.

mnt2_parmlen

The length of the mount parameter parm_point.

mnt2_sysname

The name of the target system.

mnt2_qsystem

The name of the quiesce system.

mnt2_fromsys

The name of the system from which the file system has moved.

mnt2_flags

The field containing the request flags.

mnt2_status2

The file system status extensions.

mnt2_success

This field is used to return the number of successfully moved file systems when moving a collection of file systems.

mnt2_readct

The number of reads done.

mnt2_writect

The number of writes done.

mnt2_diribc

The number of directory I/O blocks.

mnt2_readibc

The number of read I/O blocks.

mnt2_writeibc

The number of write I/O blocks.

mnt2_bytesreadhw

Total number of bytes read from high word.

mnt2_bytesreadlw

Total number of bytes read from low word.

mnt2_byteswrittenhw

Total number of bytes written to high word.

mnt2_byteswrittenlw

Total number of bytes written to low word.

mnt2_filetag

Mount tag.

mnt2_syslistoffset

Offset of system list.

mnt2_syslistlength

Length of system list.

mnt2_aggnameoffset

Length of the aggregate name in mnt2_aggname. The length does not include the null terminating character, and is only valid if mnt2_aggnameoffset has a nonzero value.

mnt2_aggnameoffset

The offset of mnt2_aggname from w_mntent2. If the value is zero, then no aggregate name is returned.

parm_point

This field contains the mountpoint parameters to be used when mounting a file system. It is a separate field in the mnte2 structure but contiguously allocated following the w_mnte2 body, its address is the sum of the address of w_mnte2 and mnt2_parmoffset.

If all entries do not fit in the buffer that is supplied, multiple calls are required. If an entry together with its mount parameter will not fit in the buffer, the entry is returned without the mount parameter. In this case, *mnt2_parmlen* contains the length of the mount parameter, and *mnt2_parmoffset* is zero.

To assure that at least one entry, including the mount parameter, is returned, it is advisable to allocate space for at least two entries.

When the final entry has been placed in the buffer, *w_getmntent()* returns no entries.

Using structure w_mntent: Before calling *w_getmntent()* with the *w_mntent* structure mapping, set the following fields in *W_MNTH*:

1. *mnth_hid* to "MNTE"
2. *mnth_size* to the size of struct *mnte*
3. *mh_bodylen* to the size of struct *w_mntent*
4. [Optional] *mnth_devno* to the device number

In the header, the field *mnth_size* returns the number of bytes of data that is put in the buffer. The fields *mnth_cur1* and *mnth_cur2* contain positioning information that *w_getmntent()* uses to store the information. If multiple calls are made, use the same buffer because the positioning information in *mnth_cur1* and *mnth_cur2* indicates where the function should continue with its list. The positioning information should not be changed between calls. Information about a specific file system can be obtained if the device number of that file system is known. In this case, the device number can be filled into the field *mnth_devno*, and the *w_getmntent* call returns a single entry with information about that file system. Or a device number value of x40000000 can be used to indicate that the returned path name should be up to 64 bytes of the mount point path name at the time of the mount.

After a successful call to *w_getmntent()*, the following *w_mntent* structure fields will be available for reference:

mnt_fstype

The file system type.

mnt_mode

File system mount mode.

mnt_dev

Device # which stat() returns for all files in this file system.

mnt_parentdev

st_dev of parent file system.

mnt_rootino

The ino of the mount point.

mnt_status

The status of the file system.

mnt_ddname

The ddname that is specified on mount.

mnt_fstype

The name of the file system type that is specified by the FILESYS statement.

mnt_fsname

The file system name, which is up to 45 characters long and ends with a NULL.

mnt_pathlen

The length of mount point path.

mnt_mountpoint

The pathname of the directory where the file system is mounted. This field ends with a NULL.

If the caller of w_getmntent() lacks search authorization to one or more of the directories in the mount point pathname, *mnt_mountpoint* is returned empty. That is, *mnt_pathlen* is zero and *mnt_mountpoint* contains a NULL as the first character.

mnt_jobname

If the file system is quiesced, this is the job that made the request.

mnt_PID

If the file system is quiesced, this is the PID that made the request.

mnt_parmoffset

Offset of mount parameter from w_mntent.

mnt_parmlen

Length of mount parameter.

mnt_parm

The file-system-specific parameter that is specified on the mount() function when the file system was mounted. This field ends with a NULL.

If no parameter was specified, *mnt_parmlen* and *mnt_parmoffset* are each zero. If a parameter was specified, its address is the sum of the address of *w_mntent* and *mnt_parmoffset*.

If all entries do not fit in the buffer that is supplied, multiple calls are required. If an entry together with its mount parameter will not fit in the buffer, the entry is returned without the mount parameter. In this case, *mnt_parmlen* contains the length of the mount parameter, and *mnt_parmoffset* is zero.

To assure that at least one entry, including the mount parameter, is returned, it is advisable to allocate space for at least two entries.

When the final entry has been placed in the buffer, w_getmntent() returns no entries.

Returned value

If successful, w_getmntent() returns the number of entries in the buffer.

If unsuccessful, w_getmntent() returns -1 and sets errno to one of the following values:

Error Code
Description

EINVAL

A parameter was specified incorrectly.

ERANGE

The result is too large to fit in the available buffer space.

Example

CELEBW49

```
/* CELEBW49

This example uses w_getmntent() to retrieve information
about currently mounted systems in the MNTE3 mapping format.

The MNTE3 mapping format is only available on z/OS V1.10 or higher,
target value of 0x410A0000.

*/
#define _OPEN_SYS
#include <sys/mntent.h>
#include <stdio.h>

main() {
    int entries, entry;
    struct {
        MNTE3H    header;
        W_MNTENT3 mount_table[10];
    } work_area;

    memset(&work_area, 0x00, sizeof(work_area));

    /* 'header' initialization to specify MNTE3 mapping format */
    memcpy(work_area.header.mnt3H_cbid, MNTE3H_ID, 4);
    work_area.header.mnt3H_cblen = sizeof(struct mnte3);
    work_area.header.mnt3H_bodylen = sizeof(struct w_mntent3);

    do {
        if ((entries = w_getmntent((char *) &work_area,
                                   sizeof(work_area))) == -1)
            perror("w_getmntent() error");

        else for (entry=0; entry<entries; entry++) {
            printf("filesystem %s is mounted at %s\n",
                   work_area.mount_table[entry].mnt3_fsname,
                   work_area.mount_table[entry].mnt3_mountpoint);
            printf(" MNTE2 and MNTE3 common: reads done is %i, writes done is %i\n",
                   work_area.mount_table[entry].mnt3_readct,
                   work_area.mount_table[entry].mnt3_writect);
            printf(" MNTE3 specific: mount time in seconds is %i\n",
                   work_area.mount_table[entry].mnt3_mntsec);
        }
    } while (entries > 0);
}
```

Output

```
filesystem ZOS110.LPP.HFS is mounted at /usr/lpp
MNTE2 and MNTE3 common: reads done is 0, writes done is 0
MNTE3 specific: mount time in seconds is 5833
filesystem ZOS110.NLS.HFS is mounted at /usr/lib/nls
MNTE2 and MNTE3 common: reads done is 0, writes done is 0
MNTE3 specific: mount time in seconds is 5833

w_getpsent(), w_getpsent64() — Get process data

Standards

| Table 73. Standards | | |
|------------------------|----------|--------------|
| Standards / Extensions | C or C++ | Dependencies |
| z/OS UNIX | both | |

Format

w_getpsent:

```
#include <sys/ps.h>

int w_getpsent(int token, W_PSPROC *bufptr, size_t length);
```

w_getpsent64:

```
#define _LARGE_TIME_API
#include <sys/ps.h>

int w_getpsent64(int token, W_PSPROC64 *bufptr, size_t length);
```

Compile requirement: Use of the w_getpsent64 function requires the long long data type. For more information on how to make the long long data type available, see [z/OS XL C/C++ Language Reference](#).

General description

Provides information about the status of any process that the calling process has access to.

token

A relative number that identifies the relative position of a process in the system. Zero represents the first process in the system. On the first call to `w_getpsent()`, pass the token 0; the function then returns the token that identifies the next process to which the caller has access. Use that token on the next call.

bufptr

The address of the buffer where the data is to be stored.

length

The length of the buffer.

The data returned is described in the `ps.h` header file. See [Table 74 on page 2055](#) for the format of the structure stored in the buffer.

Table 74. Variables Stored in Structure Returned by `w_getpsent()` or `w_getpsent64()`

| Variable Type | Variable Name | General Description |
|---------------|---------------|-----------------------------|
| unsigned int | ps_state | Process state |
| pid_t | ps_pid | Process ID |
| pid_t | ps_ppid | Parent ID |
| pid_t | ps_sid | Session ID (leader) |
| pid_t | ps_pgid | Process group ID |
| pid_t | ps_fgid | Foreground process group ID |
| uid_t | ps_euid | Effective user ID |
| uid_t | ps_ruid | Real user ID |
| uid_t | ps_suid | Saved set user ID |
| gid_t | ps_egid | Effective group ID |
| gid_t | ps_rgid | Real group ID |
| gid_t | ps_sgid | Saved set group ID |
| long | ps_size | Total size |
| time_t 1 | ps_starttime | Starting time |
| time64_t 2 | | |
| clock_t | ps_usertime | User CPU time |
| clock_t | ps_systime | System CPU time |
| int | ps_conttylen | Length of ContTTY |
| char | *ps_conttyptr | Controlling terminal |
| int | ps_pathlen | Length of <i>arg0</i> |
| char | *ps_pathptr | File name |
| int | ps_cmdlen | Length of command |
| char | *ps_cmdptr | Command and arguments |

Note:

1. This variable type is supported by `w_getpsent()` only.
2. This variable type is supported by `w_getpsent64()` only.

Note: The `ps_cmdlen` and `ps_cmdptr` elements of `W_PSPROC` identify the length and location where `w_getpsent()` is to return the command and arguments used to start the process. As of z/OS V1R11, the maximum length in bytes, including the null terminator, that can be returned is defined by `PS_CMDBLEN_LONG`. The actual maximum length of the command and arguments returned is `PS_CMDBLEN_LONG` minus the length of the path. Prior to z/OS V1R11, the maximum length in bytes, including the null terminator, that can be returned is defined by `PS_CMDBLEN`. The actual maximum length of the command and arguments returned can be less than `PS_CMDBLEN` and depends on the number of arguments. The system will truncate the command and arguments as needed to allow for the null terminator. Both `PS_CMDBLEN_LONG` and `PS_CMDBLEN` are defined in `<sys/ps.h>`.

Usage notes

1. `ps_usertime` reports the user's CPU time consumed for the address space the process is running within. When only one process is running in the address space, this CPU time represents the accumulated user CPU time for that process. When more than one process is running in an address space, the information returned is actually the accumulated CPU time consumed by the address space. It is the sum of the CPU time used by all of the work running in that address space not including the system time.
2. `ps_systime` reports the system's CPU time consumed for the address space the process is running within. When only one process is running in the address space, this time represents the accumulated system CPU time for that process. However, when more than one process is running in an address space, the information returned is actually the accumulated system CPU time consumed by all of the work running in the address space.

The `w_getpsent64()` function behaves exactly like `w_getpsent()` except it uses struct `w_psproc64` instead of struct `w_psproc` to support time beyond 03:14:07 UTC on January 19, 2038.

Returned value

If successful, `w_getpsent()` returns the process token for the next process for which the caller has access. For the last active process to which the user has access, `w_getpsent()` returns 0, indicating there are no more processes to be accessed.

If unsuccessful, `w_getpsent()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

An incorrect process token or NULL buffer address was specified.

E2BIG

An insufficient buffer length was provided.

ESRCH

No process can be accessed by the active user.

Example

CELEBW33

```
/* CELEBW33
   This example provides status information, using w_getpsent().
*/
#define _OPEN_SYS
#include <stdlib.h>
#include <stdio.h>
#include <sys/ps.h>
#include <sys/types.h>
#include <pwd.h>
#include <time.h>
#include <string.h>
```

```

int main(void) {
    int token;
    W_PSPROC buf;
    struct passwd *pw;

    token = 0;

    memset(&buf, 0x00, sizeof(buf));
    buf.ps_conttyptr = (char *) malloc(buf.ps_conttylen = PS_CONTTYBLEN);
    buf.ps_pathptr = (char *) malloc(buf.ps_pathlen = PS_PATHBLEN);
    buf.ps_cmdptr = (char *) malloc(buf.ps_cmdlen = PS_CMDBLEN_LONG);
    if ((buf.ps_conttyptr == NULL) ||
        (buf.ps_pathptr == NULL) ||
        (buf.ps_cmdptr == NULL))
        perror("buffer allocation error");

    else do {
        if ((token = w_getpsent(token, &buf, sizeof(buf))) == -1)
            perror("w_getpsent() error");
        else if (token > 0)
            if ((pw = getpwuid(buf.ps_ruid)) == NULL)
                perror("getpwuid() error");
            else printf("token %d: pid %10d, user %8s, started %s", token,
                        (int) buf.ps_pid, pw->pw_name,
                        ctime(&buf.ps_starttime));
        } while (token > 0);
    return 0;
}

```

Output:

```

token 2: pid      131074, user   MVSUSR1, started Fri Jun 16 08:09:17 2006
token 3: pid      65539, user   MVSUSR1, started Fri Jun 16 08:09:41 2006
token 6: pid      589830, user  MVSUSR1, started Fri Jun 16 10:29:17 2006
token 7: pid      851975, user  MVSUSR1, started Fri Jun 16 10:30:04 2006

```

w_iocctl(), __w_piocctl() — Control of devices

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | OS/390 V2R8 |

General Format

```

#define _OPEN_SYS
#include <termios.h>

int w_iocctl(int fildes, int cmd, int arglen, void *arg);
int __w_piocctl(const char *pathname, int cmd, int arglen, void *arg);

```

ACL format:

```

#define _OPEN_SYS
#include <termios.h>
#include <sys>

int w_iocctl(int fildes, int cmd, int arglen, void arg);
int __w_piocctl(const char pathname, int cmd, int arglen, void arg);

```

General description

The `w_ioctl()` and `__w_piocctl()` functions are general entry points for device-specific commands. The specific actions specified by `w_ioctl()` and `__w_piocctl()` vary with the device, and they are defined by the device driver.

files

A descriptor for an open character special file (used by `w_ioctl()`).

pathname

The pathname of a file (used by `__w_piocctl()`).

cmd

The command to be passed to the device driver as an integer value.

Command

Description

SIOCGPARTNERINFO

Provides an interface for an application to retrieve security information about its partner. For more information, see [z/OS Communications Server: IP Programmer's Guide and Reference](#).

arglen

The length of the argument passed to the device driver.

arg

The address of the buffer where the argument to be passed to the device driver is stored.

`w_ioctl()` and `__w_piocctl()` pass the *cmd*, *arglen*, and *arg* arguments to the device driver to be interpreted and processed. When `w_ioctl()` and `__w_piocctl()` complete successfully, the device driver returns *arglen* and *arg*, if appropriate.

Note: The `__w_piocctl()` function has a dependency on the level of the Enhanced ASCII Extensions. See “Enhanced ASCII support ” on page 2123 for details.

Returned value

If successful, `w_ioctl()` returns 0.

If unsuccessful, `w_ioctl()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EACCES

Permission is denied.

EINVAL

One of the following situations occurred:

- An incorrect length was specified for *arglen*. The correct argument length range is 0 to 50,000.
- An invalid message queue was specified when command `_IOCC_REGFILEINT` was used.

ENAMETOOLONG

The length of the *pathname* argument exceeds **PATH_MAX**, or a *pathname* component is longer than **NAME_MAX** and `{_POSIX_NO_TRUNC}` is in effect for that file. For symbolic links, the length of the pathname string substituted for a symbolic link exceeds **PATH_MAX**. **PATH_MAX** and **NAME_MAX** values can be determined by using `pathconf()`.

ENODEV

The device does not exist. The function is not supported by the device driver.

ENOENT

Either there is no file named *pathname* or *pathname* is an empty string.

ENOTDIR

A component of the *pathname* prefix is not a directory.

ENOTSUP

Operation not supported. The following occurred:

Command _IOCC_REGFILEINT was used and *fildev* (*w_iocctl*) or *pathname* (*__w_piocctl*) refers to a file residing in a R/W file system that is shared across a sysplex with zFS, or is accessed through an NFS Client. In these cases, the file is able to be changed on a remote system without the local system being aware. Because the program would not receive notification, this operation is rejected.

Use *__errno2()* to obtain more diagnostic information.

ENOTTY

An incorrect file descriptor was specified. *fildev* was not a character special file.

ACLs description

The *w_iocctl()* and *__w_piocctl()* functions are general entry points for SETFACL and GETFACL commands. SETFACL is used to set information into an access control list. GETFACL is used to retrieve information from an Access Control List.

fildev

A descriptor for an open character special file (used by *w_iocctl*).

pathname

The *pathname* of a file (used by *__w_piocctl*).

cmd

The command to be passed to the device driver as an integer value, either SETFACL or GETFACL.

arglen

The length of the user buffer passed to the HFS device driver as a value from 1 to 50,000 bytes. *arglen* is the combined size of the struct *ACL_buf* and the array of struct *ACL_entries*.

arg

arg specifies the user buffer which is mapped by struct *ACL_buf* followed immediately by an array of struct *ACL_entries*. See [z/OS UNIX System Services Programming: Assembler Callable Services Reference](#) for more information about *ACL_buf* and the *ACL_entries*.

w_iocctl() and *__w_piocctl()* pass the *cmd*, *arglen*, and *arg* arguments to the device driver to be interpreted and processed. When *w_iocctl()* and *__w_piocctl()* complete successfully, the device driver returns *arglen* and *arg*, if appropriate.

ACLs returned value

If successful, *w_iocctl()* returns 0.

If unsuccessful, *w_iocctl()* returns -1 and sets *errno* to one of the following values:

Error Code**Description****EBADF**

The *fildev* parameter is not a valid file descriptor.

EINVAL

The request is invalid or not supported.

EMVSPARM

Incorrect parameters were passed to the service.

ENODEV

The device is incorrect. The function is not supported by the device driver.

Example

CELEBW34

```
/* CELEBW34

   This example shows a general entry point for device-specific commands.

*/
#include <termios.h>
#include <stdio.h>

main() {
    char buf[256];
    int  ret;

    memset(buf, 0x00, sizeof(buf));
    if ((ret = w_iocctl(0, 1, sizeof(buf), buf)) != 0)
        perror("w_iocctl() error");
    else
        printf("w_iocctl() returned '%s'\n", buf);
}
```

Output:

```
w_iocctl() error: Invalid argument
```

Note: w_iocctl() is dependent upon the file system device driver.

wmemchr() – Locate wide character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment C99 Single UNIX Specification, Version 3 | both | |

Format

Non-XP4:

```
#include <wchar.h>

wchar_t *wmemchr(const wchar_t *s, wchar_t c, size_t n);
```

XPG4:

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

wchar_t *wmemchr(const wchar_t *s, wchar_t c, size_t n);
```

General description

Locates the first occurrence of the wide character *c* in the initial *n* wide chars of the object pointed to by *s*. If *n* has the value 0, `wmemchr()` finds no occurrence of *c* and returns a NULL pointer.

Note: The function is now available as a built-in function under ARCH(7) when LP64 is not used.

Special behavior for XPG4: If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the `wchar` header, then you must also define the `_MSE_PROTOS` feature test macro to make the declaration of the `wmemchr()` function in the `wchar` header available when you compile your program. See [Table 2 on page 4](#) for a list of XPG4 and other feature test macros.

Returned value

If successful, `wmemchr()` returns a pointer to the first occurrence of the wide character *c* in object *s*.

If the wide character *c* does not occur within the first *n* wide characters of *s*, `wmemchr()` returns the NULL pointer.

Example

```
#include <stdio>
#include <wchar>

main()
{
    wchar_t  *in = L"1234ABCD";
    wchar_t  *ptr;
    wchar_t  fnd = L'A';

    printf("\nEXPECTED: ABCD");
    ptr = wmemchr(in, L'A', 6);
    if (ptr == NULL)
        printf("\n** ERROR ** ptr is NULL, char L'A' not found\n");
    else
        printf("\nRECEIVED: %ls \n",ptr);
}
```

wmemcmp() – Compare wide character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C Amendment C99 Single UNIX Specification, Version 3 | both | |

Format

Non-XPG4:

```
#include <wchar.h>

int wmemcmp(const wchar_t * __restrict__s1,
            const wchar_t * __restrict__s2, size_t n);
```

XPG4:

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

int wmemcmp(const wchar_t *s1, const wchar_t *s2, size_t n);
```

General description

Compares the first n wide chars of the object pointed to by $s1$ to the first n wide chars of the object pointed to by $s2$.

If n has the value 0, `wmemcmp()` returns 0.

Note: The function is now available as a built-in function under ARCH(7) when LP64 is not used.

Special behavior for XPG4: If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the `wchar` header, then you must also define the `_MSE_PROTOS` feature test macro to make the declaration of the `wmemcmp` function in the `wchar` header available when you compile your program. Please see [Table 2 on page 4](#) for a list of XPG4 and other feature test macros.

Returned value

`wmemcmp()` returns an integer that is:

< 0

If $s1$ is less than $s2$.

= 0

If $s1$ is equal to $s2$.

> 0

If $s1$ is greater than $s2$.

Example

```
#include <wchar.h>
#include <stdio.h>

main()
{
    int      ptr;
    wchar_t  *in  = L"12345678";
```

```

wchar_t *out = L"12AAAAAB";

printf("\nGREATER is the expected result");
ptr = wmemcmp(in, out, 3);
if (ptr == 0)
    printf("\nArrays are EQUAL %ls %ls \n", in, out);
else
{
    if (ptr > 0)
        printf("\nArray %ls GREATER than %ls \n", in, out);
    else
        printf("\nArray %ls LESS than %ls \n", in, out);
}
}

```

Related information

wmemcpy() — Copy wide character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment C99 Single UNIX Specification, Version 3 | both | |

Format

Non-XPG4:

```

#include <wchar.h>

wchar_t *wmemcpy(wchar_t * __restrict__ s1,
                 const wchar_t * __restrict__ s2, size_t n);

```

XPG4:

```

#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

wchar_t *wmemcpy(wchar_t *s1, const wchar_t *s2, size_t n);

```

General description

Copies *n* wide chars of the object pointed to by *s2* to the object pointed to by *s1*.

Result of the copy is unpredictable if *s1* and *s2* overlap. If *n* has the value 0, *wmemcpy* copies zero wide characters.

Note: The function is now available as a built-in function under ARCH(7) when LP64 is not used.

Special behavior for XPG4: If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the *wchar* header, then you must also define the *_MSE_PROTOS* feature test macro to make the declaration of the *wmemcpy* function in the *wchar* header

available when you compile your program. Please see [Table 2 on page 4](#) for a list of XPG4 and other feature test macros.

Returned value

wmemcpy() returns the value of s1.

Example

```
#include <wchar.h>
#include <stdio.h>

main()
{
    wchar_t  *in    = L"12345678";
    wchar_t  *out   = L"ABCDEFGH";
    wchar_t  *ptr;

    printf("-nExpected result: First 4 chars of in change");
    printf(" and are the same as first 4 chars of out");
    ptr = wmemcpy(in, out, 4);
    if (ptr == in)
        printf("-nArray in %ls array out %ls -n",in, out);
    else
    {
        printf("-n*** ERROR ***");
        printf(" returned pointer wrong");
    }
}
```

wmemmove() — Move wide character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| ISO C Amendment C99 Single UNIX Specification, Version 3 | both | |

Format

Non-XPG4:

```
#include <wchar.h>

wchar_t *wmemmove(wchar_t *s1, const wchar_t *s2, size_t n);
```

XPG4:

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>
```

```
wchar_t *wmemmove(wchar_t *s1, const wchar_t *s2, size_t n);
```

General description

Copies n wide chars of the object pointed to by $s2$ to the object pointed to by $s1$. Copying takes place as if the n wide characters from $s2$ are first copied into a temporary array of n wide characters that does not overlay the objects pointed to by $s1$ and $s2$, and then copied from the temporary array into the object pointed to by $s1$.

If n has the value 0, `wmemmove()` copies zero wide characters.

Special behavior for XPG4: If you define any feature test macro specifying XPG4 behavior before the statement in your program source file to include the `wchar` header, then you must also define the `_MSE_PROTOS` feature test macro to make the declaration of the `wmemmove()` function in the `wchar` header available when you compile your program. Please see [Table 2 on page 4](#) for a list of XPG4 and other feature test macros.

Returned value

`wmemmove()` returns the value of $s1$.

Example

```
#include <wchar.h>
#include <stdio.h>

main()
{
    wchar_t *in    = L"12345678";
    wchar_t *out   = L"ABCDEFGH";

    wchar_t *ptr;

    printf("\nExpected result: First 4 chars of in and out the same");
    ptr = wmemmove(in, out, 4);
    if (ptr == in)
        printf("\nArray in %ls array out %ls \n", in, out);
    else
    {
        printf("\n*** ERROR ***");
        printf("    Returned pointer not correct.\n");
    }
}
```

wmemset() — Set wide character

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| ISO C Amendment C99 Single UNIX Specification, Version 3 | both | |

Format

Non-XP4:

```
#include <wchar.h>

wchar_t *wmemset(wchar_t *s, wchar_t c, size_t n);
```

XP4:

```
#define _XOPEN_SOURCE
#define _MSE_PROTOS
#include <wchar.h>

wchar_t *wmemset(wchar_t *s, wchar_t c, size_t n);
```

General description

Copies the value of *c* into the first *n* wide chars of the object pointed to by *s*.

If *n* has the value 0, `wmemset()` copies zero wide characters.

Note: The function is now available as a built-in function under ARCH(7) when LP64 is not used.

Special behavior for XP4: If you define any feature test macro specifying XP4 behavior before the statement in your program source file to include the `wchar` header, then you must also define the `_MSE_PROTOS` feature test macro to make the declaration of the `wmemset()` function in the `wchar` header available when you compile your program. Please see [Table 2 on page 4](#) for a list of XP4 and other feature test macros.

Returned value

`wmemset()` returns the value of *s*.

Example

```
#include <wchar.h>
#include <stdio.h>

void main()
{
    wchar_t *in = L"1234ABCD";
    wchar_t *ptr;

    printf("\nEXPECTED: AAAAAACD");
    ptr = wmemset(in, L'A', 6);
    if (ptr == in)
        printf("\nResults returned - %ls \n", ptr);
    else
    {
        printf("\n** ERROR ** wrong pointer returned\n");
    }
}
```

}

wordexp() — Perform shell word expansions

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | POSIX(ON) |

Format

```
#define _XOPEN_SOURCE
#include <wordexp.h>

int wordexp(const char *__restrict__ words,
            wordexp_t *__restrict__ pwordexp, int flags);

void wordfree(wordexp_t *pwordexp);
```

General description

The `wordexp()` function performs word expansions as described in *X/Open CAE Specification, Commands and Utilities, Issue 4, Version 2 (XCU) Section 2.6 , Word Expansions*, subject to quoting as in the **XCU** specification, **Section 2.2 , Quoting**, and places the list of expanded words into the structure pointed to by `pwordexp`.

The `words` argument is a pointer to a string containing one or more words to be expanded. The expansions will be the same as would be performed by the shell described by the **XCU** specification if `words` were the part of a command line representing the arguments to a utility. Therefore, `words` must not contain an unquoted <newline> or any of the unquoted special shell characters:

```
|  &  ;  <  >
```

except in the context of command substitution as specified in the **XCU** specification, **Section 2.6.3 , Command Substitution**. It also must not contain unquoted parentheses or braces, except in the context of command or variable substitution.

The structure type **wordexp_t** is defined in the header **<wordexp.h>** and includes the following members:

| Member Type | Member Name | Description |
|-------------|-------------|---|
| size_t | we_wordc | Count of words matched by <code>words</code> . |
| char ** | we_wordv | Pointer to list of expanded words. |
| size_t | we_offs | Slots to reserve at the beginning of <code>pwordexp->we_wordv</code> . |

The `wordexp()` function stores the number of generated words into `pwordexp->we_wordc` and a pointer to a list of pointers to words in `pwordexp->we_wordv`. Each individual field created during field splitting (see

the **XCU** specification, **Section 2.6.5 , Field Splitting**) or pathname expansion (see the **XCU** specification, **Section 2.6.6 , Pathname Expansion**) is a separate word in the *pwordexp->we_wordv* list. The words are in order as described in the **XCU** specification, **Section 2.6 , Word Expansions**. The first pointer after the last word pointer will be a NULL pointer. The expansion of special parameters described in the **XCU** specification, **Section 2.5.2 , Special Parameters** is unspecified.

It is the caller's responsibility to allocate the storage pointed to by *pwordexp*. The *wordexp()* function allocates the other space as needed, including memory pointed to by *pwordexp->we_wordv*. The *wordfree()* function frees any memory associated with *pwordexp* from a previous call to *wordexp()*.

The *flags* argument is used to control the behavior of *wordexp()*. The value of *flags* is the bitwise inclusive-OR or zero or more of the following constants, which are defined in `<wordexp.h>`:

WRDE_APPEND

Append words generated to the ones from a previous call to *wordexp()*.

WRDE_DOOFFS

Make use of *pwordexp->we_offs*. If this flag is set, *pwordexp->we_offs* is used to specify how many NULL pointers to add to the beginning of *pwordexp->we_wordv*. In other words, *pwordexp->we_wordv* will point to *pwordexp->we_offs* NULL pointers followed by *pwordexp->we_wordc* word pointers, followed by a NULL pointer.

WRDE_NOCMD

Fail if command substitution, as specified in the **XCU** specification, **Section 2.6.3 , Command Substitution**, is requested.

WRDE_REUSE

The *pwordexp* argument was passed to a previous successful call to *wordexp()*, and has not been passed to *wordfree()*. The result will be the same as if the application had called *wordfree()* and then called *wordexp()* without *WRDE_REUSE*.

WRDE_SHOWERR

Do not redirect stderr to `/dev/null`.

WRDE_UNDEF

Report error on an attempt to expand an undefined shell variable.

The *WRDE_APPEND* flag can be used to append a new set of words to those generated by a previous call to *wordexp()*. The following rules apply when two or more calls to *wordexp()* are made with the same value of *pwordexp* and without intervening calls to *wordfree()*:

1. The first such call must not set *WRDE_APPEND*. All subsequent calls must set it.
2. All of the calls must set *WRDE_DOOFFS*, or all must not set it.
3. After the second and each subsequent call, *pwordexp->we_wordv* will point to a list containing the following:
 - a. zero or more NULL pointers, as specified by *WRDE_DOOFFS* and *pwordexp->we_offs*
 - b. pointers to the words that were in the *pwordexp->we_wordv* list before the call, in the same order as before
 - c. pointers to the new words generated by the latest call, in the specified order
4. The count returned in *pwordexp->we_wordc* will be the total number of words from all of the calls.
5. The application can change any of the fields after a call to *wordexp()*, but if it does, it must reset them to the original value before a subsequent call, using the same *wordexp* value, to *wordfree()* or *wordexp()* with the *WRDE_APPEND* or *WRDE_REUSE* flag.

If *words* contains an unquoted

```
<newline> | & ; < > ( ) { }
```

in an inappropriate context, *wordexp()* will fail, and the number of expanded words will be 0.

Unless `WRDE_SHOWERR` is set in *flags*, `wordexp()` will redirect `stderr` to `/dev/null` for any utilities executed as a result of command substitution while expanding *words*. If `WRDE_SHOWERR` is set, `wordexp()` may write messages to `stderr` if syntax errors are detected while expanding *words*.

If `WRDE_DOOFFS` is set, then `pwordexp->we_offs` must have the same value for each `wordexp()` call and `wordfree()` call using a given `pwordexp`.

The following constants are defined in `<wordexp.h>` as error return values:

WRDE_BADCHAR

One of the unquoted characters:

```
<newline> | & ; < > ( ) { }
```

appears in *words* in an inappropriate context.

WRDE_BADVAL

Reference to undefined shell variable when `WRDE_UNDEF` is set in *flags*.

WRDE_CMDSUB

Command substitution requested when `WRDE_NOCMD` is set in *flags*.

WRDE_NOSPACE

Attempt to allocate memory failed.

WRDE_SYNTAX

Shell syntax error, such as unbalanced parentheses or unterminated string.

WRDE_NOSYS

POSIX shell not available.

WRDE_EOPEN

`wordexp()` was invoked in an environment that does not supported a multi-threaded fork, or `wordexp()` was invoked from a multithreaded process in TSO or MVS batch.

WRDE_INTRUPT

`wordexp()` was interrupted by a signal, such as an alarm. In this event, the caller may re-issue `wordexp()`.

For further information about the cause of a failure, please refer to `__errno2()` and `errno` in addition to the above error return values.

Returned value

If successful, `wordexp()` returns 0.

If unsuccessful, `wordexp()` returns a nonzero value, as defined in `<wordexp.h>` and described above, to indicate an error. If `wordexp()` returns the value `WRDE_NOSPACE`, then `pwordexp->we_wordc`, and `pwordexp->we_wordv` will be updated to reflect any words that were successfully expanded. In other cases, they will not be modified.

wordfree() — Free shell word expansion memory

Standards

| Standards / Extensions | C or C++ | Dependencies |
|--|----------|--------------|
| XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _XOPEN_SOURCE
#include <wordexp.h>

int wordexp(const char *words, wordexp_t *pwordexp, int flags);

void wordfree(wordexp_t *pwordexp);
```

General description

The wordfree() function frees any memory associated with *pwordexp* from a previous call to wordexp(). Please refer to the description of wordexp() for the rules governing use of wordexp() and wordfree().

Returned value

wordfree() returns no values.

[write\(\) — Write data on a file or socket](#)

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| POSIX.1 XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

```
#define _POSIX_SOURCE
#include <unistd.h>

ssize_t write(int fs, const void *buf, size_t N);
```

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <unistd.h>

ssize_t write(int fs, const void *buf, ssize_t N);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <unistd.h>

ssize_t write(int fs, const void *buf, ssize_t N);
```

General description

Writes N bytes from *buf* to the file or socket associated with *fs*. N should not be greater than `INT_MAX` (defined in the `limits.h` header file). If N is zero, `write()` simply returns 0 without attempting any other action.

If *fs* refers to a regular file or any other type of file on which a process can seek, `write()` begins writing at the file offset associated with *fs*. A successful `write()` increments the file offset by the number of bytes written. If the incremented file offset is greater than the previous length of the file, the length of the file is set to the new file offset.

If *fs* refers to a file on which a process cannot seek, `write()` begins writing at the current position. There is no file offset associated with such a file.

If `O_APPEND` (defined in the `fcntl.h` header file) is set for the file, `write()` sets the file offset to the end of the file before writing the output.

If there is not enough room to write the requested number of bytes (for example, because there is not enough room on the disk), `write()` outputs as many bytes as the remaining space can hold.

If `write()` is interrupted by a signal, the effect is one of the following:

- If `write()` has not written any data yet, it returns -1 and sets `errno` to `EINTR`.
- If `write()` has successfully written some data, it returns the number of bytes it wrote before it was interrupted.

Write operations on pipes or FIFO special files are handled in the same way a write operation on a regular file, with the following exceptions:

- A pipe has no associated file offset, so every write appends to the end of the pipe.
- If N is less than or equal to `PIPE_BUF`, the output is not interleaved with data written by other processes that are writing to the same pipe. If N is greater than `PIPE_BUF` bytes, the output can be interleaved with other data (regardless of the setting of `O_NONBLOCK`, which is defined in the `fcntl.h` header file). A write to a pipe never returns with `errno` set to `EINTR` if it has transferred any data.
- If `O_NONBLOCK` (defined in the `fcntl.h` header file) is not set, `write()` may block process execution until normal completion.
- If `O_NONBLOCK` is set, `write()` does not block process execution. If N is less than or equal to `PIPE_BUF`, `write()` succeeds completely and returns the value of N , or else it writes nothing, sets `errno` to `EAGAIN`, and returns -1. If N is greater than `PIPE_BUF`, `write()` writes as many bytes as it can and returns this number as its result, or else it writes nothing, sets `errno` to `EAGAIN`, and returns -1.

With other files that support nonblocking writes and cannot accept data immediately, the effect is one of the following:

- If `O_NONBLOCK` is not set, `write()` blocks until the data can be written.
- If `O_NONBLOCK` is set, `write()` does not block the process. If some data can be written without blocking the process, `write()` writes what it can and returns the number of bytes written. Otherwise, it sets `errno` to `EAGAIN` and returns -1.

`write()` causes the signal `SIGTTOU` to be sent if all of these conditions are true:

- The process is attempting to write to its controlling terminal and `TOSTOP` is set as a terminal attribute.
- The process is running in a background process group and the `SIGTTOU` signal is not blocked or ignored.
- The process is not an orphan.

A successful `write()` updates the change and modification times for the file.

If `fs` refers to a socket, `write()` is equivalent to `send()` with no flags set.

Behavior for sockets: The `write()` function writes data from a buffer on a socket with descriptor `fs`. The socket must be a connected socket. This call writes up to `N` bytes of data.

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

fs

The file or socket descriptor.

buf

The pointer to the buffer holding the data to be written.

N

The length in bytes of the buffer pointed to by the `buf` parameter.

If there is not enough available buffer space to hold the socket data to be transmitted, and the socket is in blocking mode, `write()` blocks the caller until additional buffer space becomes available. If the socket is in nonblocking mode, `write()` returns -1 and sets the error code to `EWOULDBLOCK`. See [“fcntl\(\) — Control open file descriptors” on page 483](#) or [“ioctl\(\) — Control device” on page 872](#) for a description of how to set the nonblocking mode.

When the socket is not ready to accept data and the process is trying to write data to the socket:

- Unless `FNDELAY` or `O_NONBLOCK` is set, `write()` blocks until the socket is ready to accept data.
- If `FNDELAY` is set, `write()` returns 0.
- If `O_NONBLOCK` is set, `write()` does not block the process. If some data can be written without blocking the process, `write()` writes what it can and returns the number of bytes written. Otherwise, it sets the error code to `EAGAIN` and returns -1.

For datagram sockets, this call sends the entire datagram, provided that the datagram fits into the TCP/IP buffers. Stream sockets act like streams of information with no boundaries separating data. For example, if an application program wishes to send 1000 bytes, each call to this function can send 1 byte or 10 bytes or the entire 1000 bytes. Therefore, application programs using stream sockets should place this call in a loop, calling this function until all data has been sent.

Special behavior for C++ and sockets: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED 1` feature test macro.

Large file support for z/OS UNIX files: Large z/OS UNIX files are supported automatically for AMODE 64 C/C++ applications. AMODE 31 C/C++ applications must be compiled with the [long long data type support](#) enabled and define the `_LARGE_FILES` feature test macro before any headers are included to enable this function to operate on z/OS UNIX files that are larger than 2 GB in size. File size and offset fields are enlarged to 63 bits in width. Therefore, any other function operating on the file is required to define the `_LARGE_FILES` feature test macro as well.

Returned value

If successful, `write()` returns the number of bytes actually written, less than or equal to `N`.

A value of 0 or greater indicates the number of bytes sent. However, this does not assure that data delivery was complete. A connection can be dropped by a peer socket and a SIGPIPE signal generated at a later time if data delivery is not complete.

If unsuccessful, `write()` returns -1 and sets `errno` to one of the following values:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

EAGAIN

Resources temporarily unavailable. Subsequent requests may complete normally.

EBADF

fs is not a valid file or socket descriptor.

ECONNRESET

A connection was forcibly closed by a peer.

EDESTADDRREQ

The socket is not connection-oriented and no peer address is set.

EFAULT

Using the *buf* and *N* parameters would result in an attempt to access storage outside the caller's address space.

EFBIG

Writing to the output file would exceed the maximum file size supported by the implementation.

An attempt was made to write a file that exceeds the system established maximum file size or the process's file size limit.

The file is a regular file, *nbyte* is greater than 0 and the starting position is greater than or equal to the offset maximum established in the open file description associated with *fields*.

EINTR

`write()` was interrupted by a signal before it had written any output.

EINVAL

The request is invalid or not supported. The STREAM or multiplexer referenced by *fs* is linked (directly or indirectly) downstream from a multiplexer.

EIO

The process is in a background process group and is attempting to write to its controlling terminal, but TOSTOP (defined in the `termios.h` header file) is set, the process is neither ignoring nor blocking SIGTTOU signals, and the process group of the process is orphaned. An I/O error occurred.

EMSGSIZE

The message was too big to be sent as a single datagram.

ENOBUFS

Buffer space is not available to send the message.

ENOSPC

There is no available space left on the output device.

ENOTCONN

The socket is not connected.

ENXIO

A hang-up occurred on the STREAM being written to.

EPIPE

`write()` is trying to write to a pipe that is not open for reading by any other process. This error also generates a SIGPIPE signal. For a connected stream socket the connection to the peer socket has been lost.

ERANGE

The transfer request size was outside the range supported by the STREAMS file associated with *fs*.

EWOULDBLOCK

socket is in nonblocking mode and no data buffers are available or the `SO_SNDTIMEO` timeout value was reached before buffers became available.

A write to a STREAMS file may fail if an error message has been received at the STREAM head. In this case, `errno` is set to the value included in the error message.

Note: z/OS UNIX System Services does not supply any STREAMS devices or pseudodevices. It is impossible for `write()` to write any data on a STREAM. None of the STREAMS `errno`s will be visible to the invoker. See [“open\(\) — Open a file”](#) on page 1157

Example

CELEBW35

```

/* CELEBW35

   This example writes a certain amount of bytes to a file, using write().

   */
#define _POSIX_SOURCE
#include <fcntl.h>
#include <sys/stat.h>
#include <sys/types.h>
#include <unistd.h>
#undef _POSIX_SOURCE
#include <stdlib.h>
#include <stdio.h>

#define mega_string_len 1000000

main() {
    char *mega_string;
    int fd, ret;
    char fn[]="write.file";

    if ((mega_string = (char*) malloc(mega_string_len)) == NULL)
        perror("malloc() error");
    else if ((fd = creat(fn, S_IWUSR)) < 0)
        perror("creat() error");
    else {
        memset(mega_string, '0', mega_string_len);
        if ((ret = write(fd, mega_string, mega_string_len)) == -1)
            perror("write() error");
        else printf("write() wrote %d bytes\n", ret);
        close(fd);
        unlink(fn);
    }
}

```

Output:

```
write() wrote 1000000 bytes
```

__writedown() — Query or change the setting of the write-down privilege of an ACEE.

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | z/OS V1R5 |

Format

```
#define _OPEN_SYS
#include <sys/stat.h>
int __writedown ( int writedownop, int writedownscope);
```

General description

The `__writedown()` function will enable callers to query or change the setting of the write-down privilege of an ACEE (access control environment element) at the address space level or task level. User's having write-down privilege can write data to a resource protected by a seclabel of lower authority then that of the seclabel represented in the address space level ACEE.

To activate the write-down privilege the userid in the target ACEE must be permitted to the IRR.WRITEDOWN.BYUSER profile in the FACILITY class. The FACILITY class must be active and RACLISTed, and the SETROPTS MLS option must be active.

See *z/OS V1R5 Planning for Multilevel Security* for more details on the usage of this function.

writedownop

The operation to be performed

__WD_QUERY

Query the current setting of the write-down privilege

__WD_ACTIVATE

Activate the write-down privilege

__WD_INACTIVATE

Inactivate the write-down privilege

__WD_RESET

Reset the write-down privilege to the users original default value.

writedownscope

Scope of the write-down operation.

- __WD_SCOPE_AS**
Perform write-down operation on the address space level ACEE.
- __WD_SCOPE_THD**
Perform write-down operation on the task level ACEE.

Returned value

For the __writedown() activate, inactivate, and reset operations:
If successful, __writedown() returns 0.
For the __writedown() query operation:
If successful, __writedown() returns one of the following values indicating the state of the current setting of the writedown privelege.
__WD_IS_ACTIVE
The write-down privilege is active for the ACEE.
__WD_IS_INACTIVE
The write-down privilege is inactive for the ACEE.
For all __writedown() operations:
If unsuccessful, all __writedown() operations return -1 and sets errno to EINVAL.

Related information

writew() – Write data on a file or socket from an array

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| XP4.2 Single UNIX Specification, Version 3 | both | |

Format

X/Open:

```
#define _XOPEN_SOURCE_EXTENDED 1
#include <sys/uio.h>

ssize_t writew(int fs, const struct iovec *iov, int iovcnt);
```

Berkeley sockets:

```
#define _OE_SOCKETS
#include <sys/uio.h>

int writew(int fs, struct iovec *iov, int iovcnt);
```

General description

The writew() function writes data to a file or socket with descriptor fs from a set of buffers. The data is gathered from the buffers specified by iov[0]...iov[iovcnt-1]. When the descriptor refers to a socket, it must be a connected socket.

**Parameter
Description**

fs

The file or socket descriptor.

iovA pointer to an array of **iovec** buffers.***iovcnt***The number of buffers pointed to by the *iov* parameter.The **iovec** structure is defined in **uio.h** and contains the following fields:

| Element | Description |
|---------|-------------|
|---------|-------------|

iov_base

Pointer to the buffer.

iov_len

Length of the buffer.

This call writes the sum of the *iov_len* bytes of data.

If there is not enough available buffer space to hold the socket data to be transmitted, and the socket is in blocking mode, `writev()` blocks the caller until additional buffer space becomes available. If the socket is in a nonblocking mode, `writev()` returns -1 and sets the error code to `EWOULDBLOCK`. See [“fcntl\(\) — Control open file descriptors” on page 483](#) or [“ioctl\(\) — Control device” on page 872](#) for a description of how to set nonblocking mode.

When the socket is not ready to accept data and the process is trying to write data to the socket:

- Unless `FNDELAY` or `O_NONBLOCK` is set, `writev()` blocks until the socket is ready to accept data.
- If `FNDELAY` is set, `writev()` returns a 0.
- If `O_NONBLOCK` is set, `writev()` does not block the process. If some data can be written without blocking the process, `writev()` writes what it can and returns the number of bytes written. Otherwise, it sets the error code to `EAGAIN` and returns -1.

For datagram sockets, this call sends the entire datagram, provided that the datagram fits into the TCP/IP buffers. Stream sockets act like streams of information with no boundaries separating data. For example, if an application program wishes to send 1000 bytes, each call to this function can send 1 byte, or 10 bytes, or the entire 1000 bytes. Therefore, application programs using stream sockets should place this call in a loop, calling this function until all data has been sent.

Special behavior for C++: To use this function with C++, you must use the `_XOPEN_SOURCE_EXTENDED` 1 feature test macro.

Returned value

If successful, `writev()` returns the number of bytes written from the buffer.

A value of 0 or greater indicates the number of bytes sent, however, this does not assure that data delivery was complete. A connection can be dropped by a peer socket and a `SIGPIPE` signal generated at a later time if data delivery is not complete.

If unsuccessful, `writev()` returns -1 and sets `errno` to one of the following values:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

EAGAIN

Resources temporarily unavailable. Subsequent requests may complete normally.

EBADF*fs* is not a valid file or socket descriptor.**ECONNRESET**

A connection was forcibly closed by a peer.

EDESTADDRREQ

The socket is not connection-oriented and no peer address is set.

EFAULT

Using the *iov* and *iovcnt* parameters would result in an attempt to access storage outside the caller's address space.

EINTR

A signal interrupted `writew()` before any data was transmitted.

EINVAL

An incorrect value for *iovcnt* was detected.

EMSGSIZE

The message was too big to be sent as a single datagram.

ENOBUFS

Buffer space is not available to send the message.

ENOTCONN

The socket is not connected.

EPIPE

For a connected stream socket the connection to the peer socket has been lost. A SIGPIPE signal is sent to the calling process.

EPROTOTYPE

The protocol is the wrong type for this socket. A SIGPIPE signal is sent to the calling process.

EWOULDBLOCK

socket is in nonblocking mode and no data buffers are available or the SO_SNDTIMEO timeout value was reached before buffers became available.

__wsinit() – Reinitialize writable static

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| C Library | both | |

Format

```
#include <unistd.h>

int __wsinit(void (*func_ptr)());
```

General description

The `__wsinit()` function reinitializes the writable static area of a module that was loaded by the `fetch()` library call. *func_ptr* must be a valid fetch pointer returned by `fetch()` or `fetchep()`. If the module contains C++, `__wsinit()` first runs any C++ static destructors, then `__wsinit()` runs the static constructors that are present in the load module.

Program variables with the static or extern storage class and writable strings receive the initial value defined in the program, if any initial value was assigned. The C header files contain external variable declarations for those variables defined by the POSIX, XPG4 and XPG4.2 standards. If the fetched module contains these variables, `__wsinit()` reinitializes them as described in [z/OS XL C/C++ Programming Guide](#).

Returned value

If successful, `__wsinit()` returns 0.

If unsuccessful, `__wsinit()` returns -1 and sets `errno` to one of the following values:

Error Code

Description

EINVAL

func_ptr is not a valid fetch pointer.

Related information

- [“unistd.h — Implementation-specific functions”](#) on page 77
- [“fetch\(\) — Get a load module”](#) on page 516

w_statfs() – Get the file system status

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```
#include <sys/statfs.h>

int w_statfs(const char *filesystem, struct w_statfs *statbuf, size_t length);
```

General description

Gets status about a specific file system.

filesystem

The name of the file system for which status is being retrieved. This file system name can be one of the following:

- The name specified in the FILESYSTEM parameter of the ROOT or MOUNT statements in the BPXPRMxx parmlib member.
- The name specified in a TSO/E MOUNT command.
- The name returned on a previous call to w_getmntent().

statbuf

A buffer that the status information is put into. The status information is mapped by the sys/statfs.h header file.

int statfs_len

Length of *statfs*

int statfs_blksize

Block size

unsigned int statfs_total_space

Total space in block size units

unsigned int statfs_used_space

Allocated space in block size units

unsigned int statfs_free_space

Space available to unprivileged users in block size units

length

The length of the buffer. The length of the buffer and the length of the structure are compared, and the shorter of the two is used to determine how much information to return in the buffer.

If the buffer length is zero, only the return value is returned. A process can use a length of zero to detect if a file system exists or not.

Special behavior for XPG4.2: w_statfs() is replaced by w_statvfs().

Returned value

If successful, w_statfs() returns the length of the data in the buffer.

If unsuccessful, w_statfs() returns -1 and sets errno to one of the following values:

Error Code

Description

EINVAL

A parameter was incorrectly specified.

Example

CELEBW36

```
/* CELEBW36 */
#define _OPEN_SYS
#include <sys/statfs.h>
#include <stdio.h>

main() {
    char fs[]="POSIX.ROOT.FS";
    struct w_statfs buf;

    if (w_statfs(fs, &buf, sizeof(buf)) == -1)
        perror("w_statfs() error");
    else {
```

```

printf("each block in %s is %d bytes big\n", fs,
      buf.statfs_blksize);
printf("there are %d blocks in use out of a total of %d\n",
      buf.statfs_used_space, buf.statfs_total_space);
printf("in bytes, that's %.0f bytes used out of a total of %.0f\n",
      ((double)buf.statfs_used_space * buf.statfs_blksize),
      ((double)buf.statfs_total_space * buf.statfs_blksize));
}
}

```

Output:

```

each block in POSIX.ROOT.FS is 4096 bytes big
there are 2089 blocks in use out of a total of 2400
in bytes, that's 8556544 bytes used out of a total of 9830400

```

w_statvfs() — Get the file system status

Standards

| Standards / Extensions | C or C++ | Dependencies |
|------------------------|----------|--------------|
| z/OS UNIX | both | |

Format

```

#define _OPEN_SOURCE 2
#include <sys/statvfs.h>

int w_statvfs(const char *filesystem, struct statvfs *buffer, size_t buflen);

```

General description

The `w_statvfs()` function gets status about a specific file system.

filesystem

The name of the file system for which status is being retrieved. This file system name can be one of the following:

- The name specified in the FILESYSTEM parameter of the ROOT or MOUNT statements in the BPXPRMxx parmlib member.
- The name specified in a TSO/E MOUNT command.
- The name returned on a previous call to `w_getmntent()`.

buffer

A buffer that the status information is put into. The information is returned in a `statvfs` structure, as defined in the `sys/statvfs.h` header file. The elements of this structure are described in [“statvfs\(\) — Get file system information” on page 1712](#).

buflen

The length of the buffer. The length of the buffer and the length of the structure are compared, and the shorter of the two is used to determine how much information to return in the buffer.

If the buffer length is zero, only the return value is returned. A process can use a length of zero to detect if a file system exists or not.

Returned value

If successful, w_statvfs() returns the length of the data in the buffer.
If unsuccessful, w_statvfs() returns -1 and sets errno to one of the following values:

| Error Code | Description |
|------------|-------------|
|------------|-------------|

| | |
|---------------|---|
| EINVAL | A parameter was specified incorrectly. For example, the file system name (<i>filesystem</i>) was not found. |
|---------------|---|

Example

```
#define _OPEN_SOURCE 2
#include <sys/statvfs.h>
#include <stdio.h>

main() {
    char fs[]="POSIX.ROOT.FS";
    struct statvfs buf;

    if (w_statvfs(fs, &buf, sizeof(buf)) == -1)
        perror("w_statvfs() error");
    else {
        printf("each block in %s is %d bytes big\n", fs,
            buf.f_frsize);
        printf("there are %d blocks available out of a total of %d\n",
            buf.f_bavail, buf.f_blocks);
        printf("in bytes, that's %.0f bytes free out of a total of %.0f\n",
            ((double)buf.f_bavail * buf.f_frsize),
            ((double)buf.f_blocks * buf.f_frsize));
    }
}
```

Output:

```
each block in POSIX.ROOT.FS is 4096 bytes big
there are 2089 blocks available out of a total of 2400
in bytes, that's 8556544 bytes free out of a total of 9830400
```

y0(), y1(), yn() – Bessel functions of the second kind

Standards

| Standards / Extensions | C or C++ | Dependencies |
|---|----------|--------------|
| SAA XPG4 XPG4.2 Single UNIX Specification, Version 3 | both | |

Format

SAA:

```
#include <math.h>

double y0(double x);
double y1(double x);
double yn(int n, double x);
```

This function must be used with the [runtime library extensions](#) or under the [SAA based language constructs](#).

General description

Bessel functions are solutions to certain types of differential equations.

The `y0()`, `y1()`, and `yn()` functions are Bessel functions of the *second kind*, for orders 0, 1, and n , respectively. The argument x must be positive. The argument n should be greater than or equal to zero. If n is less than zero, there will be a negative exponent in the result.

Note: This function works in both IEEE Binary Floating-Point and hexadecimal floating-point formats. See [“IEEE binary floating-point”](#) on page 97 for more information about IEEE Binary Floating-Point.

Returned value

If successful, the function returns the calculated value.

For `y0()`, `y1()`, or `yn()`, if x is negative, the function sets `errno` to `EDOM` and returns `-HUGE_VAL`.

For `y0()`, `y1()`, or `yn()`, if x causes overflow, the function sets `errno` to `ERANGE` and returns `-HUGE_VAL`.

Special behavior for IEEE: If x is negative, `y0()`, `y1()`, and `yn()` return the value `NaNQ`. If x is 0, `y0()`, `y1()`, and `yn()` return the value `-HUGE_VAL`. In all cases, `errno` remains unchanged.

Example

CELEBY01

```
/* CELEBY01

   This example computes y to be the order 0 Bessel function of the first
   kind for x and z to be the order 3 Bessel function of the second kind for x.

*/
#include <math.h>
#include <stdio.h>

int main(void)
{
    double x, y, z;
    x = 4.27;

    y = y0(x);          /* y = -0.3660 is the order 0 bessel */
                        /* function of the first kind for x */
    z = yn(3,x);         /* z = -0.0875 is the order 3 bessel */
                        /* function of the second kind for x */
    printf("x = %f\n y = %f\n z = %f\n", x, y, z);
}
```

Library functions for the system programming C (SPC) facilities

Restriction: The SPC facility is not supported in AMODE 64.

The library functions specific to the System Programming C (SPC) environment are described in [z/OS XL C/C++ Programming Guide](#). These system programming functions are as follows:

- `__xhotc()`
- `__xhotl()`
- `__xhott()`
- `__xhotu()`
- `__xregs()`
- `__xsacc()`
- `__xsrv()`
- `__xusr()`
- `__xusr2()`
- `__24malc()`
- `__4kmalc()`

Chapter 4. Using high performance libraries

The z/OS XL C/C++ compilers are shipped with a set of libraries for high-performance mathematical computing:

- The [Mathematical Acceleration Subsystem \(MASS\)](#) is a set of libraries of tuned mathematical intrinsic functions that provide improved performance over the corresponding standard system math library functions.
- The [Automatically Tuned Linear Algebra Software \(ATLAS\)](#) is a set of high-performance, processor-tuned linear algebra libraries.
- The [OpenBLAS](#) library is a BLAS (Basic Linear Algebra Subroutines) library, which contains a set of routines that provide matrix/vector linear algebra functions.

Using the Mathematical Acceleration Subsystem (MASS) libraries

The IBM z/OS C/C++ compilers are shipped with a set of Mathematical Acceleration Subsystem (MASS) libraries for high-performance mathematical computing. The MASS libraries consist of:

- A [library of scalar C functions](#) that is tuned for specific architectures.
- A [vector library](#) that is tuned for specific architectures.
- A [SIMD library](#) that is tuned for specific architectures.

You can [compile and link](#) a program that uses the MASS libraries and selectively use the MASS scalar library functions in conjunction with the regular system libraries.

Notes:

- Accuracy and exception handling might not be identical between MASS functions and system library functions.
- To use the MASS libraries on IBM z16[®] servers, z/OS 2.4 or later with all the following PTFs are required: [UI96552](#), [UI96655](#), [UI96656](#). Additionally, the following PTFs are required for each z/OS operating system:
 - z/OS 3.1 with the PTF [UI96659](#) installed.
 - z/OS 2.5 with the PTF [UI96658](#) installed.
 - z/OS 2.4 with the PTF [UI96657](#) installed.

Using the MASS scalar library

The MASS scalar library contains an accelerated set of frequently used math intrinsic functions. They are compatible with 31-bit C linkage, 31-bit XPLINK, and 64-bit. If you want to explicitly call the MASS scalar functions, you can take the following steps:

1. Provide the prototypes for the functions by including `math.h` and `mass.h` in your source files. See the following table for the location of header files.
2. Link the appropriate scalar library with your application. Names of libraries are described in the following table.

Table 75. Header files and library names for the MASS scalar library

| | System environment | |
|---|--|--|
| | z/OS UNIX | MVS |
| Header file location | /usr/include/math.h /usr/include/mass.h | CEE.SCEEH.H |
| Library name for z16 | /usr/lpp/cbclib/lib/ libmass.arch14.a | CBC.SCCNM14 (for functions that overlap with <math.h>) CBC.SCCNN14 (for functions that are only introduced in <mass.h>) |
| Library name for z15[®] | /usr/lpp/cbclib/lib/ libmass.arch13.a | CBC.SCCNM13 (for functions that overlap with <math.h>) CBC.SCCNN13 (for functions that are only introduced in <mass.h>) |
| Library name for z14 | /usr/lpp/cbclib/lib/ libmass.arch12.a | CBC.SCCNM12 (for functions that overlap with <math.h>) CBC.SCCNN12 (for functions that are only introduced in <mass.h>) |
| Library name for z13[®]/ z13s[®] | /usr/lpp/cbclib/lib/ libmass.arch11.a | CBC.SCCNM11 (for functions that overlap with <math.h>) CBC.SCCNN11 (for functions that are only introduced in <mass.h>) |
| Library name for zEC12/ zBC12 | /usr/lpp/cbclib/lib/ libmass.arch10.a | CBC.SCCNM10 (for functions that overlap with <math.h>) CBC.SCCNN10 (for functions that are only introduced in <mass.h>) |

Note: MASS scalar functions can run on IBM zEC12/zBC12 or newer machine models only. A set of libraries that are tuned for each machine model group is provided.

The MASS scalar functions accept double-precision parameters and return a double-precision result, or accept single-precision parameters and return a single-precision result, except sincos, which gives 2 double-precision results. They are summarized in [Table 76 on page 2086](#)

Table 76. MASS scalar functions

| Double-precision function | Single-precision function | Description | Double-precision function prototype | Single-precision function prototype |
|---------------------------|---------------------------|--|-------------------------------------|-------------------------------------|
| acos | acosf | Returns the arc cosine of x | double acos (double x); | float acosf (float x); |
| acosh | acoshf | Returns the arc hyperbolic cosine of x | double acosh (double x); | float acoshf (float x); |

| Table 76. MASS scalar functions (continued) | | | | |
|---|---------------------------|---|---------------------------------------|-------------------------------------|
| Double-precision function | Single-precision function | Description | Double-precision function prototype | Single-precision function prototype |
| | anint ^t | Returns the nearest integer to x (as a float) | | float anint (float x); |
| asin | asinf | Returns the arc sine of x | double asin (double x); | float asinf (float x); |
| asinh | asinhf | Returns the arc hyperbolic sine of x | double asinh (double x); | float asinhf (float x); |
| atan2 | atan2f | Returns the arc tangent of x/y | double atan2 (double x, double y); | float atan2f (float x, float y); |
| atan | atanf | Returns the arc tangent of x | double atan (double x); | float atanf (float x); |
| atanh | atanhf | Returns the arc hyperbolic tangent of x | double atanh (double x); | float atanhf (float x); |
| cbrt | cbrtf | Returns the cube root of x | double cbrt (double x); | float cbrtf (float x); |
| copysign | copysignf | Returns x with the sign of y | double copysign (double x, double y); | float copysignf (float x); |
| cos | cosf | Returns the cosine of x | double cos (double x); | float cosf (float x); |
| cosh | coshf | Returns the hyperbolic cosine of x | double cosh (double x); | float coshf (float x); |
| cosisin | | Returns a complex number with the real part cosine of x and the imaginary part sine of x. | double_Complex cosisin (double); | |
| dnint ^t | | Returns the nearest integer to x (as a double) | double dnint (double x); | |
| erf | erff | Returns the error function of x | double erf (double x); | float erff (float x); |
| erfc | erfcf | Returns the complementary error function of x | double erfc (double x); | float erfcf (float x); |
| exp | expf | Returns the exponential function of x | double exp (double x); | float expf (float x); |
| expm1 | expm1f | Returns (the exponential function of x) - 1 | double expm1 (double x); | float expm1f (float x); |
| hypot | hypotf | Returns the square root of $x^2 + y^2$ | double hypot (double x, double y); | float hypotf (float x, float y); |

| Table 76. MASS scalar functions (continued) | | | | |
|---|---------------------------|--|---|-------------------------------------|
| Double-precision function | Single-precision function | Description | Double-precision function prototype | Single-precision function prototype |
| lgamma | lgammaf | Returns the natural logarithm of the absolute value of the Gamma function of x | double lgamma (double x); | float lgammaf (float x); |
| log | logf | Returns the natural logarithm of x | double log (double x); | float logf (float x); |
| log10 | log10f | Returns the base 10 logarithm of x | double log10 (double x); | float log10f (float x); |
| log1p | log1pf | Returns the natural logarithm of (x + 1) | double log1p (double x); | float log1pf (float x); |
| pow | powf | Returns x raised to the power y | double pow (double x, double y); | float powf (float x, float y); |
| rint | rintf | Returns the nearest integer to x (as a double) | double rint (double x); | float rintf (float x); |
| rsqrt ^t | rsqrtf ^u | Returns the reciprocal of the square root of x | double rsqrt (double x); | float rsqrtf (float x); |
| sin | sinf | Returns the sine of x | double sin (double x); | float sinf (float x); |
| sincos ^t | | Sets *s to the sine of x and *c to the cosine of x | void sincos (double x, double* s, double* c); | |
| sinh | sinhf | Returns the hyperbolic sine of x | double sinh (double x); | float sinhf (float x); |
| sqrt | sqrtf ^u | Returns the square root of x | double sqrt (double x); | float sqrtf (float x); |
| tan | tanf | Returns the tangent of x | double tan (double x); | float tanf (float x); |
| tanh | tanhf | Returns the hyperbolic tangent of x | double tanh (double x); | float tanhf (float x); |

Notes:

- Functions denoted as function-name^t are declared in <mass.h>, and all other functions are declared in <math.h>.
- Functions denoted as function-name^u are supported under the [processor architecture](#) of IBM z15 or newer
- The trigonometric functions (sin, cos, tan) return NaN (Not-a-Number) for large arguments (where the absolute value is greater than 2⁵⁰pi).
- The pow function accepts negative x arguments with integer y arguments according to the C standard.
- In some cases, the MASS functions are not as precise as the system library, and they might handle edge cases differently (sqrt(Inf), for example).

Using the MASS vector library

The MASS vector library provides a set of functions that compute the same mathematical function for vectors of operands. If you want to explicitly call the MASS vector functions, take the following steps:

1. Provide the prototypes for the functions by including `massv.h` in your source files. See the following table for the location of header files.
2. Link the appropriate library with your application. Names of libraries are described in the following table.

| Table 77. Header files and library names for the MASS vector library | | |
|--|--|--------------------------|
| | System environment | |
| | z/OS UNIX | MVS (z/OS XL C/C++ only) |
| Header file location | <code>/usr/include/massv.h</code> | <code>CEE.SCEEH.H</code> |
| Library name for z16 | <code>/usr/lpp/cbclib/lib/libmassv.arch14.a</code> | <code>CBC.SCCNN14</code> |
| Library name for z15 | <code>/usr/lpp/cbclib/lib/libmassv.arch13.a</code> | <code>CBC.SCCNN13</code> |
| Library name for z14 | <code>/usr/lpp/cbclib/lib/libmassv.arch12.a</code> | <code>CBC.SCCNN12</code> |
| Library name for z13/z13s | <code>/usr/lpp/cbclib/lib/libmassv.arch11.a</code> | <code>CBC.SCCNN11</code> |
| Library name for zEC12/zBC12 | <code>/usr/lpp/cbclib/lib/libmassv.arch10.a</code> | <code>CBC.SCCNN10</code> |

Note: MASS vector functions can run on IBM zEC12/zBC12 or newer machine models only. A set of libraries that are tuned for each machine model group is provided .

The single-precision and double-precision floating-point functions that are contained in the vector library are summarized in [Table 78 on page 2090](#). Note that in C and C++ applications, only call by reference is supported, even for scalar arguments. Except for a few functions (described in the following paragraph), all of the floating-point functions in the vector library accept three parameters:

- A double-precision (for double-precision functions) or single-precision (for single-precision functions) vector output parameter
- A double-precision (for double-precision functions) or single-precision (for single-precision functions) vector input parameter
- An integer vector-length parameter

Except for the special cases listed below, the functions are of the form:

```
function_name (y,x,n)
```

where *y* is the target vector, *x* is the source vector, and *n* is the pointer to the vector length. The parameters *y* and *x* are assumed to be double-precision for functions with the prefix *v*, and single-precision for functions with the prefix *vs*. For example, the following code:

```
#include <massv.h>

double x[500], y[500];
int n;
n = 500;
...
vexp (y, x, &n);
```

outputs a vector *y* of length 500 whose elements are $\exp(x[i])$, where $i=0, \dots, 499$.

The functions `vdiv`, `vsincos`, `vpow`, and `vatan2` (and their single-precision versions, `vsdiv`, `vssincos`, `vspow`, and `vsatan2`) take four arguments. The functions `vdiv`, `vpow`, and `vatan2` take the arguments (z, x, y, n) . The function `vdiv` outputs a vector z whose elements are $x[i]/y[i]$, where $i=0, \dots, *n-1$. The function `vpow` outputs a vector z whose elements are $x[i]^{y[i]}$, where $i=0, \dots, *n-1$. The function `vatan2` outputs a vector z whose elements are $\text{atan}(x[i]/y[i])$, where $i=0, \dots, *n-1$. The function `vsincos` takes the arguments (y, z, x, n) , and outputs two vectors, y and z , whose elements are $\sin(x[i])$ and $\cos(x[i])$, respectively.

Note: Some of the MASS floating point vector functions are only available when compiled under the processor architecture of IBM z13[®] or newer. These functions are denoted by having a superscript ^t after their name (for example, "function^t" in the following table.)

| Table 78. MASS floating-point vector functions | | | | |
|--|---------------------------------|--|--|--|
| Double-precision function | Single-precision function | Description | Double-precision function prototype | Single-precision function prototype |
| <code>vacos</code> | <code>vsacos</code> | Sets $y[i]$ to the arc cosine of $x[i]$, for $i=0, \dots, *n-1$ | <code>void vacos (double y[], double x[], int *n);</code> | <code>void vsacos (float y[], float x[], int *n);</code> |
| <code>vacosh</code> | <code>vsacosh</code> | Sets $y[i]$ to the hyperbolic arc cosine of $x[i]$, for $i=0, \dots, *n-1$ | <code>void vacosh (double y[], double x[], int *n);</code> | <code>void vsacosh (float y[], float x[], int *n);</code> |
| <code>vasin</code> | <code>vsasin</code> | Sets $y[i]$ to the arc sine of $x[i]$, for $i=0, \dots, *n-1$ | <code>void vasin (double y[], double x[], int *n);</code> | <code>void vsasin (float y[], float x[], int *n);</code> |
| <code>vasinh</code> | <code>vsasinh</code> | Sets $y[i]$ to the hyperbolic arc sine of $x[i]$, for $i=0, \dots, *n-1$ | <code>void vasinh (double y[], double x[], int *n);</code> | <code>void vsasinh (float y[], float x[], int *n);</code> |
| <code>vatan2</code> | <code>vsatan2</code> | Sets $z[i]$ to the arc tangent of $x[i]/y[i]$, for $i=0, \dots, *n-1$ | <code>void vatan2 (double z[], double x[], double y[], int *n);</code> | <code>void vsatan2 (float z[], float x[], float y[], int *n);</code> |
| <code>vatan^t</code> | <code>vsatan^t</code> | Sets $y[i]$ to the arc tangent of $x[i]$, for $i=0, \dots, *n-1$ | <code>void vatan (double y[], double x[], int *n);</code> | <code>void vsatan (float y[], float x[], int *n);</code> |
| <code>vatanh</code> | <code>vsatanh</code> | Sets $y[i]$ to the hyperbolic arc tangent of $x[i]$, for $i=0, \dots, *n-1$ | <code>void vatanh (double y[], double x[], int *n);</code> | <code>void vsatanh (float y[], float x[], int *n);</code> |
| <code>vcbrt</code> | <code>vscbrt</code> | Sets $y[i]$ to the cube root of $x[i]$, for $i=0, \dots, *n-1$ | <code>void vcbrt (double y[], double x[], int *n);</code> | <code>void vscbrt (float y[], float x[], int *n);</code> |
| <code>vcos</code> | <code>vscos</code> | Sets $y[i]$ to the cosine of $x[i]$, for $i=0, \dots, *n-1$ | <code>void vcos (double y[], double x[], int *n);</code> | <code>void vscos (float y[], float x[], int *n);</code> |
| <code>vcosh</code> | <code>vscosh</code> | Sets $y[i]$ to the hyperbolic cosine of $x[i]$, for $i=0, \dots, *n-1$ | <code>void vcosh (double y[], double x[], int *n);</code> | <code>void vscosh (float y[], float x[], int *n);</code> |
| <code>vcosisin</code> | <code>vscosisin</code> | Sets the real part of $y[i]$ to the cosine of $x[i]$ and the imaginary part of $y[i]$ to the sine of $x[i]$, for $i=0, \dots, *n-1$ | <code>void vcosisin (double _Complex y[], double x[], int *n);</code> | <code>void vscosisin (float _Complex y[], float x[], int *n);</code> |

| Table 78. MASS floating-point vector functions (continued) | | | | |
|--|---------------------------|---|--|--|
| Double-precision function | Single-precision function | Description | Double-precision function prototype | Single-precision function prototype |
| vdint | | Sets $y[i]$ to the integer truncation of $x[i]$, for $i=0,...,n-1$ | void vdint (double y[], double x[], int *n); | |
| vdiv | vsdiv | Sets $z[i]$ to $x[i]/y[i]$, for $i=0,...,n-1$ | void vdiv (double z[], double x[], double y[], int *n); | void vsdiv (float z[], float x[], float y[], int *n); |
| vdnint | | Sets $y[i]$ to the nearest integer to $x[i]$, for $i=0,...,n-1$ | void vdnint (double y[], double x[], int *n); | |
| verf ^t | vserf ^t | Sets $y[i]$ to the error function of $x[i]$, for $i=0,...,n-1$ | void verf (double y[], double x[], int *n) | void vs erf (float y[], float x[], int *n) |
| verfc ^t | vserfc ^t | Sets $y[i]$ to the complimentary error function of $x[i]$, for $i=0,...,n-1$ | void verfc (double y[], double x[], int *n) | void vs erf c (float y[], float x[], int *n) |
| vexp | vsexp | Sets $y[i]$ to the exponential function of $x[i]$, for $i=0,...,n-1$ | void vexp (double y[], double x[], int *n); | void vsexp (float y[], float x[], int *n); |
| vexp2 ^t | vsexp2 ^t | Sets $y[i]$ to 2 raised to the power of $x[i]$, for $i=1,...,n-1$ | void vexp2 (double y[], double x[], int *n); | void vsexp2 (float y[], float x[], int *n); |
| vexpm1 | vsexpm1 | Sets $y[i]$ to (the exponential function of $x[i]$)-1, for $i=0,...,n-1$ | void vexpm1 (double y[], double x[], int *n); | void vsexpm1 (float y[], float x[], int *n); |
| vexp2m1 ^t | vsexp2m1 ^t | Sets $y[i]$ to (2 raised to the power of $x[i]$) - 1, for $i=1,...,n-1$ | void vexp2m1 (double y[], double x[], int *n); | void vsexp2m1 (float y[], float x[], int *n); |
| vhypot ^t | vshypot ^t | Sets $z[i]$ to the square root of the sum of the squares of $x[i]$ and $y[i]$, for $i=0,...,n-1$ | void vhypot (double z[], double x[], double y[], int *n) | void vshypot (float z[], float x[], float y[], int *n) |
| vlog | vslog | Sets $y[i]$ to the natural logarithm of $x[i]$, for $i=0,...,n-1$ | void vlog (double y[], double x[], int *n); | void vslog (float y[], float x[], int *n); |
| vlog2 ^t | vslog2 ^t | Sets $y[i]$ to the base-2 logarithm of $x[i]$, for $i=1,...,n-1$ | void vlog2 (double y[], double x[], int *n); | void vslog2 (float y[], float x[], int *n); |
| vlog10 | vslog10 | Sets $y[i]$ to the base-10 logarithm of $x[i]$, for $i=0,...,n-1$ | void vlog10 (double y[], double x[], int *n); | void vslog10 (float y[], float x[], int *n); |
| vlog1p | vslog1p | Sets $y[i]$ to the natural logarithm of ($x[i]+1$), for $i=0,...,n-1$ | void vlog1p (double y[], double x[], int *n); | void vslog1p (float y[], float x[], int *n); |

| Table 78. MASS floating-point vector functions (continued) | | | | |
|--|---------------------------|--|--|--|
| Double-precision function | Single-precision function | Description | Double-precision function prototype | Single-precision function prototype |
| vlog21p ^t | vslog21p ^t | Sets y[i] to the base-2 logarithm of (x[i]+1), for i=1,...,*n-1 | void vlog21p (double y[], double x[], int *n); | void vslog21p (float y[], float x[], int *n); |
| vpow | vspow | Sets z[i] to x[i] raised to the power y[i], for i=0,...,*n-1 | void vpow (double z[], double x[], double y[], int *n); | void vspow (float z[], float x[], float y[], int *n); |
| vqdrft | vsqdrft | Sets y[i] to the fourth root of x[i], for i=0,...,*n-1 | void vqdrft (double y[], double x[], int *n); | void vsqdrft (float y[], float x[], int *n); |
| vrcbrt | vsrbrt | Sets y[i] to the reciprocal of the cube root of x[i], for i=0,...,*n-1 | void vrcbrt (double y[], double x[], int *n); | void vsrbrt (float y[], float x[], int *n); |
| vrec | vsrec | Sets y[i] to the reciprocal of x[i], for i=0,...,*n-1 | void vrec (double y[], double x[], int *n); | void vsrec (float y[], float x[], int *n); |
| vrqdrft | vsrqdrft | Sets y[i] to the reciprocal of the fourth root of x[i], for i=0,...,*n-1 | void vrqdrft (double y[], double x[], int *n); | void vsrqdrft (float y[], float x[], int *n); |
| vsqrt | vsrsqrt | Sets y[i] to the reciprocal of the square root of x[i], for i=0,...,*n-1 | void vsqrt (double y[], double x[], int *n); | void vsrsqrt (float y[], float x[], int *n); |
| vsin | vssin | Sets y[i] to the sine of x[i], for i=0,...,*n-1 | void vsin (double y[], double x[], int *n); | void vssin (float y[], float x[], int *n); |
| vsincos | vssincos | Sets y[i] to the sine of x[i] and z[i] to the cosine of x[i], for i=0,...,*n-1 | void vsincos (double y[], double z[], double x[], int *n); | void vssincos (float y[], float z[], float x[], int *n); |
| vsinh | vssinh | Sets y[i] to the hyperbolic sine of x[i], for i=0,...,*n-1 | void vsinh (double y[], double x[], int *n); | void vssinh (float y[], float x[], int *n); |
| vsqrt | vssqrt | Sets y[i] to the square root of x[i], for i=0,...,*n-1 | void vsqrt (double y[], double x[], int *n); | void vssqrt (float y[], float x[], int *n); |
| vtan | vstan | Sets y[i] to the tangent of x[i], for i=0,...,*n-1 | void vtan (double y[], double x[], int *n); | void vstan (float y[], float x[], int *n); |
| vtanh | vstanh | Sets y[i] to the hyperbolic tangent of x[i], for i=0,...,*n-1 | void vtanh (double y[], double x[], int *n); | void vstanh (float y[], float x[], int *n); |

Integer functions are of the form *function_name* (x[], *n), where x[] is a vector of 4-byte (for vpopcnt4) or 8-byte (for vpopcnt8) numeric objects (integral or floating-point), and *n is the vector length.

| Table 79. MASS integer vector functions | | |
|---|--|---|
| Function | Description | Prototype |
| vpopcnt4 | Returns the total number of 1 bits in the concatenation of the binary representation of $x[i]$, for $i=0, \dots, *n-1$, where x is a vector of 32-bit objects. | unsigned int vpopcnt4 (void *x, int *n) |
| vpopcnt8 | Returns the total number of 1 bits in the concatenation of the binary representation of $x[i]$, for $i=0, \dots, *n-1$, where x is a vector of 64-bit objects. | unsigned int vpopcnt8 (void *x, int *n) |

Overlap of input and output vectors

In most applications, the MASS vector functions are called with disjoint input and output vectors; that is, the two vectors do not overlap in memory. Another common usage scenario is to call them with the same vector for both input and output parameters (for example, `vsin (y, y, &n)`). For other kinds of overlap, be sure to observe the following restrictions, to ensure correct operation of your application:

- For calls to vector functions that take one input and one output vector (for example, `vsin (y, x, &n)`):

The vectors $x[0:n-1]$ and $y[0:n-1]$ must be either disjoint or identical, or the address of $x[0]$ must be greater than the address of $y[0]$. That is, if x and y are not the same vector, the address of $y[0]$ must not fall within the range of addresses spanned by $x[0:n-1]$, or unexpected results may be obtained.

- For calls to vector functions that take two input vectors (for example, `vtan2 (y, x1, x2, &n)`):

The previous restriction applies to both pairs of vectors $y, x1$ and $y, x2$. That is, if y is not the same vector as $x1$, the address of $y[0]$ must not fall within the range of addresses spanned by $x1[0:n-1]$; if y is not the same vector as $x2$, the address of $y[0]$ must not fall within the range of addresses spanned by $x2[0:n-1]$.

- For calls to vector functions that take two output vectors (for example, `vsincos (x, y1, y2, &n)`):

The preceding restriction applies to both pairs of vectors $y1, x$ and $y2, x$. That is, if $y1$ and x are not the same vector, the address of $y1[0]$ must not fall within the range of addresses spanned by $x[0:n-1]$; if $y2$ and x are not the same vector, the address of $y2[0]$ must not fall within the range of addresses spanned by $x[0:n-1]$. Also, the vectors $y1[0:n-1]$ and $y2[0:n-1]$ must be disjoint.

Using the MASS SIMD library

The MASS SIMD library contains a set of frequently used math intrinsic functions that provide improved performance over the corresponding standard scalar system library functions, and operate on and return vector data types. If you want to explicitly call the MASS SIMD functions, take the following steps:

1. Link the appropriate scalar library with your application by using information in the following table.
2. Provide the prototypes for the functions by including `mass_simd.h` in your source files. The default installation location of these files is as follows:
 - In z/OS UNIX, `mass_simd.h` can be found in `/usr/include`.
 - Under the MVS environment (batch mode), the headers are found in `CEE.SCEEH.H`.
3. Link the appropriate SIMD library with your application by using information in the following table.

| Table 80. Header files and library names for the MASS SIMD library | | |
|--|---|--------------------------|
| | System environment | |
| | z/OS UNIX | MVS (z/OS XL C/C++ only) |
| Header file location | /usr/include/mass_simd.h | CEE.SCEEH.H |
| Library name for z16 | /usr/lpp/cbclib/lib/libmass_simd.arch14.a | CBC.SCCNN14 |
| Library name for z15 | /usr/lpp/cbclib/lib/libmass_simd.arch13.a | CBC.SCCNN13 |
| Library name for z14 | /usr/lpp/cbclib/lib/libmass_simd.arch12.a | CBC.SCCNN12 |
| Library name for z13/z13s | /usr/lpp/cbclib/lib/libmass_simd.arch11.a | CBC.SCCNN11 |

Note: MASS SIMD functions can run on IBM zEC12/zBC12 or newer machine models only.

The double-precision MASS SIMD functions have arguments and return values of type `vector double`. The available MASS SIMD functions are summarized in [Table 81 on page 2094](#).

| Table 81. MASS SIMD functions | | |
|-------------------------------|---|---|
| Double-precision function | Description | Double-precision function prototype |
| cosd2 | Computes the cosine of each element of vx. | vector double cosd2 (vector double vx); |
| divd2 | Computes the quotient vx/vy. | vector double divd2 (vector double vx, vector double vy); |
| expd2 | Computes the exponential function of each element of vx. | vector double expd2 (vector double vx); |
| logd2 | Computes the natural logarithm of each element of vx. | vector double logd2 (vector double vx); |
| powd2 | Computes each element of vx raised to the power of the corresponding element of vy. | vector double powd2 (vector double vx, vector double vy); |
| recipd2 | Computes the reciprocal of each element of vx. | vector double recipd2 (vector double vx); |
| sind2 | Computes the sine of each element of vx. | vector double sind2 (vector double vx); |
| sqrt2 | Computes the square root of each element of vx. | vector double sqrt2 (vector double vx); |

Compiling and linking a program with MASS

This section describes the specifics of compiling and linking your application with the MASS libraries. The MASS libraries cannot be used with the prelinker.

Required compiler features

To compile a program that utilizes any MASS functions, you need to enable the following compiler features:

- [Exception trapping disabled](#)
- [IEEE floating point representation](#)
- [Long external names](#)
- [Round-to-nearest rounding mode](#)
- [The processor architecture of IBM zEnterprise® EC12 \(zEC12\)\) and IBM zEnterprise BC12 \(zBC12\)\) or newer](#)

To use MASS SIMD functions, you need to enable the following compiler features:

- [The processor architecture of IBM z13 or newer](#)
- [Vector programming support](#)

Note: While you might still be able to compile your MASS application without satisfying the above requirements, the program will likely not give correct results.

Compilation step - MASS headers

To use MASS functions in your application, you need to include the appropriate MASS header(s) for the type of MASS function being used (for a complete list of MASS functions available, see [“Using the MASS scalar library”](#) on page 2085, [“Using the MASS vector library”](#) on page 2089, and [“Using the MASS SIMD library”](#) on page 2093).

The default installation of MASS places the MASS headers in your default header search path. If you cannot find the MASS headers in your default search path, contact your system programmer.

The following examples demonstrate the relationship among MASS functions, headers, and libraries, and show how to use MASS in your source program.

Sample 1

```
/* sample1.c: using the MASS-only scalar function 'rsqrt' */
#include <math.h>
#include <mass.h> /* The 'rsqrt' function is declared in <mass.h>, not <math.h> */

int main(void) {
    double input = 16;
    double output;

    output = rsqrt(input);

    /* ... Code to utilize the results in "output" goes here */
}
```

To compile sample1.c with z/OS XL C/C++, run the following command:

```
xlc -qARCH=10 -qFLOAT=IEEE -c sample1.c
```

Sample 2

```
/* sample2.c: using the MASS scalar function 'pow' */
#include <math.h> /* The 'pow' function is declared in <math.h>, not <mass.h> */
#include <mass.h>

int main(void) {
    double base = 3;
    double exponent = 2;
    double output;

    output = pow(base, exponent);
}
```

```

/* ... Code to utilize the results in "output" goes here */
}

```

To compile sample2.c with Open XL C/C++ for z/OS, run the following command:

```

ibm-clang64 -march=zEC12 -c sample2.c

```

Sample 3

```

/* sample3.c: call the MASS vector function 'vlog2' */
#include <massv.h>

int main(void) {
    int size = 1000;
    double input[size];
    double output[size];

    input[0] = 8;
    input[1] = 16;
    ...
    input[999] = 42;

    vlog2(output, input, &size);

    /* ... Code to utilize the results in "output[]" goes here */
}

```

To compile sample3.c with z/OS XL C/C++, run the following command:

```

xlc -qARCH=11 -qFLOAT=IEEE -c sample3.c

```

Sample 4

```

/* sample4.c: all the MASS SIMD function 'powd2' */
#include <mass_simd.h>

int main(void) {
    vector double bases = {0, 1};
    vector double exponents = {2, 2};
    vector double output;

    output = powd2(bases, exponents);

    /* ... Code to utilize the results in "output" goes here */
}

```

To compile sample4.c with Open XL C/C++ for z/OS, run the following command:

```

ibm-clang64 -march=z14 -mzvector -c sample4.c

```

Sample 5

```

/* sample5.c: call the MASS scalar functions 'pow' and 'rsqrt', and
the vector function 'vlog10'
Compile command: xlc -qARCH=10 -qFLOAT=IEEE -c sample5.c
*/
#include <math.h>      /* This includes the prototype for 'pow' */
#include <mass.h>      /* This includes the prototype for 'rsqrt' */
#include <massv.h>     /* This includes the prototype for 'vlog10' */

int main(void) {
    int size = 1000;
    double input[size];
    double result[size];
    int i;

    for (i = 0; i < size; i++) {
        input[i] = i; /* Trivially initialize the input vector */
    }
}

```

```

    vlog10(result, input, &size);
    double output = pow(result[27], result[525]);

    output = rsqrt(output);

    /* ... Code to utilize the results in "output" goes here */
}

```

To compile `sample5.c` with z/OS XL C/C++, run the following command:

```
xlc -qARCH=10 -qFLOAT=IEEE -c sample5.c
```

Link step - MASS libraries

IBM provides the MASS library in both z/OS UNIX and MVS. There is no performance difference based on where the library resides. This is simply to allow z/OS UNIX users to link with MASS in z/OS UNIX, and MVS users to link with MASS in MVS.

Although z/OS UNIX users can link with the copy of the MASS libraries which resides in PDS's (and vice-versa), IBM does not recommend this because it does not provide a performance gain, and it adds unnecessary complexity to your build process.

Linking in z/OS UNIX

To link your program with the MASS library, include the appropriate library name(s) with the **-l** linker option, depending on which type of MASS functions are used, as well as which processor architecture is specified.

For MASS scalar functions

`-lmass.arch10`, `-lmass.arch11`, `-lmass.arch12`, `-lmass.arch13`, or `-lmass.arch14`

For MASS vector functions

`-lmassv.arch10`, `-lmassv.arch11`, `-lmassv.arch12`, `-lmassv.arch13`, or `-lmassv.arch14`

For MASS SIMD functions

`-lmass_simd.arch11`, `-lmass_simd.arch12`, `-lmass_simd.arch13`, or
`-lmass_simd.arch14`

Sample 1

Assume `sample1.o` was compiled under the processor architecture of zEC12 and zBC12, to link the MASS-only scalar function `rsqrt`, run the following command.

In Open XL C/C++ for z/OS:

```
ibm-clang64 sample1.o -lmass.arch10
```

Sample 2

Assume `sample2.o` was compiled under the processor architecture of zEC12 and zBC12, to link the MASS scalar function `pow`, run the following command.

In z/OS XL C/C++:

```
xlc sample2.o -lmass.arch10
```

Sample 3

Assume `sample3.o` was compiled under the processor architecture of IBM z13, to link the MASS vector function `vlog2`, run the following command.

In Open XL C/C++ for z/OS:

```
ibm-clang64 sample3.o -lmassv.arch11
```

Sample 4

Assume sample4.o was compiled under the [processor architecture](#) of IBM z15, to link the MASS SIMD function powd2, run the following command.

In z/OS XL C/C++:

```
xlc sample4.o -lmass_simd.arch13
```

Sample 5

Assume sample5.o was compiled under the [processor architecture](#) of zEC12 and zBC12, to link the MASS scalar function pow and rsqrt, run the following command.

In Open XL C/C++ for z/OS:

```
ibm-clang64 sample5.o -lmass.arch10 -lmassv.arch10
```

Linking in MVS

To link your program with the MASS library under the [MVS environment](#) in batch mode, you must append the MASS library you want to use to your SYSLIB concatenation.

The MVS library names for applications that are compiled under the [processor architecture](#) of zEC12 and zBC12 and newer are:

- CBC.SCCNM10 if you are using MASS scalar functions which are also available through <math.h>
- CBC.SCCNN10 for all other MASS functions

The MVS library names for applications that are compiled under the [processor architecture](#) of IBM z13 and newer are:

- CBC.SCCNM11 if you are using MASS scalar functions which are also available through <math.h>
- CBC.SCCNN11 for all other MASS functions

The MVS library names for applications that are compiled under the [processor architecture](#) of IBM z14 and newer are:

- CBC.SCCNM12 if you are using MASS scalar functions which are also available through <math.h>
- CBC.SCCNN12 for all other MASS functions

The MVS library names for applications that are compiled under the [processor architecture](#) of IBM z15 and newer are:

- CBC.SCCNM13 if you are using MASS scalar functions which are also available through <math.h>
- CBC.SCCNN13 for all other MASS functions

For example, if your current SYSLIB concatenation is:

```
//SYSLIB DD DSN=CEE.SCEELKEX,DISP=SHR
// DD DSN=CEE.SCEELKED,DISP=SHR
// DD DSN=CBC.SCCN0BJ,DISP=SHR
```

and you want to link each of the sample programs presented above (using NOXPLINK), here are the SYSLIB concatenations you would use:

Sample 1

```
//SYSLIB DD DSN=CBC.SCCNN10,DISP=SHR
// DD DSN=CEE.SCEELKEX,DISP=SHR
// DD DSN=CEE.SCEELKED,DISP=SHR
// DD DSN=CBC.SCCN0BJ,DISP=SHR
```

Sample 2

```
//SYSLIB DD DSN=CBC.SCCNM10,DISP=SHR
// DD DSN=CEE.SCEELKEX,DISP=SHR
// DD DSN=CEE.SCEELKED,DISP=SHR
// DD DSN=CBC.SCCN0BJ,DISP=SHR
```

Sample 3

```
//SYSLIB DD DSN=CBC.SCCNN11,DISP=SHR
//      DD DSN=CEE.SCEELKEX,DISP=SHR
//      DD DSN=CEE.SCEELKED,DISP=SHR
//      DD DSN=CBC.SCCNOBJ,DISP=SHR
```

Sample 4

```
//SYSLIB DD DSN=CBC.SCCNN13,DISP=SHR
//      DD DSN=CEE.SCEELKEX,DISP=SHR
//      DD DSN=CEE.SCEELKED,DISP=SHR
//      DD DSN=CBC.SCCNOBJ,DISP=SHR
```

Sample 5

```
//SYSLIB DD DSN=CBC.SCCNM10,DISP=SHR
//      DD DSN=CBC.SCCNN10,DISP=SHR
//      DD DSN=CEE.SCEELKEX,DISP=SHR
//      DD DSN=CEE.SCEELKED,DISP=SHR
//      DD DSN=CBC.SCCNOBJ,DISP=SHR
```

If you wanted to link the above examples with XPLINK and/or LP64, you would include the exact same data sets for MASS, except your initial SYSLIB would have CEE . SCEEBND2 instead of CEE . SCEELKEX and CEE . SCEELKED.

```
//SYSLIB DD DSN=CEE.SCEEBND2,DISP=SHR
//      DD DSN=CBC.SCCNOBJ
```

Using the Automatically Tuned Linear Algebra Software (ATLAS) libraries

The compilers are shipped with a set of Automatically Tuned Linear Algebra Software (ATLAS) libraries for algebra high-performance computing. This documentation is intended only as a high level description of ATLAS and the IBM specific extensions and naming convention. For more in depth information about ATLAS, consult the ATLAS documentation at the [ATLAS home page \(math-atlas.sourceforge.net\)](http://math-atlas.sourceforge.net).

Description and functionality provided

The ATLAS libraries contain all the Basic Linear Algebra Subprograms (BLAS) and a subset of the Linear Algebra Package (LAPACK) routines with interfaces provided for both C and Fortran F77 versions of the routines across platforms and architectures. Versions are provided and tuned herein for both the single-threaded and multi-threaded execution on IBM zEC12/zBC12 and IBM z13 hardware models. C and C++ calling programs are supported, with 31-bit C linkage, 31-bit XPLINK linkage, or 64-bit linkage.

Note: ATLAS is only provided as a z/OS UNIX package.

If you want to call ATLAS functionality in your program, take the following steps:

- Provide the prototype for the functions by including the appropriate header file (see [“Supplied ATLAS libraries and their corresponding header files”](#) on page 2099 for header file names).

Note: For C++, you must enclose the appropriate header files within an `extern "C"` declaration.

- Link with the appropriate ATLAS libraries (see [“Supplied ATLAS libraries and their corresponding header files”](#) on page 2099 for library names).
- Use the appropriate compiler and linker flags (see [“Required compiler features”](#) on page 2101).

Supplied ATLAS libraries and their corresponding header files

The following main libraries are provided with ATLAS.

Note: In the subsequent names, replace * with any specific name (specific header file name or library file name).

ATLAS main library

ATLAS main library contains ATLAS specific variants of the BLAS, CBLAS, and LAPACK routines.

Table 82. Sample interface routine provided: *ATL_dgemm*

| | Operation type | |
|--|-------------------------------|--------------------|
| | Single threaded | Multithreaded |
| Library name for z14 | libatlas.arch12.a | libtatlas.arch12.a |
| Library name for z13/z13s | libatlas.arch11.a | libtatlas.arch11.a |
| Library name for zEC12/zBC12 | libatlas.arch10.a | libtatlas.arch10.a |
| Library location | /usr/lpp/cbclib/lib/atlas | |
| Header files to be used with the library | Various atlas_*.h | |
| Header file location | /usr/lpp/cbclib/include/atlas | |

CBLAS library

CBLAS library contains the implementation of the C routines of the BLAS algorithms - also known as the CBLAS interface.

Table 83. Sample interface routine provided: *cblas_dgemm*

| | Operation type | |
|--|-------------------------------|--------------------|
| | Single threaded | Multithreaded |
| Library name for z14 | libcblas.arch12.a | libtcblas.arch12.a |
| Library name for z13/z13s | libcblas.arch11.a | libtcblas.arch11.a |
| Library name for zEC12/zBC12 | libcblas.arch10.a | libtcblas.arch10.a |
| Library location | /usr/lpp/cbclib/lib/atlas | |
| Header files to be used with the library | cblas.h | |
| Header file location | /usr/lpp/cbclib/include/atlas | |

LAPACK library

LAPACK library contains the implementation of the C routines of the LAPACK algorithms - also known as the CLAPACK interface.

Table 84. Sample interface routine provided: *clapack_dgesv*

| | Operation type | |
|--|-------------------------------|---------------------|
| | Single threaded | Multithreaded |
| Library name for z14 | liblapack.arch12.a | libtlapack.arch12.a |
| Library name for z13/z13s | liblapack.arch11.a | libtlapack.arch11.a |
| Library name for zEC12/zBC12 | liblapack.arch10.a | libtlapack.arch10.a |
| Library location | /usr/lpp/cbclib/lib/atlas | |
| Header files to be used with the library | clapack.h | |
| Header file location | /usr/lpp/cbclib/include/atlas | |

Fortran BLAS library

Fortran BLAS library contains the implementation of the Fortran 77 routines of the BLAS algorithms - also known as the BLAS interface.

| Table 85. Sample interface routine provided: <i>dgemm_</i> | | |
|--|-------------------------------|---------------------|
| | Operation type | |
| | Single threaded | Multithreaded |
| Library name for z14 | lib77blas.arch12.a | libt77blas.arch12.a |
| Library name for z13/z13s | lib77blas.arch11.a | libt77blas.arch11.a |
| Library name for zEC12/zBC12 | lib77blas.arch10.a | libt77blas.arch10.a |
| Library location | /usr/lpp/cbclib/lib/atlas | |
| Header files to be used with the library | Various atlas_*f77*.h | |
| Header file location | /usr/lpp/cbclib/include/atlas | |

Notes:

- For each of the above mentioned base libraries, the single-threaded and multi-threaded versions of the same base library contain the same list of functions.
- Only static libraries are provided.
- The libraries (archives) contain 31-bit C linkage, 31-bit XPLink linkage, and 64-bit linkage objects. The linker, based on supplied options and/or environment variables will choose the appropriate archive members of specified libraries.
- For C++, you must enclose the appropriate header files within an extern "C" declaration. For example:

```
extern "C"
{
    #include <cbblas.h>
}
```

Required compiler features

The following compiler features are required to compile and link a program that utilizes ATLAS functionality.

- [IEEE floating point representation](#)
- [Round-to-nearest rounding mode](#)
- The [processor architecture](#) level of IBM zEnterprise EC12 (zEC12)) and IBM zEnterprise BC12 (zBC12)) or newer
- The [processor architecture](#) of IBM z13 or newer to enable ATLAS vector functionality
- [Vector programming support](#) to enable ATLAS vector functionality
- The [target operating system release](#) of z/OS 2.1 or newer

Note: You might still be able to compile and link your ATLAS application without satisfying the above requirements, but the program will likely not give the correct results.

Examples - Compiling, linking, and running a simple matrix multiplication ATLAS program

This simple sample achieves a multiplication of two matrices, A and B. A and B have elements randomly generated with values between 0 and 1. The multiplication is achieved in the following ways:

- By calling dgemm/cblas_dgemm BLAS functionality provided by ATLAS
- By a manual calculation of the same

The resulting matrices C and D contain the same elements.

Sample output produced by all executables across all platforms and architectures should look like this:

```
Matrix A has 3 rows and 6 columns:
0.566 0.974 0.202 0.941 0.294 0.427
0.580 0.539 0.772 0.248 0.832 0.848
0.080 0.533 0.434 0.163 0.576 0.416
```

```
Matrix B has 6 rows and 4 columns:
0.309 0.316 0.569 0.182
0.725 0.389 0.472 0.649
0.448 0.368 0.354 0.665
0.994 0.740 0.649 0.616
0.133 0.906 0.447 0.590
0.773 0.774 0.893 0.913
```

```
Matrix C has 3 rows and 4 columns:
2.276 1.926 1.978 2.013
1.928 2.270 2.148 2.387
1.165 1.356 1.185 1.469
```

```
Matrix D has 3 rows and 4 columns:
2.276 1.926 1.978 2.013
1.928 2.270 2.148 2.387
1.165 1.356 1.185 1.469
```

Pay attention to the fact that matrices C and D are congruent.

Also note that matrix data is organized or ordered in the Fortran way, namely columns major.

Sample 1

This program contains a C invocation of the Fortran BLAS function dgemm_ provided by the ATLAS framework.

Observation: In this sample, the invocation of dgemm_ has no previously declared prototype, hence the compiler might issue a warning message. Prototypes may be declared by including the atlas_f77 header files, but source files might not have these header files specified (i.e. old source code written prior to ATLAS).

Source code:

```
#include <stdio.h>
#include <time.h>
#include <stdlib.h>

void init(double* matrix, int row, int column)
{
    for (int j = 0; j < column; j++){
        for (int i = 0; i < row; i++){
            matrix[j*row + i] = ((double)rand())/RAND_MAX;
        }
    }
}

void print(const char * name, const double* matrix, int row, int column)
{
    printf("Matrix %s has %d rows and %d columns:\n", name, row, column);
    for (int i = 0; i < row; i++){
        for (int j = 0; j < column; j++){
            printf("%.3f ", matrix[j*row + i]);
        }
        printf("\n");
    }
    printf("\n");
}

int main(int argc, char * argv[])
```

```

{
    int rowsA, colsB, common;
    int i,j,k;

    if (argc != 4){
        printf("Using defaults\n");
        rowsA = 2; colsB = 4; common = 6;
    }
    else{
        rowsA = atoi(argv[1]); colsB = atoi(argv[2]); common = atoi(argv[3]);
    }

    double A[rowsA * common]; double B[common * colsB];
    double C[rowsA * colsB]; double D[rowsA * colsB];

    char transA = 'N', transB = 'N';
    double one = 1.0, zero = 0.0;

    srand(time(NULL));

    init(A, rowsA, common); init(B, common, colsB);

    dgemm_(&transA, &transB, &rowsA, &colsB, &common, &one, A,
        &rowsA, B, &common, &zero, C, &rowsA);

    for(i=0;i<colsB;i++){
        for(j=0;j<rowsA;j++){
            D[i*rowsA+j]=0;
            for(k=0;k<common;k++){
                D[i*rowsA+j]+=A[k*rowsA+j]*B[k+common*i];
            }
        }
    }

    print("A", A, rowsA, common); print("B", B, common, colsB);
    print("C", C, rowsA, colsB); print("D", D, rowsA, colsB);

    return 0;
}

```

In z/OS XL C/C++

You can use the following commands to compile and link the program in z/OS XL C/C++:

To compile the program for ARCH(10):

```

xlc -c -qfloat=ieee -qround=n -qarch=10 -qtarget=zosv2r1 -I
/usr/lpp/cbclib/include/atlas -qfloat=ieee -o sample.o sample.c

```

To link the program for ARCH(10):

```

xlc sample.o -L /usr/lpp/cbclib/lib/atlas -lf77blas.arch10
-latlas.arch10 -lf2c.arch10 -qfloat=ieee -o sample

```

To compile the program for ARCH(11):

```

xlc -c -qfloat=ieee -qround=n -qarch=11 -qtarget=zosv2r1 -I
/usr/lpp/cbclib/include/atlas -qfloat=ieee -o sample.o sample.c

```

To link the program for ARCH(11):

```

xlc sample.o -L /usr/lpp/cbclib/lib/atlas -lf77blas.arch11
-latlas.arch11 -lf2c.arch11 -qfloat=ieee -o sample

```

To compile the program for ARCH(12) and higher ARCHITECTURE levels:

```

xlc -c -qfloat=ieee -qround=n -qarch=12 -qtarget=zosv2r3 -I
/usr/lpp/cbclib/include/atlas -qfloat=ieee -o sample.o sample.c

```

To link the program for ARCH(12) and higher ARCHITECTURE levels:

```

xlc sample.o -L /usr/lpp/cbclib/lib/atlas -lf77blas.arch12
-latlas.arch12 -lf2c.arch12 -qfloat=ieee -o sample

```

In Open XL C/C++ for z/OS

You can use the following commands to compile and link the program in Open XL C/C++ for z/OS:

To compile the program for **-march=zEC12**:

```
ibm-clang64 -c -fno-rounding-math -march=zEC12 -mzos-target=zosv2r4 -I
/usr/lpp/cbclib/include/atlas -o sample.o sample.c
```

To link the program for **-march=zEC12**:

```
ibm-clang64 sample.o -L /usr/lpp/cbclib/lib/atlas -lf77blas.arch10
-latlas.arch10 -lf2c.arch10 -o sample
```

To compile the program for **-march=z13**:

```
ibm-clang64 -c -fno-rounding-math -march=z13 -mzos-target=zosv2r4 -I
/usr/lpp/cbclib/include/atlas -o sample.o sample.c
```

To link the program for **-march=z13**:

```
ibm-clang64 sample.o -L /usr/lpp/cbclib/lib/atlas -lf77blas.arch11
-latlas.arch11 -lf2c.arch11 -o sample
```

To compile the program for **-march=z14** and higher:

```
ibm-clang64 -c -fno-rounding-math -march=z14 -mzos-target=zosv2r5 -I
/usr/lpp/cbclib/include/atlas -o sample.o sample.c
```

To link the program for **-march=z14** and higher:

```
ibm-clang64 sample.o -L /usr/lpp/cbclib/lib/atlas -lf77blas.arch12
-latlas.arch12 -lf2c.arch12 -o sample
```

Sample 2

This program contains a C++ invocation of the Fortran BLAS function `dgemm_` provided by the ATLAS framework.

Observation: As opposed to sample 1, the compiler must be explicitly instructed that the function `dgemm_` has C linkage and thus no mangling should be attempted. This can be achieved either as specified, or by including the appropriate header file with the extern "C" designation.

Source code:

```
#include <stdio.h>
#include <time.h>
#include <stdlib.h>

extern "C"
{
    int dgemm_(char *, char *, int *, int *, int *, double *, double *, int *,
              double *, int *, double *, double *, int *);
}

void init(double* matrix, int row, int column)
{
    for (int j = 0; j < column; j++){
        for (int i = 0; i < row; i++){
            matrix[j*row + i] = ((double)rand())/RAND_MAX;
        }
    }
}

void print(const char * name, const double* matrix, int row, int column)
{
    printf("Matrix %s has %d rows and %d columns:\n", name, row, column);
    for (int i = 0; i < row; i++){
        for (int j = 0; j < column; j++){
            printf("%.3f ", matrix[j*row + i]);
        }
    }
}
```

```

    }
    printf("\n");
}
printf("\n");
}

int main(int argc, char * argv[])
{
    int rowsA, colsB, common;
    int i,j,k;

    if (argc != 4){
        printf("Using defaults\n");
        rowsA = 2; colsB = 4; common = 6;
    }
    else{
        rowsA = atoi(argv[1]); colsB = atoi(argv[2]); common = atoi(argv[3]);
    }

    double A[rowsA * common]; double B[common * colsB];
    double C[rowsA * colsB]; double D[rowsA * colsB];

    char transA = 'N', transB = 'N';
    double one = 1.0, zero = 0.0;

    srand(time(NULL));

    init(A, rowsA, common); init(B, common, colsB);

    dgemm_(&transA, &transB, &rowsA, &colsB, &common, &one, A,
        &rowsA, B, &common, &zero, C, &rowsA);

    for(i=0;i<colsB;i++){
        for(j=0;j<rowsA;j++){
            D[i*rowsA+j]=0;
            for(k=0;k<common;k++){
                D[i*rowsA+j]+=A[k*rowsA+j]*B[k+common*i];
            }
        }
    }

    print("A", A, rowsA, common); print("B", B, common, colsB);
    print("C", C, rowsA, colsB); print("D", D, rowsA, colsB);

    return 0;
}

```

In z/OS XL C/C++

You can use the following commands to compile and link the program in z/OS XL C/C++:

To compile the program for ARCH(10):

```

xlC -c -qfloat=ieee -qround=n -qarch=10 -qtarget=zosv2r1 -I
/usr/lpp/cbclib/include/atlas -qfloat=ieee -o sample.o sample.C

```

To link the program for ARCH(10):

```

xlC sample.o -L /usr/lpp/cbclib/lib/atlas -lf77blas.arch10
-latlas.arch10 -lf2c.arch10 -qfloat=ieee -o sample

```

To compile the program for ARCH(11):

```

xlC -c -qfloat=ieee -qround=n -qarch=11 -qtarget=zosv2r1 -I
/usr/lpp/cbclib/include/atlas -qfloat=ieee -o sample.o sample.C

```

To link the program for ARCH(11):

```

xlC sample.o -L /usr/lpp/cbclib/lib/atlas -lf77blas.arch11
-latlas.arch11 -lf2c.arch11 -qfloat=ieee -o sample

```

To compile the program for ARCH(12) and higher ARCHITECTURE levels:

```

xlC -c -qfloat=ieee -qround=n -qarch=12 -qtarget=zosv2r3 -I
/usr/lpp/cbclib/include/atlas -qfloat=ieee -o sample.o sample.C

```

To link the program for ARCH(12) and higher ARCHITECTURE levels:

```
xlc sample.o -L /usr/lpp/cbclib/lib/atlas -lf77blas.arch12
-latlas.arch12 -lf2c.arch12 -qfloat=ieee -o sample
```

In Open XL C/C++ for z/OS

You can use the following commands to compile and link the program in Open XL C/C++ for z/OS:

To compile the program for **-march=zEC12**:

```
ibm-clang++64 -c -fno-rounding-math -march=zEC12 -mzos-target=zosv2r4 -I
/usr/lpp/cbclib/include/atlas -o sample.o sample.C
```

To link the program for **-march=zEC12**:

```
ibm-clang++64 sample.o -L /usr/lpp/cbclib/lib/atlas -lf77blas.arch10
-latlas.arch10 -lf2c.arch10 -o sample
```

To compile the program for **-march=z13**:

```
ibm-clang++64 -c -fno-rounding-math -march=z13 -mzos-target=zosv2r4 -I
/usr/lpp/cbclib/include/atlas -o sample.o sample.C
```

To link the program for **-march=z13**:

```
ibm-clang++64 sample.o -L /usr/lpp/cbclib/lib/atlas -lf77blas.arch11
-latlas.arch11 -lf2c.arch11 -o sample
```

To compile the program for **-march=z14** and higher:

```
ibm-clang++64 -c -fno-rounding-math -march=z14 -mzos-target=zosv2r5 -I
/usr/lpp/cbclib/include/atlas -o sample.o sample.C
```

To link the program for **-march=z14** and higher:

```
ibm-clang++64 sample.o -L /usr/lpp/cbclib/lib/atlas -lf77blas.arch12
-latlas.arch12 -lf2c.arch12 -o sample
```

Sample 3

This program contains a C invocation of the CBLAS function `cbblas_dgemm_` provided by the ATLAS framework.

Observation: Same result and functionality as if `dgemm_` would be called, but this program uses the CBLAS version of the functions.

Source code:

```
#include <time.h>
#include <stdlib.h>
#include <cbblas.h>

void init(double* matrix, int row, int column)
{
    for (int j = 0; j < column; j++){
        for (int i = 0; i < row; i++){
            matrix[j*row + i] = ((double)rand())/RAND_MAX;
        }
    }
}

void print(const char * name, const double* matrix, int row, int column)
{
    printf("Matrix %s has %d rows and %d columns:\n", name, row, column);
    for (int i = 0; i < row; i++){
        for (int j = 0; j < column; j++){
            printf("%.3f ", matrix[j*row + i]);
        }
        printf("\n");
    }
}
```

```

    }
    printf("\n");
}

int main(int argc, char * argv[])
{
    int rowsA, colsB, common;
    int i,j,k;

    if (argc != 4){
        printf("Using defaults\n");
        rowsA = 2; colsB = 4; common = 6;
    }
    else{
        rowsA = atoi(argv[1]); colsB = atoi(argv[2]); common = atoi(argv[3]);
    }

    double A[rowsA * common]; double B[common * colsB];
    double C[rowsA * colsB]; double D[rowsA * colsB];

    enum CBLAS_ORDER order = CblasColMajor;
    enum CBLAS_TRANSPOSE transA = CblasNoTrans;
    enum CBLAS_TRANSPOSE transB = CblasNoTrans;

    double one = 1.0, zero = 0.0;

    srand(time(NULL));

    init(A, rowsA, common); init(B, common, colsB);

    cblas_dgemm(order,transA,transB, rowsA, colsB, common ,1.0,A,
                rowsA ,B, common ,0.0,C, rowsA);

    for(i=0;i<colsB;i++){
        for(j=0;j<rowsA;j++){
            D[i*rowsA+j]=0;
            for(k=0;k<common;k++){
                D[i*rowsA+j]+=A[k*rowsA+j]*B[k+common*i];
            }
        }
    }

    print("A", A, rowsA, common); print("B", B, common, colsB);
    print("C", C, rowsA, colsB); print("D", D, rowsA, colsB);

    return 0;
}

```

In z/OS XL C/C++

You can use the following commands to compile and link the program in z/OS XL C/C++:

To compile the program for ARCH(10):

```

xlc -c -qfloat=ieee -qround=n -qarch=10 -qtarget=zosv2r1 -I
/usr/lpp/cbclib/include/atlas -qfloat=ieee -o sample.o sample.c

```

To link the program for ARCH(10):

```

xlc sample.o -L /usr/lpp/cbclib/lib/atlas -lcblas.arch10
-latlas.arch10 -qfloat=ieee -o sample

```

To compile the program for ARCH(11):

```

xlc -c -qfloat=ieee -qround=n -qarch=11 -qtarget=zosv2r1 -I
/usr/lpp/cbclib/include/atlas -qfloat=ieee -o sample.o sample.c

```

To link the program for ARCH(11):

```

xlc sample.o -L /usr/lpp/cbclib/lib/atlas -lcblas.arch11
-latlas.arch11 -qfloat=ieee -o sample

```

To compile the program for ARCH(12) and higher ARCHITECTURE levels:

```
xlc -c -qfloat=ieee -qround=n -qarch=12 -qtarget=zosv2r3 -I
/usr/lpp/cbclib/include/atlas -qfloat=ieee -o sample.o sample.c
```

To link the program for ARCH(12) and higher ARCHITECTURE levels:

```
xlc sample.o -L /usr/lpp/cbclib/lib/atlas -lcblas.arch12
-latlas.arch12 -qfloat=ieee -o sample
```

In Open XL C/C++ for z/OS

You can use the following commands to compile and link the program in Open XL C/C++ for z/OS:

To compile the program for **-march=zEC12**:

```
ibm-clang64 -c -fno-rounding-math -march=zEC12 -mzos-target=zosv2r4 -I
/usr/lpp/cbclib/include/atlas -o sample.o sample.c
```

To link the program for **-march=zEC12**:

```
ibm-clang64 sample.o -L /usr/lpp/cbclib/lib/atlas -lcblas.arch10
-latlas.arch10 -lf2c.arch10 -o sample
```

To compile the program for **-march=z13**:

```
ibm-clang64 -c -fno-rounding-math -march=z13 -mzos-target=zosv2r4 -I
/usr/lpp/cbclib/include/atlas -o sample.o sample.c
```

To link the program for **-march=z13**:

```
ibm-clang64 sample.o -L /usr/lpp/cbclib/lib/atlas -lcblas.arch11
-latlas.arch11 -o sample
```

To compile the program for **-march=z14** and higher:

```
ibm-clang64 -c -fno-rounding-math -march=z14 -mzos-target=zosv2r5 -I
/usr/lpp/cbclib/include/atlas -o sample.o sample.c
```

To link the program for **-march=z14** and higher:

```
ibm-clang64 sample.o -L /usr/lpp/cbclib/lib/atlas -lcblas.arch12
-latlas.arch12 -o sample
```

Sample 4

This program contains a C++ invocation of the CBLAS function `cbblas_dgemm_` provided by the ATLAS framework.

Observation: Same result and functionality as if `dgemm_` would be called, but this program uses the CBLAS version of the functions.

Source code:

```
#include <time.h>
#include <stdlib.h>

extern "C"
{
#include <cbblas.h>
}

void init(double* matrix, int row, int column)
{
    for (int j = 0; j < column; j++){
        for (int i = 0; i < row; i++){
            matrix[j*row + i] = ((double)rand())/RAND_MAX;
        }
    }
}
```

```

void print(const char * name, const double* matrix, int row, int column)
{
    printf("Matrix %s has %d rows and %d columns:\n", name, row, column);
    for (int i = 0; i < row; i++){
        for (int j = 0; j < column; j++){
            printf("%.3f ", matrix[j*row + i]);
        }
        printf("\n");
    }
    printf("\n");
}

int main(int argc, char * argv[])
{
    int rowsA, colsB, common;
    int i,j,k;

    if (argc != 4){
        printf("Using defaults\n");
        rowsA = 2; colsB = 4; common = 6;
    }
    else{
        rowsA = atoi(argv[1]); colsB = atoi(argv[2]); common = atoi(argv[3]);
    }

    double A[rowsA * common]; double B[common * colsB];
    double C[rowsA * colsB]; double D[rowsA * colsB];

    enum CBLAS_ORDER order = CblasColMajor;
    enum CBLAS_TRANSPOSE transA = CblasNoTrans;
    enum CBLAS_TRANSPOSE transB = CblasNoTrans;

    double one = 1.0, zero = 0.0;

    srand(time(NULL));

    init(A, rowsA, common); init(B, common, colsB);

    cblas_dgemm(order,transA,transB, rowsA, colsB, common ,1.0,A,
                rowsA ,B, common ,0.0,C, rowsA);

    for(i=0;i<colsB;i++){
        for(j=0;j<rowsA;j++){
            D[i*rowsA+j]=0;
            for(k=0;k<common;k++){
                D[i*rowsA+j]+=A[k*rowsA+j]*B[k+common*i];
            }
        }
    }

    print("A", A, rowsA, common); print("B", B, common, colsB);
    print("C", C, rowsA, colsB); print("D", D, rowsA, colsB);

    return 0;
}

```

In z/OS XL C/C++

You can use the following commands to compile and link the program in z/OS XL C/C++:

To compile the program for ARCH(10):

```

xlC -c -qfloat=ieee -qround=n -qarch=10 -qtarget=zosv2r1 -I
/usr/lpp/cbclib/include/atlas -qfloat=ieee -o sample.o sample.C

```

To link the program for ARCH(10):

```

xlC sample.o -L /usr/lpp/cbclib/lib/atlas -lcblas.arch10
-latlas.arch10 -qfloat=ieee -o sample

```

To compile the program for ARCH(11):

```

xlC -c -qfloat=ieee -qround=n -qarch=11 -qtarget=zosv2r1 -I
/usr/lpp/cbclib/include/atlas -qfloat=ieee -o sample.o sample.C

```

To link the program for ARCH(11):

```
xlC sample.o -L /usr/lpp/cbclib/lib/atlas -lcblas.arch11  
-latlas.arch11 -qfloat=ieee -o sample
```

To compile the program for ARCH(12) and higher ARCHITECTURE levels:

```
xlC -c -qfloat=ieee -qround=n -qarch=12 -qtarget=zosv2r3 -I  
/usr/lpp/cbclib/include/atlas -qfloat=ieee -o sample.o sample.C
```

To link the program for ARCH(12) and higher ARCHITECTURE levels:

```
xlC sample.o -L /usr/lpp/cbclib/lib/atlas -lcblas.arch12  
-latlas.arch12 -qfloat=ieee -o sample
```

In Open XL C/C++ for z/OS

You can use the following commands to compile and link the program in Open XL C/C++ for z/OS:

To compile the program for **-march=zEC12**:

```
ibm-clang++64 -c -fno-rounding-math -march=zEC12 -mzos-target=zosv2r4 -I  
/usr/lpp/cbclib/include/atlas -o sample.o sample.C
```

To link the program for **-march=zEC12**:

```
ibm-clang++64 sample.o -L /usr/lpp/cbclib/lib/atlas -lcblas.arch10  
-latlas.arch10 -o sample
```

To compile the program for **-march=z13**:

```
ibm-clang++64 -c -fno-rounding-math -march=z13 -mzos-target=zosv2r4 -I  
/usr/lpp/cbclib/include/atlas -o sample.o sample.C
```

To link the program for **-march=z13**:

```
ibm-clang++64 sample.o -L /usr/lpp/cbclib/lib/atlas -lcblas.arch11  
-latlas.arch11 -o sample
```

To compile the program for **-march=z14** and higher:

```
ibm-clang++64 -c -fno-rounding-math -march=z14 -mzos-target=zosv2r5 -I  
/usr/lpp/cbclib/include/atlas -o sample.o sample.C
```

To link the program for **-march=z14** and higher:

```
ibm-clang++64 sample.o -L /usr/lpp/cbclib/lib/atlas -lcblas.arch12  
-latlas.arch12 -o sample
```

Examples - Compiling, linking, and running a complex ATLAS sample

This section assumes that a complex test sample, `inv tst.c`, ships with the ATLAS source code. This program is a complex sample that combines ATLAS specific, CBLAS, and LAPACK functionality that has to be compiled using the C compiler.

Example of ATLAS specific functions being called in this sample: `ATL_flushcache`, `ATL_assert`, `ATL_DivBySize`, and `ATL_MulBySize`.

Example of CBLAS specific functions being called in this sample: `cblas_asum`, `cblas_sasum`, `cblas_dzasum`, `cblas_copy`, `cblas_gemm`, `cblas_symm`, and `cblas_hemm`.

ATLAS header files being used: `atlas_misc.h`, `atlas_lapack.h`, `cblas.h`, `atlas_cblastypealias.h`, `atlas_tst.h`, `atlas_level3.h`, and `clapack.h`.

You can use the following commands to compile and link the program in z/OS XL C/C++:

To compile `invstst.c` for ARCH(10):

```
xlc -c -qfloat=ieee -qround=n -qarch=10 -qtarget=zosv2r1 -I
/usr/lpp/cbclib/include/atlas -qlANGLVL=EXTC99 -DL2SIZE=4194304
-DAdd_ -DF77_INTEGER=int -DStringSunStyle -DATL_NCPU=20 -DATLCINT
-DSREAL -DWALL -DATL_CPUMHZ=5564 -DATL_OS_s390 -o invstst.o invstst.c
```

To link the program for ARCH(10):

```
xlc invstst.o -L /usr/lpp/cbclib/lib/atlas -ltstatlas.arch10
-llapack.arch10 -lcbblas.arch10 -lf77blas.arch10 -latlas.arch10
-lf2c.arch10 -o invstst
```

To compile `invstst.c` for ARCH(11):

```
xlc -c -qfloat=ieee -qround=n -qarch=11 -qtarget=zosv2r1 -I
/usr/lpp/cbclib/include/atlas -qlANGLVL=EXTC99 -DL2SIZE=4194304
-DAdd_ -DF77_INTEGER=int -DStringSunStyle -DATL_NCPU=20 -DATLCINT
-DSREAL -DWALL -DATL_CPUMHZ=5564 -DATL_OS_s390 -o invstst.o invstst.c
```

To link the program for ARCH(11):

```
xlc invstst.o -L /usr/lpp/cbclib/lib/atlas -ltstatlas.arch11
-llapack.arch11 -lcbblas.arch11 -lf77blas.arch11 -latlas.arch10
-lf2c.arch11 -o invstst
```

To compile `invstst.c` for ARCH(12) and higher ARCHITECTURE levels:

```
xlc -c -qfloat=ieee -qround=n -qarch=12 -qtarget=zosv2r3 -I
/usr/lpp/cbclib/include/atlas -qlANGLVL=EXTC99 -DL2SIZE=4194304
-DAdd_ -DF77_INTEGER=int -DStringSunStyle -DATL_NCPU=20 -DATLCINT
-DSREAL -DWALL -DATL_CPUMHZ=5564 -DATL_OS_s390 -o invstst.o invstst.c
```

To link the program for ARCH(12) and higher ARCHITECTURE levels:

```
xlc invstst.o -L /usr/lpp/cbclib/lib/atlas -ltstatlas.arch12
-llapack.arch12 -lcbblas.arch12 -lf77blas.arch12 -latlas.arch12
-lf2c.arch12 -o invstst
```

where:

- L2SIZE represents the size of the L2 cache on the target machine, namely the machine on which the executable will be run.
- Add_, F77_INTEGER, and StringSunStyle are Fortran defines outlining the inter-language interaction between C and Fortran code on z/OS.
- ATL_NCPU represents the number of CPUs on the target hardware where the executable will be run.
- ATLCINT and SREAL are ATLAS specific defines.
- WALL instructs the ATLAS framework to issue all possible warnings.
- ATL_CPUMHZ represents the speed of the target architecture where the executable will be run.
- ATL_OS_s390 instructs ATLAS that a z/OS operating system is used for compile operations.

When ran, the executable will produce the following output:

| NREPS | ORDER | UPLD | N | LDA | TIME | MFLOP | RESID |
|--|-------|-------|-------|-------|-------|---------|--------------|
| ===== | ===== | ===== | ===== | ===== | ===== | ===== | ===== |

Related external information

For details about the ATLAS libraries, such as lists of functions included in the various libraries, visit the [ATLAS home page \(math-atlas.sourceforge.net\)](http://math-atlas.sourceforge.net).

Using OpenBLAS library

OpenBLAS library is a BLAS (Basic Linear Algebra Subroutines) library, which contains a set of routines that provide matrix/vector linear algebra functions. OpenBLAS runs on IBM z14® or newer and supports dynamic linking to it.

Installation location

- /usr/lpp/cbclib/lib/
 - Dynamic library: libopenblas.dll
 - Side deck: libopenblas.x
- /usr/lpp/cbclib/include/openblas/
 - Header files: cblas.h and others (not included as MVS data sets)

Using OpenBLAS with an application running unauthorized

You can compile your program with the OpenBLAS library. For example, in Open XL C/C++ for z/OS:

```
ibm-clang64 main.c -c -I/usr/lpp/cbclib/include/openblas/
```

You can use the following command to link the OpenBLAS library in Open XL C/C++ for z/OS.

```
ibm-clang64 main.o /usr/lpp/cbclib/include/openblas/
```

Set the LIBPATH environment variable.

```
export LIBPATH=$LIBPATH:/usr/lpp/cbclib/lib/
```

Then, run the executable file.

```
a.out
```

Using OpenBLAS with an application running authorized

When running authorized, certain operations, such as printing, are restricted. OpenBLAS might need to print error messages under certain circumstances, so it is good practice to supply your print functions for OpenBLAS to call instead of the default print functions when running authorized; otherwise, OpenBLAS might abend if an error condition is encountered.

To supply alternative functions, take the following steps:

1. Write your alternative functions for `printf`, `fprintf`, `vfprintf`, and `pererror`, which use authorized services only and have the same prototypes as the original functions. The alternative functions must handle errors in a way that is appropriate for the application. For example, they can write to a job log by using authorized services, such as Write To Operator, or they can send a return code to the calling program.
2. In your application program, include `cblas.h` and `common.h`.
3. In your application program, before calling any other OpenBLAS functions, call the following functions to set OpenBLAS to use your alternative functions instead of the defaults, passing each a pointer to your corresponding alternative function:
 - `__openblas_set_printf`

- `__openblas_set_fprintf`
- `__openblas_set_vfprintf`
- `__openblas_set_perror`

4. Specify the following compile options when compiling your application program:

```
-DzOS -D__OPENBLAS_AUTHORIZED_ZOS
```

Example

The following example shows how an application program calls OpenBLAS running authorized.

```
/* main.c */

#include <stdio.h>
#include <stdarg.h>
#include "cblas.h"
#include "common.h"

// User-supplied alternative print functions for running authorized
// Note: The commented-out calls to vprintf, fprintf, and perror must be replaced by
//      user-supplied code that uses only authorized services.

// User-supplied alternative function for printf
int my_printf (const char *fmt, ...) {
    va_list args;
    va_start (args, fmt);
    /* vprintf (fmt, args); */ // Replace with code using only authorized services
    va_end (args);
    return 0;
}

// User-supplied alternative function for fprintf
int my_fprintf (FILE *fp, const char *fmt, ...) {
    va_list args;
    va_start (args, fmt);
    /* fprintf (fp, fmt, args); */ // Replace with code using only authorized services
    va_end (args);
    return 0;
}

// User-supplied alternative function for vfprintf
int my_vfprintf (FILE *fp, const char *fmt, char **args) {
    /* vfprintf (fp, fmt, args); */ // Replace with code using only authorized services
    return 0;
}

// User-supplied alternative function for perror
void my_perror (const char *msg) {
    extern int errno;
    /* printf ("my_perror: %s errno=%d\n", msg, errno); */ // Replace with code using only
    authorized services
}

main(){
    // Set OpenBLAS to use the alternative print functions
    __openblas_set_printf (&my_printf);
    __openblas_set_fprintf (&my_fprintf);
    __openblas_set_vfprintf (&my_vfprintf);
    __openblas_set_perror (&my_perror);

    // Application code that calls OpenBLAS goes here
}
```

Compiling, linking, and running an application running authorized that uses OpenBLAS

You can compile your program with the OpenBLAS library. For example, in Open XL C/C++ for z/OS:

```
ibm-clang64 main.c -DzOS -D__OPENBLAS_AUTHORIZED_ZOS -c -I/usr/lpp/cbclib/include/openblas/
```

You can use the following command to link the OpenBLAS library. For example, in Open XL C/C++ for z/OS:

```
ibm-clang64 main.o /usr/lpp/cbclib/lib/libopenblas.x
```

Set the LIBPATH environment variable.

```
export LIBPATH=$LIBPATH:/usr/lpp/cbclib/lib/
```

Then, run the executable file.

```
a.out
```

Appendix A. IBM z/OS C/C++ compiler feature reference

The following table describes the usage of the supported features by the z/OS XL C/C++ and Open XL C/C++ for z/OS compilers.

| Feature | z/OS XL C/C++ | Open XL C/C++ for z/OS |
|---|--|--|
| 31-bit addressing mode | Specify ILP32 to select the 31-bit addressing mode, under which the compiler generates AMODE 31 code. | Specify -m32n , -m32n-d11 , or -m32 to select the 31-bit addressing mode, under which the compiler generates AMODE 31 code. |
| 64-bit addressing mode | Specify LP64 to select the 64-bit addressing mode, under which the compiler generates AMODE 64 code. | Specify -m64 to select the 64-bit addressing mode, under which the compiler generates AMODE 64 code. |
| C11 standard based compilation | Specify LANGLVL(EXTC1X) for C11 standard-based compilation, invoking all the currently supported C11 features and other implementation-specific language extensions. | Specify -std=c11 for ISO C 2011 standard based compilation or -std=gnu11 for ISO C 2011 standard based compilation with GNU extensions. |
|  C++ exception handling | C++ exception handling is enabled by default. Specify NOEXH to disable C++ exception handling support. | C++ exception handling is enabled by default. You can disable C++ exception handling support with the -fignore-exceptions option. |
| Compiler option to define macros | Specify DEFINE to define a macro. . | Specify -D to define a macro. |
| Extended language level | Specify LANGLVL(EXTENDED) to enable the extended language level. See detail . | Additional z/OS library functions are available only when the macro <code>_EXT</code> is defined. |
| Generate object code for DLLs or DLL applications | Specify DLL to generate object code for DLLs or DLL applications. | Specify -m32 or -m64 to enable the XPLINK linkage, which supports DLL by default; or specify -m32n to enable the DLL linkage in 31-bit addressing mode. |
| Generate reentrant code | Specify NORENT to not generate reentrant code from non-reentrant code. Any naturally reentrant code remains reentrant. | Specify -mno-rent to not generate reentrant code from non-reentrant code. Any naturally reentrant code remains reentrant. |
| Hexadecimal floating-point representation | Specify FLOAT(HEX) for hexadecimal floating-point representation. | Specify -mzos-float-kind=hex for hexadecimal floating-point representation. |
| IEEE decimal floating-point types | Specify DFP to enable support for decimal floating-point types. | Not supported. |
| IEEE floating-point representation | Specify FLOAT(IEEE) for IEEE floating-point representation. | Specify -mzos-float-kind=ieee for IEEE floating-point representation. |

| Feature | z/OS XL C/C++ | Open XL C/C++ for z/OS |
|--|---|---|
| ISO C/C++ compliant | Specify LANGLVL(ANSI) and later ISO standards and extensions to compile code that is ISO C/C++ compliant. | Supports specific language standards under the -std=<standard_version> option. |
| List stored line numbers | Specify GONUMBER NOGONUMBER to generate line number tables that correspond to the input source file for Debug Tool and CEEDUMP processing. | Not supported. |
| List function relative offset addresses | Specify OFFSET to list offset addresses relative to entry points of functions. | Not supported. |
| Long external names | Specify LONGNAME or any language level that supports the <code>long long</code> data type (such as C99 and later) to support external names of mixed case and up to 1024 characters long. | The compiler supports long external names by default. Specify -mshort-name to enable support for short names. |
| <code>long long</code> data type support | Specify LANGLVL(LONGLONG) or any language level of C99 and newer to support the <code>long long</code> data type. | Always supported. |
| MVS environment | Compile your programs in a batch environment, which runs a batch job and uses dataset-based files for input or output. | Compile your programs in a batch environment, which runs a batch job and uses dataset-based files for input or output. |
| Operating system parameter list | Specify PLIST(OS) to make the original operating system parameter list available. | Not supported. |
| Processor architecture | Specify ARCHITECTURE to generate code for a specific processor architecture. | Specify -march to generate code for a specific processor architecture. |
| Round-to-nearest rounding mode | Specify ROUND(N) to enable the round-to-nearest rounding mode. | Specify -fno-rounding-math and -march=zEC12 or higher to enable the round-to-nearest rounding mode. |
| Runtime library extensions | Additional z/OS library functions are available only when the macro <code>_EXT</code> is defined or LANGLVL(EXTENDED) is specified. | Additional z/OS library functions are available only when the macro <code>_EXT</code> is defined. |
| SAA-based language constructs | Specify LANGLVL(SAA) or LANGLVL(SAAL2) to enable the SAA or SAAL2 language level. | Not supported. |
| Target operating system release | Specify TARGET to generate an object module for the target operating system or runtime library. | Specify -mzos-target (www.ibm.com/docs/en/open-xl-c-cpp-zos/latest?topic=options-mzos-target) to control which z/OS level is assumed for running your program. |

| Feature | z/OS XL C/C++ | Open XL C/C++ for z/OS |
|-------------------------------|--|---|
| Vector programming support | See VECTOR on how to enable vector programming support. | Specify the following options to enable vector programming support: -mvx , -mzvector , -fvectorize , or -fslp-vectorize . |
| XPLINK linkage | Specify XPLINK to use the XPLINK linkage that is designed to increase performance on z/OS. | Specify -m32 and -m64 to generate XPLINK linkage code. |
| z/OS UNIX invocation commands | Provides two basic invocation commands, xlc and xlc (xlc++) , along with several other compiler invocation commands to support various C/C++ language levels and compilation environments under z/OS UNIX. | Provides the ibm-clang and ibm-clang64 invocation commands to compile and link C programs and the ibm-clang++ and ibm-clang++64 invocation commands to compile and link C++ programs. . |

[Compiler options](#)

Open XL C/C++ 2.1 for z/OS feature reference

The following table describes the features of Open XL C/C++ 2.1 for z/OS.

| Feature | Description |
|--|--|
| 31-bit addressing mode | Specify -m32n , -m32n-d11 , or -m32 to select the 31-bit addressing mode, under which the compiler generates AMODE 31 code. |
| 64-bit addressing mode | Specify -m64 to select the 64-bit addressing mode, under which the compiler generates AMODE 64 code. |
| C11 standard based compilation | Specify -std=c11 for ISO C 2011 standard based compilation or -std=gnu11 for ISO C 2011 standard based compilation with GNU extensions. |
|  C++ exception handling | C++ exception handling is enabled by default. You can disable C++ exception handling support with the -fignore-exceptions option. |
| Compiler option to define macros | Specify the -D compiler option to define a macro. |
| Extended language level | Additional z/OS library functions are available only when the macro <code>_EXT</code> is defined. |
| Generate object code for DLLs or DLL applications | Specify -m32 or -m64 to enable the XPLINK linkage, which supports DLL by default; or specify -m32n to enable the DLL linkage in 31-bit addressing mode. |
| Generate reentrant code | Specify -mno-rent to not generate reentrant code from non-reentrant code. Any naturally reentrant code remains reentrant. |
| Hexadecimal floating-point representation | Specify -mzos-float-kind=hex for hexadecimal floating-point representation. |
| IEEE decimal floating-point types | Not supported. |
| IEEE floating-point representation | Specify -mzos-float-kind=ieee for IEEE floating-point representation. |
| ISO C/C++ compliant | Supports specific language standards under the -std=<standard_version> option. |
| List stored line numbers | Not supported. |
| List function relative offset addresses | Not supported. |
| Long external names | The compiler supports long external names by default. Specify -mshort-name to enable support for short names. |
| long long data type support | Always supported. |
| MVS environment | Compile your programs in a batch environment, which runs a batch job and uses dataset-based files for input or output. |
| Operating system parameter list | Not supported. |
| Processor architecture | Specify -march to generate code for a specific processor architecture. |
| Round-to-nearest rounding mode | Specify -fno-rounding-math and -march=zEC12 or higher to enable the round-to-nearest rounding mode. |
| Runtime library extensions | Additional z/OS library functions are available only when the macro <code>_EXT</code> is defined. |
| SAA-based language constructs | Not supported. |

| Feature | Description |
|---------------------------------|--|
| Target operating system release | Specify -mzos-target (www.ibm.com/docs/en/open-xl-c-cpp-zos/latest?topic=options-mzos-target) to control which z/OS level is assumed for running your program. |
| Vector programming support | Specify the following options to enable vector programming support: -mvx , -mzvector , -fvectorize , or -fslp-vectorize . |
| XPLINK linkage | Specify -m32 and -m64 to generate XPLINK linkage code. |
| z/OS UNIX invocation commands | Provides the ibm-clang and ibm-clang64 invocation commands to compile and link C programs and the ibm-clang++ and ibm-clang++64 invocation commands to compile and link C++ programs. |

Open XL C/C++ 1.1 for z/OS feature reference

The following table describes the features of Open XL C/C++ 1.1 for z/OS.

| Feature | Description |
|--|---|
| 64-bit addressing mode | Specify -m64 to select the 64-bit addressing mode, under which the compiler generates AMODE 64 code. |
| C11 standard based compilation | Specify -std=c11 for ISO C 2011 standard based compilation or -std=gnu11 for ISO C 2011 standard based compilation with GNU extensions. |
|  C++ exception handling | C++ exception handling is enabled by default. You can disable C++ exception handling support with the -fignore-exceptions option. |
| Compiler option to define macros | Specify the -D compiler option to define a macro. |
| Extended language level | Additional z/OS library functions are available only when the macro <code>_EXT</code> is defined. |
| Generate object code for DLLs or DLL applications | The compiler generates XPLINK linkage code by default and does not require an option to enable DLL support. |
| Generate reentrant code | Specify -mno-rent to not generate reentrant code from non-reentrant code. Any naturally reentrant code remains reentrant. |
| Hexadecimal floating-point representation | Not supported. |
| IEEE decimal floating-point types | Not supported. |
| IEEE floating-point representation | The compiler generates an IEEE floating-point representation. |
| ISO C/C++ compliant | Supports specific language standards under the -std=<standard_version> option. |
| List stored line numbers | Not supported. |
| List function relative offset addresses | Not supported. |

| Feature | Description |
|---------------------------------|---|
| Long external names | Supported |
| long long data type support | Always supported. |
| MVS environment | Not supported. |
| Operating system parameter list | Not supported. |
| Processor architecture | Specify -march to generate code for a specific processor architecture. |
| Round-to-nearest rounding mode | Specify -fno-rounding-math and -march=zEC12 or higher to enable the round-to-nearest rounding mode. |
| Runtime library extensions | Additional z/OS library functions are available only when the macro <code>_EXT</code> is defined. |
| SAA-based language constructs | Not supported. |
| Target operating system release | Specify -mzos-target (www.ibm.com/docs/en/open-xl-c-cpp-zos/latest?topic=options-mzos-target) to control which z/OS level is assumed for running your program. |
| Vector programming support | Specify the following options to enable vector programming support: -mvx , -mzvector , -fvectorize , or -fslp-vectorize . |
| XPLINK linkage | The compiler generates XPLINK linkage code. |
| z/OS UNIX invocation commands | Provides the ibm-clang and ibm-clang64 invocation commands to compile and link C programs and the ibm-clang++ and ibm-clang++64 invocation commands to compile and link C++ programs. |

Related information

- For more information about the features and options that are supported by the Open XL C/C++ 1.1 for z/OS compiler, see the [Open XL C/C++ 1.1 for z/OS documentation](#).

Appendix B. Function support table

Preinitialized environments for authorized programs

Preinitialized Environments for Authorized Programs is a new feature of z/OS Language Environment. It is intended to provide support for authorized components or products to create preinitialized environments that are capable of executing C, C++, and Language Environment-conforming assembler code in supervisor state, on a TCB or an SRB, or in cross-memory mode (with some restrictions).

Table 87 on page 2125 lists all the functions in the z/OS XL C/C++ Runtime Library and their support of Preinitialized Environments for Authorized Programs.

Note: The function table does not include compiler built-in functions (builtin.h).

Enhanced ASCII support

Restriction: Enhanced ASCII and __LIBASCII are independent, and should not be used together. Using Enhanced ASCII and __LIBASCII together is not supported.

Enhanced ASCII support provides the means to write z/OS XL C/C++ applications which will execute with ASCII data representation.

Enhanced ASCII support makes it easier to port internationalized C/C++ applications developed on or for ASCII platforms to z/OS platforms by providing conversion from ASCII to EBCDIC and EBCDIC to ASCII.

In order to use Enhanced ASCII support, a C or C++ module must be compiled specifying ASCII as the data representation. Application compile units will be bound to ASCII versions of external variables and interfaces at compile time if they:

1. Use headers to declare external variables and interfaces used in compile unit source.
2. Are compiled with the ASCII option.

New ASCII function-versions and other support functions have been added to the z/OS XL C/C++ Runtime Library to handle ASCII data in files, data manipulations, and conversions between ASCII and EBCDIC. The compile-time binding will determine which ASCII or EBCDIC function version is called during runtime execution.

Table 87 on page 2125 lists all the functions in the z/OS XL C/C++ Runtime Library and their support of Enhanced ASCII processing.

Note: The function table does not include compiler built-in functions (builtin.h).

Table 86 on page 2123 lists all the External Variables and their support status in Enhanced ASCII. For other information about these variables, see [“External variables”](#) on page 98.

Table 86. Status of External Variables in Enhanced ASCII

| External Variable | Enhanced ASCII Support Level |
|-------------------|------------------------------|
| daylight | Neutral |
| environ | Yes |
| errno | Neutral |
| getdate_err | Neutral |
| h_errno | Neutral |
| locs | No |
| loc1 | No |

Table 86. Status of External Variables in Enhanced ASCII (continued)

| External Variable | Enhanced ASCII Support Level |
|-------------------|------------------------------|
| __loc1 | Neutral |
| loc2 | No |
| optarg | Neutral |
| opterr | Neutral |
| optind | Neutral |
| optopt | Neutral |
| signgam | Neutral |
| stderr | Neutral |
| stdin | Neutral |
| stdout | Neutral |
| t_errno | Neutral |
| timezone | Neutral |
| tzname | Yes |

For a description of Limitations to the use of Enhanced ASCII, see [z/OS XL C/C++ Programming Guide](#).

Enhanced ASCII extensions

Applications compiled ASCII were permitted to use library functions that did not have ASCII support for character data with the understanding that all ASCII to EBCDIC conversion was the responsibility of the application.

As service updates or new releases extend Enhanced ASCII to previously unsupported functions, it is necessary to protect the ASCII applications that have been calling those functions (with user-supplied character conversions).

A new feature test macro is defined to control the exposure of extensions to Enhanced ASCII. This feature test macro is `_ENHANCED_ASCII_EXT` and should be set to a non-zero, numeric value indicating the level of Enhanced ASCII support desired. Otherwise, the default value of 0x41020000 is assumed, which will limit exposure to only the Enhanced ASCII support provided in the z/OS V1R2 base. Numeric values less than the default will behave as if the default were specified. The special value 0xFFFFFFFF provides exposure to all Enhanced ASCII support, regardless of the service level, available for the TARGET release.

Functions whose Enhanced ASCII support exposure is controlled by values of this feature test macro, other than the default value or the special 0xFFFFFFFF value, will have the specific value documented in [Table 87 on page 2125](#).

Note: Functions which are introduced in a release, and include Enhanced ASCII support, are not controlled using this macro. For example, `getnameinfo()` first appears in z/OS V1R4 base and has Enhanced ASCII support. It is always available in its ASCII form since there was no prior release containing the function.

[Table 87 on page 2125](#) lists all the functions in the z/OS XL C/C++ Runtime Library and their support of Enhanced ASCII processing.

Library function support

[Table 87 on page 2125](#) shows all the z/OS XL C/C++ Runtime Library functions in alphabetical order, their support of Enhanced ASCII processing and their support of Preinitialized Environments for Authorized Programs.

Enhanced ASCII

Each function is identified by the extent to which it supports Enhanced ASCII processing:

- Yes = supports Enhanced ASCII.
- No = does not support Enhanced ASCII.
- Neutral = not sensitive to the issue of ASCII/EBCDIC character encoding.

Following is a list of values for feature test macro `_ENHANCED_ASCII_EXT`:

0x41020000

z/OS V1.2 base support plus all functions first introduced in subsequent releases. This is the default.

0x41020010

Includes support added with APAR PQ63405

0x41060000

Includes support added in z/OS V1.6.

0x41070000

Includes support added in z/OS V1.7

0x410A0000

Includes support added in z/OS V1.10

0xFFFFFFFF

Exposes all Enhanced ASCII support regardless of service level for the TARGET release.

Each higher value includes all support exposed with the lesser values.

Functions which are used for conversion to ASCII or EBCDIC are labelled with those data types.

Preinitialized Environments for Authorized Programs

Each function is identified by the extent to which it supports Preinitialized Environments for Authorized Programs:

Yes

the function supports Preinitialized Environments for Authorized Programs.

No

the function does not support Preinitialized Environments for Authorized Programs.

| Table 87. Library function support table | | | | |
|--|------------------------------|---|---|-------|
| Function | Enhanced ASCII Support Level | Minimum Value for <code>_ENHANCED_ASCII_EXT</code> Feature Test Macro | Preinitialized Environments for Authorized Programs Support Level | Notes |

Notes:

1. ASCII support provided only for XPG4 (or higher) interface.
2. ASCII support provided only for X/Open Sockets interface.
3. ASCII support is for the sun_path element of struct sockaddr_un when working with the AF_UNIX address family.
4. Preinitialized Environments for Authorized Programs support provided only for non-posix signals.
5. Preinitialized Environments for Authorized Programs support provided only if locale file resides in a dataset, not in a z/OS UNIX file system.
6. Preinitialized Environments for Authorized Programs support provided only for non-posix form of the function.

7. Preinitialized Environments for Authorized Programs support provided only for non z/OS UNIX file system DLLs.
8. Preinitialized Environments for Authorized Programs support provided only when dispatchable unit mode is task and cross memory mode is PASN=HASN=SASN. In addition, the RECOVERY=ESTAE parameter must be used on the CELAAUTH macro invocation.
9. This function table does not include compiler built-in functions (builtin.h).

Appendix C. Accessibility

Accessible publications for this product are offered through [IBM Documentation for z/OS \(www.ibm.com/docs/en/zos\)](http://www.ibm.com/docs/en/zos).

If you experience difficulty with the accessibility of any z/OS documentation see [How to Send Feedback to IBM](#) to leave documentation feedback.

Notices

This information was developed for products and services that are offered in the USA or elsewhere.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not grant you any license to these patents. You can send license inquiries, in writing, to:

*IBM Director of Licensing
IBM Corporation
North Castle Drive, MD-NC119
Armonk, NY 10504-1785
United States of America*

For license inquiries regarding double-byte character set (DBCS) information, contact the IBM Intellectual Property Department in your country or send inquiries, in writing, to:

*Intellectual Property Licensing
Legal and Intellectual Property Law
IBM Japan Ltd.
19-21, Nihonbashi-Hakozakicho, Chuo-ku
Tokyo 103-8510, Japan*

The following paragraph does not apply to the United Kingdom or any other country where such provisions are inconsistent with local law: INTERNATIONAL BUSINESS MACHINES CORPORATION PROVIDES THIS PUBLICATION "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF NON-INFRINGEMENT, MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. Some states do not allow disclaimer of express or implied warranties in certain transactions, therefore, this statement may not apply to you.

This information could include technical inaccuracies or typographical errors. Changes are periodically made to the information herein; these changes will be incorporated in new editions of the publication. IBM may make improvements and/or changes in the product(s) and/or the program(s) described in this publication at any time without notice.

This information could include missing, incorrect, or broken hyperlinks. Hyperlinks are maintained in only the HTML plug-in output for IBM Documentation. Use of hyperlinks in other output formats of this information is at your own risk.

Any references in this information to non-IBM websites are provided for convenience only and do not in any manner serve as an endorsement of those websites. The materials at those websites are not part of the materials for this IBM product and use of those websites is at your own risk.

IBM may use or distribute any of the information you supply in any way it believes appropriate without incurring any obligation to you.

Licensees of this program who wish to have information about it for the purpose of enabling: (i) the exchange of information between independently created programs and other programs (including this one) and (ii) the mutual use of the information which has been exchanged, should contact:

*IBM Corporation
Site Counsel
2455 South Road*

Poughkeepsie, NY 12601-5400
USA

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program described in this document and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement or any equivalent agreement between us.

Any performance data contained herein was determined in a controlled environment. Therefore, the results obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems and there is no guarantee that these measurements will be the same on generally available systems. Furthermore, some measurements may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

All statements regarding IBM's future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

COPYRIGHT LICENSE:

This information contains sample application programs in source language, which illustrate programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs. The sample programs are provided "AS IS", without warranty of any kind. IBM shall not be liable for any damages arising out of your use of the sample programs.

Terms and conditions for product documentation

Permissions for the use of these publications are granted subject to the following terms and conditions.

Applicability

These terms and conditions are in addition to any terms of use for the IBM website.

Personal use

You may reproduce these publications for your personal, noncommercial use provided that all proprietary notices are preserved. You may not distribute, display or make derivative work of these publications, or any portion thereof, without the express consent of IBM.

Commercial use

You may reproduce, distribute and display these publications solely within your enterprise provided that all proprietary notices are preserved. You may not make derivative works of these publications, or

reproduce, distribute or display these publications or any portion thereof outside your enterprise, without the express consent of IBM.

Rights

Except as expressly granted in this permission, no other permissions, licenses or rights are granted, either express or implied, to the publications or any information, data, software or other intellectual property contained therein.

IBM reserves the right to withdraw the permissions granted herein whenever, in its discretion, the use of the publications is detrimental to its interest or, as determined by IBM, the above instructions are not being properly followed.

You may not download, export or re-export this information except in full compliance with all applicable laws and regulations, including all United States export laws and regulations.

IBM MAKES NO GUARANTEE ABOUT THE CONTENT OF THESE PUBLICATIONS. THE PUBLICATIONS ARE PROVIDED "AS-IS" AND WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING BUT NOT LIMITED TO IMPLIED WARRANTIES OF MERCHANTABILITY, NON-INFRINGEMENT, AND FITNESS FOR A PARTICULAR PURPOSE.

IBM Online Privacy Statement

IBM Software products, including software as a service solutions, ("Software Offerings") may use cookies or other technologies to collect product usage information, to help improve the end user experience, to tailor interactions with the end user, or for other purposes. In many cases no personally identifiable information is collected by the Software Offerings. Some of our Software Offerings can help enable you to collect personally identifiable information. If this Software Offering uses cookies to collect personally identifiable information, specific information about this offering's use of cookies is set forth below.

Depending upon the configurations deployed, this Software Offering may use session cookies that collect each user's name, email address, phone number, or other personally identifiable information for purposes of enhanced user usability and single sign-on configuration. These cookies can be disabled, but disabling them will also eliminate the functionality they enable.

If the configurations deployed for this Software Offering provide you as customer the ability to collect personally identifiable information from end users via cookies and other technologies, you should seek your own legal advice about any laws applicable to such data collection, including any requirements for notice and consent.

For more information about the use of various technologies, including cookies, for these purposes, see IBM's Privacy Policy at ibm.com/privacy and IBM's Online Privacy Statement at ibm.com/privacy/details in the section entitled "Cookies, Web Beacons and Other Technologies," and the "IBM Software Products and Software-as-a-Service Privacy Statement" at ibm.com/software/info/product-privacy.

Policy for unsupported hardware

Various z/OS elements, such as DFSMSdfp, JES2, and MVS, contain code that supports specific hardware servers or devices. In some cases, this device-related element support remains in the product even after the hardware devices pass their announced End of Service date. z/OS may continue to service element code; however, it will not provide service related to unsupported hardware devices. Software problems related to these devices will not be accepted for service, and current service activity will cease if a problem is determined to be associated with out-of-support devices. In such cases, fixes will not be issued.

Minimum supported hardware

The minimum supported hardware for z/OS releases identified in z/OS announcements can subsequently change when service for particular servers or devices is withdrawn. Likewise, the levels of other software products supported on a particular release of z/OS are subject to the service support lifecycle of those

products. Therefore, z/OS and its product publications (for example, panels, samples, messages, and product documentation) can include references to hardware and software that is no longer supported.

- For information about software support lifecycle, see: [IBM Lifecycle Support for z/OS \(www.ibm.com/software/support/systemsz/lifecycle\)](http://www.ibm.com/software/support/systemsz/lifecycle)
- For information about currently-supported IBM hardware, contact your IBM representative.

Programming interface information

This publication documents *intended* Programming Interfaces that allow the customer to write z/OS XL C/C++ programs.

Standards

The following standards are supported in combination with the Language Environment element:

- The C language is consistent with *Programming languages - C (ISO/IEC 9899:1999)* and a subset of *Programming languages - C (ISO/IEC 9899:2011)*. For more information, see [International Organization for Standardization \(ISO\) \(www.iso.org\)](http://www.iso.org).
- The C++ language is consistent with *Programming languages - C++ (ISO/IEC 14882:1998)*, *Programming languages - C++ (ISO/IEC 14882:2003(E))*, and a subset of *Programming languages - C++ (ISO/IEC 14882:2011)*.

The following standards are supported in combination with the Language Environment and z/OS UNIX System Services elements:

- A subset of *IEEE Std. 1003.1-2001 (Single UNIX Specification, Version 3)*. For more information, see [IEEE \(www.ieee.org\)](http://www.ieee.org).
- *IEEE Std 1003.1-1990, IEEE Standard Information Technology—Portable Operating System Interface (POSIX)—Part 1: System Application Program Interface (API) [C language]*, copyright 1990 by the Institute of Electrical and Electronic Engineers, Inc.
- The core features of *IEEE P1003.1a Draft 6 July 1991, Draft Revision to Information Technology—Portable Operating System Interface (POSIX), Part 1: System Application Program Interface (API) [C Language]*, copyright 1992 by the Institute of Electrical and Electronic Engineers, Inc.
- *IEEE Std 1003.2-1992, IEEE Standard Information Technology—Portable Operating System Interface (POSIX)—Part 2: Shells and Utilities*, copyright 1990 by the Institute of Electrical and Electronic Engineers, Inc.
- The core features of *IEEE Std P1003.4a/D6-1992, IEEE Draft Standard Information Technology—Portable Operating System Interface (POSIX)—Part 1: System Application Program Interface (API)—Amendment 2: Threads Extension [C language]*, copyright 1990 by the Institute of Electrical and Electronic Engineers, Inc.
- The core features of *IEEE 754-1985 (R1990) IEEE Standard for Binary Floating-Point Arithmetic (ANSI)*, copyright 1985 by the Institute of Electrical and Electronic Engineers, Inc.
- *X/Open CAE Specification, System Interfaces and Headers, Issue 4 Version 2*, copyright 1994 by The Open Group
- *X/Open CAE Specification, Networking Services, Issue 4*, copyright 1994 by The Open Group
- *X/Open Specification Programming Languages, Issue 3, Common Usage C*, copyright 1988, 1989, and 1992 by The Open Group
- United States Government's *Federal Information Processing Standard (FIPS) publication for the programming language C, FIPS-160*, issued by National Institute of Standards and Technology, 1991

Trademarks

IBM, the IBM logo, and ibm.com are trademarks or registered trademarks of International Business Machines Corp., registered in many jurisdictions worldwide. Other product and service names might be

trademarks of IBM or other companies. A current list of IBM trademarks is available on the Web at [Copyright and Trademark information \(www.ibm.com/legal/copytrade.shtml\)](http://www.ibm.com/legal/copytrade.shtml).

Adobe, Acrobat, PostScript and all Adobe-based trademarks are either registered trademarks or trademarks of Adobe Systems Incorporated in the United States, other countries, or both.

Microsoft, Windows, Windows NT, and the Windows logo are trademarks of Microsoft Corporation in the United States, other countries, or both.

UNIX is a registered trademark of The Open Group in the United States and other countries.

Java and all Java-based trademarks and logos are trademarks or registered trademarks of Oracle and/or its affiliates.

Linux® is a trademark of Linus Torvalds in the United States, other countries, or both.

Other company, product, or service names may be trademarks or service marks of others.
